MATCHING QUESTIONS

Match the following:

- | | |
|-----------------------------------|--|
| 1. ____ Endarterectomy | a. Antireflux procedure |
| 2. ____ Partial laryngectomy | b. Removal of the urinary bladder |
| 3. ____ Cystectomy | c. Removal of the vocal cord and a section of the larynx |
| 4. ____ Fundoplication | d. Procedure done for glaucoma |
| 5. ____ Salpingectomy | e. Removal of the Fallopian tubes |
| 6. ____ Trabeculectomy | f. Urinary diversion procedure |
| 7. ____ Supraglottic laryngectomy | g. Incision into the ear drum |
| 8. ____ Myringotomy | h. Incision into an artery with removal of atheromatous material |
| 9. ____ Ileal conduit | i. Procedure used for pancreatic cancer |
| 10. ____ Whipple procedure | j. Removal of the hyoid bone, glottis and false vocal cords |

Medication

11. ____ Atropine sulfate
12. ____ Hydroxyzine hydrochloride
13. ____ Midazolam hydrochloride
14. ____ Morphine sulfate
15. ____ Panax ginseng
16. ____ Pentobarbital sodium
17. ____ Valeriana officinalis

Medical Problem

18. ____ Paralytic ileus
19. ____ Cullen's sign
20. ____ Dehiscence
21. ____ Evisceration

Interaction that may result when anesthetic is administered

22. ____ Anxiety and seizures occur with sudden withdrawal
23. ____ Increase hypotensive action of anesthetics
24. ____ Can induce electrolyte imbalance
25. ____ Increase bleeding intra- and postoperatively
26. ____ If stopped suddenly potentiate cardiovascular collapse

Nutrient

27. ____ Vitamin C
28. ____ Vitamin K
29. ____ Vitamin A
30. ____ Iron
31. ____ Zinc

Used for

- a. Permits smoother induction of anesthetic
- b. Decreases amount of anesthetic needed
- c. Provides amnesia
- d. Decreases respiratory and gastric secretions
- e. Decreases anxiety
- f. Prolongs sedative effects of anesthesia
- g. Inhibits platelet aggregation

Description

- a. Absent bowel sounds
- b. Separation of approximated wound edges
- c. Bowel protruding from a surgical incision
- d. An indication of intraabdominal bleeding

Medication Category

- a. Anticoagulant
- b. Phenothiazines
- c. Corticosteroids
- d. Tranquilizers
- e. Diuretics

Role in wound healing

- a. Tissue synthesis
- b. Replaces elements from blood loss
- c. Capillary formation
- d. Protein synthesis
- e. Clot formation

(continued)

Disease Process

32. ____ Diabetes mellitus
33. ____ Gastric esophageal reflux disease
34. ____ Obesity
35. ____ Bronchospasms

Resulting postoperative complication

- a. Wound dehiscence
- b. Airway obstruction
- c. Impaired wound healing
- d. Pulmonary aspiration

APPLICATION QUESTIONS

- The nurse goes in to meet and assess her client who had a vulvectomy 2 days ago. The client is dozing in bed in Fowler's position but states she is uncomfortable, when asked. Which action should the nurse take first?
 - Call the physician
 - Reposition the client in semi-Fowler's
 - Administer pain medication
 - Explain it is normal to be uncomfortable after the surgery.
- The nurse should interpret a weight gain of 5.5 lb over 24 hours in a client with a biologic cardiac valve replacement as a sign of the development of which problem?
 - Graft rejection
 - Pericarditis
 - Congestive heart failure
 - Pyelonephritis
- After which surgical procedure would the nurse plan to monitor the client's ankle-brachial index (ABI)?
 - Off pump coronary artery bypass
 - Dynamic cardiomyoplasty
 - Carotid endarterectomy
 - Femoral-popliteal bypass
- The evening nurse goes in to care for a client who had a modified mastectomy that morning. Which fact is essential for the nurse to know to provide safe care?
 - The involved arm should be wearing an elastic sleeve.
 - The involved arm should not be used for BP measurement.
 - The involved arm should be not be exercised for 10 days.
 - The involved arm should be maintained at the level of the heart.
- Which assessment finding(s) on a client who had a transurethral resection of the prostate for BPH 4 hours ago would indicate the need to notify the physician?
 - Red bloody urine with small clots
 - BP of 110/50 mmHg, pulse 130 bpm
 - Urinary output of 200 ml. greater than intake
 - Pain related to bladder spasms
- The nurse should interpret a complaint of joint pain from a client with a mechanical heart valve as potentially indicative of which problem?
 - Streptococcal infection
 - Vegetative embolus
 - Bleeding
 - Hypoxemia
- A client with atrial fibrillation suddenly complains of acute, severe pain in the left arm. On assessment the nurse finds the arm to be cold, pale, and without palpable pulses. Which problem should the nurse suspect?
 - Myocardial infarction
 - Compartment syndrome
 - Arterial embolus
 - Hypovolemic shock
- When caring for a postoperative client who has had a thyroidectomy, which medication should the nurse ensure is immediately available at the bedside?
 - Calcium gluconate
 - Propylthiouracil
 - SSKI
 - Synthroid

9. A client having surgery for glaucoma asks the nurse how the doctor will know if the surgery is successful. Which would be an appropriate response for the nurse to make?
 - a. IOP will decrease
 - b. Ability to read small print will improve
 - c. Pupil will remain permanently dilated
 - d. Peripheral vision will increase
10. Which advice would be appropriate for the nurse to give to a client with dumping syndrome?
 - a. Take a drink after every four to five bites of food at a meal
 - b. Eat several small meals per day of wet foods
 - c. Remain in an upright position for 30–60 minutes after eating
 - d. Avoid foods that are concentrated carbohydrates
11. When caring for a client who has had a kidney transplant, the nurse assesses for signs of rejection. For which S&S would the nurse observe? Mark all that apply.
 - a. Change in urinary output
 - b. Flank pain
 - c. Edema
 - d. Sudden weight gain
12. After which procedure would the nurse be expected to titrate IV fluids to replace output during the first 24 hours?
 - a. Liver transplant
 - b. Heart transplant
 - c. Kidney transplant
 - d. Lung transplant
13. Which action should the nurse take when during assessment, he/she finds the client who is 2 days post a liver transplant has a temperature persistent of 101.5°F, pulse 95, and respiratory rate of 18?
 - a. Reposition the client
 - b. Administer oxygen
 - c. Administer pain medication
 - d. Call the physician
14. When conducting discharge teaching for a transplant client, the nurse must make sure the client and family understand the importance of which self-care activities? Mark all that apply.
 - a. Medication compliance
 - b. Reporting of S&S etc.
 - c. Keeping follow-up appointments
 - d. Establishing a set sleep/wake routine
15. Which directions would the nurse give to a client who is being prepared for discharge following a pneumonectomy? Mark all that apply.
 - a. Continue breathing exercises at home.
 - b. Exercise arm and shoulder five times per day.
 - c. Practice standing straight with shoulders even in front of the mirror.
 - d. Do not lift more than 20 lb for at least a month.
 - e. Stop any activity that causes dyspnea, chest pain, or excessive fatigue.
 - f. Obtain influenza and pneumonia vaccines.
 - g. Expect an intermittent cough with increased sputum.
16. A client with which problem needs careful assessment for the development of ARDS?
 - a. Pericarditis
 - b. Anemia
 - c. Acute pancreatitis
 - d. Pyelonephritis
17. A client having cryosurgery for removal of a squamous cell carcinoma asks if the procedure will hurt. Which is the correct answer for the nurse to give?
 - a. "You will not feel anything."
 - b. "There will be a brief tingling pain."
 - c. "There will be no pain but you may experience a slight odd smell."
 - d. "There will be a momentary, stabbing pain."
18. When planning for the postoperative care of clients having a thyroidectomy, which piece of equipment is most essential for the nurse to have available at the bedside?
 - a. Suction machine
 - b. Tracheostomy set
 - c. Cardiac monitor
 - d. Humidifier
19. Which S&S occurring in a client 48 hours postadrenalectomy indicate that glucocorticoid dosage needs to be increased?
 - a. Marked weakness, anorexia, nausea or vomiting.
 - b. Severe dyspnea, tachycardia, apprehension
 - c. Paresthesias, numbness and tingling in the extremities, muscle spasms
 - d. Orthostatic hypotension, depressed reflexes, slow mentation.
20. A visitor with an obvious upper respiratory infection arrives to see a client 24 hours postoperative from an adrenalectomy. The nurse explains that it is very important that the client not be exposed to anyone

(continued)

- with a contagious illness. The visitor asks why. Which fact should be the basis of the nurse's answer?
- The client is unable to fight infection because of loss of stress hormones.
 - Fluid and electrolyte fluctuations create an environment in which infective organisms can thrive.
 - Risk of infection is greatly increased because of excess cortisol.
 - The immune system is suppressed as part of the preparation for surgery and it takes 3–4 weeks for it to regain normal function.
- When teaching self-care to a client who has had abdominal liposuction, which information should the nurse include?
 - Wear the compression garment when up for 2 weeks
 - Take aspirin as needed for discomfort
 - Expect asymmetry in the first few weeks after which it will taper off.
 - Avoid weight gain so effect of surgery is not negated.
 - Which statement made by a client who has had a blepharoplasty indicates the need for further teaching?
 - "I will avoid reading for 2–3 days."
 - "I will not be able to wear my contact lenses for at least 2 weeks."
 - "I will apply warm compresses to control swelling."
 - "I need to avoid alcohol for 3 weeks."
 - A client scheduled for a nephrectomy asks during the preoperative teaching session when the drain in the wound will be removed. Which is the best reply for the nurse to give?
 - At the same time the sutures are removed.
 - Not until urinary output is clear and at least 600 ml/24 hours.
 - After narcotics are no longer required for pain relief.
 - When drainage has decreased to less than 30 ml/d.
 - Which problem places a client scheduled for a nephrostomy at the greatest risk for postoperative hemorrhage?
 - Diabetes mellitus
 - History of urinary tract infections
 - Uncontrolled hypertension
 - Pernicious anemia
 - Which information should be included in the teaching plan for a client who has had a ureterosigmoidostomy?
 - Lifelong prophylactic antibiotics will be needed.
 - Annual sigmoidoscopy should be obtained starting 10 years after surgery.
 - Fluid intake should not exceed 1200 ml/d.
 - Diet should be high in fiber and low in fat

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

- Surgical removal of one or more of the fallopian tubes is referred to as a salpingectomy.
- A hysterectomy may be performed to control life-threatening bleeding/hemorrhage and in the event of intractable pelvic infection.
- After a vasectomy, applying ice to the scrotum intermittently for several hours will help to reduce swelling and relieve discomfort.
- The client on a cardiopulmonary bypass pump is maintained in a state of hypothermia in order to decrease metabolic needs.

5. Postoperatively, the client who has had a CABG procedure usually is instructed to avoid excessive arm movements for 6–8 weeks.
6. What piece of equipment must be kept at the bedside of postoperative amputees? Answer: tourniquet.
7. To check for development of abdominal distention, the nurse measures abdominal girth.
8. When caring for a client who had a kidney removed, the nurse would expect the Jackson–Pratt drain to be removed when drainage has decreased to less than 30 ml/d.
9. The client who has had a craniotomy is at greatest risk for ICP during the first 24–48 hours after surgery because this is the time during which edema peaks.
10. The client with a middle fossa craniotomy should be positioned with the head of the bed elevated 30–40 degrees.
11. Transplantation from one part of the body to another is called a(n) autograft.
12. The live donor is primarily used in kidney transplants.
13. Cornea transplant is the only type of transplant done as outpatient surgery.
14. A major indicator for heart transplant is cardiomyopathy.
15. Graft rejection, immunosuppressant related, and technical are the three major types of transplant-associated complications.
16. The kidney client must be weighed daily.
17. In addition to loss of vision, bleeding and infection, a complication associated with eye surgery is increased IOP.
18. The two greatest risk associated with inner ear surgery are infection and leakage of CSF.
19. A life-threatening complication of a long bone fracture is a fat embolism.
20. Infection most often occurs when an amputation is traumatic.
21. List four categories of medication that interact with anesthetic agents.
 - a. _____
 - b. _____
 - c. _____
 - d. _____Answers may include corticosteroids, diuretics, phenothiazines, tranquilizers, insulin, antibiotics, antiseizure medication, and monoamine oxidase inhibitors.
22. Identify three causes of airway obstruction following a surgical procedure.
 - a. _____
 - b. _____
 - c. _____Answers may include tongue blocking the airway, hypoxemia, bronchospasm, and hypoventilation.

(continued)

23. List four symptoms of hemorrhage.
- a. _____
 - b. _____
 - c. _____
 - d. _____

Answers may include increased pulse rate, restlessness, cold moist skin, low hemoglobin level, and decreased cardiac output.

24. Identify two types of exercises a client can be taught to perform to decrease the postoperative complication deep vein thrombosis.
- a. _____
 - b. _____

Answers may include straight leg raises, quadriceps sets, gluteal tightening, and ankle pumps.

25. The medication commonly used to reverse the effects of opioids is _____.
- Answer: Narcan (It is a narcotic antagonist and blocks opiate receptor sites.)

26. Hypoxia can be assessed by performing _____ and _____.
- Answer: Oxygen saturation level and capillary refill.

27. Normal bowel sounds following a surgical procedure generally are audible within _____ hours.
- Answer: 24–48 hours. (Peristalsis should begin about 6 hours after the surgical procedure, but can take up to 24 hours to be considered normal bowel sounds.)

28. Identify three examples of nonnarcotic pain management.
- a. _____
 - b. _____
 - c. _____

Answers may include: Imagery, relaxation, heat/cold, distraction, back rub, and noncontact therapeutic touch.

29. A herbal medicine that neutralizes antibiotics is _____.
- Answer: Kava-kava, which also potentiates central nervous system depressants, anesthetics, alcohol, and corticosteroids.

30. Arthritic changes of the cervical spine can result in _____.
- Answer: difficult intubation.

31. A bluish tinge around the umbilicus that is an indicator of either intra-abdominal bleeding peritoneal bleeding is called _____.
- Answer: Cullen's sign.

32. List three causes of urinary retention in a postoperative client.
- a. _____
 - b. _____
 - c. _____

Correct answers may include: medication (opioids, atropine), epidural anesthesia, recumbent position, abdominal surgery, prolonged immobility, sympathetic nerve stimulation due to pain, anxiety, and fear.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Dilation and curettage may be necessary for a woman with dysfunctional bleeding. *True.*
2. An advantage to use of a biologic heart valve for valve replacement is that it lasts longer than a mechanical valve. *False*
Biological valves do not last as long as mechanical valves but they have the advantage of being less likely to cause thromboemboli.
3. Dynamic cardiomyoplasty is performed to correct hypertrophic cardiomyopathy. *False*
Hypertrophic cardiomyopathy is a contraindication to dynamic cardiomyoplasty.
4. The pericardium can be removed without any significant harmful effects on the client. *True*
5. Speech is lost with a supraglottic laryngectomy. *False*
Voice quality is changed with a supraglottic laryngectomy; it is only lost with a total laryngectomy.
6. Tracheostomy suctioning is a clean procedure. *False*
Tracheostomy care and suctioning requires use of sterile technique.
7. Clients with a tracheostomy cannot swim. *False*
Clients with a tracheostomy can swim but only with a special device to prevent water from entering the respiratory tract.
8. A pillow is placed under the stump of an above the knee amputation (AK) to support it in an elevated position. *False*
The stump is kept in an extended position to avoid development of a contracture at the hip.
9. Nasogastric drainage decreases as peristalsis returns after gastric surgery. *True*
10. A client with an ileal conduit should take a shower with the urine collection bag in place. *False*
The stoma should be uncovered during showering or bathing but should be patted, not rubbed, to cleanse and dry it.
11. Clients having a skin lesion removed by cryosurgery should be told that they will feel a tingling sensation when the freezing substance is applied. *True*
12. Phantom breast pain can occur following a mastectomy *True*
13. Reducing tension on the suture lines is an important part of the care for a client with a vulvectomy. *True*
14. Surgically induced menopause occurs in premenopausal women who have a bilateral salpingo-oophorectomy. *True*
15. The goal of surgery done to treat glaucoma is to lower IOP. *True.*
16. The United Network for Organ Sharing (UNOS) is responsible for ensuring available organs are distributed equitably. *True*
17. The National Organ Transplant Act established the organ donor card system. *False*
The Uniform Anatomical Gift Act established the organ donor card system.
18. Before organs can be harvested, the family must give written consent. *True*
19. Psychological readiness and severe functional disability are not criteria for determining transplant need. *False*
Criteria for determining transplant need are end-stage organ failure, short life expectancy, severe functional disability, absence of other serious health problems, psychological readiness and financial status.

(continued)

20. A complication of breast augmentation is the formation of scar tissue around the implant, which makes the breast feel tight or hard. *True*
21. Preoperative preparation of the operative site includes shaving the site prior to the client going to the operating room. *False*
Shaving in of the surgical site occurs in the operating room.
22. Shivering during the immediate postoperative patient is indicative of a need for continued use of oxygen. *True*
Shivering increases the oxygenation needs of the client due to the expenditure of energy.
23. Hypoxemia is defined as a PO_2 level less than 65 mmHg. *False*
Hypoxemia is a PO_2 level <60 mmHg.
24. Clients in the PACU are usually assessed every 15 minutes. *True*
An assessment is performed every 10–15 minutes of the clients' condition, which includes VS.
25. A client whose skin that is cool, moist, and pale is experiencing hypotension. *False*
Though cool, moist skin is a symptom of hypotension and shock when the skin becomes pale the client is hemorrhaging.
26. Warm blankets are provided to clients in PACU to reduce hypothermia. *True*
During surgery client's experience hypothermia both due to the coldness of the room and administration of anesthetic agents.
27. The basal metabolic rate of a client increases during surgery. *True*
During surgery the client's basal metabolic rate increases, which requires use of more calories than client typically consumes.
28. Gynecological surgery places a client at risk for deep vein thrombosis. *True*
29. Only the use of sequential compression devices can prevent the development of deep vein thrombosis. *False*
Lower leg and ankle exercises performed by the client and use of TEDS can assist in preventing deep vein thrombosis.
30. A client with skeletal deformities has a higher risk of postoperative pulmonary complications. *True*
Other diseases and behaviors that increase the postoperative risk of pulmonary complications include smoking, chronic obstructive pulmonary disease, and respiratory infection.
31. Antiseizure medications should not be administered during surgery even for the client who routinely takes this category of medication. *False*
Antiseizure medications will be administered intravenously during surgery to prevent the occurrence of seizure activity.
32. Nurses are not to provide education on what a client should expect to see in the operating room. *False*
It is important to instruct the client on the general environment of the operating room to decrease their preoperative anxiety and to decrease the number of unknowns.
33. Clients do not need to ambulate in order for peristalsis to return following a surgical procedure. *False*
Ambulation facilitates the return of peristalsis.
34. A change in the color of a stoma, such as a colostomy, from bright red to pale gray is not unusual. *False*
A stoma with adequate circulation is always bright red. Any change in color is indicative of loss of circulation to the bowel.
35. Surgical clients should receive total parenteral nutrition if they are not able to take in nutrients for more than 3 days. *True*
Surgical clients will deplete their protein stores within 3–5 days if the only nutrition being given is IV fluids.

MATCHING ANSWERS

- | | |
|---------------------------------------|--|
| 1. <u>h</u> Endarterectomy | a. Antireflux procedure |

| 34. <u>a*</u> Obesity | c. Impaired wound healing |
| 35. <u>b</u> Bronchospasms | d. Pulmonary aspiration |

*The correct answer is a. Though obesity can also be a cause of pulmonary aspiration, the more likely postoperative complication is wound dehiscence.

APPLICATION ANSWERS

- The nurse goes in to meet and assess her client who had a vulvectomy 2 days ago. The client is dozing in bed in Fowler's position but states she is uncomfortable, when asked. Which action should the nurse take first?
 - Call the physician
 - Reposition the client in semi-Fowler's
 - Administer pain medication
 - Explain it is normal to be uncomfortable after the surgery

Rationale

Correct answer: b.

Change client's position to semi-Fowler's to alleviate discomfort and tension on suture line; sitting in a Fowler's position puts direct pressure on suture line(s) and causes discomfort. Pain medication cannot be administered without first checking for an order and determining when it was last given. In addition, change in position that may relieve the discomfort can be done immediately while the nurse is at the bedside, so it is the first action the nurse should take. Explaining discomfort is normal may relieve

anxiety but client's have a right to pain relief whether pain is expected or not.

2. The nurse should interpret a weight gain of 5.5 lb over 24 hours in a client with a biologic cardiac valve replacement as a sign of the development of which problem?
 - a. Graft rejection
 - b. Pericarditis
 - c. Congestive heart failure
 - d. Pyelonephritis

Rationale

Correct answer: c.

Weight gain, dyspnea, and tachycardia are symptoms of CHF, which can occur with graft failure. Hyperacute graft rejection is almost exclusively limited to transplanted kidneys and is a rare event because of careful cross matching before transplant. Symptoms of pericarditis include severe precordial pain, which is worse when lying supine and reduced when sitting up, fever, tachycardia, and myalgia. Symptoms of pyelonephritis include fever, chills, flank pain, costovertebral angle tenderness, and signs of lower UTI.

3. After which surgical procedure would the nurse plan to monitor the client's ankle-brachial index (ABI)?
 - a. Off pump coronary artery bypass
 - b. Dynamic cardiomyoplasty
 - c. Carotid endarterectomy
 - d. Femoral-popliteal bypass

Rationale

Correct answer: d.

Ankle-brachial index is a test of arterial status in the lower extremity. Normal arteries in the foot (dorsalis pedis and posterior tibial) have an index of 1.0–1.2. An index below 1.0 indicates arterial obstruction. After a bypass graft procedure in the leg, ABI is measured every 8 hours for the first 24 hours and then once a day. Peripheral pulses, color, and sensation in the extremity are also monitored. Arterial status of the foot is not a major concern after off pump coronary artery bypass, dynamic cardiomyoplasty, or carotid endarterectomy.

4. The evening nurse goes in to care for a client who had a modified mastectomy that morning. Which fact is essential for the nurse to know to provide safe care?
 - a. The involved arm should be wearing an elastic sleeve.
 - b. The involved arm should not be used for BP measurement.
 - c. The involved arm should be not be exercised for 10 days.

- d. The involved arm should be maintained at the level of the heart.

Rationale

Correct answer: b.

BP should not be measured on the arm on the operative side because the procedure interferes with circulation and can cause venous congestion in the affected extremity. Elastic sleeves are used in the management of lymphedema after a mastectomy. Limited exercises of the affected arm are started on the evening of surgery. The involved arm should not be kept in a dependent position for an extended length of time and if edema is present, it should be elevated as much time as possible.

5. Which assessment finding(s) on a client who had a transurethral resection of the prostate for BPH 4 hours ago would indicate the need to notify the physician?
 - a. Red bloody urine with small clots
 - b. BP of 110/50 mmHg, pulse 130 bpm
 - c. Urinary output of 200 ml greater than intake
 - d. Pain related to bladder spasms

Rationale

Correct answer: b.

A rapid pulse with a low BP is a potential sign of excessive blood loss and physician should be notified based on this finding. Some hematuria is usual for several days after surgery. A urinary output of 200 ml or greater than intake is adequate. Bladder spasms are expected to occur following surgery.

6. The nurse should interpret a complaint of joint pain from a client with a mechanical heart valve as potentially indicative of which problem?
 - a. Streptococcal infection
 - b. Vegetative embolus
 - c. Bleeding
 - d. Hypoxemia

Rationale

Correct answer: c.

Mechanical valves require that a client be on anticoagulant therapy for life because of the risk of thromboemboli. Therefore, the client is at risk for bleeding associated with anticoagulation, signs of which are joint pain, black or tarry stools, blood in the urine, and bleeding gums. Streptococcal infection occurs anywhere in the body and symptoms depend in part on location of the infection. Osteomyelitis may be streptococcal in origin and bone pain occurs but not necessarily joint pain. A vegetative embolus is a complication of infective endocarditis in which a piece of the platelet fibrin bacteria mass called vegetation which

(continued)

forms on the heart valves breaks off and travels in the blood stream. Symptoms of an embolus depend on where it lodges in the body and to what extent blood flow to the tissues is disrupted. Hypoxemia refers to decreased oxygen in the blood defined as a below normal PaO₂; hypoxia is oxygen lack at the tissue level. Joint pain due to hypoxia is seen in vasoocclusive crisis in sickle cell disease.

7. A client with atrial fibrillation suddenly complains of acute, severe pain in the left arm. On assessment the nurse finds the arm to be cold, pale, and without palpable pulses. Which problem should the nurse suspect?
- Myocardial infarction
 - Compartment syndrome
 - Arterial embolus
 - Hypovolemic shock

Rationale

Correct answer: c.

Arterial emboli are often associated with atrial fibrillation and often cause acute arterial occlusion the S&S of which are pain in the affected area, paralysis, absence of pulses, pallor, paresthesias, numbness and coolness. MI can cause an arterial embolus but an MI itself does not cause these symptoms. Compartment syndrome occurs when pressure, usually from edema, bleeding, or restrictive dressing, increases in a limited anatomic space and compromises circulation and function of tissues within the space. It is not caused by atrial fibrillation and symptoms are unrelenting pain, pallor, pulselessness, and paresthesias. Symptoms of hypovolemic shock are systemic, not limited to one extremity.

8. When caring for a postoperative client who has had a thyroidectomy, which medication should the nurse ensure is immediately available at the bedside?
- Calcium gluconate
 - Propylthiouracil
 - SSKI
 - Synthroid

Rationale

Correct answer: a.

Calcium gluconate should be immediately available at the bedside of a client who has had a thyroidectomy because of the risk of hypocalcemic tetany. Propylthiouracil, an antithyroid drug, blocks synthesis of thyroid hormone and is used in the treatment of hyperthyroidism. SSKI decreases blood flow to the thyroid gland. Synthroid is a thyroid hormone replacement drug and is used in the treatment of hypothyroidism.

9. A client having surgery for glaucoma asks the nurse how the doctor will know if the surgery is successful.

Which would be an appropriate response for the nurse to make?

- IOP will decrease
- Ability to read small print will improve
- Pupil will remain permanently dilated
- Peripheral vision will increase

Rationale

Correct answer: a.

The reason surgery is done for glaucoma is to lower IOP because increased IOP causes progressive loss of vision. Surgery is done when medication is ineffective. Damage done by increased IOP is permanent; therefore, ability to read is not improved. The pupil is not affected by the surgery so contraction and dilation occur normally. Glaucoma causes loss of peripheral vision before loss of central vision and this loss is irreversible.

10. Which advice would be appropriate for the nurse to give to a client with dumping syndrome?
- Take a drink after every four to five bites of food at a meal
 - Eat several small meals per day of wet foods
 - Remain in an upright position for 30–60 minutes after eating
 - Avoid foods that are concentrated carbohydrates

Rationale

Correct answer: d.

Foods that are concentrated carbohydrates should be avoided. Dumping syndrome has vasomotor (tachycardia, diaphoresis, flushing, weakness, palpitations, and anxiety) and GI symptoms (distention, nausea, vomiting, and diarrhea) and occurs when there is a rapid entry of boluses of hyperosmolar food directly into the small intestine. To decrease the symptoms of dumping syndrome, a client also should eat six small meals per day of dry foods and should not drink fluids with meals; avoid very hot or cold foods; and lie down for 30–60 minutes after eating.

11. When caring for a client who has had a kidney transplant, the nurse assesses for signs of rejection. For which S&S would the nurse observe? Mark all that apply.
- Change in urinary output
 - Flank pain
 - Edema
 - Sudden weight gain

Rationale

Correct answers: a, b, c, and d.

Change in urinary output, flank pain, edema, and sudden weight gain that is reflective of edema because water has weight are all symptoms of rejection of a kidney transplant.

12. After which procedure would the nurse be expected to titrate IV fluids to replace output during the first 24 hours?
- Liver transplant
 - Heart transplant
 - Kidney transplant
 - Lung transplant

Rationale

Correct answer: c.

Maintenance of fluid and electrolyte status is a key aspect of care following liver, heart, kidney, and lung transplants. However, it is only following a kidney transplant that I&O is checked hourly and IV fluids are titrated to replace output for the first 12–24 hours.

13. Which action should the nurse take when during assessment, he/she finds the client who is 2 days post a liver transplant has a temperature persistent of 101.5°F, pulse 95, and respiratory rate of 18?
- Reposition the client
 - Administer oxygen
 - Administer pain medication
 - Call the physician

Rationale

Correct answer: d.

Because immunosuppressed clients do not have as robust an immune response to infection and symptoms will be more subtle such as a temperature of 101.5°F, tachycardia, and tachypnea. Infection and its treatment are the critical concerns in this situation for this client and none of the other options address these.

14. When conducting discharge teaching for a transplant client, the nurse must make sure the client and family understand the importance of which self care activities? Mark all that apply.
- Medication compliance
 - Reporting of S&S etc.
 - Keeping follow-up appointments
 - Establishing a set sleep/wake routine

Rationale

Correct answers: a, b, and c.

Establishing a set sleep/wake routine is not essential for the transplant client and is not a part of routine discharge teaching for these clients.

15. Which directions would the nurse give to a client who is being prepared for discharge following a pneumonectomy? Mark all that apply.
- Continue breathing exercises at home.
 - Exercise arm and shoulder five times per day.

- Practice standing straight with shoulders even in front of the mirror.
- Do not lift more than 20 lb for at least a month.
- Stop any activity that causes dyspnea, chest pain, or excessive fatigue.
- Obtain influenza and pneumonia vaccines.
- Expect an intermittent cough with increased sputum.

Rationale

Correct answers: a, b, c, e, and f.

Breathing exercises need to be continued usually for about 3 weeks. Arm and shoulder exercises need to be continued five times a day with 10–20 repetitions each time. Clients need to practice standing straight with shoulders even because the shoulder on the affected side will tend to be lower due to the transection of muscles and natural tendency to guard sore areas. Looking in the mirror is the best way to see how the shoulder needs to be held for posture to be correct. Any activity that causes dyspnea, chest pain, or excessive fatigue should be stopped; these are signs of exceeding the ability of the remaining lung to meet the demand for oxygen. Chest pain may indicate inadequate oxygen reaching the myocardium. Obtaining the pneumonia and influenza vaccines is important because with only one remaining lung there is almost no respiratory reserve and so the ability to cope with a respiratory infection is severely compromised.

It is incorrect to tell the client not to lift more than 20 lb for at least a month because heavy lifting must be avoided for 3–6 months. An intermittent cough with increased sputum is not expected. In fact if this occurs, it should be reported immediately.

16. A client with which problem needs careful assessment for the development of ARDS?
- Pericarditis
 - Anemia
 - Acute pancreatitis
 - Pyelonephritis

Rationale

Correct answer: c.

ARDS is a complication of acute pancreatitis usually developing 3–7 days after the onset of the pancreatitis. It is most common in clients with severe volume depletion. The complication associated with pericarditis is pericardial effusion, with anemia the risk is for congestive heart failure. With pyelonephritis, intractable infection that may require surgery, even nephrectomy, to eradicate it.

(continued)

17. A client having cryosurgery for removal of a squamous cell carcinoma asks if the procedure will hurt. Which is the correct answer for the nurse to give?
- “You will not feel anything.”
 - “There will be a brief tingling pain.”
 - “There will be no pain but you may experience a slight odd smell.”
 - “There will be a momentary, stabbing pain.”

Rationale

Correct answer: b.

A brief tingling pain is felt with cryosurgery. An unpleasant odor can occur when electrocautery is used to burn abnormal tissue as in cases of cervical dysplasia or genital warts.

18. When planning for the postoperative care of clients having a thyroidectomy, which piece of equipment is most essential for the nurse to have available at the bedside?
- Suction machine
 - Tracheostomy set
 - Cardiac monitor
 - Humidifier

Rationale

Correct answer: b.

A tracheostomy set is needed at the bedside because of the risk of respiratory distress from compression of the trachea from bleeding or edema, laryngeal spasm from hypocalcemic tetany, or vocal cord spasm secondary to laryngeal nerve damage.

19. Which S&S occurring in a client 48 hours postadrenalectomy indicate that glucocorticoid dosage needs to be increased?
- Marked weakness, anorexia, nausea, or vomiting.
 - Severe dyspnea, tachycardia, apprehension
 - Paresthesias, numbness and tingling in the extremities, muscle spasms
 - Orthostatic hypotension, depressed reflexes, slow mentation.

Rationale

Correct answer: a.

Marked weakness, anorexia, nausea, or vomiting are S&S indicating that the dose of glucocorticoids needs to be increased. Severe dyspnea, tachycardia, and apprehension are S&S of respiratory/cardiovascular problems such as pulmonary edema. Paresthesias, numbness, tingling in the extremities, and muscle spasms are symptoms of hypocalcemic tetany. Orthostatic hypotension occurs postadrenalectomy but does not indicate a need for increased glucocorticoids nor do depressed reflexes and slow mentation.

20. A visitor with an obvious upper respiratory infection arrives to see a client 24 hours postoperative from an adrenalectomy. The nurse explains that it is very important that the client not be exposed to anyone with a contagious illness. The visitor asks why. Which fact should be the basis of the nurse's answer?
- The client is unable to fight infection because of loss of stress hormones.
 - Fluid and electrolyte fluctuations create an environment in which infective organisms can thrive.
 - Risk of infection is greatly increased because of excess cortisol.
 - The immune system is suppressed as part of the preparation for surgery and it takes 3–4 weeks for it to regain normal function.

Rationale

Correct answer: c.

Excess cortisol increases the risk of infection because it decreases the inflammatory response. Loss of epinephrine and norepinephrine are not the important factors in the increased risk of infection. Fluid and electrolyte fluctuations do not create an environment in which infective organisms can thrive. The immune system is not suppressed in preparation for surgery.

21. When teaching self-care to a client who has had abdominal liposuction, which information should the nurse include?
- Wear the compression garment when up for 2 weeks
 - Take aspirin as needed for discomfort
 - Expect asymmetry in the first few weeks after which it will taper off.
 - Avoid weight gain so effect of surgery is not negated.

Rationale

Correct answer: d.

Weight gain will negate the effect of the surgery. The compression garment must be worn for 7–10 days. Aspirin, as well as all anticoagulants, must be avoided because of the risk of bleeding. Asymmetry is a complication of the liposuction, it is not expected.

22. Which statement made by a client who has had a blepharoplasty indicates the need for further teaching?
- “I will avoid reading for 2–3 days.”
 - “I will not be able to wear my contact lenses for at least 2 weeks.”
 - “I will apply warm compresses to control swelling.”
 - “I need to avoid alcohol for 3 weeks.”

Rationale

Correct answer: c.

Iced compresses are used to control swelling and discoloration. All other statements correctly apply to the client who has had a blepharoplasty.

23. A client scheduled for a nephrectomy asks during the preoperative teaching session when the drain in the wound will be removed. Which is the best reply for the nurse to give?
- At the same time the sutures are removed.
 - Not until urinary output is clear and at least 600 ml/24 hr.
 - After narcotics are no longer required for pain relief.
 - When drainage has decreased to less than 30 ml/d

Rationale

Correct answer: d.

The Jackson–Pratt drain is removed when there is less than 30 ml of drainage in 24 hours. Sutures are removed in 7–10 days when the incision has healed. Urinary output is via the remaining kidney and has no relationship to the need for a drain in the operative area. Incisional pain is managed with opioid analgesics but pain is unrelated to drainage and the need for a drain.

24. Which problem places a client scheduled for a nephrostomy at the greatest risk for postoperative hemorrhage?
- Diabetes mellitus
 - History of urinary tract infections

- Uncontrolled hypertension
- Pernicious anemia

Rationale

Correct answer: c.

BP needs to be tightly controlled in clients undergoing a nephrostomy because of the risk of hemorrhage. Diabetes mellitus, prior urinary tract infections, or pernicious anemia do not increase the risk of hemorrhage from the procedure.

25. Which information should be included in the teaching plan for a client who has had a ureterosigmoidostomy?
- Lifelong prophylactic antibiotics will be needed.
 - Annual sigmoidoscopy should be obtained starting 10 years after surgery.
 - Fluid intake should not exceed 1200 ml/d.
 - Diet should be high in fiber and low in fat.

Rationale

Correct answer: b.

An annual sigmoidoscopy is recommended starting 10 years after surgery because of the increased risk of neoplasia developing in the sigmoid colon at the site of anastomosis of the ureters. Prophylactic antibiotics are not given, however, because there is the risk of kidney infection from reflux of feces, any temperature of 101°F or more, costovertebral angle pain, or significant changes in color, consistency, or amount of output should be reported to the health care provider. There is no limitation on fluid intake and no dietary restrictions.

CARDIOVASCULAR PROBLEMS

PERICARDITIS

- Pericarditis refers to the inflammation of the layers of the pericardium.
- It may involve the diaphragm.
- It may be primary or secondary to other diseases.
- It is a frequent complication of end-stage renal disease.

Etiology: It may result from bacterial, viral, or fungal infections, immunologic disorders, connective tissue diseases, neoplasms, renal failure, myocardial infarction (MI), myocardial injury, radiation, or drugs.

Precipitating factors: Clients with conditions that leave them immunocompromised as noted above.

S&S:

- Chest pain that worsens when deep breathing or lying in a supine position and improves when sitting up taking shallow breaths (this is one means to discriminate from acute MI since chest pain in MI is usually not effected by change in position)
- Dyspnea
- Malaise
- Fever
- Cough
- Elevated ESR and WBC
- Pericardial friction rub heard most commonly on expiration

Clinical Alert

Pericardial effusion with the potential for cardiac tamponade is a rare but life-threatening complication.

Dx: Presence of pericardial friction rub upon auscultation of lung sounds, ECG reveals diffuse ST segment elevation and PR segment depression, abnormal CBC, changes to cardiac enzymes in response to inflammatory processes, positive blood cultures, ESR, echocardiography shows thickening and calcification of pericardium, hemodynamic monitoring, CXR, CT scan, and MRI

Rx: Treat underlying cause and initiate measures to relieve symptoms, treat pain with NSAIDs, and treat with antibiotics or antivirals as needed

Nursing Process Elements

- Monitor vital signs (VS) and heart sounds
- Administer pain medication to treat malaise and other flu-like symptoms
- Administer NSAIDs as ordered
- Allow for rest periods
- Monitor for signs of decreased cardiac output
- Provide comfort measures such as increased fluids, rest periods, and distraction techniques

Client teaching for self-care

Teach client to

- know the nature of the disease and ways to prevent recurrence
- adhere to medication schedule
- adopt ways to modify lifestyle to conserve energy and reduce fatigue during acute episode of illness
- recognize signs of recurrence such as chest pain, fever, and malaise

MYOCARDITIS

- Myocarditis refers to the inflammation of the myocardium.
- This inflammatory process causes edema and damage to the cells of the heart.
- It results in weakening of the heart muscle and decreased contractility.

Etiology: Infectious agents such as bacteria, viruses, protozoa, or helminths, toxins, systemic disease, radiation, and selective drugs.

Precipitating factors: Most common are viral infections especially for immunocompromised individuals (i.e., HIV).

S&S:

- Initially may be asymptomatic
- Tachycardia and dysrhythmia
- Unexplained heart failure
- Fever and chills
- Pleuritic chest pain with presence of friction rub
- Fatigue
- Dyspnea
- Palpitations
- Rales

Clinical Alert

Presentation of myocarditis is often subacute and, if left untreated, can become a chronic condition that ultimately leads to dysrhythmias, congestive heart failure (CHF), or death.

Dx: Elevated viral titers and ESR, increased serum cardiac enzymes, nonspecific ST–T wave changes on ECG. Definitive diagnosis established with positive endomyocardial biopsy

Rx: IV antibiotics or antiviral, antipyretics, treat for signs of heart failure or dysrhythmias (medications to improve cardiac output or to treat dysrhythmias), monitor for complications such as cardiac tamponade or pneumothorax or bleeding postbiopsy

Nursing Process Elements

- Modify ADLs to respond to fatigue
- Address anxiety
- Provide emotional support
- Monitor VS and heart sounds
- Be alert for signs of heart failure
- Maintain bed rest or limited activity to decrease demands on cardiac function
- Place client in semi-Fowler's position to facilitate gas exchange
- Administer antibiotics or antivirals as well as other medications as needed

Nursing Assessment Alert

Monitor for digitalis toxicity since clients with myocarditis have increased sensitivity to digitalis.

Client teaching for self-care

Teach client to

- conserve energy
- plan activities throughout the day to allow for rest periods
- avoid NSAIDs since these have been found to increase myocardial damage
- follow a heart-healthy diet
- adhere to medication regimen

- know early signs of heart failure such as dyspnea and peripheral edema to avoid recurrence or complications

ENDOCARDITIS

- Endocarditis refers to the infection of the endocardial surface (lining) of the heart including the valves.
- The inflammatory process allows the formation of clots or vegetations to form on the heart valves and these areas become an area to which bacteria migrate and multiply.
- The presence of the vegetation fosters bacterial growth.
- It has acute and subacute classifications.

Etiology: Rheumatic heart disease, clients with prosthetic heart valves, IV drug use, mitral valve prolapse (very common cause), and infection-causing organisms usually bacteria (*Streptococci*, *Enterococci*, or *Staphylococcus aureus*).

Precipitating factors: Underlying cardiac conditions, dental, surgical, or invasive procedures, or urological procedures. There must be some mechanism to allow entrance of bacteria to the bloodstream.

S&S:

- Malaise
- Anorexia
- Fever
- Fatigue
- Weight loss
- Night sweats
- Heart murmurs
- Elevated ESR and WBC

Clinical Alert

Infective endocarditis has a 20–30% mortality rate.

Dx: Positive blood cultures, laboratory work reflecting an infectious or inflammatory process, and presence of valvular vegetations on echocardiogram

Rx: Prolonged course of antibiotics to eliminate all microorganisms from the vegetative growth (4–6 weeks in duration) and to prevent complications. Clients with valve damage may require surgical repair or replacement of damaged valves

Nursing Process Elements

- Monitor VS and heart sounds (assess for presence of murmurs)

- Administer IV antibiotics and monitor for side effects such as renal or ototoxicity associated with high doses or prolonged therapy
- Monitor for signs of heart failure
- Assess for signs of embolic event or dysrhythmias
- Provide adequate rest periods

Client teaching for self-care

Teach client

- ways to avoid recurrence of infection such as use of antibiotic prophylaxis for dental or urological procedures
- ways to modify lifestyle so as to avoid excessive fatigue and to stop activities that result in chest pain, faintness, or dyspnea
- about the importance of completing medication schedule for antibiotics and to not stop therapy prematurely since this may lead to recurrence or complications
- about the side effects of medications

RHEUMATIC FEVER

- Rheumatic fever is a systemic inflammatory autoimmune disease.
- It usually follows a group A beta-hemolytic streptococcal infection.
- It can involve the heart, joints, skin, and brain.

Etiology: It is a delayed illness of an upper respiratory infection caused by a group A beta-hemolytic streptococcal infection.

Precipitating factors: An upper respiratory infection, such as strep throat, scarlet fever, tonsillitis, pharyngitis, approximately 2–6 weeks prior.

S&S:

- Fever
- Joint pain, migratory polyarthritis
- Joint swelling; redness, or warmth
- Abdominal pain
- Skin rash (erythema marginatum)
- Aschoff bodies, inflammatory hemorrhagic bullous lesions located on the myocardium usually found on autopsy
- Sydenham's chorea also called St. Vitus Dance—emotional instability, muscular weakness and rapid, uncoordinated jerky movements affecting primarily the face, feet, and hands
- Epistaxis (nosebleeds)
- Carditis

- Subcutaneous nodules located on extensor surfaces of knees, elbows, and knuckles
- Cardiac murmur

Dx: Based on clinical presentation with signs and symptoms of carditis, polyarthritis, chorea, characteristic rash, and subcutaneous nodules being major manifestations.

Rx: Anti-inflammatory medications such as aspirin or corticosteroids; antibiotic therapy (penicillin, erythromycin), includes the continuous use of low dose antibiotics to prevent recurrence; supportive therapy for other symptoms

Clinical Alert

Salicylates are avoided until the diagnosis is confirmed or denied as they may mask some symptoms of rheumatic fever.

Nursing Process Elements

- Assess for risk factors
- Monitor VS
- Assess laboratory values for elevated erythrocyte sedimentation rate, C-reactive protein
- Monitor heart sounds and ECG
- Medicate as prescribed for pain
- Implement comfort measures
- Administer antibiotics as prescribed
- Maintain bed rest during acute stage
- Maintain fluid balance
- Provide emotional support
- Provide client and family education with respect to prophylactic antibiotic therapy to reduce the risk of recurrent rheumatic fever
- Instruct client and family in proper and prompt treatment of strep throat and scarlet fever
- Provide client and family education on the course and recurrence of rheumatic fever

CARDIAC DYSRHYTHMIA

- Cardiac dysrhythmias refers to any disturbance or abnormality in the cardiac conduction system causing an alteration in cardiac rate or rhythm.
- Normal conduction goes from the Sinoatrial (SA) Node → Atrioventricular (AV) Node → bundle of His → bundle branches → Purkinje fibers.

- Dysrhythmias may be benign or lethal.
- The terms “arrhythmia” and “dysrhythmia” are used interchangeably.
- Normal ECG interpretation:
 - Heart rate is 60–100 bpm.
 - Rhythm is regular.
 - P wave is present and there is one in front of every QRS.
 - PR interval is 0.12–0.20 seconds.
 - QRS is 0.06–0.10 seconds.

Etiology: There are two major categories of dysrhythmias:

- Alteration in impulse formation
 - Rate: tachycardia (over 100 bpm) or bradycardia (under 60 bpm)
 - Rhythm: regular or irregular
 - Ectopic: impulse starts outside the SA node, may be in the atria, junction, or ventricles
- Alteration in conductivity
 - Heart blocks
 - Reentry phenomena: activation of the muscle twice for one impulse

Precipitating factors: Ischemia, electrolyte disturbances, fever, acidosis, stress, exercise, pain, hypoxia, anemia, hypovolemia, cardiac and systemic diseases, atherosclerosis, medications, trauma, metabolic disorders, caffeine, alcohol, and aging.

S&S:

- May be asymptomatic
- Dizziness, angina, disorientation, hypotension, syncope, palpitations, diaphoresis, fatigue, shortness of breath, changes in pulse rate or rhythm
- Lethal dysrhythmias may progress to absence of pulse, heart sounds, blood pressure, and consciousness. Pupils can become dilated and cyanosis and seizures can develop leading to death

Dx: 12-lead ECG, continuous ECG monitoring, intermittent ECG recording, stress test, electrophysiology studies, history and physical examination. Diagnostic studies to help determine cause of dysrhythmias may include blood chemistry, chest X-ray, and echocardiogram

Rx: Depends on the dysrhythmia

SINUS TACHYCARDIA

In sinus tachycardia,

- pacemaker site is SA node,
- heart rate is between 101 bpm and 160 bpm,
- rhythm is regular,

- P waves present and one in front of every QRS,
- PRI is normal, and
- QRS is normal.

Etiology: Usually a symptom of an underlying condition which causes a compensatory response that enhances automaticity. There is either an increase in sympathetic nervous system response or a decrease in parasympathetic nervous system response. Increases cardiac workload and oxygen use.

Precipitating factors: Fever, exercise, fear, strong emotions, stress, alcohol, caffeine, nicotine, stimulants, thyrotoxicosis, myocardial ischemia, shock, hemorrhage, and anemia.

S&S:

- Often asymptomatic
- Increased pulse rate, palpitations, dyspnea, syncope, angina, disorientation, and anxiety
- Can produce pulmonary edema if prolonged and severe

Assessment Alert

Reduced diastolic filling time may lead to decreased cardiac output with syncope and hypotension. It can be an early sign of cardiac dysfunction.

Dx: 12-lead ECG

Rx: Treat or eliminate underlying cause

- May need no intervention if client is asymptomatic
- Treat heart rate if unable to find or treat cause or symptoms persist
- Give oxygen at 2–4 lpm (liters per minute), if oxygen saturation decreases
- Beta blockers, verapamil, digoxin, or adenosine may be used to slow heart rate

Nursing Process Elements

- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Medicate for fever
 - Provide emotional support
 - Treat pain
 - Stop exercise
 - Eliminate caffeine and stimulants
 - Follow medical regime
- Assess S&S for developing complications

- Provide client education
- Administer medications as prescribed

Client teaching for self-care

Teach client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
 - exercise in moderation
- about the causes and treatments for sinus tachycardia
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

SINUS BRADYCARDIA

In sinus bradycardia,

- pacemaker site is SA node,
- heart rate is less than 60 bpm,
- rhythm is regular,
- P waves present and one in front of every QRS,
- PRI is normal, and
- QRS is normal.

Etiology: It may be a result of increased vagal activity or decreased automaticity due to injury or ischemia of the sinus node.

Precipitating factors: Normally seen in well-trained athletes and often when people are sleeping. Other causes include vagal stimulation (severe pain, vomiting, bearing down during defecation, carotid massage), medications (digoxin, beta blockers, calcium channel blockers), increased intracranial pressure, metabolic disorders, hypothermia, ischemia of the sinus node, and inferior wall MI.

S&S:

- Often asymptomatic
- Decreased heart rate
- May cause hemodynamic instability such as syncope, dyspnea, hypotension, angina, decreased level of consciousness, ST-segment changes

Assessment Alert

Always assess the client for hemodynamic instability before treating dysrhythmia.

Dx: 12-lead ECG, history and physical examination

Rx: None if client is asymptomatic. If client is becoming hemodynamically unstable, treat the cause and raise the heart rate.

- Stop or prevent further vagal stimulation
- Stop or decrease medications as ordered
- Decrease intracranial pressure
- Treat underlying conditions
- Decrease cardiac workload
- Give oxygen 2–4 lpm, if oxygen saturation is decreased
- Give medication to increase heart rate: Atropine 0.5–1.0 mg IVP
- Start emergency transcutaneous pacing if necessary

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Decrease or stop medications (beta blockers, digoxin) as ordered
 - Provide emotional support
 - Decrease cardiac workload
 - Maintain client safety
 - Prepare for emergency treatment
 - Follow medical regime
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed

Client teaching for self-care

Instruct client

- about the causes and treatments for sinus bradycardia
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

PREMATURE ATRIAL CONTRACTIONS

In premature atrial contractions (PAC),

- pacemaker site is atrial tissue,
- rate is variable but underlying rate is normal,

- rhythm is irregular with normal rhythm being interrupted with an early beat,
- P waves are present for each QRS, but P wave for early beat will look different from sinus P waves and the P wave may be hidden in the previous T wave,
- PRI will be 0.12–0.20 seconds but may be shorter or longer for the early beat, and
- QRS is normal.

Etiology: Irritable foci in the atria assume the pacemaker function for a single beat. Irritable foci is often due to hypoxia.

Precipitating factors: Can occur in people with normal hearts. Causes include increase in stimulants such as caffeine or nicotine, stress, alcohol, stretched myocardium, hypoxemia, hypokalemia, hypermetabolic state, or atrial ischemia.

S&S:

- Often asymptomatic
- May feel heart “skip a beat”
- A pulse deficit (difference between apical and radial pulse) may exist
- May feel a pause when taking the pulse

Assessment Alert

The most common cause for a pause in the heartbeat is a PAC.

Dx: 12-lead ECG

Rx: If infrequent, no treatment is necessary. If increasing in frequency and causing symptoms, treatment is focused on treating and/or eliminating the cause

- Decrease or stop stimulants
- Stress reduction
- Decrease or stop alcohol intake
- Treat CHF or underlying medical conditions
- Give oxygen 2–4 lpm as prescribed
- Treat electrolyte imbalances

Nursing Process Elements

- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Provide emotional support
 - Treat underlying medical condition

- Give oxygen
- Treat electrolyte imbalance
- Eliminate caffeine and stimulants
- Follow medical regime
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed

Client teaching for self-care

Teach client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
 - reduce alcohol intake
- about the causes and treatments for premature atrial contractions
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

ATRIAL TACHYCARDIA

In case of atrial tachycardia,

- pacemaker site is atrial tissue,
- rate is 101–250 bpm,
- rhythm is regular,
- P waves may or may not be present for each QRS. If present the P waves will look different from sinus P waves. P wave may be hidden in the previous T wave,
- PRI may or may not be measurable depending on the rate, and
- QRS is normal.

Etiology: Irritable foci in the atria assumes the pacemaker function which is rapid and sustained. Reentry phenomenon or abnormal automaticity.

Precipitating factors: Basically the same causes as PAC but atrial tachycardia is clinically more significant because the rate is prolonged and more rapid. Causes include increase in stimulants such as caffeine or nicotine, stress, alcohol, stretched myocardium, fever, sepsis, hypoxemia, hypokalemia, hypermetabolic state, atrial ischemia, and heart disease.

S&S:

- May be asymptomatic if rate is slower
- May feel heart “racing,” palpitations
- A pulse deficit (difference between apical and radial pulse) may exist

- Dizziness, dyspnea, anxiety, diaphoresis, angina, fatigue, and polyuria
- If sustained may lead to angina, heart failure, and MI

Assessment Alert

The more rapid the rate, the more likely a client is to experience symptoms since there is a decrease in diastolic filling time, increase in myocardial oxygen consumption, decrease in oxygen supply and decrease in cardiac output.

Dx: 12-lead ECG, continuous ECG monitoring, intermittent ECG recording if required, stress test, electrophysiology studies, history and physical examination

Rx: Decrease heart rate; stop reentry phenomenon

- Vagal stimulation
 - Have client “bear down” like having a bowel movement
 - Carotid sinus massage on one side at a time by a physician
- Treat CHF or underlying medical conditions
- Give oxygen 2–4 lpm as prescribed
- Medications to decrease heart rate:
 - Adenosine (Adenocard) 6-mg IV bolus followed with 20-ml saline flush; repeat with 12-mg bolus if necessary (contraindicated with people with severe asthma)
 - Amiodarone, diltiazem, and digoxin
- Electrical synchronized cardioversion

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Provide emotional support
 - Treat underlying medical condition
 - Give oxygen
 - Treat electrolyte imbalance
 - Eliminate caffeine and stimulants
 - Follow medical regime
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed
- Prepare for emergency electrical synchronized cardioversion

Client teaching for self-care

Instruct client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
- to reduce alcohol intake
- about the causes and treatments for atrial tachycardia
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

ATRIAL FLUTTER

In the case of atrial flutter,

- there are multiple pacemaker sites in the atrial tissue,
- atrial rate is between 250 bpm and 400 bpm; ventricular rate depends on AV conduction and is usually 75–150 bpm,
- atrial rhythm is regular, ventricular may be regular or irregular,
- P waves are saw-toothed and are called flutter or F waves,
- PRI is not measurable. Conduction ratio of atrial to ventricular may be 2:1, 3:1, 4:1, 5:1, 6:1, or variable, and
- QRS is normal.

Etiology: Intra-atrial reentry mechanism which causes a rapid and regular atrial rhythm.

Precipitating factors: Preexisting cardiac disease such as CHF, coronary artery disease (CAD), MI, cardiomyopathy; pulmonary embolism, thyrotoxicosis, abnormal conduction syndromes, and conditions that stimulate the sympathetic nervous system such as anxiety, caffeine, stress, and alcohol intake.

S&S:

- May be asymptomatic if ventricular rate is slower
- May feel heart “fluttering,” palpitations
- A pulse deficit may exist
- Dizziness, dyspnea, anxiety, diaphoresis, angina, fatigue, and decreased urinary output
- If sustained may lead to angina, heart failure, and MI

Clinical Alert

May lose the benefit of the atrial kick, which causes a further decrease in cardiac output.

Dx: 12-lead ECG

Rx: Decrease heart rate; stop reentry phenomenon

- Vagal stimulation may be used to help slow down rate to accurately identify rhythm
 - Have client “bear down” like having a bowel movement
 - Carotid sinus massage on one side at a time by a physician
- Treat underlying medical conditions
- Give oxygen 2–4 lpm as prescribed
- Medication to convert rhythm
 - first line ibutilide (Corvert)
 - second line flecainide, propafenone, procainamide, and amiodarone
- Medications to slow conduction via AV node
 - Calcium channel blockers, beta blockers, and digoxin
- Electrical synchronized cardioversion
- Atrial overdrive pacing
- Radiofrequency ablation (RFA)

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Provide emotional support
 - Treat underlying medical condition
 - Treat electrolyte imbalance
 - Eliminate caffeine and stimulants
 - Follow medical regime
- Start oxygen at 2–4 lpm if ordered
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed
- Prepare for emergency elective cardioversion or surgery

Client teaching for self-care

Instruct client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
 - reduce alcohol intake
- about the causes and treatments for atrial flutter
- about when to seek medical care

- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

ATRIAL FIBRILLATION

In the case of atrial fibrillation,

- pacemaker sites are multiple reentry circuits in the atrial tissue,
- atrial rate is between 300 bpm and 600 bpm; ventricular rate depends on AV conduction and is usually 100–180 bpm,
- rhythm is irregularly irregular; irregular R-to-R intervals,
- P waves not identifiable, presence of chaotic fibrillatory wavelets,
- PRI is not measurable, and
- QRS is normal.

Clinical Alert

It is the most frequently encountered dysrhythmia in United States.

Etiology: Several intra-atrial reentry circuits which cause atria to quiver rather than contract.

Precipitating factors: Preexisting cardiac disease such as left ventricular hypertrophy, CHF, valvular heart disease, acute MI, myocarditis, and pericarditis; pulmonary embolism, hypertension, thyrotoxicosis, pneumonia, abnormal conduction syndromes, and conditions that stimulate the sympathetic nervous system such as anxiety, caffeine, stress, and alcohol intake.

S&S:

- May be asymptomatic if ventricular rate is slower
- May feel heart “fluttering,” palpitations
- A pulse deficit may exist
- Dizziness, dyspnea, anxiety, diaphoresis, angina, fatigue, and decreased urinary output
- If sustained may lead to angina, heart failure, thrombus formation, stroke, and MI

Assessment Alert

Loses the benefit of the atrial kick, which causes a further decrease in cardiac output.

Peripheral pulses are irregular and of variable strength.

Dx: 12-lead ECG

Rx: Stop reentry phenomenon and convert to NSR; control ventricular rate

- Treat underlying medical conditions
- Give oxygen 2–4 lpm as prescribed
- Medication to convert rhythm
 - Emergency drugs IV ibutilide (Corvert), amiodarone
 - Long term medications to maintain client in NSR include amiodarone, disopyramide, flecainide, and moricizine
- Medications to slow conduction via AV node
 - Calcium channel blockers, beta blockers, and digoxin
- Anticoagulants
- Electrical synchronized cardioversion
- Atrial pacing
- Cox-Maze III surgical procedure

Nursing Process Elements

- Assess client for hemodynamic stability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Treat underlying cause
 - Provide emotional support
 - Treat underlying medical condition
 - Eliminate caffeine and stimulants
 - Follow medical regime
- Start oxygen at 2–4 lpm if ordered
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed
- Prepare for emergency elective cardioversion or surgery

Client teaching for self-care

Teach client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
 - reduce alcohol intake
- about the causes and treatments for atrial flutter
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

PREMATURE VENTRICULAR CONTRACTIONS

In the case of premature ventricular contractions (PVC),

- pacemaker site is an irritable foci in the ventricular tissue,
- the normal rate is 60–100 bpm,
- the rhythm is irregular: PVC interrupts normal rhythm; it has a full compensatory pause,
- P wave is not present,
- PRI is absent, and
- QRS is wide and bizarre (>0.12 seconds).

Etiology: Irritable foci in the ventricle assumes the pacemaker function for one beat. Reentry phenomenon or abnormal automaticity may also be causes.

Precipitating factors: Acute ischemia, preexisting cardiac diseases such as CHF, CAD, mitral valve prolapse, or acute MI, metabolic abnormalities such as hypokalemia, hypoxemia, acidosis, digitalis toxicity, sympathomimetic drugs, and conditions that stimulate the sympathetic nervous system such as anxiety, caffeine, stress, and alcohol intake.

S&S:

- May be asymptomatic
- May feel heart “skip a beat,” palpitations
- Depends on frequency of PVCs and on concomitant factors

Nursing Intervention Alert

Treatment is indicated only when symptoms of decreased CO exist.

Dx: 12-lead ECG, continuous ECG monitoring, intermittent ECG recording if intermittent, stress test, electrophysiology studies, history and physical examination

Rx: Treat if client is experiencing symptoms

- Treat underlying medical conditions
- Check electrolytes
- Give oxygen 2–4 lpm as prescribed
- Eliminate stimulants
- Check for digitalis toxicity
- Monitor drugs for proarrhythmic effect
- Beta blockers may be given to reduce response to sympathetic stimulation

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm

- Assess for underlying cause
- Monitor electrolytes
- Treat underlying cause
 - Provide emotional support
 - Treat underlying medical condition
 - Eliminate caffeine and stimulants
 - Follow medical regime
- Start oxygen at 2–4 lpm if ordered
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed

Client teaching for self-care

Teach client

- to make necessary lifestyle changes
 - eliminate stimulants
 - reduce anxiety
 - reduce alcohol intake
 - stop tobacco use
- about the causes and treatments for PVCs
- about when to seek medical care
- about the medication regime
 - the side effect of medication
 - how to take pulse
- to monitor pulse and blood pressure

VENTRICULAR TACHYCARDIA

In the case of ventricular tachycardia (VT),

- pacemaker site is an irritable foci in the ventricular tissue which takes over as pacemaker for three or more consecutive beats,
- the atrial rate is indeterminable while the ventricular rate is 101–250 bpm,
- the rhythm is usually regular but may be slightly irregular,
- P wave is usually buried in the preceding QRS complex,
- PRI is indeterminable, and
- QRS is wide and bizarre (>0.12 seconds).

Etiology: Irritable foci in the ventricle assume the pacemaker function for three or more consecutive beats usually as a result of a reentry phenomenon.

Precipitating factors: Acute ischemia, preexisting cardiac diseases such as CHF, CAD, mitral valve prolapse, or acute MI and metabolic abnormalities such as hypokalemia, hypoxemia, acidosis, digitalis toxicity, and proarrhythmic effect of certain antidysrhythmic medications.

S&S:

- May feel heart “skip a beat,” palpitations
- Depends on frequency of PVCs and on concomitant factors

Nursing Intervention Alert

Pulseless VT is a serious dysrhythmia and must be treated immediately.

Dx: 12-lead ECG, continuous ECG monitoring, intermittent ECG recording if intermittent, stress test, electrophysiology studies, history and physical examination

Rx: Treat if client is experiencing symptoms

- Cardiac monitoring
- Treat underlying medical conditions
- Check electrolytes
- Give oxygen 2–4 lpm as prescribed
- Check for digitalis toxicity
- Monitor drugs for proarrhythmic effect
- Pulseless VT—treat with defibrillation
- Stable VT with rate <100—monitor client
- Stable VT with rate >100—treat
 - Pharmacologically: amiodarone, beta blockers, and lidocaine
 - Overdrive pacing
 - Synchronized cardioversion
 - Implantable cardioverter defibrillator (ICD)

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Monitor electrolytes
- Treat underlying cause
- Provide emotional support
- Give oxygen
- Follow medical regime
- Assess S&S for developing complications
- Provide client education
- Administer medications as prescribed
- Prepare for emergency interventions

Client teaching for self-care

- Teach client
 - about the causes and treatments for VT

- about when to seek medical care
- about the medication regime
 - the side effects of medication
 - how to take pulse
- to monitor pulse and blood pressure
- about the emergency treatments
- about the use of implanted cardioverters
- to understand how AED works
- Ensure family members know CPR

VENTRICULAR FIBRILLATION

In the case of ventricular fibrillation (VF),

- pacemaker site is chaotic electrical activity in the ventricles with multiple foci,
- the rate cannot be determined,
- the rhythm is grossly irregular,
- there is no P wave,
- PRI is indeterminable, and
- QRS consists of bizarre undulating waves.

Etiology: Multiple irritable foci in the ventricles cause rapid, ineffective, and disorganized depolarization of the ventricles. Ventricles quiver.

Precipitating factors: Acute ischemia, preexisting cardiac disease such as CHF, CAD, or acute MI; hyperkalemia, hypoxemia, acidosis, digitalis toxicity, proarrhythmic effect of certain antidysrhythmic medications, and electrical shock.

S&S:

- No pulse
- Loss of consciousness
- No blood pressure
- No respirations

Nursing Intervention Alert

Medical emergency. Clinically VF is indistinguishable from asystole.

Dx: 12-lead ECG

Rx:

- Defibrillation
- CPR
- Antidysrhythmic drugs if initial attempts at defibrillation are not successful
 - Amiodarone
- Advanced life support

Nursing Process Elements

- Assess client for hemodynamic instability
- Monitor VS and cardiac rhythm
- Assess for underlying cause
- Monitor electrolytes
- Treat underlying cause
- Administer medications as prescribed
- Prepare for emergency interventions

Client teaching for self-care

Teach client to

- know what are the causes and treatments for VF
- know when to seek medical care
- understand medication regime
 - know the side effects of medication
 - know how to take pulse
- monitor pulse and blood pressure
- understand emergency treatments
- understand the use of implanted defibrillators
- prepare a living will and a medical power of attorney

HEART FAILURE

- Heart failure (HF) is also referred to as congestive heart failure (CHF).
- Its onset can be chronic or acute heart failure (pulmonary edema or cardiogenic shock).
- It refers to the inability of the heart to pump sufficient blood to meet the needs of tissues for oxygen and nutrients.
- The incidence and prevalence of CHF increase with age.

Etiology: Damage to the heart, regardless of the cause, leads to decreased cardiac output and decreased tissue perfusion. Fluid overload or inadequate tissue perfusion results in altered ventricular filling and emptying.

- Types:

—Left-sided heart failure

Left ventricle is unable to pump blood effectively into systemic circulation and thus blood returns back into pulmonary circulation

—Right-sided heart failure

Right ventricle is unable to effectively pump blood into pulmonary circulation and blood returns back into systemic circulation

Think Smart/Test Smart

When thinking about heart failure remember: the *Ls go together and the Rs go together*. In Left-sided failure, there is a backup of blood/pressure in the Lung. In Right-sided failure, there is a backup of blood/pressure in the Rest of the body.

- High-output failure Cardiac output is adequate but exceeded by metabolic needs of the tissues
- Biventricular failure Both ventricles fail to function adequately
- Classification according to New York Heart Association criteria:
 - Class I Normal activity does not initiate symptoms
 - Class II Normal activity does initiate symptoms but symptoms subside with rest
 - Class III Minimal activity initiates symptoms but symptoms subside with rest
 - Class IV Any activity initiates symptoms and symptoms are present at rest

Precipitating factors: Underlying cardiac disease, pulmonary disease, hyperthyroidism, anemia, or pregnancy.

S&S:

- Left heart failure (pulmonary symptoms remember “Left and Lung”)—tachypnea, tachycardia, cough, bibasilar crackles, gallop rhythm, increased pulmonary artery pressure, hemoptysis, fatigue, cyanosis, dyspnea, orthopnea, nocturia, and paroxysmal nocturnal dyspnea (PND)
- Right heart failure (systemic symptoms remember “Right and Rest of the body”)—peripheral edema, hepatomegaly, splenomegaly, ascites, jugular vein distension (JVD), increased central venous pressure, weakness, anorexia, nausea, indigestion, weight gain, mental changes, bounding pulses, oliguria, and cool extremities
- Biventricular failure—symptoms of both right and left heart failure

Clinical Alert

OB

CHF is progressive over time—early intervention and management enhances quality and length of life.

Woman who become pregnant and have been classified as having Class I or Class II of heart disease according to the New York Heart Association Classification (1994) usually experience a normal pregnancy without complications. Women in

Classes III and IV may have difficulty achieving a pregnancy and are at risk for complications including fetal demise and heart failure. All women with existing heart disease will require vigilant monitoring during pregnancy because of the risk of heart failure. The workload of the heart peaks at the end of the second trimester or the beginning of the third trimester. The greatest risk for the development of heart failure would be as the woman reaches this period of gestation. If the cardiac condition allows, the woman will be allowed to enter labor spontaneously, although induction may be necessary due to cardiac difficulty. A low forceps delivery with adequate pain management usually produces the least cardiac stress.

Dx: Clinical manifestations, chest X-ray, echocardiogram, increased CVP, increased pulmonary artery pressure, ABG analysis, and liver function test

Rx: Reduce oxygen demands of the myocardium by eliminating and managing contributing factors. Decrease cardiac workload by decreasing afterload and preload, improve contractility, and manage symptoms

Think Smart/Test Smart

Remember the terms “preload” and “afterload” refer to the ventricles, primarily used in reference to the left ventricle.

Preload refers to the amount of blood sitting in the left ventricle “ready to go” when the ventricle contracts. The more blood in the ventricle, the more the ventricular wall is stretched; the greater the stretch, the greater the contractility, and the greater the cardiac output.

Afterload refers to the amount of pressure beyond the left ventricle, i.e., the pressure in the aorta and arterial system. The greater the afterload, the smaller is the cardiac output. Therefore, if the afterload is decreased, the cardiac output will increase.

- Low-sodium diet
- Medications include angiotensin-converting enzyme (ACE) inhibitors, diuretics, digitalis, beta blockers, nitrates, antihypertensives, positive inotropes (dopamine, dobutamine), direct vasodilators, and morphine sulfate
- Physical and psychological rest

- Oxygen
- If medical intervention is unsuccessful then mechanical assist devices (intra-aortic balloon pump [IABP], left ventricular assist devices), and heart transplant

Nursing Process Elements

- Monitor I&O
- Check weight daily
- Assess for signs of fluid overload
- Monitor level of consciousness
- Assess VS, heart and lung sounds
- Monitor for cardiac dysrhythmias
- Maintain bed rest with HOB elevated
- Instruct client to avoid valsalva maneuver
- Assess and record abdominal girth
- Monitor ABGs
- Oxygen as prescribed
- Provide emotional rest
- Monitor electrolytes
- Administer medications as ordered
- Provide client teaching
- Provide low-sodium diet as ordered

Nursing Alert

Monitor for hypokalemia with potassium depleting diuretics

Client teaching for self-care

Instruct client

- to perform activity without adding to fatigue, so he/she should pace and prioritize daily activities
- to avoid extremes in temperature that would tax cardiac function
- to stop activity if experiencing lightheadedness or shortness of breath
- to plan for periods of rest alternating with periods of activity
- to maintain a low-sodium diet
- to take potassium replacement if taking a potassium depleting diuretic and/or include foods high in potassium in the diet, e.g., orange and tomato juice, bananas, raisins, figs, prunes, apricots, spinach, cauliflower, and potatoes
- to take diuretics at times that allow for uninterrupted sleep
- to adhere to medical regime
- to weigh self daily and report to physician a greater than 3-lb weight gain

- how to take pulse and report to physician if pulse is <60 bpm or >120 bpm
- to know S&S of complications or worsening of HF

HYPERTENSION

- Hypertension is a disorder characterized by BP readings greater than 140 mmHg systolic and/or 90 mmHg diastolic, noted on the averaged results of at least two readings, several weeks apart.
- BP is the product of cardiac output and peripheral resistance.
- Approximately one-fourth of the adult population in the United States has hypertension.
- It develops most commonly between the age of 25 and 55 years.
- There is an increased incidence in the African American population.
- It can be a sign, a risk factor, or a disease.

Etiology: 90–95% of all cases are *primary* (also called *essential* or *idiopathic*) hypertension where there is no known cause but there is an alteration in one or more of the factors affecting cardiac output and/or peripheral resistance. The remaining cases are called *secondary* hypertension and a specific cause can be identified: such conditions include adrenal disorders, renal disorders, pregnancy-induced hypertension, and medications.

- Hypertensive crisis
 - Hypertensive emergency: BP must be lowered immediately (MI, dissecting abdominal aneurysm, and intracranial hemorrhage)
 - Hypertensive urgency: BP must be lowered within a few hours

Precipitating: factors for primary hypertension: Hyperlipidemia, obesity, physical inactivity, positive family history, stress, age, ethnicity, high sodium intake, cigarette smoking, and excessive alcohol intake.

S&S:

- Often asymptomatic, is called “the silent killer”
- Sustained elevated BP readings
- Occipital morning headaches, blurred vision, vertigo, fatigue, dyspnea on exertion, palpitations, retinal changes, epistaxis, pain in calf muscles, angina, polyuria, weight gain, edema, nocturia, and diminished or absent peripheral pulses
- Symptoms may occur as target organs develop vascular damage

Assessment Alert

A rise in systolic BP when a client moves from a supine to standing position is indicative of essential hypertension.

Dx: Consistently elevated BP readings above 140/90 mmHg. History to identify risk factors and physical examination. Diagnostic tests may include blood chemistry, urinalysis, kidney function tests, ECG, chest X-ray, and echocardiogram

Rx: Controlling hypertension and preventing complications.

- A stepwise approach is recommended starting with modification to lifestyle, which includes
 - managing weight
 - limiting alcohol intake
 - increasing aerobic physical activity
 - reducing sodium intake to no more than 2.4 g/d
 - giving up smoking
 - reducing stress
 - consuming a diet high in fruits, vegetables, whole grains, and nonfat dairy products
- Medications are then added as needed
 - No specific medication is recommended
 - Diuretics (Thiazide, Loop, and Potassium sparing) and beta blockers or both are initial drug choices starting with low doses and then increasing the doses as needed
 - Other drugs to use include ACE inhibitors, angiotensin II receptor blockers, alpha blockers, and calcium antagonists

Nursing Process Elements

- Monitor blood pressure lying, sitting, and standing, in both arms
- Assess for risk factors
- Assess for S&S of developing complications (CHF, renal involvement, and neurovascular)
- Monitor laboratory tests (BUN, creatinine, and electrolytes)
- Use cardiac monitoring when starting a client on cardiac meds (beta blockers, calcium antagonists)
- Accurately measure daily I&O
- Weigh the client daily before breakfast
- Administer medications as prescribed and monitor closely
- Provide client education to maintain a healthy lifestyle
- Collaborate with dietary to establish an appropriate diet

Client teaching for self-care

Teach client

- to make necessary lifestyle changes including modification of risk factors
 - maintain blood pressure <140 mmHg systolic and <90 mmHg diastolic
 - maintain ideal weight
 - keep total cholesterol <200 mg/dL
 - stop all forms of tobacco use

- eat a diet low in sodium, saturated fats, excess calories, and processed foods, but high in fruits, vegetables, and nonfat dairy products
- increase physical activity
- use relaxation techniques
- about hypertension and its complications
- about medication regime
 - supplement potassium if on Loop diuretic
 - know side effects of medications including S&S of hypotension
 - know to report S&S of CHF (weight gain, orthopnea, edema, especially if on a beta blocker)
 - change position slowly to prevent dizziness due to orthostatic hypotension
 - not take over-the-counter cold medications or nasal decongestants
 - not suddenly stop taking medications (may cause rebound hypertension)
- how to take and monitor blood pressure and apical pulse
- about the need for adherence to medical regime and that treatment is palliative and not curative

ATHEROSCLEROSIS

- Atherosclerosis refers to the chronic form of arteriosclerosis. There is thickening and hardening of large and medium arteries, which supply blood to the heart, brain, kidneys, extremities, and internal viscera.
- In atherosclerosis, injury to the vessel wall and deposits of lipids, cholesterol, cellular waste, and fibrin interfere with blood flow through the arteries producing ischemia to the tissues and organs.
- It develops slowly, insidiously, and progressively over a lifetime.
- It is the most common cause of MI.

Etiology: Precipitated by an unknown factor which leads to the development of fatty streaks which gradually build to atheromas.

Precipitating factors: Hypertension, hyperlipidemia, obesity, elevated serum triglyceride level, smoking, genetic predisposition, high-fat diets, physical inactivity, stress, age, gender, disease processes such as diabetes mellitus, hormone status and use of oral contraceptives, elevated serum iron levels, and toxic substances in the environment.

S&S:

- Asymptomatic until there is 75% or more impaired blood flow to tissues or organs
- Tissue hypoxia leads to acidosis, cellular damage and when severe enough, can cause necrosis
- Depends on the degree of ischemia to affected tissues or organ: pain, diminished pulses, systolic bruits, and pallor

Assessment Alert

The best treatment is the identification of risk factors. Look for xanthomas, which are lipid-containing nodules of the skin.

Dx: Often based on symptoms and history of risk factors

Rx: Prevention and elimination of modifiable risk factors. Control of chronic diseases especially diabetes mellitus, obesity, hypertension and hyperlipidemia through lifestyle changes and compliance to medical regime. Medications to reduce hyperlipidemia include HMG-CoA reductase inhibitors (simvastatin [Zocor]), bile acid-sequestering resins (cholestyramine [Questran]), nicotinic acid (Niacin), fibric-acid derivatives (gemfibrozil [Lopid]), and Omega-3 fish oils

Nursing Process Elements

- Assess for risk factors
- Assess for S&S
- Assess laboratory tests for elevated cholesterol, homocysteine, triglycerides, and iron levels
- Provide client education to maintain a healthy lifestyle
- Support client in adhering to medical regime

Client teaching for self-care

Instruct client

- to maintain blood pressure <90 mmHg diastolic and <140 mmHg systolic
- to maintain ideal weight
- to keep total cholesterol <200 mg, LDL <100 mg, HDL >40 mg
- to stop all forms of tobacco use
- to eat a low-fat, high-fiber diet. The American Heart Association recommends <30% of daily calories from fat, 55% from CHO, and 15% from protein; dietary cholesterol <300 mg and limit sodium to <3000 mg, decrease intake of processed foods
- to follow regular exercise routine
- about stress management and stress reduction
- about the importance of adherence to medical regime for chronic illnesses
- that drug therapy is palliative and not curative

CORONARY ARTERY DISEASE

- Coronary artery disease (CAD) refers to the narrowing of the coronary arteries obstructing blood flow to the myocardium producing ischemia.

- Atherosclerosis is the most common cause of CAD.
- Highest incidence of CAD is found in the Western world.
- It is the leading cause of death in the United States for both men and women.
- Women are at greater risk of CAD after menopause.

Etiology: Narrowing of the artery walls by atherosclerosis producing ischemia to the myocardium. Begins in childhood and generally manifests in adulthood.

Precipitating factors: Hypertension, hyperlipidemia, obesity, elevated serum triglyceride level, smoking, genetic predisposition, high-fat diets, physical inactivity, stress, age, gender, disease processes such as diabetes mellitus, hormone status and use of oral contraceptives, elevated serum iron levels, and toxic substances in the environment.

S&S:

- Generally asymptomatic until 75% or more of a coronary artery is occluded
- Approximately 15% of individuals remain asymptomatic even with advanced CAD
- S&S are dependent on the degree of arterial narrowing and resulting ischemia
- May present as angina pectoris or MI
- Pain, heaviness, or tightness located in chest, arms, jaw, and shoulders when ischemia is severe
- Pain often develops when there is a decrease in blood flow to the myocardium or an increase in myocardial oxygen demand brought on by exercise, stress, cold temperatures, anemia, hyperthyroidism, and substance abuse
- Dyspnea on exertion

Assessment Alert

Pain lasts no longer than 3 minutes and is relieved with rest.

Dx: Often based on symptoms and history of risk factors and tests including cholesterol panel, triglyceride level, homocysteine levels, CBC, exercise stress test, ECG, cardiac radionuclear scan, echocardiogram, coronary angiography, and cardiac catheterization

Rx: Prevention and elimination of modifiable risk factors.

- Control of chronic diseases especially diabetes mellitus, obesity, hypertension, and hyperlipidemia through lifestyle changes and compliance to medical regime
- Medications to reduce hyperlipidemia include HMG-CoA reductase inhibitors (simvastatin [Zocor]), bile acid-sequestering resins (cholestyramine [Questran]), nicotinic acid (Niacin), fibric-acid derivatives (gemfibrozil [Lopid]) and Omega-3 fish oils

- Drugs that reduce oxygen demand or increase oxygen supply to the myocardium include nitrates, beta blockers, calcium channel blockers, antihypertensives, and antiplatelet agents such as low-dose aspirin
- Revascularization procedures such as transluminal coronary angioplasty, laser angioplasty, coronary atherectomy, intracoronary stents and surgical interventions including coronary artery bypass grafting (CABG), minimally invasive coronary bypass (MIDCAB), and transmyocardial laser revascularization (TMLR)

Nursing Process Elements

- Assess for risk factors
- Assess for S&S
- Assess laboratory tests for elevated cholesterol, homocysteine, triglycerides, and iron levels
- Provide client education to maintain a healthy lifestyle
- Support client in adhering to medical regime
- Provide client teaching for drug therapies
- Provide client teaching pre- and postrevascularization procedure
 - Client will be awake during coronary angiogram or cardiac catheterization
 - Client may experience a hot flash and metallic taste as dye is injected
 - Client will be on bed rest with affected extremity immobilized following procedure to decrease risk of bleeding
- Provide client teaching pre- and postrevascularization surgery
- Postrevascularization Nursing Process Elements
 - Observe for bleeding from surgical site
 - Monitor for ECG changes: T-wave changes, ST segment elevation, dysrhythmias
 - Monitor for chest pain
 - Monitor VS
 - Monitor I&O; if dye was used, have client drink large amounts of fluid to decrease renal toxicity

Client teaching for self-care

Instruct client

- to maintain blood pressure <90 mmHg diastolic and <140 mmHg systolic
- to maintain ideal weight
- to keep total cholesterol <200 mg, LDL <100 mg, HDL >40 mg
- to stop all forms of tobacco use
- to eat a low-fat, high-fiber diet. The American Heart Association recommends <30% of daily calories from fat, 55% from CHO, and 15% from protein; keep dietary cho-

- lesterol <300 mg and limit sodium to <3000 mg; decrease intake of processed foods
- to follow a regular exercise routine
- how to take pulse rate and alert doctor if pulse is <60 or >120
- about stress management and stress reduction
- about the importance of adherence to medical regime for chronic illnesses
- understand that drug and medical therapies are palliative and not curative
- to stop and rest at onset of chest discomfort

ANGINA PECTORIS

- Angina pectoris is also known as acute coronary syndrome.
- It refers to the chest pain brought on by myocardial ischemia.
- It is caused due to an imbalance of coronary blood supply and demand.
- The most common cause is atherosclerosis.

Etiology: Reduction of coronary blood flow or increased oxygen demand to the myocardium producing ischemia. Decreased oxygen supply causes cells to switch from aerobic to anaerobic metabolism. Lactic acid builds up. Cell membrane permeability is affected and histamine, bradykinins, and enzymes are released which stimulate nerve fibers.

- Types of angina:
 - Stable Consistent pattern with exertion and pain relieved with rest
 - Unstable Increase in frequency, duration, and severity of pain
 - Prinzmetal's or variant Pain at rest and usual cause is coronary artery vasospasm

Precipitating factors: Hypertension, hyperlipidemia, obesity, elevated serum triglyceride level, smoking, genetic predisposition, high-fat diets, physical inactivity, stress, age, gender, disease processes such as diabetes mellitus, hormone status and use of oral contraceptives, elevated serum iron levels, and toxic substances in the environment.

S&S:

- Generally asymptomatic until 75% or more of a coronary artery is occluded
- S&S are dependent on the degree of arterial narrowing and resulting ischemia and the location
- Pain, heaviness, or tightness located in chest (often substernal or retrosternal), arms, jaw, shoulders, back, or abdomen
- Pain develops when there is a decrease in blood flow to the myocardium or an increase in myocardial oxygen

- demand brought on by exercise, stress, cold temperatures, anemia, hyperthyroidism, and substance abuse (cocaine)
- Pain may be accompanied by nausea, vomiting, weakness, dyspnea, indigestion, dizziness, anxiety, diaphoresis, pallor, hypotension, and pulse changes
- Women often present with atypical symptoms such as GI distress
- Elderly and diabetic clients may present with dyspnea or weakness without pain

Assessment Alert

Pain lasts for less than 15 minutes and is relieved with rest and/or nitroglycerine.

Dx: Based on symptoms, history of risk factors, and tests including cardiac enzymes (CPK-MB, troponin, and myoglobin), cholesterol panel, triglyceride level, CBC, exercise stress test, ECG (T wave inversion, ST segment depression), cardiac radionuclear scan, echocardiogram, coronary angiography, and cardiac catheterization

Rx: To decrease myocardial oxygen consumption and increase myocardial oxygen supply

- Stop activity and rest in semi-Fowler's position
- Take nitroglycerine sublingually
- Administer oxygen 2–4 lpm via nasal cannula
- Thrombolytic therapy if thrombi is the cause
- Prevention and elimination of modifiable risk factors
- Control of chronic diseases especially diabetes mellitus, obesity, hypertension, and hyperlipidemia through lifestyle changes and compliance to medical regime
- Medications to reduce hyperlipidemia include HMG-CoA reductase inhibitors (simvastatin [Zocor]), bile acid-sequestering resins (cholestyramine [Questran]), nicotinic acid (Niacin), fibric acid derivatives (gemfibrozil [Lopid]), and Omega-3 fish oils
- Drugs that reduce oxygen demand or increase oxygen supply to the myocardium include nitrates, beta blockers, calcium channel blockers, antihypertensives, and antiplatelet agents such as low-dose aspirin
- Revascularization procedures such as transluminal coronary angioplasty, laser angioplasty, coronary atherectomy, intracoronary stents and surgical interventions including CABG, MIDCAB, and TMLR (see Chapter 18.)

Nursing Process Elements

- Have client stop activity and rest in semi-Fowler's position
- Give client nitroglycerine sublingually
- Administer oxygen 2–4 lpm via nasal cannula

- Assess PQRST of pain where P—position, Q—quality and quantity, R—radiation and relief, S—severity and symptoms, and T—timing
- Assess for risk factors
- Assess for S&S
- Assess laboratory tests for elevated cardiac enzymes, cholesterol, triglycerides, and iron levels
- Assess 12-lead ECG for ST-wave changes
- Provide emotional support
- Provide client education to maintain a healthy lifestyle
- Support client in adhering to medical regime
- Provide client teaching for drug therapies
- Provide client teaching pre- and postrevascularization procedure
 - Client will be awake during coronary angiogram or cardiac catheterization
 - Client may experience a hot flash and metallic taste as dye is injected
 - Client will be on bed rest with affected extremity immobilized following procedure to decrease risk of bleeding
- Provide client teaching pre- and postrevascularization surgery
- Postrevascularization Nursing Process Elements
 - Observe for bleeding from surgical site
 - Monitor for ECG changes: T-wave changes, ST segment elevation, and dysrhythmias
 - Monitor for chest pain
 - Monitor VS
 - Monitor I&O; if dye was used, have client drink large amounts of fluid to decrease renal toxicity

Client teaching for self-care

Instruct client

- to reduce the risks of angina by balancing oxygen supply and demand
- to stop activity or stress and take Nitroglycerine when pain occurs
- about the proper use of nitroglycerine
 - Go to hospital if no pain relief after nitroglycerine
 - Know the side effects: headache and hypotension
 - Keep in original bottle
 - Keep with you at all times
 - Replace every 3 months
- to maintain blood pressure <90 mm Hg diastolic and <140 mm Hg systolic
- to maintain ideal weight
- to keep total cholesterol <200 mg, LDL <100 mg, HDL >40 mg
- to stop all forms of tobacco use

- to eat a low-fat, high-fiber diet. The American Heart Association recommends <30% of daily calories from fat, 55% from CHO, and 15% from protein; keep dietary cholesterol <300 mg and limit sodium to <3000 mg; decrease intake of processed foods
- to follow a regular exercise routine
- how to take pulse rate and alert doctor if pulse is <60 or >120
- about stress management and stress reduction
- about the importance of adherence to medical regime for chronic illnesses
- that drug and medical therapies are palliative and not curative

MYOCARDIAL INFARCTION

- Myocardial infarction (MI) is also known as Acute Coronary Syndrome.
- It refers to the chest pain brought on by acute obstruction of coronary blood flow.
- MI occurs suddenly.
- It results in imbalance of myocardial oxygen supply and demand.
- It causes the death of myocardial cells.

Think Smart/Test Smart

Remember the three *I*s of the progression of pathophysiology of an MI: *I*schemic tissue progresses to *I*njured tissue, which in turn progresses to *I*nfarcted or dead tissue.

Etiology: Obstruction of coronary blood flow due to thrombus, emboli, or vasospasm. May also result if oxygen supply is diminished such as with acute hypovolemia or if oxygen demand is increased as with tachycardia.

Precipitating factors: Hypertension, hyperlipidemia, obesity, elevated serum triglyceride level, smoking, genetic predisposition, high-fat diets, physical inactivity, stress, age, gender, disease processes such as diabetes mellitus, hormone status and use of oral contraceptives, elevated serum iron levels, toxic substances in the environment.

S&S:

- Acute substernal pain described as crushing which may radiate to back or jaw
- Feeling of impending doom
- Shortness of breath
- Shocked, pale, and anxious
- Nausea and vomiting

Assessment Alert

Pain lasts more than 20 minutes and is not relieved with rest and/or nitroglycerine.

Dx: Based on presenting symptoms, history of risk factors, ECG (T-wave inversion, ST-segment elevation, and abnormal Q wave), and serum cardiac enzyme values (CK-MB, Myoglobin, and Troponin)

Rx: Goal is to minimize myocardial damage and preserve function

Think Smart/Test Smart

Remember MONA for the care of the client with an MI in the Emergency Room: Morphine sulfate, Oxygen, Nitroglycerine, Aspirin.

- Have client stop activity and rest in semi-Fowler's position
- Administer oxygen
- Reperfuse area of damage with thrombolytic medication
 - Goal is to give within 30 minutes of arrival in ER
 - Make certain no absolute contraindications are present (e.g., active bleeding, hemorrhagic CVA within 2 months, severe uncontrolled hypertension, recent major surgery or trauma, pregnancy; if giving streptokinase, history of allergic reaction to streptokinase, recent streptococcal infection)
- Analgesics, generally morphine sulfate given IV bolus
- Drugs that reduce oxygen demand or increase oxygen supply to the myocardium include nitrates, beta blockers, ACE inhibitors, calcium channel blockers, antihypertensives, and antiplatelet agents such as low-dose aspirin
- Revascularization procedures such as transluminal coronary angioplasty, laser angioplasty, coronary atherectomy, intracoronary stents and surgical interventions including CABG, MIDCAB, and TMLR

Think Smart/Test Smart

When answering questions about treatment of an MI, remember "Time is muscle." The faster reperfusion of cardiac muscle is established following an MI, the less muscle is lost. Conversely, the longer cardiac muscle goes without oxygenated blood, the more muscle is lost. Therefore, speed of treatment is critical.

Nursing Process Elements

- Maintain bed rest with semi-Fowler's position
- Administer oxygen 2–4 lpm via nasal cannula
- Establish IV access
- Provide pain relief
- Assess for S&S
- Assess laboratory tests for elevated cardiac enzymes, elevated WBC, increased ESR, and elevated cholesterol level
- Assess 12-lead ECG for T-wave, ST-segment, and Q-wave changes
- Monitor for dysrhythmias
- Monitor VS, oxygen saturation, urinary output, and hemodynamic parameters
- Provide emotional support
- If thrombolytics are given
 - Have two to three IV sites established prior to infusion
 - Handle client gently, no IM injections
 - Observe for signs of active bleeding
 - Monitor for allergic or anaphylactic reaction with streptokinase
 - Have antidote to streptokinase which is aminocaproic acid (Amicar) available
- Progress diet from NPO, to clear liquids, etc.
- Administer stool softener as ordered
- Provide client education for cardiac rehabilitation and to maintain a healthy lifestyle
- Support client in adhering to medical regime
- Provide client teaching for drug therapies
- Provide client teaching pre- and postrevascularization procedure
 - Client will be awake during coronary angiogram or cardiac catheterization
 - Client may experience a hot flash and metallic taste as dye is injected
 - Client will be on bed rest with affected extremity immobilized following procedure to decrease risk of bleeding
- Provide client teaching pre- and postrevascularization surgery
- Postrevascularization Nursing Process Elements
 - Observe for bleeding from surgical site
 - Monitor for ECG changes: T wave changes, ST segment elevation, dysrhythmias
 - Monitor for chest pain
 - Monitor VS
 - Monitor I&O; if dye was used, have client drink large amounts of fluid to decrease renal toxicity

Client teaching for self-care

Instruct client

- to reduce the risks of MI by balancing oxygen supply and demand
- about the cause, process, and treatment of MI
- about the medication regimen
- to make necessary lifestyle changes including modification of risk factors
 - maintain blood pressure <90 mm Hg diastolic and <140 mm Hg systolic
 - maintain ideal weight
 - keep total cholesterol <200 mg, LDL <100 mg, HDL >40 mg
 - stop all forms of tobacco use
 - eat a low-fat, high-fiber diet. The American Heart Association recommends <30% of daily calories from fat, 55% from CHO, and 15% from protein; keep dietary cholesterol <300 mg and limit sodium to <3000 mg; decrease intake of processed foods
- to enroll in cardiac rehabilitation program
- how to take pulse rate and alert doctor if pulse is <60 or >120
- about stress management and stress reduction
- about the importance of adherence to medical regime
- to understand that drug and medical therapies are palliative and not curative
- about S&S of MI. Get to ER if chest pain lasts longer than 15 minutes and is not relieved with rest and nitroglycerine

VALVULAR HEART DISEASE

- Valvular heart disease refers to a disease or condition that interferes with the unidirectional blood flow of the heart.
- It can affect all four valves in the heart: aortic, pulmonic, mitral, and tricuspid.

Etiology: Can be a result of acquired valvular disorders or congenital heart defects resulting in stenosis which impedes the forward flow of blood through a valve or regurgitation which causes a backward flow of blood through a valve.

Precipitating factors: Rheumatic Fever, endocarditis, MI, calcium deposits, congenital defects, and syphilis.

S&S:

- Asymptomatic at first
- Pulmonary congestion, dyspnea, and pulmonary hypertension
- Decreased cardiac output, S3 or S4 heart sounds, murmur, tachycardia, and angina
- Fatigue and S&S of CHF

Clinical Alert

With valvular heart disease, hemodynamic changes occur both in front of and behind the affected valve. Blood flow and pressures are reduced in front of the affected valve and pressures are increased behind the affected valve.

During pregnancy, there is an increased volume of blood as well as the need for increased cardiac output. These factors can lead a pregnant woman with valvular disease to develop heart failure. The greatest risk occurs as the woman approaches the third trimester of pregnancy.

At the time of labor, prophylactic antibiotics are recommended to prevent bacterial endocarditis in the woman with symptomatic valvular disease.

Dx: Client history and physical examination, cardiac catheterization, CXR, ECG, and echocardiogram

Rx:

- Pharmacological interventions include digitalis glycosides (Digoxin) to increase force of the contraction of the heart, diuretics, and ACE inhibitors to reduce preload and afterload
- Antibiotics are prescribed prior to any dental work or invasive procedures to decrease the risk of endocarditis
- Surgery to repair or replace a diseased valve provides definitive treatment for valve repair
- Repair rather than replacement of diseased valve is the preferred treatment because it provides a lower risk of complications and mortality

(See cardiac surgery in Chapter 18 for Nursing Process Special Considerations.)

PEDS CONGENITAL HEART DEFECTS

- A congenital heart defect is a structural defect of the heart and/or great vessels present at birth or shortly thereafter.
- Congenital heart defects are categorized as acyanotic (increased pulmonary blood flow) and cyanotic (blood flow bypasses the lungs).
 - Acyanotic defects include defects that cause oxygenated blood to recirculate through the lungs and heart and defects that obstruct blood flow from the heart. Acyanotic heart defects that recirculate the blood are often termed “left to right” as blood flows from the oxygenated left side through a defect into the unoxygenated right side.
 - Atrial septal defect (ASD)
 - Ventricular septal defect (VSD)

- Patent ductus arteriosus
- Coarctation of the aorta

—Cyanotic defects involve a shunt that bypasses the lungs and delivers venous (deoxygenated) blood from the right side of the heart into the arterial circulation. These defects are frequently called “right to left” shunts.

- Transposition of the great vessels
- Truncus arteriosus
- Tetralogy of Fallot
- They are a major cause of death in children during the first year of life.
- They occur in about 8–10 of 1000 live births.

Acyanotic Heart Defects

Septal defects

- Atrial septal defect (ASD)
 - In ASD, there is an opening between the right and left atria.
 - Shunting of blood occurs from the left atrium (slightly higher pressure) oxygen-rich blood to the right atrium (lower pressure) increasing the amount of blood to the right ventricle and then to the lungs.

Etiology: Cause is generally unknown.

Precipitating factors: Rubella during pregnancy, chromosomal abnormalities, maternal age over 40 years, alcoholism, and type I diabetes.

S&S:

- Often asymptomatic, if the defect is small. Defect may close on its own within 12–18 months
- When defect is large, may cause CHF (shortness of breath, easy fatigability, or poor growth pattern), respiratory infections, and cardiac enlargement
- Murmur
- S&S may not begin to develop until 4–6 weeks after birth

Rx:

- Small ASDs may close on their own by 12–18 months
- If ASD does not close and defect is not too large, it may be closed by placement of a device called an Amplatzer Septal Occluder during a cardiac catheterization
- If ASD is large, open heart surgery is needed
- If CHF develops, especially with VSD, client may be managed medically with diuretics and digoxin

Postoperative course: Same as for clients undergoing open heart surgery. Client will be in an ICU for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.

Nursing Process Elements

See VSD

**Client teaching for self-care**

See VSD

- Ventricular septal defect
 - In VSD, there is an opening between the right and left ventricle.
 - Shunting of blood occurs from the left ventricle (high pressure) oxygen-rich blood to the right ventricle (low pressure) increasing the amount of blood to the lungs.
 - It is the most common congenital defect

Etiology: Cause is generally unknown.**Precipitating factors:** Rubella during pregnancy, chromosomal abnormalities, maternal age over 40 years, alcoholism, and type I diabetes.**S&S:**

- CHF is common
- Shortness of breath, easy fatigability, or poor growth pattern, respiratory infections, and cardiac enlargement
- Murmur

**Assessment Alert**

Systolic murmur heard over the pulmonary valve area which is caused from the large volume of blood going through the pulmonary valve.

Dx: Physical examination, echocardiogram, ECG, and chest X-ray**Rx:**

- CHF is managed medically with diuretics and digoxin
- Palliative surgery (including pulmonary artery banding) may be done to improve the child's condition and promote growth prior to corrective surgery
- Corrective open heart surgery

Postoperative Course: Same as for clients undergoing open heart surgery. Client will be in an ICU for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.**Nursing Process Elements**

Preoperatively

- Provide emotional support for client and family
- Provide information about the anatomy and physiology of the heart and the surgical procedure, postoperative procedures and equipment including equipment for hemodynamic monitoring, ventilator, endotracheal tube, pacing wires, chest tube and nasogastric tube, ICU policies

and visiting hours, possible complications and treatments, pain management, and sensory stimuli and overload

Postoperatively

- Monitor hemodynamic measures
- Assess cardiac monitoring
- Assess peripheral pulses
- Assess bowel sounds and measure abdominal girth every 8 hours
- Measure and record I&O hourly including chest tube and NG drainage
- Monitor laboratory values especially Hct and Hgb, ABGs, CBC, APPT, and electrolytes
- Keep temporary pacemaker at bedside
- Monitor core body temperature and keep temperature above 96.8°F (36°C)
- Assess pain level
- Administer medications as ordered
- Note ETT placement and ventilator settings
- Provide emotional support to client and family
- Evaluate respiratory status
- Assess incisions for presence of infection and drainage
- Turn client and have client take a deep breath
- Assess for S&S of complications including thrombophlebitis, pulmonary embolism, CHF, and cardiac tamponade

**Client teaching for self-care**

Instruct client

- to schedule rest periods to prevent fatigue
- to resume usual activities gradually
- to report S&S of CHF including weight gain, increased pulse rate, and difficulty in breathing
- about follow-up routine with cardiologist
- about wound care
- that following closure there should be no further treatment required or activity restrictions

Patent ductus arteriosus

The ductus arteriosus is a fetal structure that allows blood going from the right ventricle to bypass the lungs and enter the aorta. Since the blood is oxygenated by the placenta, this blood is oxygen rich. As the fetal lungs are not used for respiration, a minimal amount of blood is needed to feed the lung tissue. When the ductus arteriosus fails to close shortly after birth, the infant is diagnosed as having a patent ductus arteriosus (PDA).

- PDA is an acyanotic heart defect.
- It is a common anomaly in the preterm infant.

Etiology: Unknown. Associated with preterm deliveries and respiratory involvement in the neonate.

Precipitating factors: Prematurity and respiratory distress in the neonate.

S&S:

- Murmur
- Recurrent apnea, increased PaCO₂, and decreased PaO₂
- CHF

Dx: Assessment of signs and symptoms with confirmation by echocardiogram

Rx: Respiratory care, diuretics. Indomethacin, a prostaglandin synthetase inhibitor may precipitate closure. If unsuccessful, surgical ligation will be required

Nursing Process Elements

- Monitor all newborns for signs of respiratory congestion, murmur, and apnea
- When indomethacin is administered, monitor the infant for bleeding and renal function
- Preoperative and postoperative care is focused on promoting respiratory function, monitoring for infection, renal function, and promoting growth
- The infant should be monitored for necrotizing enterocolitis, NEC, a complication of respiratory distress during the newborn period. Monitor for regurgitation or feeding residual, abdominal distress, and positive guaiac

Client teaching for self-care

Explain to parents

- the causes and signs and symptoms of PDA
- surgical procedures and medications used in treatment

Coarctation of the aorta

- Coarctation of the aorta is an obstructive congenital heart defect where there is narrowing of the aorta restricting outflow.
- In this defect, the left ventricle has to work harder to force blood through a narrowed vessel.

Etiology: Cause is generally unknown but seems to be linked to chromosomal abnormalities such as Turner's syndrome.

Precipitating factors: Rubella during pregnancy, chromosomal abnormalities, maternal age over 40 years, alcoholism, and type I diabetes.

S&S: Depends on the degree of narrowing of the aorta

- If severe, infants will have significant changes within several hours to days after birth and closure of the ductus arteriosus
 - High blood pressure and bounding pulses in the arms
 - Decreased or absent pulses in the groin and legs
 - CHF
 - Cool lower extremities

- If less severe, it may not be detected for several years
 - Headache
 - Dizziness
 - Epistaxis
 - High blood pressure in the arms
 - Diminished lower extremity pulses
 - Murmur

Dx: Echocardiogram, MRI, CT scan, and ECG

Rx: For infants with severe coarctation, urgent open heart surgery is preformed to repair the narrowing. In older children with less narrowing, a cardiac catheterization with balloon dilatation may be an option or open heart surgery for repair

Postoperative course: Same as for clients undergoing heart surgery. Client will be in an ICU for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.

Nursing Process Elements

Preoperatively

- Provide emotional support for client and family
- Provide information about the anatomy and physiology of the heart and the surgical procedure, postoperative procedures and equipment including equipment for hemodynamic monitoring, ventilator, endotracheal tube, pacing wires, chest tube and nasogastric tube, ICU policies and visiting hours, possible complications and treatments, pain management, and sensory stimuli and overload

Postoperatively

- Monitor hemodynamic measures
- Assess cardiac monitoring
- Assess peripheral pulses
- Assess bowel sounds and measure abdominal girth every 8 hours
- Measure and record I&O hourly including chest tube and NG drainage
- Monitor laboratory values especially H&H, ABGs, CBC, APPT, and electrolytes
- Keep temporary pacemaker at bedside
- Monitor core body temperature and keep temperature above 96.8°F (36°C)
- Assess pain level
- Administer medications as ordered
- Note ETT placement and ventilator settings
- Provide emotional support to client and family
- Evaluate respiratory status
- Assess incisions for presence of infection and drainage
- Turn client and have client take a deep breath
- Assess for S&S of complications including thrombophlebitis, pulmonary embolism, CHF, and cardiac tamponade

**Client teaching for self-care**

Instruct parents/caregiver

- to schedule rest periods to prevent fatigue
- to resume usual activities gradually
- to report S&S of CHF including weight gain, increased pulse rate, and difficulty in breathing
- to have knowledge of long-term follow-up routine with cardiologist
- about wound care

Cyanotic Heart Defects**Tetralogy of Fallot**

- Tetralogy of Fallot is a congenital heart defect that includes four structural anomalies:
 - VSD
 - Juxtaposition of the aorta (aorta overrides the septum and receives blood from both the right and left ventricles)
 - Right ventricular hypertrophy
 - Pulmonary stenosis
- It involves a right to left shunt which mixes unoxygenated and oxygenated blood into the systemic circulation.

Etiology: Cause is generally unknown.

Precipitating factors: Rubella during pregnancy, chromosomal abnormalities, maternal age over 40 years, alcoholism, and type I diabetes.

S&S:

- Cyanosis—The extent of cyanosis is dependent on the amount of narrowing of the pulmonary valve and right ventricular outflow tract
- Dyspnea, tachypnea
- Fatigue
- Loud and harsh heart murmur
- Clubbing of the fingers and toes
- Poor growth pattern
- Polycythemia

**Nursing Intervention Alert**

The arterial oxygen saturation of babies with Tetralogy of Fallot can suddenly drop, especially when the baby is crying or stressed. This phenomenon is called a “tet spell” or “blue spell.” A tet spell can sometimes be treated by comforting the infant and flexing the knees forward and upward or else the child may squat down. Most often, however, immediate medical attention is necessary.

Dx: Hyperoxia test where the cyanosis does not improve with supplemental oxygen, echocardiogram, cardiac catheterization

Rx: Depends on the degree of hypoxia. If oxygen levels are critically low soon after birth, a prostaglandin infusion is usually initiated to keep the ductus arteriosus open. These infants usually require open heart surgery in the neonatal period. Palliative surgery is often used as a temporary measure to improve the physical condition of the child to allow growth. Complete repair is usually performed in the first year of life.

Postoperative course: Same as for clients undergoing open heart surgery. Client will be in an ICU for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.

**Nursing Process Elements**

Preoperatively

- Provide emotional support for client and family
- Provide information about the anatomy and physiology of the heart and the surgical procedure, postoperative procedures and equipment including equipment for hemodynamic monitoring, ventilator, endotracheal tube, pacing wires, chest tube and nasogastric tube, ICU policies and visiting hours, possible complications and treatments, pain management, and sensory stimuli and overload

Postoperatively

- Monitor hemodynamic measures
- Assess cardiac monitoring
- Assess peripheral pulses
- Assess bowel sounds and measure abdominal girth every 8 hours
- Measure and record I&O hourly including chest tube and NG drainage
- Monitor laboratory values especially H&H, ABGs, CBC, APPT, and electrolytes
- Keep temporary pacemaker at bedside
- Monitor core body temperature and keep temperature above 96.8°F (36°C)
- Assess pain level
- Administer medications as ordered
- Note ETT placement and ventilator settings
- Provide emotional support to client and family
- Evaluate respiratory status
- Assess incisions for presence of infection and drainage
- Turn client and have client deep breath
- Assess for S&S of complications including thrombophlebitis, pulmonary embolism, CHF, cardiac tamponade

**Client teaching for self-care**

Instruct family/caregiver

- to schedule rest periods to prevent fatigue
- to resume usual activities gradually

- to report S&S of CHF including weight gain, increased pulse rate, and difficulty in breathing
- to have knowledge of long-term follow-up routine with cardiologist
- about wound care
- about available resources

Transposition of the great vessels

- Transposition of the great vessels is a congenital heart defect where the pulmonary artery exits from the left ventricle and the aorta exits from the right ventricle.
- There are two separate and parallel systems, thus there is no communication between the pulmonary and systemic circulations.
- This condition is not compatible with life unless there is a large ASD or VSD that allows the oxygenated and unoxygenated blood to mix.

Etiology: Cause is generally unknown.

Precipitating factors: Rubella during pregnancy, chromosomal abnormalities, maternal age over 40 years, alcoholism, and type I diabetes.

S&S: The baby

- is blue at birth and cyanosis does not improve with oxygen supply
- is very lethargic and depressed
- has a very poor Apgar score

Dx: Clinical presentation with no improvement with oxygen; echocardiogram

Rx: Prostaglandin is started intravenously to maintain the small connection (the ductus arteriosus) between the pulmonary and systemic circulations. If an ASD is not present or is small, an ASD may be created or enlarged by balloon septostomy. Open heart surgery to adjust the vessels may be required shortly after birth

Pre- and postoperative care: If open heart surgery is needed, the usual preoperative care for a client undergoing open heart surgery will be needed including physical, emotional, and psychosocial assessment; provide emotional support for client and family, client education concerning the anatomy and physiology of the heart and the surgical procedure, postoperative procedures and equipments including hemodynamic monitoring equipment, ventilator, endotracheal tube, pacing wires, chest tubes, nasogastric tube, ICU policies and visiting hours, possible complications and treatments, pain management and sensory stimuli and sensory overload.

Postoperative course: Baby will be in NICU for many weeks depending on the severity of the situation, if palliative surgery is performed, and when corrective surgery is performed.

Nursing Process Elements

- Monitor hemodynamic measures
- Assess cardiac monitoring
- Assess peripheral pulses
- Assess bowel sounds and measure abdominal girth every 8 hours
- Measure and record I&O hourly including chest tube and NG drainage
- Monitor laboratory values especially H&H, ABGs, CBC, APPT, and electrolytes
- Keep temporary pacemaker at bedside
- Monitor core body temperature and keep temperature above 96.8 F (36 C)
- Assess pain level
- Administer medications as ordered
- Note ETT placement and ventilator settings
- Provide emotional support to client and family
- Evaluate respiratory status
- Assess incisions for presence of infection and drainage
- Turn client and have client take a deep breath
- Assess for S&S of complications including thrombophlebitis, pulmonary embolism, CHF, cardiac tamponade, and dysrhythmias
- Refer family to appropriate agencies and support services

Client teaching for self-care

Teach parents or caregiver to:

- Schedule rest periods to prevent fatigue
- Resume usual activities gradually
- Report S&S of CHF and complications
- About long-term follow-up routine with cardiologist
- About wound care
- About appropriate community and support agencies

ANEURYSMS

- Aneurysm refers to a localized dilatation, weakness, or outpouching of the wall of a blood vessel.
- Most commonly, aneurysms occur in the abdominal aorta and peripheral arteries because of the high blood flow pressure in these vessels.
- It may involve one or all of the layers of the vessel wall.
- Classification
 - Fusiform: Uniform, spindle-shaped, large aneurysm involving the entire circumference of the vessel.
 - Saccular: An outpouching on one side only of a vessel, for example, berry aneurysm.
 - Dissecting: A separation of the arterial wall layers to form a cavity that fills with blood.
 - True: Affects all three layers of the vessel wall and occurs over a long time usually as a result of atherosclerosis and hypertension.
 - False: Usually a result from a traumatic break in the vessel wall rather than progressive weakening of the vessel wall.

- It occurs most often in men aged 50–70 years.
- The type of aneurysm is determined by its location.

Etiology: Risk factors that weaken the vessel wall combine with high blood flow pressures to gradually dilate the vessel.

Precipitating factors: Atherosclerosis, hypertension, trauma, infection, syphilis, and connective tissue diseases.

S&S:

- Generally asymptomatic until aneurysm becomes large enough to press on other structures or the aneurysm starts to leak or rupture.
 - Thoracic aortic aneurysm: deep, diffuse chest pain, hoarseness, dysphagia, dyspnea, brassy cough
 - Abdominal aortic aneurysm: palpable pulsating mass, systolic bruit, abdominal or back pain, cool extremities, diminished femoral pulses
 - Dissecting abdominal aortic aneurysm: sudden, severe tearing or ripping pain in the back or anterior chest, pallor, diaphoresis, tachycardia, initially elevated blood pressure, undetectable peripheral pulses, shock

Clinical Alert

Half of all aneurysms greater than 6 cm in size will rupture within 1 year.

Dx: Based on history and physical examination, CXR, aortography, ultrasonogram, CT scan, MRI, renal function studies

Rx: Prevention of aneurysm rupture by control of blood pressure and smoking cessation, surgical resection of the aneurysm, and graft replacement

Nursing Process Elements

- Preoperative care
 - Assess risk factors
 - Assess for S&S of complications
 - Regulate blood pressure and pulse according to parameters
 - Assess peripheral circulation: capillary refill, pulses, LOC, pulse oximetry, temperature, sensation, neurochecks
 - Monitor laboratory values
 - Assist in pain management
 - Decrease client's anxiety
 - Provide pre- and postoperative teaching
- Postoperative care
 - Monitor hourly circulation checks, urine output, neurochecks
 - Monitor hemodynamic parameters, VS, CVP, PAP, PCWP

- Assess for complications: presence of back pain (may indicate retroperitoneal hemorrhage), respiratory distress, paralytic ileus, graft occlusion, cardiac dysrhythmias, hypovolemia, shock, paralysis, and renal failure
- Maintain client flat in bed without sharp flexion
- Prevent thrombophlebitis: sequential boots, turning, dorsiflexion of feet
- Assist in pain management
- Assist in wound management
- Provide postoperative teaching to client

Client teaching for self-care

Instruct client to

- report S&S of complications
- observe limited lifting for 4–6 weeks
- monitor incision for bleeding or infection
- ensure proper wound care
- maintain blood pressure <90 mmHg diastolic and <140 mmHg systolic
- avoid constipation and straining
- keep total cholesterol <200 mg, LDL <100 mg, HDL >40 mg
- stop all forms of tobacco use
- eat a low-cholesterol, low-saturated-fat diet
- develop a gradual progressive exercise routine
- take pulse rate and alert doctor if pulse is <60 or >120
- ensure stress management and stress reduction
- Adhere to medical regime

PERIPHERAL VASCULAR DISEASE

- Peripheral vascular disease (PVD) refers to an abnormal condition that causes interference with blood flow to or from the extremities.
- It can be arterial or venous.
- It may be acute or chronic.

Etiology: Pooling of blood or decrease in blood supply and nutrients to extremity leads to hypoxia and tissue damage.

- Arterial—Vessel compression, vasospasm, or structural defect.
- Venous—Occlusive disorders or ineffective blood return.

Precipitating factors: Arteriosclerosis, atherosclerosis, hypertension, obesity, diabetes mellitus, smoking, stress, immobility, heart disease, pregnancy, hypercoagulability, trauma, and sedentary occupations.

S&S:

- Arterial
 - intermittent claudication
 - burning sensation in the extremities
 - cool, numb extremities

- pallor when extremity elevated
- rubor when extremity in dependent position
- skin is thin and shiny with hair loss and discoloration
- thickened toenails
- decreased or absent peripheral pulses
- ulcers or skin breakdown often on toes
- Venous
 - aching relieved with elevation of extremity
 - tenderness in the extremity
 - normal temperature
 - discoloration of the lower extremity, brawny
 - skin is thick and tough
 - edema
 - positive Homan's sign
 - present peripheral pulses
 - ulcers often around ankles

Assessment Alert

Pain that occurs in the foot at rest and is relieved when the foot is in a dependent position is a sign of more advanced disease.

Dx: History and physical examination, digital subtraction angiography, Doppler ultrasound, angiography, plethysmography, arteriogram, stress testing, oscillometry, coagulation studies, cholesterol and lipid studies

Rx: Goals are to provide adequate tissue perfusion, relieve discomfort and prevent complications.

- Medications: Aspirin, pentoxifylline (Trental), cilostazol (Pletal), vasodilator, prostaglandins, anticoagulants
- Medical treatment: Regular walking program where the client walks to the point of intermittent claudication then stops and rests for 3 minutes before continuing; weight reduction; smoking cessation
- Surgical treatment: Angioplasty, bypass grafting, endarterectomy, thrombectomy

Nursing Process Elements

- Assess pain and provide pain relief
- Assess circulation—check pedal pulses, sensation, capillary refill, edema, and temperature
- Assess skin integrity
- Elevate legs above heart to decrease edema
- Measure circumference of ankle and calf daily
- Provide pre- and postoperative care instructions

Client teaching for self-care

Instruct client to

- inspect skin for breakdown
- protect extremities from injury
- maintain a daily walking program
- elevate legs above heart for a fixed period of time each day
- avoid flexing and crossing legs
- not stand or sit for long periods of time
- avoid wearing constricting clothing
- stop smoking
- maintain ideal weight

BUERGER'S DISEASE (THROMBOANGITIS OBLITERANS)

- Buerger's disease is an inflammatory occlusive vascular condition in which the small and medium arteries and veins become thrombotic.
- It may occur in the upper or lower extremities but occurs usually in the leg or foot.
- It occurs most often in males between the age of 25 and 40 years.
- It involves periods of exacerbation and remission.

Etiology: Cause is unknown. Inflammation occurs in the adventitia leading to thrombi formation, abscesses, vasospasms, and vessel occlusion.

Precipitating factors: Genetic predisposition, cigarette smoking, chewing tobacco, autoimmune reaction.

S&S:

- Burning, numbness, or tingling of the extremity
- Intermittent claudication
- Pain at rest
- Smoking, cold temperatures, or emotional distress may trigger symptoms
- Intolerance to cold
- Decreased distal pulses
- Involved digits or extremity pale or cyanotic
- Skin shiny and thin
- Nails are thick and malformed
- Ulceration and gangrene in later stages

Assessment Alert

Small, red, tender vascular cords may be palpable in the affected extremity.

Dx: Based on client history and symptoms. Doppler studies, angiography, and MRI may be used to determine location and extent of disease

Rx:

- Stop smoking and tobacco use
- Keep extremity warm
- Decrease stress
- Protect extremity from injury
- Perform Buerger-Allen exercises
- Medications include analgesics, steroids, antibiotics to decrease pain and inflammation; calcium channel blockers (Cardizem) to decrease vasospasms; antiplatelets (Trental) to decrease blood viscosity, and vasodilators
- Surgery—Arterial bypass grafting, sympathectomy, and amputation

Nursing Process Elements

- Assess pain and provide pain relief
- Assess circulation—check pedal pulses, sensation, capillary refill, edema, temperature
- Assess skin integrity
- Measure circumference of ankle and calf daily
- Promote Buerger-Allen exercises
- Provide pre- and postoperative care instructions

Client teaching for self-care

Instruct client to

- inspect skin for breakdown
- keep extremity warm
- protect extremities from injury
- maintain a daily walking program
- avoid restricting clothing
- do Burger-Allen exercises
- elevate legs above heart for a period of time each day
- avoid flexing and crossing legs
- not stand or sit for long periods of time
- stop smoking
- identify and alleviate precipitating factors that increase pain
- engage in a weight reduction program if needed

RAYNAUD'S DISEASE

- Raynaud's disease involves intermittent episodes of arterial spasms of the fingers, toes, ears, or nose.
- It occurs most frequently in women between the age of 15 and 45 years.

Etiology: Arterial spasms limit arterial blood flow to the digits, ears, or nose. Unknown etiology.

Precipitating factors: Autoimmune disorders such as systemic lupus erythematosus, and rheumatoid arthritis, genetic predisposition, stress, cold temperatures, caffeine, and tobacco use.

S&S:

- Intermittent color changes of the involved digits or areas
- Absence or decrease in pulse during spasms
- Coldness, numbness, tingling in one or more digits often brought on by cold temperatures or emotional upsets
- Pain increases as disease progresses
- Nails may become thick and brittle
- Ulceration and gangrene are serious complications

Assessment Alert

Triphasic color changes—involved areas become white (ischemia) then blue (collection of deoxygenated blood) and then red (spasms stop and circulation continues).

Dx: Based on symptoms and confirmed by arteriogram. Called Raynaud's phenomenon early-on when involvement is unilateral and limited generally to one or two digits. Considered Raynaud's Disease after 2–3 years by when symptoms have progressed to bilateral and increased involvement

Rx: Treatment of underlying disease, elimination of precipitating factors. Medications include analgesics, vasodilators, calcium channel blockers, sympathectomy

Nursing Process Elements

- Assess symptoms
- Determine presence of precipitating factors
- Assess extremities for complications including edema, ulcerations, and gangrene
- Teach client ways to eliminate precipitating factors: stop tobacco use, protect extremities from cold and injury, reduce stress

Client teaching for self-care

Instruct client to

- inspect skin for breakdown
- keep involved areas warm by the use of gloves, hats, wool socks, and comfortable shoes. May need to wear gloves when working with cold foods and in an air-conditioned environment

- ensure proper stress management
- protect extremities from injury
- avoid restricting clothing
- avoid flexing and crossing legs
- not stand or sit for long periods of time
- stop smoking
- identify and alleviate precipitating factors that increase pain

ARTERIOSCLEROSIS OBLITERANS

- Arteriosclerosis obliterans refers to a gradual narrowing of arteries leading to occlusion of the artery due to thrombosis and injury to the intima.
- It most often affects the abdominal aorta or the lower extremities.
- It occurs most frequently in men between the age of 50 and 60 years.

Etiology: Caused by arteriosclerosis.

Precipitating factors: Hypertension, diabetes mellitus, hyperlipidemia, obesity, elevated serum triglyceride level, smoking, genetic predisposition, high-fat diets, physical inactivity, stress, and gender.

S&S:

- Decreased or absent peripheral pulses in the lower extremities
- Skin on lower legs is shiny and thin with hair loss
- Pain and paresthesias
- Pallor when legs are elevated for 1–2 minutes and rubor when legs are in a dependent position

Assessment Alert

Pain may be both intermittent claudication and occur at rest.

Dx: History and physical examination, angiography, Doppler studies, and oscillometry

Rx: Prevention and elimination of risk factors, Buerger-Allen exercises, control of chronic diseases, medications to reduce hyperlipidemia, vasodilators, analgesics, and anticoagulants, surgery—bypass graft, endarterectomy, sympathectomy, angioplasty, and amputation

Nursing Process Elements

- Assess symptoms
- Determine presence of precipitating factors

- Assess extremities for complications including edema, ulcerations, and gangrene
- Assist client with Buerger-Allen exercises
- Encourage client to do a slow progressive walking program
- Provide pre- and postoperative teaching

Client teaching for self-care

Instruct client to

- inspect skin for breakdown
- ensure stress management
- protect extremities from injury
- avoid restricting clothing
- avoid flexing and crossing legs
- not stand or sit for long periods of time
- stop smoking
- identify and alleviate precipitating factors that increase pain
- do Buerger-Allen exercises
- eat a low-fat diet
- maintain good foot care

THROMBOPHLEBITIS

- Thrombophlebitis refers to thrombus formation on the wall of a vein with resulting inflammation.
- It may occur in superficial (SVT—generally in the upper extremities) or deep (DVT—generally in the lower extremities) veins.
- The most commonly affected veins are the saphenous, femoral, and popliteal.

Etiology: Precipitated by Virchow's triad factors—stasis of blood, injury to the vessel wall, and hypercoagulability of the blood. As a thrombus increases in size, it causes partial to complete occlusion of the vessel.

Precipitating factors: Bed rest, intravenous catheters, obesity, immobilization, pregnancy, childbirth, oral contraception, MI, CHF, malignancies, altered coagulability states, atherosclerosis, varicosities, multiple sclerosis, pelvic and abdominal surgeries, atrial fibrillation, and cigarette smoking.

S&S:

- Vary depending on thrombus size, location, and adequacy of collateral circulation. May be asymptomatic
- SVT—Tenderness, redness, palpable cord-like vein, increased warmth over involved vein
- DVT—Unilateral edema, tenderness over involved vein, warm skin, elevated temperature, cyanosis of affected extremity, general malaise

Assessment Alert

Homan's sign is no longer considered the classic manifestation of DVT because less than 20% of clients with DVT actually have a positive Homan's sign.

Dx: Ascending phlebography (injection of contrast medium into a vein), Doppler ultrasound, plethysmography (measures changes in fluid volume passing through a vessel), blood cultures, WBC, ESR, venous pressure measurement (high in affected limb until collateral circulation is developed)

Rx:

- SVT—relief of symptoms and reversal of inflammation process
 - Warm moist heat application
 - Anti-inflammatory medications
 - Antibiotic therapy
 - Anticoagulants if condition is progressing
- DVT
 - Anticoagulant therapy with heparin (APTT at 1.5–2 times the control) or with low molecular weight heparin (LMWH) such as enoxaparin (Lovenox) which is prescribed according to weight 1 mg/kg subcutaneously every 12 hours
 - Bed rest with leg elevated
 - Oral anticoagulation with warfarin (Coumadin) is initiated along with heparin and LMWH. Therapeutic international normalized ratio (INR) is 2.0–3.0
 - Thrombolytic therapy with streptokinase, urokinase, or tissue plasminogen activator
 - Surgical intervention: venous thrombectomy, transvenous filtration device placed in the inferior vena cava

Nursing Process Elements

- Assess for risk factors
- Assess pain level
- Provide bed rest with elevation of affected extremity
- Apply continuous warm moist compresses if ordered
- Administer medications
 - Heparin
 - Use infusion pump to administer IV heparin
 - Inject heparin into fatty layer of abdomen above iliac crest and 2 inches away from umbilicus
 - Insert needle at 90 degree angle
 - Do not aspirate
 - Apply pressure after injection but do not massage

- Assess for S&S of bleeding: petechiae, epistaxis, bleeding gums

- Have antidote protamine sulfate available

—Warfarin

- Instruct client to use soft tooth brush and to maintain bleeding precautions

- Have antidote vitamin K available

- Instruct client on factors that may affect anticoagulant response

- Monitor laboratory values
- Apply antiembolic stockings if ordered
- Monitor for possible complications like pulmonary emboli
- Measure involved extremity daily
- Provide client teaching

Client teaching for self-care

Teach client

- to adhere to medical regime
- about the importance of maintaining hydration
- to avoid standing and sitting for long periods or crossing legs
- to not wear constrictive clothing
- to not use tobacco
- to not use oral contraceptives
- about using antiembolism hose
- to maintain bleeding precautions when on Coumadin
- to avoid food which contains high levels of vitamin K like green leafy vegetables
- to follow drug regime and laboratory schedule
- to wear medic-alert bracelet
- to adhere to a progressive exercise regime
- about the S&S to report

PULMONARY EMBOLISM

- In pulmonary embolism (PE), a thrombus dislodges and travels through the venous circulation to the right side of the heart and lodges in a pulmonary artery.
- Most pulmonary emboli arise from detached venous thrombus originating in the deep veins of the legs, the right side of the heart, or the pelvic area.
- PE can manifest itself as one large clot, several tiny clots, or a shower of clots in the lungs.

Etiology: Obstruction of pulmonary artery by blood clot or other emboli (fatty or air); usually resulting from DVT that breaks loose and travels to pulmonary vasculature; characterized by VQ inequality (ventilation greater than perfusion)

Precipitating factors: DVT following orthopedic or abdominal surgery, use of oral contraceptives, pregnancy, prolonged immobility, any conditions characterized by venous stasis, hypercoagulability, and vein wall damage (Virchow's triad).

S&S:

- Dyspnea, tachypnea, crackles (rales), and wheezing
- Tachycardia and sharp, localized chest pain
- Restlessness and anxiety
- Hypoxemia
- Hemoptysis
- Hypotension
- If DVT is present there will be calf swelling, warmth at site, and mild fever

Assessment Alert

PE is difficult to diagnosis; therefore, the nurse needs to monitor in S&S for any client at risk.

Dx: VQ scan demonstrates a ventilation/perfusion mismatch, pulmonary angiography, ABGs, and CXR

Rx: For acute episode, IV heparin and thrombolytic agents (urokinase, streptokinase) to inhibit coagulation and prevent further clots; proactive treatment of clients at risk for DVT with low-dose SQ heparin and then oral anticoagulants; if heparin contraindicated may insert inferior vena cava filter, very rarely pulmonary embolectomy

Nursing Process Elements

- Elevate head of bed
- Maintain bed rest
- Administer oxygen
- Promote controlled breathing technique
- Monitor VS, LOC, and respiratory status
- Auscultate heart and lung sounds
- Do not massage legs
- Maintain hydration
- Apply elastic stockings (antiembolic) and pneumatic compression devices
- Monitor laboratory work for effectiveness of anticoagulant therapy
- Administer pain medications as needed
- Reduce anxiety

Client teaching for self-care

- Instruct client to avoid risk factors for further DVT
- Provide teaching related to anticoagulant therapy to avoid unnecessary bleeding
- Teach the importance of follow-up care

VARICOSE VEINS

- Varicose veins are irregular, dilated, tortuous veins with incompetent valves.
- Any veins may be involved but most commonly affects the veins of the lower body.
- Saphenous veins of the leg are the most affected.
- Varicose veins of the rectum are called hemorrhoids.
- Varicose veins of the esophagus are called varices.
- They are more common in women over the age of 35 years.

Etiology: Sustained stretching of the vein due to increased intravenous pressure prevents the valves from closing properly. As the amount of blood increases in the vein, there is increased venous stasis, the vein continues to stretch, the pressure increases, and the valves become increasingly incompetent.

- Primary varicose veins—no involvement of deep veins.
- Secondary varicose veins—caused by the obstruction of deep veins.

Precipitating factors: Prolonged standing, obesity, pregnancy, family predisposition, trauma to vein or valve, congenital weakness, and thrombophlebitis.

S&S:

- May be asymptomatic
- Pain in leg
- Leg fatigue
- Leg heaviness
- Visible dilated veins
- Feeling of heat in the leg
- Edema
- Itching over affected area
- Stasis ulcers
- Discoloration of the skin above the ankles

Assessment Alert

Positive Trendelenburg test to check for valve competency. Client is placed in supine position with legs elevated. As the client sits up and dangles legs, veins normally fill from the distal end. If the veins fill from the proximal end, there are varicosities.

Dx: Visual presence of varicosities and client history. Diagnostic tests include the tourniquet test, Doppler ultrasonic flow, angiographic studies, and plethysmography

Rx: There are no cures. Goals are to improve venous circulation, prevent skin breakdown, and provide pain relief.

Treatment is palliative: antiembolism stockings, walking, elevating legs throughout the day, compression sclerotherapy, and vein stripping

Nursing Process Elements

- Assess pain and provide pain relief
- Assess circulation—check pedal pulses, sensation, capillary refill, edema, and temperature
- Promote a regular exercise routine
- Apply antiembolism stockings and remove every 8 hours for short periods and reapply
- Assess skin integrity
- Elevate legs above heart to decrease edema
- Measure circumference of ankle and calf daily
- Teach client to not wear restrictive clothing or cross legs and to avoid prolonged periods of sitting or standing
- Provide pre- and postoperative care
 - Sclerotherapy involves injecting a sclerosing agent into the vein; compression bandages are worn for up to 6-weeks postoperation
 - Vein ligation: Postoperation, do hourly circulation checks, elevate extremity, and apply sequential compression hose

Client teaching for self-care

Instruct client to

- wear properly fitting antiembolism hose
- remove hose at least every day for an hour
- inspect skin for breakdown
- protect extremities from injury
- maintain a daily walking program
- elevate legs above heart for a fixed period of time each day
- avoid flexing and crossing legs

VENOUS STASIS ULCERS

- Venous stasis ulcer is a chronic disorder where the flow of blood through a vein is slowed or halted causing ischemia to the extremities and ulcer formation.
- More than 85% of leg ulcers are venous.

Etiology: When blood return from the legs is slowed either from valve incompetence or thrombosis, high pressure develops. Venous hypertension causes stretching of the veins and rupture of small veins and venules and further decrease in blood return. Eventually stasis causes edema and ulceration.

Precipitating factors: Thrombophlebitis, hypertension, varicose veins, trauma, pregnancy, obesity, and prolonged standing or sitting.

S&S:

- Brownish discoloration and leathery quality of the skin
- Edema of the extremity
- Pain that reduces when leg is elevated
- Moist ulcers are most often found around the malleolus

Assessment Alert

Pulses are palpable and extremity is warm.

Dx: History and physical examination

Rx: Compression wrap (Unna boot), elevation of extremity, bed rest, wound care (antibiotic or fungal therapy, hydrocortisone or zinc oxide as indicated), surgical or enzymatic debridement, and skin grafting

Nursing Process Elements

- Provide bed rest with legs elevated
- Provide wound care
- Give medications as prescribed
- Assess for risk factors
- Pre- and postoperative teaching

Client teaching for self-care

Teach client to

- inspect skin for breakdown
- protect extremities from injury
- avoid restricting clothing
- avoid flexing and crossing legs
- not stand or sit for long periods of time
- identify and alleviate precipitating factors that increase pain
- care of boot or compression bandage
- plan periods of rest with legs elevated
- use elastic stockings after ulcer heals
- adhere to medical regime since ulcers generally reoccur

PEDS

KAWASAKI DISEASE

- Kawasaki disease (KD) is also called “mucocutaneous lymph node syndrome.”
- It causes acute systemic vasculitis, i.e., inflammation of arterioles, venules, and capillaries.
- It may progress to coronary artery aneurysms and coronary thrombosis.

Etiology: Unknown. Because of seasonal outbreaks, an infectious etiology may be involved. KD does not spread from person to person contact as is typical in infectious diseases.

Precipitating factors: Occurs more frequently in children younger than 5 years of age.

S&S:

- High fever that does not respond to typical treatment
- Bilateral conjunctivitis
- Strawberry tongue and cracking of the lips
- Edema of the periphery
- Desquamation of the palms of the hands and soles of the feet

Dx: History and physical examination

Rx: Salicylate therapy, intravenous gamma globulin administration

Nursing Process Elements

- Monitor cardiac function, I&O, and daily weights
- Give medication as ordered, monitor for aspirin toxicity
- Administer IVIG per manufacturer's recommendation
- Promote comfort: oral care, skin care, oral hydration

Client teaching for self-care

Teach client

- about skin care: avoiding lotions and soaps
- about oral care for comfort
- Monitor temperature
- Safe salicylate administration
- Complications of IVIG

WORKSHEET

SHORT ANSWER QUESTIONS

1. The nurse places a client on cardiac telemetry and notices the following pattern. Identify the rate, rhythm, and the cardiac pattern.

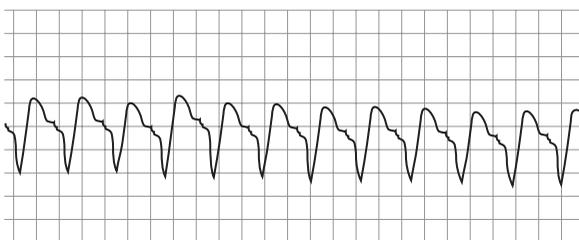

Rate _____

Rhythm _____

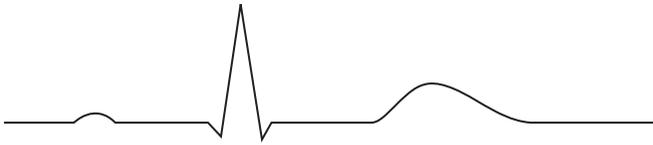

Pattern _____

2. The nurse notices the following rhythm on the cardiac monitor. What would be the correct rate and rhythm interpretation?

(continued)

3. Label the following: P wave, PR interval, QRS, and QT interval and state what each represents.

4. Briefly list the things a nurse should do before giving thrombolytics to a client suspected of having a myocardial infarction.
5. What are the three “I”s that describe the progression of pathophysiology when a patient has an MI?.
6. Discuss briefly the etiology and precipitating factors of endocarditis.
7. Discuss briefly why anticoagulant therapy is initiated for clients experiencing atrial fibrillation.
8. List 5 points of information to be included in a teaching plan for a client newly diagnosed with hypertension.
9. State what is meant by the PQRST of pain assessment for an MI patient.
10. Identify the Virchow’s triad factors of thrombophlebitis.
11. The nurse is to give digoxin 1.25-mg IV push. The nurse has digoxin 0.5 mg per 2 ml. The nurse would give _____ ml.
12. A client who is being treated for congestive heart failure has lost 4 lbs so far. How much fluid has the client lost?
13. Identify the statements below as to whether they are true for Mechanical or Tissue (biologic) heart valves.
- _____ Considered to be more durable
 - _____ Three basic types—xenografts, homografts, and autografts
 - _____ Less likely to cause thromboemboli
 - _____ Requires lifetime anticoagulant therapy
 - _____ Often used for younger clients

APPLICATION QUESTIONS

- The nurse realizes that more teaching is needed when the client on a cardiac low-cholesterol diet makes which choice from the menu?
 - Stewed chicken, green beans, and noodles
 - Liver and onions, salad with ranch dressing, and milk
 - Ham and bean soup, salad with vinaigrette dressing, and cornbread
 - Pork roast, brown rice, and beets
- When taking a client’s medical history, which are the precipitating factors for myocardial infarction? (Select all that apply.)
 - Hypothyroidism
 - Cigarette smoking
 - Hyperlipidemia
 - Rheumatic fever
 - Elevated serum iron level
 - High density lipids <40 mg
 - Using oral contraceptives
- When the nurse performs an admission assessment on a client, the nurse notes that the client has xanthomas present on both eyelids. The laboratory value that the nurse would want to check based on this assessment finding is
 - triglyceride level
 - homocystine level
 - cardiac enzymes—CPK-MB, troponin, and myoglobin
 - cholesterol panel

4. A client presents to the clinic with the following symptoms: a burning sensation in the lower extremities, thickened toe nails, and pain in legs when walking. The nurse would assess the client for which additional factor consistent with Burger's disease (thromboangitis obliterans)?
 - a. Bounding peripheral pulses
 - b. Rubor when the extremities are elevated
 - c. Intolerance to heat
 - d. Symptoms triggered by stress
5. A goal for a client with arteriosclerosis obliterans is to increase arterial blood supply to the extremities. Which of the following nursing interventions would be appropriate for this goal?
 - a. Elevate the extremities above the level of the heart for 15 minutes four times a day.
 - b. Have client perform Buerger-Allen exercises four times a day.
 - c. Maintain client on bed rest with legs in a neutral position.
 - d. Position client in high-Fowler's position with legs straight.
6. Which of the following assessment findings are consistent with the diagnosis of venous stasis?
 - a. Absent or diminished peripheral pulses
 - b. Hair loss on the extremity
 - c. Moist ulcers around the malleolus
 - d. Edema of the extremity
 - e. Coolness of the extremity
 - f. Leathery quality of the extremity
 - g. Pallor of the extremity
7. A client is returned to the unit after having a repair of an abdominal aortic aneurysm. The nurse should place the client in which of the following positions?
 - a. High-Fowler's
 - b. Sims
 - c. Semi-Fowler's
 - d. Flat
8. The nurse is giving a client low molecular weight heparin, enoxaparin. The correct nursing interventions when administering this medication include all of the following except
 - a. using a TB syringe
 - b. injecting the medicine using Z-track method
 - c. not rubbing the site postinjection
 - d. administering the medicine in the anterolateral abdominal wall
9. In order to prevent the postoperative complication of thrombophlebitis in a client who has had mitral valve replacement, the nurse would have the client engage in which of the following activities?
 - a. Perform dorsiflexion of the feet several times every hour while awake
 - b. Cough and take deep breaths every hour while awake
 - c. Sit up in a chair for several hours during the afternoon
 - d. Eat a high-fiber, high-calorie diet
10. The nurse is caring for a client who has just arrived on the unit following a cardiac catheterization. Which of the following assessments would be most immediate?
 - a. Heart and lung sounds
 - b. Pain at the catheter insertion site
 - c. Pulses distal to the insertion site
 - d. Urine output
11. A client comes into the ER complaining of "his heart racing." Cardiac monitor shows atrial tachycardia with a ventricular rate of 190 bpm. The nurse anticipates that the physician will order adenosine (Adenocard) to be given. Prior to giving the medication the nurse should do which of the following?
 - a. Determine when the client last ate
 - b. Ask the laboratory to draw serum BUN and creatinine levels
 - c. Ask the client if he/she has a history of asthma
 - d. Have the client sign a consent
12. Metoprolol tartrate (Lopressor) is ordered for a client who has had a myocardial infarction. The nurse would expect which therapeutic result from administration of this drug?
 - a. Increased urinary output
 - b. Decreased coronary artery spasms
 - c. Increased cardiac output
 - d. Decreased resting heart rate
13. A client's cardiac monitor strip shows the following: HR 42/min, rhythm regular, PRI 0.16 seconds, QRS 0.06 seconds. The client is experiencing dizziness, nausea, and chest pain rated as 3 on a scale of 1–10 with 10 being the worst pain. The drug of choice to treat this dysrhythmia is
 - a. Lidocaine (Xylocaine)
 - b. Adenosine (Adenocard)
 - c. Atropine sulfate
 - d. Epinephrine (Adrenalin)
14. A client is admitted to the ER with new onset atrial fibrillation with a ventricular response of 110/min.

(continued)

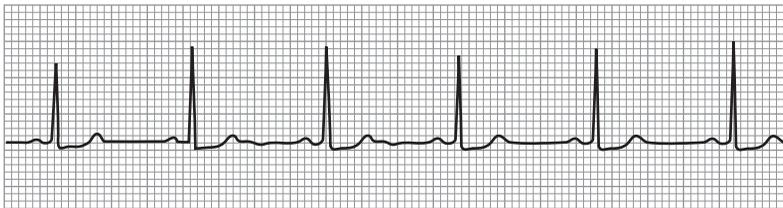

The nurse would anticipate which of the following treatment options to be ordered. (Select all that apply.)

- a. Defibrillation
 - b. Start oxygen at 2–4 lpm
 - c. Anticoagulant therapy
 - d. Medicate with beta blocker
 - e. Start Lidocaine drip
 - f. Atrial pacing
15. The nurse is assessing a newborn infant who is exhibiting the following signs and symptoms: elevated blood pressure, bounding brachial pulses, diminished pedal pulses, elevated Jugular venous distention (JVD), and cardiac murmur. Based on the assessment, the nurse would suspect that the client may have which of the following conditions?
 - a. Congestive heart failure
 - b. Coarctation of the aorta
 - c. Mitral valve prolapse
 - d. Transposition of the great vessels
 16. The nurse has assessed a client and has determined that the client is exhibiting signs and symptoms of left heart failure. Identify which of the following are indicative of left heart failure.
 - a. Tachypnea, loss of appetite, ST elevation on the ECG
 - b. Hemoptysis, cogwheel murmur, midsternal chest pain
 - c. Ascites, oliguria, fatigue
 - d. Orthopnea, bibasilar crackles, gallop rhythm
 17. The nurse is providing nutritional counseling for a client who is receiving a loop diuretic. Which meal plan would be most appropriate for this client?
 - a. Raisin bran cereal, tomato juice, whole grain toast
 - b. Boiled chicken, green beans, tossed salad
 - c. Vegetable soup, low-salt crackers, skim milk
 - d. Poached fish, beets, macaroni and cheese
 18. The nurse is reading a 6-second cardiac rhythm strip and notes 9 QRS complexes in it. The client's heart rate is
 - a. 54
 - b. 63
 - c. 81
 - d. 90
 19. A client has been diagnosed with pericardial effusion. The nurse would prepare the client for which of the following procedures?
 - a. Myotomy
 - b. Pericardiectomy
 - c. Pericardiostomy
 - d. Dynamic cardiomyoplasty
 20. Which instruction would be inappropriate to give a client following coronary artery bypass graft surgery?
 - a. No driving for 6–8 weeks
 - b. Avoid smoking or tobacco use for 4–6 weeks
 - c. No heavy lifting for 6–8 weeks
 - d. Can resume sexual intercourse in 3–4 weeks
 21. A nurse checks the client's arterial blood gas results which are as follows: pH, 7.38; PO₂, 88 mm Hg; PCO₂, 33 mm Hg; HCO₃, 24 mEq/l; and O₂ saturation, 96%. Which is the correct interpretation of these results?
 - a. Metabolic acidosis
 - b. Metabolic alkalosis
 - c. Normal values
 - d. Respiratory alkalosis
 22. Which of the following instructions regarding a cardiac nuclear scan should a nurse give the client?
 - a. Avoid coffee, tea, and cocoa the morning of the test
 - b. Take a clear liquid diet for 24 hours before the test
 - c. Dress in comfortable clothing and walking shoes
 - d. Take all medications as prescribed prior to the test
 23. Which assessment finding in a neonate should the nurse interpret as a sign of possible coarctation of the aorta?
 - a. Triphasic color changes in the upper extremities
 - b. Pulsating abdominal mass with a systolic bruit and cool lower extremities
 - c. Decreased distal pulses, thick, malformed nails, cyanotic upper extremity digits
 - d. Bounding pulses in the arms and absent pulses in the groin and legs
 24. The nurse is administering a beta blocker to a client admitted with an MI. The client's wife asks what the medication will do. Which fact should be the foundation of the nurse's reply? The medication will:
 - a. reduce the amount of oxygen needed by the heart muscle
 - b. decrease the risk of a blood clot
 - c. enhance the affinity of oxygen for hemoglobin
 - d. increase the volume of blood in the coronary arteries
 25. The nurse would expect to administer morphine sulfate, oxygen, nitroglycerine and aspirin to a client with which problem?
 - a. Raynaud's disease
 - b. Myocardial infarct
 - c. Valvular heart disease
 - d. Kawasaki disease

ANSWERS & RATIONALES

ANSWERS FOR SHORT ANSWER QUESTIONS

1. The nurse places a client on cardiac telemetry and notices the following pattern. Identify the rate, rhythm, and the cardiac pattern.

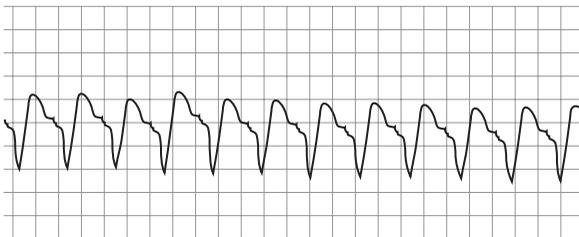

Answer

Rate 78 ($1500 \div 19 = 78$)

Rhythm regular

Pattern normal sinus rhythm

2. The nurse notices the following rhythm on the cardiac monitor. What would be the correct rate and rhythm interpretation?

Answer

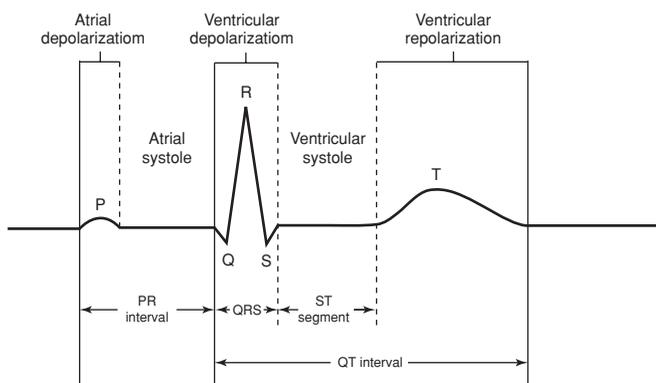

Ventricular rate 136 ($1500 \div 11 = 136$)

QRS wide and bizarre

Rhythm regular

Interpretation ventricular tachycardia

3. Label the following: P wave, PR interval, QRS, and QT interval and state what each represents.

(continued)

4. Briefly list the things a nurse should do before giving thrombolytics to a client suspected of having a myocardial infarction.

Answer

Before giving a thrombolytic, the nurse should establish 2–3 IV sites, give no IM injections, assess for allergies especially if receiving streptokinase, handle the client gently, continuously monitor the client's cardiac pattern, assess laboratory values for bleeding times and elevation in cardiac enzymes, and provide emotional support.

5. What are the three “T’s” that describe the progression of pathophysiology when a patient has an MI?

Answer

Ischemia progresses to injury progresses to infarction

6. Discuss briefly the etiology and precipitating factors of endocarditis.

Answer

Etiology: Rheumatic heart disease, clients with prosthetic heart valves, IV drug use, mitral valve prolapse (very common cause), and infectious organisms usually bacteria (*Streptococci*, *Enterococci*, or *Staphylococcus aureus*)

Precipitating factors: Underlying cardiac conditions, dental, surgical or invasive procedures, or urological procedures. There must be some mechanism to allow bacteria entrance to the bloodstream.

7. Discuss briefly why anticoagulant therapy is initiated for clients experiencing atrial fibrillation.

Answer

Since the atria are quivering and not squeezing, blood can pool in the atria and thrombus formation may occur. Anticoagulant therapy helps prevent thrombus formation.

8. List 5 points of information to be included in a teaching plan for a client newly diagnosed with hypertension..

Answer

- a. Necessary lifestyle changes including modification of risk factors
- b. Complications of hypertension
- c. Medication regimen
- d. Methods for monitoring blood pressure and apical pulse
- e. Need for adherence to medical regime and that treatment is palliative and not curative

9. State what is meant by the PQRST of pain assessment for an MI patient.

Answer

- P—position
 Q—quality and quantity
 R—radiation and relief
 S—severity and symptoms
 T—timing

10. Identify the Virchow's triad factors of thrombophlebitis.

Answer

- a. Stasis of blood
- b. Injury to the vessel wall
- c. Hypercoagulability of the blood

11. The nurse is to give digoxin 1.25-mg IV push. The nurse has digoxin 0.5 mg per 2 ml. The nurse would give _____ ml.

Answer

The nurse is to give digoxin 1.25-mg IV push. The nurse has digoxin 0.5 mg per 2 ml. The nurse would give 0.5 ml.

12. A client who is being treated for congestive heart failure has lost 4 lbs so far. How much fluid has the client lost?

Answer

One liter of fluid = 2.2 lbs. Thus, $4 \div 2.2 = 1.8$.

The client has lost 1.8 liters of fluid so far.

13. Identify the statements below as to whether they are true for Mechanical or Tissue (biologic) heart valves.

- a. _____ Considered to be more durable
- b. _____ Three basic types—xenografts, homografts, and autografts
- c. _____ Less likely to cause thromboemboli
- d. _____ Requires lifetime anticoagulant therapy
- e. _____ Often used for younger clients

Answer

- a. Mechanical Considered to be more durable
- b. Tissue Three basic types- xenografts, homografts, and autografts
- c. Tissue Less likely to cause thromboemboli
- d. Mechanical Requires lifetime anticoagulant therapy
- e. Mechanical Often used for younger clients

APPLICATION ANSWERS

1. The nurse realizes that more teaching is needed when the client on a cardiac low-cholesterol diet makes which choice from the menu?

- a. Stewed chicken, green beans, and noodles
- b. Liver and onions, salad with ranch dressing, and milk
- c. Ham and bean soup, salad with vinaigrette dressing, and cornbread
- d. Pork roast, brown rice, and beets

Rationale

Correct answer: b.

The client should avoid liver because organ meat is high in cholesterol.

2. When taking a client's medical history, which are the precipitating factors for myocardial infarction? (Select all that apply.)

- a. Hypothyroidism
- b. Cigarette smoking
- c. Hyperlipidemia
- d. Rheumatic Fever
- e. Elevated serum iron level
- f. High density lipids <40 mg
- g. Using oral contraceptives

Rationale

Correct answers: b, c, e, f, and g.

Hypothyroidism is not a risk factor for MI. Rheumatic fever is a risk factor for valve disease.

3. When the nurse performs an admission assessment on a client, the nurse notes that the client has xanthomas present on both eyelids. The laboratory value the nurse would want to check based on this assessment finding is

- a. triglyceride level
- b. homocystine level
- c. cardiac enzymes—CPK-MB, troponin, and myoglobin
- d. cholesterol panel

Rationale

Correct answer: d.

Cholesterol accumulates in tumor nodules on the skin. Triglyceride level is a measure of fats in the blood stream. Elevated homocystine levels are considered an independent risk factor for atherosclerosis. Cardiac enzymes elevate with MI.

4. A client presents to the clinic with the following symptoms: a burning sensation in the lower extremities, thickened toe nails, and pain in legs when walking. The nurse would assess the client for which additional factor consistent with Burger's disease (thromboangitis obliterans)?

(continued)

- a. Bounding peripheral pulses
- b. Rubor when the extremities are elevated
- c. Intolerance to heat
- d. Symptoms triggered by stress

Rationale

Correct Answer: d.

Symptoms are triggered by stress.

5. A goal for a client with arteriosclerosis obliterans is to increase arterial blood supply to the extremities. Which of the following nursing interventions would be appropriate for this goal?
- a. Elevate the extremities above the level of the heart for 15 minutes four times a day.
 - b. Have client perform Buerger-Allen exercises four times a day.
 - c. Maintain client on bed rest with legs in a neutral position.
 - d. Position client in high-Fowler's position with legs straight.

Rationale

Correct answer: b.

These exercises help drain static blood from the legs when elevated and then increase the amount of blood going to the legs when in a dependent position and when the legs are flat, the person exercises their ankles and feet increasing circulation. Answer "a" drains static blood from the legs and is used with varicose veins. Answers "c" and "d" do not drain stagnant blood from the legs and thus will not increase arterial blood flow to them.

6. Which of the following assessment findings are consistent with the diagnosis of venous stasis?
- a. Absent or diminished peripheral pulses
 - b. Hair loss on the extremity
 - c. Moist ulcers around the malleolus
 - d. Edema of the extremity
 - e. Coolness of the extremity
 - f. Leathery quality of the extremity
 - g. Pallor of the extremity

Rationale

Correct answers: c, d, and f.

Moist ulcers around the malleolus, leathery quality to the skin of the extremity, and edema of the extremity are signs of venous stasis. Absent pulses, coolness, pallor and hair loss are all signs of arterial insufficiency.

7. A client is returned to the unit after having a repair of an abdominal aortic aneurysm. The nurse should place the client in which of the following positions?

- a. High-Fowler's
- b. Sims
- c. Semi-Fowler's
- d. Flat

Rationale

Correct answer: d.

The client should be placed in a flat position so that flexion of the graft is prevented.

8. The nurse is giving a client low molecular weight heparin, enoxaparin. The correct nursing interventions when administering this medication include all of the following except
- a. using a TB syringe
 - b. injecting the medicine using Z-track method
 - c. not rubbing the site postinjection
 - d. administering the medicine in the anterolateral abdominal wall

Rationale

Correct answer: b.

Z-track method is used for IM injections in order to trap medicine in the muscle.

9. In order to prevent the postoperative complication of thrombophlebitis in a client who has had mitral valve replacement, the nurse would have the client engage in which of the following activities?
- a. Perform dorsiflexion of the feet several times every hour while awake
 - b. Cough and take deep breaths every hour while awake
 - c. Sit up in a chair for several hours during the afternoon
 - d. Eat a high-fiber, high-calorie diet

Rationale

Correct answer: a.

Performing dorsiflexion of the feet several times every hour while awake prevents venous stasis. Answers "b" and "c" help prevent pneumonia and answer "d" aids healing.

10. The nurse is caring for a client who has just arrived on the unit following a cardiac catheterization. Which of the following assessments would be most immediate?
- a. Heart and lung sounds
 - b. Pain at the catheter insertion site
 - c. Pulses distal to the insertion site
 - d. Urine output

Rationale

Correct answer: c.

All assessments would need to be done but the risk of a clot-decreasing circulation is most important.

11. A client comes into the ER complaining of “his heart racing.” Cardiac monitor shows atrial tachycardia with a ventricular rate of 190 bpm. The nurse anticipates that the physician will order adenosine (Adenocard) to be given. Prior to giving the medication the nurse should do which of the following?
- Determine when the client last ate
 - Ask the laboratory to draw serum BUN and creatinine levels
 - Ask the client if he/she has a history of asthma
 - Have the client sign a consent

Rationale

Correct answer: c.

Adenosine (Adenocard) can cause bronchospasms in asthmatic clients.

12. Metoprolol tartrate (Lopressor) is ordered for a client who has had a myocardial infarction. The nurse would expect which therapeutic result from administration of this drug?
- Increased urinary output
 - Decreased coronary artery spasms
 - Increased cardiac output
 - Decreased resting heart rate

Rationale

Correct answer: d.

It is a beta-adrenergic blocking agent, which slows the heart rate.

13. A client’s cardiac monitor strip shows the following: HR 42/min, rhythm regular, PRI 0.16 seconds, QRS 0.06 seconds. The client is experiencing dizziness, nausea, and chest pain rated as 3 on a scale of 1–10 with 10 being the worst pain. The drug of choice to treat this dysrhythmia is
- Lidocaine (Xylocaine)
 - Adenosine (Adenocard)
 - Atropine Sulfate
 - Epinephrine (Adrenalin)

Rationale

Correct answer: c.

Atropine sulfate blocks vagal impulses to the heart and increases heart rate. Lidocaine is used for control of ventricular dysrhythmias. Adenosine is used to restore NSR in clients with supraventricular tachycardia. Epinephrine is a catecholamine which acts on alpha and beta receptors and is used for anaphylactic reactions and relief of bronchospasms.

14. A client is admitted to the ER with new onset atrial fibrillation with a ventricular response of 110/min.

The nurse would anticipate which of the following treatment options to be ordered. (Select all that apply.)

- Defibrillation
- Start oxygen at 2–4 lpm
- Anticoagulant therapy
- Medicate with beta blocker
- Start Lidocaine drip
- Atrial pacing

Rationale

Correct answers: b, c, d, and f.

Elective cardioversion and not defibrillation may be used. Lidocaine is used to treat ventricular dysrhythmias.

15. The nurse is assessing a newborn infant who is exhibiting the following signs and symptoms: elevated blood pressure, bounding brachial pulses, diminished pedal pulses, elevated Jugular venous distention (JVD), and cardiac murmur. Based on the assessment, the nurse would suspect that the client may have which of the following conditions?
- Congestive heart failure
 - Coarctation of the aorta
 - Mitral valve prolapse
 - Transposition of the great vessels

Rationale

Correct answer: b.

There is narrowing of the aorta restricting outflow so that there is elevated pressure in the upper extremities and diminished outflow to the lower extremities.

16. The nurse has assessed a client and has determined that the client is exhibiting signs and symptoms of left heart failure. Identify which of the signs and symptoms are indicative of left heart failure.
- Tachypnea, loss of appetite, ST elevation on the ECG
 - Hemoptysis, cogwheel murmur, midsternal chest pain
 - Ascites, oliguria, fatigue
 - Orthopnea, bibasilar crackles, gallop rhythm

Rationale

Correct answer: d.

Blood backs into the lungs causing congestion and respiratory symptoms and a gallop rhythm develops from increased blood flow across the valves. Answer “b” consists of signs and symptoms of pulmonary air embolism. Answer “c” consists of signs and symptoms of right heart failure.

(continued)

17. The nurse is providing nutritional counseling for a client who is receiving a loop diuretic. Which meal plan would be most appropriate for this client?
- Raisin bran cereal, tomato juice, whole grain toast
 - Boiled chicken, green beans, tossed salad
 - Vegetable soup, low-salt crackers, skim milk
 - Poached fish, beets, macaroni and cheese

Rationale

Correct answer: a.

Tomato juice and raisins contain potassium, which is lost through loop diuretics.

18. The nurse is reading a 6-second cardiac rhythm strip and notes 9 QRS complexes in it. The client's heart rate is
- 54
 - 63
 - 81
 - 90

Rationale

Correct answer: d.

$$9 \times 10 = 90$$

19. A client has been diagnosed with pericardial effusion. The nurse would prepare the client for which of the following procedures?
- Myotomy
 - Pericardiectomy
 - Pericardiostomy
 - Dynamic cardiomyoplasty

Rationale

Correct answer: c.

Pericardiostomy is the creation of an opening into the pericardium. It is usually done to drain a pericardial effusion. Myotomy is the cutting into a muscle. Pericardiectomy is the excision of a part of the pericardium. Dynamic cardiomyoplasty is a procedure done to improve the pumping action of the myocardium.

20. Which instruction would be inappropriate to give a client following coronary artery bypass graft surgery?
- No driving for 6–8 weeks
 - Avoid smoking or tobacco use for 4–6 weeks
 - No heavy lifting for 6–8 weeks
 - Can resume sexual intercourse in 3–4 weeks

Rationale

Correct answer: b.

Smoking and use of tobacco should be stopped entirely not just for 4–6 weeks. All other instructions are appropriate for the client following coronary artery bypass graft surgery.

21. A nurse checks the client's arterial blood gas results which are as follows: pH, 7.38; PO₂, 88 mmHg; PCO₂, 33 mmHg; HCO₃⁻, 24 mEq/l; and O₂ saturation 96%. Which is the correct interpretation of these results?
- Metabolic acidosis
 - Metabolic alkalosis
 - Normal values
 - Respiratory alkalosis

Rationale

Correct answer: c.

The blood gas results listed are all in normal range so no acid-base imbalance is present.

22. Which of the following instructions regarding a cardiac nuclear scan should a nurse give the client?
- Avoid coffee, tea, and cocoa the morning of the test
 - Take a clear liquid diet for 24 hours before the test
 - Dress in comfortable clothing and walking shoes
 - Take all medications as prescribed prior to the test

Rationale

Correct answer: c.

23. Which assessment finding in a neonate should the nurse interpret as a sign of possible coarctation of the aorta?
- Triphasic color changes in the upper extremities
 - Pulsating abdominal mass with a systolic bruit and cool lower extremities.
 - Decreased distal pulses, thick, malformed nails, cyanotic upper extremity digits
 - Bounding pulses in the arms and absent pulses in the groin and legs

Rationale

Correct answer: d.

Bounding pulses in the upper extremities and decreased or absent pulses in the groin and legs occurring several hours to days after birth and the closure of the ductus arteriosus are signs of severe coarctation of the aorta.

Triphasic skin changes in the affected parts are characteristic of Raynaud's disease. A pulsating abdominal mass with a systolic bruit and cool lower extremities are signs of an abdominal aortic aneurysm. Decreased distal pulses, thick, malformed nails, cyanotic upper extremity digits are symptoms of thromboangitis obliterans (Buerger's disease).

24. The nurse is administering a beta blocker to a client admitted with an MI. The client's wife asks what the medication will do. Which fact should be the foundation of the nurse's reply? The medication will:

- a. reduce the amount of oxygen needed by the heart muscle
- b. decrease the risk of a blood clot
- c. enhance the affinity of oxygen for hemoglobin
- d. increase the volume of blood in the coronary arteries

Rationale

Correct answer: a.

Drugs that reduce oxygen demand or increase the oxygen supply to the myocardium are part of the immediate care of clients with an MI. These drugs include nitrates, beta blockers, calcium channel blockers, antihypertensives, and antiplatelet agents. Beta blockers reduce oxygen demand by the myocardium.

25. The nurse would expect to administer morphine sulfate, oxygen, nitroglycerine and aspirin to a client with which problem?

- a. Raynaud's disease
- b. Myocardial infarct
- c. Valvular heart disease
- d. Kawasaki disease

Rationale

Correct answer: b.

MONA (morphine sulfate, oxygen, nitroglycerine and aspirin) are administered in the emergency room to clients with myocardial infarcts. The treatment of Raynaud's consist of elimination of precipitating factors, medications such as analgesics, vasodilators, and calcium channel blockers, or sympathectomy. Treatment of valvular heart disease includes digitalis, diuretics, ACE inhibitors, antibiotics prior to dental work or invasive procedures to prevent endocarditis, and surgical repair or replacement. Salicylate therapy and intravenous gamma globulin administration is the treatment for Kawasaki disease.

This page intentionally left blank

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 2: Hematologic Problems

| | | | |
|--------------|-----|------------------------|-----|
| ▶ Anemia | 677 | ▶ Lymphedema | 689 |
| ▶ Hemophilia | 686 | ▶ Thrombocytopenia | 687 |
| ▶ Leukemia | 683 | ▶ Vitamin K Deficiency | 688 |

ANEMIA

Anemia is caused by a reduction in the number of circulating red blood cells (RBCs). Reduced RBCs can be due to:

- decrease in total blood volume,
- decreased production,
- impaired maturation, and
- increased destruction or hemolysis.

Anemias are classified and named based on the cause of the reduction in circulating red blood cells. Nursing management for prevention and risk factor reduction of anemia are:

- dietary teaching,
- awareness of exposure to environmental toxins,
- injury prevention,
- early and periodic screening for conditions that may cause blood loss,
- early detection of chronic bleeding disorders, and
- genetic counseling for hereditary anemic disorders.

Various types of anemia.

ACUTE HEMORRHAGIC ANEMIA

Caused by rapid or sudden loss of blood volume

Etiology: Trauma, surgery, platelet dysfunction, and coagulation disorders

S&S:

- Signs and symptoms are those of hypovolemia and hypoxemia
- Decreased hemoglobin and hematocrit are late signs
- Severity of symptoms correlates to amount of blood loss
- If not controlled, irreversible shock can occur

Nursing Process Elements

- Educate clients about the potential need for transfusion of blood products

- Monitor for signs and symptoms of transfusion reaction for any blood products given

CHRONIC ANEMIA

Due to gradual loss of blood

Etiology:

- Gastrointestinal: gastritis, peptic ulcers, hemorrhoids, esophageal ulcerations, or chronic use of aspirin or NSAIDs
- Vaginal: excessive menses, postpartum bleeding, reproductive hormone abnormalities, benign or malignant uterine lesions
- Malnourishment

S&S:

- Client may remain asymptomatic
- Common symptoms when present are fatigue, dyspnea, tachycardia
- Lab findings: decreased RBCs, Hgb, Hct, MCV, and MCHC

Nursing Process Elements

Client teaching for self-care

- Client education on diet and foods high in iron and vitamins, spacing of activities and frequent rest periods.
- Client education on compliance with routine screenings and blood tests.

APLASTIC ANEMIA

- Results from impaired erythrocyte production
- Characterized by a reduction or cessation of all blood-producing elements thus RBCs, platelets, and white blood cells are affected

Etiology:

- Fifty percent of clients have no knowledge of causative etiologic agent
- Aplastic anemia can be drug, chemical, or infection induced
- It can be congenital

S&S:

- Pallor of skin and mucous membranes
- Fatigue
- Palpitations
- Exertional dyspnea
- Infections of the skin and mucous membranes in severe cases
- Hemorrhagic: bleeding into skin and mucous membranes, spontaneous bleeding from nose, gums, vagina, or rectum
- Development of symptoms gradually over weeks or months

Dx:

- Initial diagnosis most often through laboratory analysis of blood
- Definitive diagnosis through bone marrow analysis

Nursing Process Elements

- Primary foci of nursing care: Monitor for signs of bleeding, which is a risk because of decreased platelets, and prevent infection, which is a risk because of immunosuppression.
- Monitor any puncture sites for bleeding and signs of infection
- Minimize any invasive procedures such as venipuncture, injections, bladder catheterization
- Avoid rectal temperatures, medications, or enemas
- Test urine and stool for occult blood
- Plan activities so that fatigue is prevented
- Monitor for excessive fatigue
- Assist client in developing coping strategies to deal with prolonged hospitalization

Client teaching for self-care

- Importance of strict hand washing for family and visitors
- Need for meticulous personal hygiene
- Ways to reduce risk of hemorrhage such as not using a toothbrush for oral care and padding any sharp corners on furniture
- Rationale for protective isolation if applicable

HEMOLYTIC ANEMIA

- Destruction of erythrocytes at a rate greater than bone marrow can compensate for the reduction.
- Two types of hemolysis
 - Extravascular: premature removal of erythrocytes from circulation by the spleen
 - Intravascular: erythrocytes lyse as a result of an enzyme deficiency in the cell membrane, or mechanical injury to the cell membrane

AUTOIMMUNE HEMOLYTIC ANEMIA

There are three classifications

- Warm-reacting
 - Most often idiopathic
 - More common in women
 - May be associated with SLE, RA, chronic lymphocytic leukemia, and myeloma

- Pathophysiology: antibodies develop against own erythrocytes and combine more easily at body temperature hence the term warm-reacting
- Common signs and symptoms: jaundice, pallor, and splenomegaly
- Cold-reacting
 - Less common, usually affecting older adults
 - Raynaud's phenomenon is an example
 - Associated with mononucleosis, mycoplasma pneumoniae, Epstein-Barr virus, mumps, and Legionnaires' disease
 - Pathophysiology: immunoglobulin M antibodies react with antigens on the erythrocyte at temperatures below 88 °F causing red cells to clump in capillary beds
 - Signs and Symptoms: cyanosis, pain, paresthesias, and hemoglobinuria
- Drug-induced
 - Causes about a fifth of cases
 - Most frequently caused by methyldopa, penicillin, quinine, and quinidine
 - Pathophysiology: response is abnormal antibody production specific to the drug

Dx:

- Positive Coombs' test
- Decreased Hct, increased reticulocyte count
- Increased bilirubin

Rx: Determined by the severity of condition

**Nursing Process Elements**

Promote use of effective strategies to cope with a chronic condition

**Client teaching for self-care**

- Importance of compliance with drug therapy
- Avoidance of cold if applicable

HEREDITARY SPHEROCYTOSIS

Alteration in the erythrocyte shape leads to osmotic swelling of the RBC and vulnerability to destruction by the spleen due to the cell's inability to move through the spleen's microcirculation.

S&S: pallor, fatigue, exertional dyspnea, jaundice, and enlarged spleen, increased reticulocyte count, increased serum bilirubin

Rx: splenectomy often with cholecystectomy as well

**Nursing Process Elements**

- Plan care to conserve energy.
- Provide perioperative care as discussed in Chapter 18.

SICKLE CELL DISEASE

- Inherited hemoglobinopathies that cause abnormal sickle-shaped hemoglobin to partially or totally replace normally shaped hemoglobin
- Two most common forms are:
 - sickle cell trait: Individuals who are heterozygous for the disease are said to have the “trait” and are carriers for the disease.
 - sickle cell anemia: Individuals who are homozygous for the trait, have predominantly sickle hemoglobin, and are symptomatic.
- Affected person produces an abnormal form of hemoglobin called hemoglobin S
 - Nonaffected individuals produce a form of hemoglobin call hemoglobin A (Adult hemoglobin)
 - A fetal form of hemoglobin is found in all newborns. At approximately 4–6 months of age, the hemoglobin converts to an adult form of hemoglobin.
 - Affected individuals are normal at birth but symptoms appear at 4–6 months of age.
- Under conditions of decreased oxygen tension in the blood, the hemoglobin S red blood cell, which has normal oxygen-carrying capacity, forms a sickle shape
 - Sickled RBCs tend to clump together increasing blood viscosity and obstructing blood flow through small vessels resulting in tissue hypoxia.
 - RBCs with hemoglobin S are more fragile than RBCs with hemoglobin A (the adult form of hemoglobin). Normal RBCs last approximately 120 days. RBCs with hemoglobin S have a life span of 10–20 days. Shortened life span leads to a chronic anemia.
 - Amount of sickling correlates with the severity of symptoms: the more the sickling, the more severe the symptoms.
- Three forms of crisis are associated with sickle cell disease
 - Vaso-occlusive crisis: When oxygen levels in the blood drop, the RBCs assume the sickle shape, clump together, and obstruct small blood vessels.
 - Anemic crisis: An ongoing problem for the individual with sickle cell anemia.
 - Sequestration crisis: A pooling of blood in the spleen of individuals with sickle cell anemia that leads to circulatory collapse. It tends to occur in children younger than 6 years of age. By the age of 7, the spleens of most children with the disease become nonfunctioning due to

repeated infarcts and would no longer be susceptible to sequestration crisis.

Etiology:

- Inherited as autosomal recessive
 - Both parents must be at least carriers
- Primarily affects blacks
 - Also seen in individuals of Mediterranean and Hispanic descent

Risk Factors:

- Contributing factors for a vasoocclusive crisis include any condition that decreases oxygen in the blood, increases the uptake of oxygen from the blood, or slows the blood flow.
 - High altitudes, flying in unpressurized planes, exercise, infection, fever, cold weather, and emotional stress can lead to a vasoocclusive crisis.

S&S:

- Vaso-occlusive crisis
 - The major symptom of a vaso-occlusive crisis is pain due to ischemia; pain may be localized, migratory, or generalized
 - Hand and foot syndrome: a self limiting vaso-occlusive crisis causing swelling and pain of the hands or feet
 - Vaso-occlusive crisis involving the brain can lead to a cerebral vascular accident (stroke), blindness, and convulsions
 - Acute chest syndrome is another serious vaso-occlusive crisis involving the lungs and causing cough, chest and abdominal pain, and fever
 - Other symptoms depend upon the location of the vaso-occlusive crisis
- Sequestration crisis
 - Sudden onset of paleness, hypovolemic shock
- Anemia
 - Pallor, jaundice, delayed growth
- Other symptoms include cholelithiasis, which is not usually seen in children without the disease
- Chronic problems
 - Leg ulcers
 - Renal problems as a result of repeated infarctions
 - Ocular problems as a result of repeated infarctions resulting in retinal detachment and blindness
 - Musculoskeletal problems including necrosis and uneven growth
 - Bacterial infection susceptibility from lack of spleen function
 - Pulmonary problems can include pneumonia, fat embolism, and pulmonary hypertension
 - Cardiac problems as a result of increased cardiac workload
 - Priapism in males

Dx:

- Prenatal diagnosis can be made by chorionic villi sampling or amniocentesis
- Newborn screening is mandatory in most states
- Hemoglobin electrophoresis
- Screenings can include sickle turbidity test (Sickledex) which does not differentiate those with the trait (carriers) from those with the disease
- Reticulocyte count will be elevated due to fragility of RBCs

Rx:

- Therapeutic management involves promoting optimal oxygenation conditions
- Routine vaccinations plus pneumococcal, meningococcal, and yearly flu vaccines are recommended
- During crisis
 - Intravenous fluids for hydration
 - Narcotic analgesics
 - Oxygen therapy
 - Blood transfusions if vaso-occlusive crisis is in a critical area such as the brain

Nursing Intervention Alert

Meperidine (Demerol) should not be administered to children with sickle cell as they are particularly sensitive to the neurologic complications related to the buildup of meperidine metabolites.

Nursing Process Elements

- During crisis
 - Monitor vital signs and pulse oximetry
 - Monitor for changes in mental status
 - Assess respiratory function
 - Promote rest to decrease oxygen utilization
 - Encourage hydration with clear liquids
 - Monitor pain and administer narcotics as needed
 - Reduce emotional stress
 - Administer blood as ordered
 - Minimize exertion and promote rest periods
- Assess psychosocial status and provide referrals to support services and resources
- Provide client/family teaching on crisis triggers and activities necessary to reduce risk of crisis, behaviors that promote positive coping with a chronic illness, and importance of medical follow-up care

**Client teaching for self-care**

- General health practices to promote normal growth and development
 - Nutrition to support RBC production: high protein, calcium, vitamins, and iron
 - Immunizations
 - Prevention of infection including importance of avoiding infectious individuals and good hand washing
- Information about the disease process
- Signs and symptoms of crisis
- Treatment of crisis

THALASSEMIA

- Most common inherited single-gene disorder
- Most often affects people of Mediterranean descent
- Characterized by decreased RBC production and chronic hemolytic anemia
- Two types
 - Thalassemia minor: mild, usually asymptomatic anemia that does not require treatment
 - Thalassemia major (aka Cooley's anemia): severe anemia resulting in growth failure and death between the ages of 17 and 30

Rx: Transfusion therapy is used for symptom alleviation or to maintain hemoglobin at a more normal level

**Nursing Process Elements**

- Monitor for transfusion reaction
- Provide supportive care
- Teach about disease process and progression

IRON DEFICIENCY ANEMIA

Inadequate amount of iron impairs formation of hemoglobin and RBCs and results in decreased ability of the blood to transport oxygen to the tissues.

Etiology:

- Chronic blood loss
- Poor nutrition (inadequate intake or absorption of iron)

S&S:

- Pallor
- Sensitivity to cold
- Fatigue
- Exertional dyspnea

- Severe deficiency symptoms include brittle spoon-shaped nails with longitudinal ridges, smooth shiny tongue, and cheilosis
- Decreased Hgb, Hct, iron ferritin, and reticulocytes

Rx:

- Identify cause and correct
- Iron rich diet with avoidance of teas and coffee (which reduce iron)
- Oral iron supplements, for example, ferrous sulfate (Feosol), iron dextran (DexFerrum)
- Transfusion if necessary

**Nursing Process Elements**

- Assess cardiovascular and respiratory status to detect decreased activity tolerance and dyspnea on exertion
- Monitor stool, urine, and emesis for occult blood
- Administer medications prescribed to replace iron stores
- Provide mouth and skin care
- Protect the client from falls caused by weakness and fatigue

**Client teaching for self-care**

- Correct method for taking iron supplements
- When to contact the physician
- Components of a proper diet and foods high in iron

VITAMIN B12 DEFICIENCY ANEMIA

- Chronic, progressive, macrocytic anemia
- Lack of B12 results in defective maturation of RBCs.

Etiology:

- Inadequate dietary intake of vitamin B12 which is a particular risk with strict vegetarian diets
- Prolonged iron deficiency, malabsorption secondary to intestinal disease or intestinal resection
- Lack of absorption as a result of deficiency of intrinsic factor resulting from autoimmune disease
- Gastric mucosal atrophy or gastric resection

**Think Smart/Test Smart**

Be sure to distinguish among the various types of vitamin B12 deficiency based on cause. When vitamin B12 deficiency anemia is caused by a

lack of intrinsic factor, a substance normally secreted by the gastric mucosa, it is called pernicious anemia. Because vitamin B12 is absorbed in the ileum and intrinsic factor is required for its absorption, clients with pernicious anemia must receive lifelong injections of vitamin B12.

S&S:

- Pallor
- Anorexia and dyspepsia
- Weight loss
- Constipation or diarrhea
- Gait disturbances
- Paresthesias of the hands and feet
- Dyspnea
- Glossitis, sore mouth
- Scleral jaundice
- Bone marrow aspiration shows increased megaloblasts, few maturing erythrocytes, and defective leukocyte maturation
- Positive *Romberg* test and *Shilling* test

Rx:

- Increased dietary intake of vitamin B12: animal proteins especially organ meats, eggs and dairy products; dried beans, nuts, green leafy vegetables, and Brewer's yeast for deficiency due to inadequate intake.
- Vitamin B12 supplement if needed.
- Transfusion therapy if severely symptomatic.
- Weekly B12 injections for pernicious anemia and when B12 cannot be absorbed for reasons other than deficiency of intrinsic factor; may become monthly injections as disease is controlled.

**Nursing Process Elements**

- Assess cardiovascular status to detect signs of compromise as the heart works harder to compensate for the reduced oxygen-carrying capacity of the blood
- Administer prescribed medications
- Provide mouth care before and after meals for glossitis
- Prevent client from falling
- Monitor and record vital signs
- Maintain activity as tolerated
- Monitor lab values to detect effectiveness of therapy

**Client teaching for self-care**

- Foods high in vitamin B12 if dietary deficiency is the cause of the anemia
- Need for lifelong, monthly B12 injections if pernicious anemia or other inability to absorb vitamin B is the cause of the anemia

POLYCYTHEMIA VERA

- Bone marrow disorder characterized by an abnormal increase in RBCs (erythrocytosis) often accompanied by leukocytosis and thrombocytosis (abnormally high number of circulating platelets)
- Causes increased blood viscosity and platelet dysfunction (platelet dysfunction can increase susceptibility to bleeding problems)
- Despite the increased number of RBCs, generalized hypoxia exists because the abnormal cells have an impaired oxygen-carrying capacity
- Untreated survival time is 1–2 years; with treatment, 7–15 years

Etiology: Unknown**S&S:**

- None in early disease
- With hypervolemia from increased blood viscosity: headache, vertigo, tinnitus, blurred vision, red appearing skin, thromboemboli (DVT, CVA, MI, pulmonary embolism, etc).
- Epistaxis, ecchymoses, and GI bleeding from platelet dysfunction

Rx: Periodic phlebotomy to remove RBCs and return Hct and Hgb to normal. Myelosuppressive therapy may also be used but carries the risk of leukemia transformation especially in younger clients.

**Nursing Process Elements****Client teaching for self-care**

- Attend to signs of thrombi or emboli and give importance to seeking immediate attention
- Provide interventions to decrease the risk of thrombus formation
- Drink adequate amounts of fluid (3 l/d) to decrease blood viscosity

- Avoid smoking and wearing of constricting clothing.
- Wear support hose when out of bed and elevate feet whenever sitting.
- Take anticoagulants as ordered and take precautions against bleeding.
- Exercise only as directed by health care provider.

NEUTROPENIA

- Neutrophil count of less than 2000/mm³
- Another name for agranulocytosis

Etiology: Primary or secondary to leukemia, aplastic anemia, hypersplenism, various chemicals, or drugs such as propylthiouracil and the sulfonamides

Rx: Treatment or removal of underlying cause

Nursing Process Elements

- Provide assessments and interventions aimed at preventing infection which may be life threatening
- Institute neutropenic precautions

LEUKEMIA

- Cancer of blood forming organs causing an uncontrolled production of white blood cells (leukocytes, myelocytes, and their precursors) by the bone marrow
- Stem cells of the bone marrow produce an immature WBC that is incapable of fighting infection
- Bone marrow fills with immature WBCs limiting the production of RBCs and platelets leading to the major symptoms of leukemia: infection, anemia, and bleeding episodes
- Four primary categories of leukemia according to the type of WBC involved and the rate of cell growth
 - Acute lymphoblastic leukemia (ALL)
 - Acute myelogenous leukemia (AML)
 - Chronic lymphoblastic leukemia (CLL)
 - Chronic myelogenous leukemia (CML)
 - Lymphoblastic denotes cancerous changes in lymphocytes
 - Myelogenous denotes cancerous changes in granulocytes and monocytes
 - Forms of leukemia other than ALL are often referred to under the generic term ANLL (acute nonlymphoblastic leukemia).

PEDS Most common pediatric leukemia is acute lymphoblastic (or lymphoid) leukemia

- Classified as acute or chronic based on cell differentiation progression, that is, maturity of the WBCs
 - All leukemic cells are immature, but those involved in acute leukemia are more immature.
 - Acute leukemia affects immature cells causing rapid onset and progression.

With the more mature WBC in the chronic form of leukemia, these cells can do a better job of fighting infection.

PEDS Most pediatric leukemias are the acute form.

Etiology: Although not fully understood, multiple factors have been associated with the development of leukemia.

- Genetic factor
 - Identical twins have a higher incidence of concordance in the development of leukemia than fraternal twins.
 - Selected chromosomal disorders including Down's syndrome and Fanconi's syndrome have been associated with a higher risk for leukemia.
- Infectious agents have been suspected of contributing to the development of leukemia. A virus has been documented in cats as a causative agent for feline leukemia
- Exposure to radiation and selected chemical toxins

S&S:

- Acute leukemia: rapid onset and progression of symptoms because immature cells are affected.
 - Lack of normal WBCs results in numerous infections
 - Early symptoms
 - Fever
 - Bruising
 - Lymphadenopathy
 - Pallor
 - Malaise
 - Fatigue due to anemia
 - WBC count may be normal, decreased, or increased
 - Other symptoms
 - Bone pain (from bone marrow over crowding)
 - Increased abdominal girth
 - Hepatosplenomegaly
 - Dehydration

- DIC
- Nausea and vomiting
 - Headache
 - Blurred vision
- Chronic leukemia: insidious onset, slow progression over many years because mature cells are affected
 - WBC count is usually elevated
 - Usual disease presentation is nonspecific flu-like symptoms
 - Early symptoms
 - Fatigue
 - Weakness
 - Anorexia
 - Weight loss
 - Enlarged spleen and liver, which are palpable
 - Fever
 - Pallor, lethargy, and anorexia
 - Bruising, petechiae, and purpura
 - Bone pain (due to overcrowded bone marrow)

ACUTE LYMPHOBLASTIC LEUKEMIA

- **PEDS** Peak incidence occurs in children between 2 and 6 years of age
- Boys are affected more commonly than girls

Etiology: ALL is caused by a single lymphoid stem cell with abnormal maturation and accumulation of malignant cells in bone marrow.

Dx:

- Peripheral blood smear demonstrates immature WBCs. Total WBCs may be low or elevated at initial diagnosis. A low WBC count at the time of diagnosis is associated with a better prognosis; a high WBC with the greater number of immature cells, the worse the prognosis.
- Bone marrow aspiration provides definitive diagnosis. The iliac crest is the most frequent site for this test in children.
- Following diagnosis, a lumbar puncture may be performed to determine the presence of CNS involvement.

Rx:

- The goal of treatment is remission, that is, the absence of all leukemic symptoms including a bone marrow containing less than 5% blasts (normal bone marrow).
- Treatment includes chemotherapy and radiation.
- Chemotherapy involves several drugs used in combination to prevent the development of resistance. The particular combination of chemical agents is called the protocol and varies from institution to institution.
- Four phases of chemotherapy

—Induction is the first phase of therapy with a goal of remission. This usually occurs during the first 4–6 weeks of treatment.

—Consolidation is the second phase of treatment. Once the child is in remission, additional drugs will be administered to eradicate residual leukemic cells.

—Intensification, the third phase, is designed to prevent the emergence of cells which are resistant to chemotherapy.

—Maintenance therapy is the fourth phase which continues for several years to preserve the remission.

- Irradiation of the CNS or testes may be added if leukemic involvement has been noted in these areas.
- Relapse is the term given to reappearance of leukemic cells after a remission has been obtained. When remission occurs, the chemotherapy protocol is modified to include drugs not previously used.
- Hematopoietic stem cell transplant provides the best opportunity for cure but carries serious morbidity and mortality concerns. The source of the stem cells is an antigen-matched donor or from umbilical cord blood.

Nursing Process Elements

- Prior to diagnosis, provide the child and parents with information about the diagnostic process.
- Provide emotional support to the child and parents as they undergo the numerous invasive procedures involved in the diagnosis.
- Explain expected effects of chemotherapy that depresses the bone marrow leading to low WBCs, RBCs, and platelets.

RBCs

—The child will be tired.

—Additional rest periods will be needed.

—Blood transfusions may be required if the child's hemoglobin and hematocrit drop too low.

Platelets

—The child will be at risk for hemorrhage.

—Care in handling the child is required to prevent or reduce bruising.

—Soft toothbrush or gauze covered finger may be used for oral care if bleeding gums become problematic.

—Increase in liquid intake and use of stool softeners will be needed to prevent constipation and straining with elimination.

WBCs

—The child's ability to fight infections will be diminished.

—It is required to make certain that all persons in contact with the child wash hands scrupulously.

—Good skin care will be needed to maintain a healthy first line of defense.

- Aseptic technique will be used for all invasive procedures.
- Fresh flowers and plants should be kept away from the child as they may harbor organisms.
- Live organism vaccinations should be avoided.
- All family members should to receive a flu shot.
- Exposure to a large number of visitors or anyone with any sign of contagious illness should be avoided.
- If the WBC count becomes extremely low, reverse or protective isolation may be instituted to reduce exposure.
- The child should be monitored for signs and symptoms of infection.
- Management of chemotherapy toxicity
 - Control/reduce nausea and vomiting by the use of antiemetics.
 - Administer antiemetics prior to the chemotherapy rather than waiting until nausea occurs.
 - Maintain the environment free of nauseating stimuli, for example, keep the emesis basin handy but out of sight.
 - Odors may be problematic so keep the room fresh without perfumes and other strong odors.
 - Plan chemotherapy administration for other than around meal time whenever possible.
 - Monitor intake and output
 - Combat anorexia which is a symptom of the disease and a response to the chemotherapy, because a well nourished cell is more responsive to the chemotherapy so maintaining good nutrition is paramount to treatment success.
 - Provide small frequent feedings of bland foods.
 - Provide high protein and high calorie snacks.
 - Keep in mind that foods from home may be more acceptable to the hospitalized child than hospital food.
 - Obtain daily weights.
 - Treat mouth ulcers which are a painful complication of many chemotherapeutic agents.
 - Rinse the mouth with plain water several times a day to reduce development of oral ulcers.
 - Use a soft toothbrush for oral care.
 - Avoid the use of alcohol in mouthwashes.
 - Use local anesthetics as necessary.
 - Avoid spicy acidic food.
 - If the child is to receive a drug that has alopecia as a known side effect, prepare the child for this side effect. The child may want to shave his or her head before the hair falls out or may chose to wear scarves and hats to cover the hair loss. If a child chooses to wear a wig, the wig should be selected prior to hair loss.
 - If a chemotherapeutic agent is to be given that makes the skin more susceptible to sunlight, cover the skin

and use sun blocks at all times since even a mild exposure can cause a severe burn.

Client teaching for self-care

- The family needs to know how to administer the chemotherapeutic agents the child receives at home.
- The child and family should be prepared for the specific side effects of the drugs that the child is receiving.
- Cytotoxic chemicals will be excreted from the child's body for up to 48 hours after administration and family members should be protected from exposure.
 - Double flush the commode after the child uses it.
 - Place a plastic liner over the mattress to prevent the mattress from absorbing chemicals excreted from the body.
 - Wash the child's clothing and bed linens separately from the rest of the family laundry.

ACUTE MYELOGENOUS LEUKEMIA

- Primarily affects ages 12–20 and over age 55

Etiology: It is caused by a single myeloid stem cell resulting in immature myeloblasts to develop in bone marrow

Dx: Diagnosis is by bone marrow biopsy.

Rx:

- Bone marrow transplant: HLA identical allogeneic or autologous
- Autologous stem cell transplant: Client's own blood cells collected and centrifuged to remove malignant cells, then stored and reinfused after client's bone marrow is destroyed.
- Chemotherapy: Cytarabine and doxorubicin are commonly used.

Remission occurs in 50–70% of clients. Allogeneic bone marrow transplant use is increasing in frequency as a treatment option.

CHRONIC LYMPHOBLASTIC LEUKEMIA

- CLL primarily affects ages 50–70, found more commonly in men
- Proliferation of small abnormal mature B lymphocytes occurs
- Abnormal lymphocyte accumulation begins in the lymph nodes, spreading to other lymphatic tissue and the spleen

Dx: Diagnosis is through blood smear

S&S:

- Additional symptoms specific to CLL are pruritic vesicular skin lesions, anemia thrombocytopenia, and spleen enlargement

- Clotting episode may be the first manifestation of the disease due to increased blood viscosity

Rx: Treatment (alkylating agents such as chlorambucil or glucocorticoids) usually only occurs when symptoms present, no treatment is curative

Average lifespan after diagnosis is 4.5–5.5 years.

CHRONIC MYELOGENOUS LEUKEMIA

- Primarily affects ages 30–50
- CML is 14% of all leukemia cases.
- It commonly changes from a chronic phase to an accelerated or blastic phase progressing quickly to fulminant mirroring an acute leukemia with anemia and thrombocytopenia.
- During the blastic phase, blood vessels are blocked by the leukemic cells. Leukemic infiltrates into various tissues, epidural tumors which can cause spinal cord compression, and lytic bone lesions may occur.

Assessment Alert

Adverse effects of interferon-alpha therapy

Early effects lasting about 2 weeks are: fever, chills, malaise, arthralgia, fatigue, and headache.

Late toxic effects are: hepatitis, proteinuria, hypothyroidism, depression and psychosis

Adverse effects of Imatinib are fluid retention which can cause sudden ascites, pulmonary edema, or pleural or pericardial effusion; gastrointestinal irritation and hematologic changes.

Etiology: CML results from an acquired injury (not inherited or present at birth) to a bone marrow stem cell's DNA leading to uncontrolled proliferation of granulocytes.

S&S: Classic symptoms of chronic leukemia are fatigue, weakness, anorexia, weight loss, and splenomegaly.

Dx: Diagnosis through blood smear which shows granulocytes in all stages of maturity, blasts to mature neutrophils

Rx: BMT done for early disease in otherwise healthy clients; hydroxyurea, which requires frequent blood checks because of its myelosuppressive effects, is used for chronic phase in other clients. In the blastic phase, anthracycline, cytosine arabinoside, or interferon alpha therapy are used but with very limited success.

- Overall survival rate is poor, with only 30% surviving 5 years after diagnosis
- Complications are usually treatment related

Nursing Process Elements

Client teaching for self-care

- Disease process and therapy effects
- Infection and bleeding prevention
- What symptoms need to be immediately reported
- Medications and side effects
- Need for good nutrition and fluid intake
- Stomatitis risk reduction through meticulous oral care
- Chemotherapy regimen and need for periodic blood counts
- Community resources and support groups
- Ongoing medical follow-up

HEMOPHILIA

- Bleeding disorder related to deficiency of a clotting factor
 - The normal individual has more than 10 different clotting factors that work together to form a clot
 - Clotting factors are produced by the liver and found in the plasma
- Two primary forms of hemophilia based on the deficient clotting factor

—Classic hemophilia or hemophilia A is a deficiency of Factor VIII, the antihemophilic factor

—Christmas disease, also called hemophilia B is a deficiency of Factor IX, plasma thromboplastin component

- Severity of the disease is based on the level of factor in the blood and can range from mild to severe. The severity of the disease runs in families.

Etiology: Both forms of hemophilia are inherited as sex linked recessive, carried by the female and primarily affecting males.

Risk Factors: The gene that controls the production of the involved clotting factors is located on the long arm of the X chromosome. Since women have two X chromosomes, each child of a carrier female has a 50/50 chance of receiving the affected X. Men have only one X chromosome. When the man reproduces, he gives his Y chromosome to the son who will not be affected, but his daughters will receive the affected X and can further transmit the disease.

S&S: Any injury can lead to a bleeding episode. The symptoms and severity of bleeding is dependent upon the type and site of injury and can include

- Ecchymoses (bruises)
- Epistaxis (nosebleed)
- Hematuria (blood in the urine)
- Hemarthrosis (bleeding into the joints)

Dx:

- It may be diagnosed in the newborn nursery after a circumcision that fails to clot or as a toddler learning to walk
- Partial prothrombin time (PTT) is delayed. Prothrombin time (PT), thrombin time (TT), and fibrinogen and platelet count are normal
- Carrier determination is possible in classic hemophilia with DNA testing
- It can be diagnosed by chorionic villi sampling or amniocentesis

Rx:

- IV administration of the missing factor (either factor VII or factor IX)
 - Administered at first evidence of a bleed
 - Dose is individualized based on child's degree of deficiency
 - Prophylactic factor is administered in the morning as it has a short half-life
- Factor is a blood product found in fresh or fresh frozen plasma
 - Factor is now available in a recombinant form (lab made) but may still be stabilized with the addition of albumin

—Factor may be stored in the refrigerator in the client's home for ready use

- DDAVP (desmopressin acetate) may be administered to the child with mild hemophilia to increase factor VIII activity

Nursing Process Elements

- Controlling bleeding episodes
 - RICE—rest, ice, compression, and elevation
- Avoid any drug known to affect bleeding time including aspirin and ibuprofen
- With bleeding into joints, a goal of treatment is to avoid loss of joint function
 - Immobilization and elevation during an acute bleed
 - Range of motion, once the bleed is contained

Client teaching for self-care

- In addition to the pathophysiology of hemophilia, the need to recognize symptoms of a hemorrhage and preparation to implement appropriate first aid by the family and child.
- Safe and effective administration of the factor: Toddlers may have a subcutaneous venous port inserted to make intravenous insertion easier. Older children are taught to start their own intravenous line for the administration of the factor.
- Activities to promote growth and development while protecting the child from hemorrhages: Discuss with the parents and child, sports activities that are safe; contact sports must be avoided, but sports such as golf and swimming will allow for normal competition without placing the child in danger.
- Good oral hygiene: Avoiding dental care may lead to dental caries and loss of teeth which may cause a bleeding episode.
- In case surgery or tooth extraction is required, the need to keep the child in a controlled environment with prophylactic factor administration.

THROMBOCYTOPENIA

- Decreased number of circulating platelets
- Normal adult platelet count is 150,000 to 400,000/mm³; below 60,000/mm³ there is a risk of bleeding with trauma; below 20,000/mm³, spontaneous, life-threatening hemorrhage can occur.

Etiology:

- Thrombocytopenia can result from decreased production, decreased survival time, increased destruction, and sequestration of blood in the spleen, loss from hemorrhage, or increased use.

- Most common type of thrombocytopenia is idiopathic thrombocytopenic purpura in which there is increased destruction.

—Acute ITP: self limiting with a duration of less than 6 months; typically follows a viral disease

—Chronic ITP: Autoimmune disease of young adulthood

—Drug induced ITP: Causative drugs include alcohol, digitoxin, thiazides, rifampin, aspirin and NSAIDs; lasts 1–2 weeks after drug is discontinued

S&S: Petechiae (occur only with thrombocytopenia), ecchymosis, purpura, bleeding (e.g., nose bleeds, bleeding gums, hypermenorrhea, hematuria)

Dx: Decreased platelet count; increased bleeding time

Rx: ITP: corticosteroid and immunosuppressive therapy to decrease antibody production; splenectomy since spleen is the organ where platelets are destroyed.

Platelet concentrate as a temporary measure to control bleeding.

Nursing Process Elements

- Monitor for bleeding
- Institute bleeding precautions if platelet count below $20,000/\text{mm}^3$
 - Test all urine and stool for blood
 - No rectal treatments (temperatures, suppositories, enemas, etc.)
 - No IM injections

—Put firm pressure on all venipuncture sites for 5 minutes and on arterial puncture sites for 10 minutes.

Assessment Alert

Assess effectiveness of any platelet transfusion by checking platelet count before transfusion and 1 hour after. If no change has occurred in the count, the transfusion was ineffective. Keep in mind that viability of platelets between collection and transfusion is only several days and viability after transfusion is 24–48 hours as opposed to the life of normal platelets which is 10 days.

Client teaching for self-care

Take precautions to prevent trauma and bleeding:

- Use a soft toothbrush, swab, or gauze covered finger for mouth care.
- Do not use dental floss.
- Shave with an electric razor to decrease the risk of accidental cuts.
- Put nothing in the rectum.
- Put firm, consistent pressure on any bleeding area for 5–10 minutes.
- Avoid aspirin containing products and any other medications or herbs with an anticoagulant effect.

VITAMIN K DEFICIENCY

Vitamin K is a fat soluble vitamin essential for synthesis of clotting factors II, VII, IX, and X.

Sources: diet from foods such as green leafy vegetables, produced by intestinal bacteria

Etiology:

- Decreased dietary intake
- Decreased intestinal production as a result of destruction of intestinal flora by broad spectrum antibiotic therapy
- Lack of absorption of the vitamin because of intestinal problems such as malabsorption syndrome, Crohn's disease and ulcerative colitis
- Impaired action of the vitamin by drugs such as coumarin, aspirin, and quinine

S&S: Bleeding

Dx: Prolonged PT and PTT

Rx:

- Correct underlying problem

- Menadione (water soluble vitamin K) PO or IV (works in 6–24 hours)
- Transfusion of fresh frozen plasma for immediate effect

PEDS

At birth, the neonate is lacking vitamin K because the gut is sterile so vitamin K is not being produced. To cover the period of time between birth and when intestinal flora is established and begins to synthesize adequate amounts of vitamin K, aqueous menadione is administered as part of initial newborn care.

Nursing Process Elements

- Assess for bleeding: bruising, hematuria, bleeding gums, etc.
- Teach precautions related to preventing trauma and decreasing risk of bleeding

LYMPHEDEMA

Abnormal collection of lymphatic fluid in a part as a result of obstructed lymphatic flow

Etiology:

- Primary: results from abnormalities in development of the lymph system
- Secondary: results from injury to the lymph nodes from surgery, for example, lymph node dissection in diagnosis and management of cancer, radiation, or parasites

S&S:

- Soft, pitting edema, which changes over time to hard, nonpitting edema.
- Occurs more often in left lower extremity than in right and is aggravated by pregnancy, obesity, warm weather, menstruation, and prolonged standing.
- Severe enlargement of an extremity is called elephantiasis.

Complication: Infection

Rx: Diuretics, long term antibiotics, intermittent pneumatic compression stocking

Nursing Process Elements

- Assess for signs of infection
- Assess for skin breakdown

Client teaching for self-care

- Avoid constricting clothing or accessories.
- Elevate affected extremity.
- Use compression stocking/garment or pump as ordered.
- Exercise involved limb to stimulate lymph flow.
- If a lower extremity, avoid prolonged standing.
- Follow any prescribed medication and dietary guidelines.

HODGKIN'S DISEASE

- It is a malignant disorder of the lymph nodes.
- Reed Sternberg cell is the signature cell of the disease.
- Disease has a predictable pattern of spread.
- Prognosis depends heavily on stage of disease at time of diagnosis.
- Accurate staging is essential to determining the correct treatment protocol.

Etiology: Unknown but some association with the Epstein–Barr virus noted

S&S:

- Unexplained fever

- Night sweats
- Generalized pruritus
- Anorexia and weight loss
- Cough
- Hepatomegaly and splenomegaly
- Fatigue and weakness
- Malaise and lethargy
- Recurrent infection and fever
- Enlarged, nontender, firm and movable cervical, axillary, or inguinal lymph predictable pattern of spread

Dx: Lymph node biopsy is positive for Reed–Sternberg cells (Hodgkin's disease)

Rx:

- Radiation for stages IA, IB, IIA, IIB
- Chemotherapy for stages III and IV using MOPP regimen (mechlorethamine (nitrogen mustard), vincristine (Oncovin), prednisone and procarbazine)

Nursing Process Elements

- Decrease risk of skin injury and infection.

NON-HODGKIN'S LYMPHOMA

- It is also called malignant lymphoma.
- Tumors occur throughout lymphatic organs in an unpredictable pattern.

Etiology: Environmental or genetic factors

S&S:

- Anorexia and weight loss
- Unexplained fever
- Night sweats
- Cough
- Hepatomegaly and splenomegaly
- Malaise and lethargy
- Recurrent infection
- Prominent, painless, and generalized lymphadenopathy

Dx: Bone marrow aspiration and biopsy reveals small, diffuse lymphocytic cells (malignant lymphoma)

Rx:

- Radiation therapy
- Transfusion of packed RBCs
- Diet high in protein, calories, vitamins, minerals, iron, and calcium
- Chemotherapy: Cytosan, Oncovin, and Adriamycin

Nursing Process Elements

- Monitor for bleeding, infection, jaundice, and electrolyte imbalance to detect the complications of lymphoma
- Assess and manage side effects of therapy
- Provide mouth and skin care
- Encourage fluids

- Administer medications as prescribed
- Administer transfusion therapy
- Encourage the client to express feelings

Client teaching for self-care

- Recognize early signs and symptoms of motor and sensory deficits that can indicate spinal cord compression.

WORKSHEET

MATCHING QUESTIONS

- | | |
|-----------------------------------|--|
| 1. Acute lymphoblastic leukemia | a. characterized by a reduction or cessation of all blood-producing elements |
| 2. Acute myelogenous leukemia | b. primarily affects children ages 2–4 |
| 3. Chronic lymphoblastic leukemia | c. brittle spoon-shaped nails with longitudinal ridges is a symptom |
| 4. Chronic myelogenous leukemia | d. results from an acquired injury to a bone marrow stem cell DNA |
| 5. Aplastic anemia | e. proliferation of small abnormal mature B lymphocytes |
| 6. Hemolytic anemia | f. primarily affects ages 12–20 and over age 55 |
| 7. Iron deficiency anemia | g. Hereditary spherocytosis |
| 8. Pernicious anemia | h. Unpredictable pattern of malignant tumors throughout lymphatic organs |
| 9. Christmas disease | i. Related to absence of Intrinsic factor |
| 10. Non-Hodgkin's lymphoma | j. Form of erythematosis |
| 11. Thrombocytopenia | k. Below normal number of circulating platelets |
| 12. Classic hemophilia | l. Factor IX |
| 13. Polycythemia vera | m. Associated with the Reed Sternberg cell |
| 14. Hodgkin's disease | n. Factor VIII |
| 15. Thalassemia major | o. Most common inherited single-gene disorder |

TRUE & FALSE QUESTIONS

- | | | |
|--|------------------|------------------|
| 1. Reduced hemoglobin and hematocrit would be seen early with acute hemorrhagic anemia. | <u> </u> T | <u> </u> F |
| 2. White blood cell count is usually elevated with chronic leukemias. | <u> </u> T | <u> </u> F |
| 3. Hemoglobin in sickle cell disease has abnormal oxygen-carrying capacity. | <u> </u> T | <u> </u> F |
| 4. Thalassemia most often affects African-Americans. | <u> </u> T | <u> </u> F |
| 5. DDAVP (desmopressin acetate) may be administered to the child with mild hemophilia to increase factor VIII activity. | <u> </u> T | <u> </u> F |
| 6. Each child of a female who is a carrier of hemophilia has a 50/50 chance of receiving the affected X chromosome. | <u> </u> T | <u> </u> F |
| 7. The major symptom of a vaso-occlusive crisis is pain due to ischemia. | <u> </u> T | <u> </u> F |
| 8. ALL commonly changes from a chronic phase to an accelerated phase progressing quickly to fulminant mirroring an acute leukemia. | <u> </u> T | <u> </u> F |
| 9. Severity of symptoms of sickle cell anemia varies with the degree of sickling. | <u> </u> T | <u> </u> F |
| 10. Failure of a circumcision to clot may be the first sign of hemophilia. | <u> </u> T | <u> </u> F |
| 11. A person who is heterozygous for the sickle cell trait is called a carrier. | <u> </u> T | <u> </u> F |
| 12. Symptoms of sickle cell anemia are present within a week after birth. | <u> </u> T | <u> </u> F |
| 13. Hemophilia varies from person to person in severity. | <u> </u> T | <u> </u> F |
| 14. Desmopressin acetate increases factor VIII activity. | <u> </u> T | <u> </u> F |
| 15. Priapism is a potential problem for males with sickle cell disease. | <u> </u> T | <u> </u> F |
| 16. Decreased hemoglobin and hematocrit are early signs of hemorrhagic anemia. | <u> </u> T | <u> </u> F |
| 17. Monitoring for signs of bleeding which is a risk because of decreased platelets and preventing infection which is a risk because of immunosuppression are the two primary nursing concerns related to the care of the client with aplastic anemia. | <u> </u> T | <u> </u> F |
| 18. The most common pediatric leukemia is acute myelogenous leukemia. | <u> </u> T | <u> </u> F |
| 19. Chronic leukemia typically begins with nonspecific flu-like symptoms. | <u> </u> T | <u> </u> F |
| 20. An elevated WBC count at the time of diagnosis of acute lymphoblastic leukemia is predictive of a good prognosis with a likelihood of cure. | <u> </u> T | <u> </u> F |

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. For the client with sickle cell disease, traveling to an area of high altitude creates the risk of _____.
2. Sequestration crisis occurs primarily in persons with sickle cell disease who are less than _____ years of age.
3. The normal platelet count in an adult ranges from _____ to _____.
4. Severe enlargement of an extremity due to obstructed lymph flow is called _____.
5. A client with neutropenia would have a neutrophil count of less than _____.
6. Agranulocytosis is another name for _____.
7. Prolonged PT and PTT are diagnostic of _____ deficiency.
8. The major complication associated with lymphedema is _____.
9. Life threatening spontaneous hemorrhage is a risk when the platelet count drops to _____.
10. The most common type of thrombocytopenia is _____.
11. The generic name for Oncovin is _____.
12. Firm pressure should be maintained on any venipuncture site for _____ minutes when caring for a client with thrombocytopenia.
13. Cytotoxic chemicals used in the treatment of acute lymphoblastic leukemia will be excreted from the child's body for up to _____ hours after administration.
14. The life of transfused platelets is _____ to _____ days.
15. Acute idiopathic thrombocytic purpura has a duration of less than _____.

APPLICATION QUESTIONS

1. For the client in sickle cell crisis, the nurse should frequently assess for
 - a. amount of fluid intake
 - b. level of pain
 - c. prolonged erection in males
 - d. lower leg ulcers
2. How should the nurse interpret laboratory results consisting of a positive Coombs' test, decreased Hct, increased reticulocyte count, and increased bilirubin? These results are consistent with
 - a. Hereditary spherocytosis
 - b. Autoimmune hemolytic anemia
 - c. Sickle cell disease
 - d. Acute lymphocytic leukemia
3. When teaching the leukemia client and his family, which is the reason why the nurse stresses the importance of hand washing, reducing the number of visitors, and monitoring temperature?
 - a. High risk of cross-contamination
 - b. High risk for infection

- c. Risk of poor hygiene
d. Risk of ineffective healing
4. When initiating care for a client in the emergency department with an estimated blood loss of 3 l from a chain saw injury, for which factor should the nurse assess first?
- Hypovolemia
 - Pain
 - Impaired cognition
 - Peripheral paresthasias
5. Which information should the nurse give to a sickle cell client in regard to hand and foot syndrome?
- Without immediate treatment, necrosis and need for amputation can occur.
 - Incidence of hand and foot syndrome declines with age.
 - Prodromal signs of hand and foot disease are muscle spasms and mottling of the skin.
 - Episodes of hand and foot syndrome are self limiting.
6. How should the nurse interpret sudden onset of paleness and symptoms of hypotension in clients with sickle cell disease?
- The client is bleeding.
 - A vaso-occlusive crisis is beginning.
 - The client is experiencing a sequestration crisis.
 - Systemic vasodilation has occurred.
7. While doing health teaching with a client newly diagnosed with polycythemia vera, the client asks the nurse what causes blood clots to be such a problem with this disease. Which is the reason that should form the basis of the nurse's response?
- Viscosity is increased.
 - Blood volume is decreased.
 - Arterial diameter is narrowed.
 - Platelet activity is decreased.
8. Which information should the nurse give to a client newly diagnosed with pernicious anemia?
- Symptoms will begin to disappear once you begin eating a diet high in iron.
 - You should expect intermittent episodes of nausea and diaphoresis once therapy is started.
 - Injections of vitamin B12 will be required for the rest of your life.
 - It is important to avoid eating foods that cause increased peristalsis and loose stool.
9. During a home visit to a client with ITP who lives alone, which findings would suggest to the nurse that additional teaching related to self-care is required? Mark all that apply.
- A bottle of aspirin in on the counter with the client's other medications.
 - There is an electric razor in the bathroom.
 - There is no dental floss with the client's dental care equipment
 - There is an appointment on the client's calendar with an oral surgeon.
 - There are golf clubs in the entry hall.
10. A client just diagnosed with thrombocytopenia related to a thiazide diuretic asks the nurse how long the condition will last. Which is the correct answer for the nurse to give?
- 1–2 weeks
 - 2–4 weeks
 - 1–6 months
 - It is unpredictable
11. A client who has come to the clinic because of hypermenorrhea asks if this problem will make her anemic. The nurse's response should reflect understanding that the client is at risk for which type of anemia as a result of the hypermenorrhea? Mark all that apply.
- Acute hemorrhagic anemia
 - Chronic hemorrhagic anemia
 - Iron deficiency anemia
 - Hemolytic anemia
12. Which symptoms reported by a client 3 days after starting on Interferon alpha therapy for the blastic phase of chronic myelogenous leukemia are expected adverse effects of the medication? Mark all that apply.
- Depression
 - Chills
 - Joint pain
 - Ankle edema
 - Headache
13. Which are the three major pathophysiological effects of leukemia that direct the plan of nursing care?
- Infection
 - Bleeding
 - Neural excitability
 - Anemia
 - Decreased glomerular filtration
 - Impaired myocardial perfusion

(continued)

14. A child is scheduled for a bone marrow aspiration as part of the diagnostic evaluation for acute lymphocytic leukemia. The nurse's explanation of the procedure will be based on the knowledge that the procedure will be performed on which part of the body?
- Sternum
 - Scapula
 - Iliac crest
 - Sacrum
15. Which is an appropriate nursing intervention for the client with a lymphocyte count of $19,000/\text{mm}^3$?
- Institution of DVT precautions
 - Institution of protective isolation
 - Institution of bleeding precautions
 - Institution of seizure precautions
16. For which adverse effects must the nurse monitor a client with leukemia who is receiving Imatinib? Mark all that apply.
- Ascites
 - Hepatitis
 - Pulmonary edema
 - Hypothyroidism
 - Hyperparathyroidism
17. As part of a community health education event, a nurse is speaking about sickle cell anemia. A question that is asked is, "How early can sickle cell disease be diagnosed?" Which is the correct answer for the nurse to give?
- Prenatal detection is possible.
 - It can be diagnosed within 48 hours of birth.
 - It can be diagnosed between 4 and 6 months of age.
 - It can be diagnosed whenever symptoms develop.
18. When planning care for a client with aplastic anemia, which nursing order should be included?
- Test urine and stool for occult blood.
 - Monitor for signs of pulmonary edema.
 - Encourage flossing after each meal.
 - Prevent chilling.
19. Which instruction should the nurse give to the parents of a child receiving out-client chemotherapy for acute lymphoblastic leukemia? Mark all that apply.
- Launder the child's clothing and linens separately.
 - Wear gloves when touching the child.
 - Limit contact with the child to no more than 10 minutes/hour.
 - Use a plastic mattress cover on the child's bed.
 - Double flush the toilet after the child uses it.
 - Use disposable eating utensils for the child.
20. Which direction would be given to the parent of a child with hemophilia?
- Administer prophylactic factor at bedtime.
 - Store factor in the refrigerator.
 - Give ibuprofen for joint pain.
 - Plan frequent rest periods throughout the day.
21. Which statement made by the parent of a child with a diagnosis of thalassemia minor indicates the need for further explanation about the disease?
- Being of Mediterranean descent put my child at risk for the disease.
 - My child will need lifelong treatment but will have a normal lifespan.
 - My child will be anemic but won't have symptoms that require treatment.
 - The problem is too few red blood cells are made and some get destroyed.
22. Which statement made by a client with sickle cell anemia indicates a correct understanding of an aspect of the disease?
- I inherited my disease from my father and his side of the family.
 - Any children I have will also have the disease.
 - If I had my spleen removed, my symptoms would basically disappear.
 - My red blood cells only sickle when oxygen tension in my blood decreases.
23. Increase in which food would most appropriately be among the nurse's recommendations for the diet of a client with vitamin B12 deficiency as a result of inadequate intake?
- Yellow vegetables
 - Red meats
 - Poultry
 - Dairy products
24. When assessing a client with sickle cell disease, the nurse should be alert for signs of which chronic problems that are related to the disease? Mark all that apply.
- Vision loss
 - Gastrointestinal bleeding
 - Leg ulcers

- d. ___ Osteoporosis
 e. ___ Pulmonary hypertension
25. While reinforcing information about methods of preventing infection, the client with sickle cell disease asks the nurse why she is at risk for infection. Which fact should form the basis of the nurse's response?
- a. The lack of a functioning spleen increases the risk of infection.
 b. When the number of white blood cells is decreased, the risk of infection is increased.
 c. Repeated infarctions in various body tissues increase the risk of infection.
 d. Increased cardiac workload decreases the effectiveness of humoral immunity.

ANSWERS & RATIONALES

MATCHING ANSWERS

- | | |
|--|--|
| 1. <u> b </u> Acute lymphoblastic leukemia | a. characterized by a reduction or cessation of all blood-producing elements |
| 2. <u> f </u> Acute myelogenous leukemia | b. primarily affects children ages 2–4 |
| 3. <u> e </u> Chronic lymphoblastic leukemia | c. brittle spoon-shaped nails with longitudinal ridges is a symptom |
| 4. <u> d </u> Chronic myelogenous leukemia | d. results from an acquired injury to a bone marrow stem cell's DNA |
| 5. <u> a </u> Aplastic anemia | e. proliferation of small abnormal mature B lymphocytes |
| 6. <u> g </u> Hemolytic anemia | f. primarily affects ages 12–20 and over age 55 |
| 7. <u> c </u> Iron deficiency anemia | g. hereditary spherocytosis |
| 8. <u> i </u> Pernicious anemia | h. unpredictable pattern of malignant tumors throughout lymphatic organs |
| 9. <u> l </u> Christmas disease | i. related to absence of Intrinsic factor |
| 10. <u> h </u> Non-Hodgkin's lymphoma | j. form of erythematosis |
| 11. <u> k </u> Thrombocytopenia | k. below normal number of circulating platelets |
| 12. <u> n </u> Classic hemophilia | l. involves factor IX |
| 13. <u> j </u> Polycythemia vera | m. associated with the Reed Sternberg cell |
| 14. <u> m </u> Hodgkin's disease | n. involves factor VIII |
| 15. <u> o </u> Thalassemia major | o. most common inherited single-gene disorder |

TRUE & FALSE ANSWERS

1. Reduced hemoglobin and hematocrit would be seen early with acute hemorrhagic anemia. *False*
Decreased hemoglobin and hematocrit are late signs of acute hemorrhagic anemia.
2. White blood cell count is usually elevated with chronic leukemias. *True*
3. Hemoglobin in sickle cell disease has abnormal oxygen-carrying capacity. *False*
Hemoglobin in sickle cell disease has normal oxygen-carrying capacity.
4. Thalassemia most often affects African-Americans. *False*
Thalassemia most often affects persons of Mediterranean descent.
5. DDAVP (Desmopressin acetate) may be administered to the child with mild hemophilia to increase factor VIII activity. *True*
6. Each child of a female who is a carrier of hemophilia has a 50/50 chance of receiving the affected X chromosome. *True*
7. The major symptom of a vaso-occlusive crisis is pain due to ischemia. *True*
8. ALL commonly changes from a chronic phase to an accelerated phase progressing quickly to fulminant mirroring an acute leukemia. *False*
CML, not ALL, commonly changes from a chronic phase to an accelerated phase progressing quickly to fulminant mirroring an acute leukemia.
9. Severity of symptoms of sickle cell anemia varies with the degree of sickling. *True*
10. Failure of a circumcision to clot may be the first sign of hemophilia. *True*
11. A person who is heterozygous for the sickle cell trait is called a carrier. *False*
A person who is homozygous for the sickle cell trait will have the disease; persons who are heterozygous for the trait are called carriers.
12. Symptoms of sickle cell anemia are present within a week after birth. *False*
Symptoms of sickle cell anemia develop between 4–6 months of age when the fetal form of hemoglobin converts to an adult form.
13. Hemophilia varies from person to person in severity. *True*
14. Desmopressin acetate increases factor VIII activity. *True*
15. Priapism is a potential problem for males with sickle cell disease. *True*
16. Decreased hemoglobin and hematocrit are early signs of hemorrhagic anemia. *False*
Decreased hemoglobin and hematocrit are late signs of hemorrhagic anemia.
17. Monitoring for signs of bleeding, which is a risk because of decreased platelets, and preventing infection, which is a risk because of immunosuppression are the two primary nursing concerns related to the care of the client with aplastic anemia. *True*
18. The most common pediatric leukemia is acute myelogenous leukemia. *False*
The most common pediatric leukemia is acute lymphoblastic leukemia.
19. Chronic leukemia typically begins with nonspecific flu-like symptoms. *True*
20. An elevated WBC count at the time of diagnosis of acute lymphoblastic leukemia is predictive of a good prognosis with a likelihood of cure. *False*
A high WBC with ALL means there is an increased number of immature white blood cells and this is associated with a poorer prognosis than if there are fewer immature white blood cells.

ANSWERS FOR FILL IN THE BLANKS

1. For the client with sickle cell disease, traveling to an area of high altitude creates the risk of vaso-occlusive crisis.
2. Sequestration crisis occurs primarily in persons with sickle cell disease who are less than 6 years of age.
3. The normal platelet count in an adult ranges from 150,000 to 400,000 /mm³.
4. Severe enlargement of an extremity as a result of obstructed lymph flow is called elephantiasis.
5. A client with neutropenia would have a neutrophil count of less than 2000/mm³.
6. Agranulocytosis is another name for neutropenia.
7. Prolonged PT and PTT are diagnostic of vitamin K deficiency.
8. The major complication associated with lymphedema is infection.
9. Life threatening spontaneous hemorrhage is a risk when the platelet count drops to 20,000 mm³.
10. The most common type of thrombocytopenia is ITP (idiopathic thrombocytopenic purpura).
11. The generic name for Oncovin is vincristine.
12. Firm pressure should be maintained on any venipuncture site for 5 minutes when caring for a client with thrombocytopenia.
13. Cytotoxic chemicals used in the treatment of acute lymphoblastic leukemia will be excreted from the child's body for up to 48 hours after administration.
14. The life of transfused platelets is 1 to 2 days.
15. Acute idiopathic thrombocytic purpura has a duration of less than 6 months.

APPLICATION ANSWERS

1. For the client in sickle cell crisis, the nurse should frequently assess for
 - a. amount of fluid intake
 - b. level of pain
 - c. prolonged erection in males
 - d. lower leg ulcers
2. How should the nurse interpret laboratory results consisting of a positive Coombs' test, decreased Hct, increased reticulocyte count, and increased bilirubin? These results are consistent with
 - a. Hereditary spherocytosis
 - b. Autoimmune hemolytic anemia
 - c. Sickle cell disease
 - d. Acute lymphocytic leukemia

Rationale

Correct answer: b.

Pain is the primary symptom of sickle cell crisis. Prolonged erection and lower leg ulcers are chronic problems associated with sickle cell disease.

(continued)

Rationale

Correct answer: b.

A positive Coombs' test, decreased Hct, increased reticulocyte count, and increased bilirubin are indicative of autoimmune hemolytic anemia. Hereditary spherocytosis is associated with increased fragility of red blood cells, an elevated reticulocyte count and an elevated serum bilirubin along with the presence of spherocytes on a peripheral blood smear. The major laboratory findings related to sickle cell anemia are the large percentage of hemoglobin S present on electrophoresis and the percentage of irreversibly sickled red blood cells. In addition the hematocrit is decreased and the reticulocyte count and white blood cell count are usually increased. Laboratory findings associated with acute lymphocytic leukemia are decreased hemoglobin, hematocrit and platelet count and a white cell count that may be normal, low or elevated.

3. When teaching the leukemia client and his family, which is the reason why the nurse stresses the importance of hand washing, reducing the number of visitors, and monitoring temperature?
- High risk of cross-contamination
 - High risk for infection
 - Risk of poor hygiene
 - Risk of ineffective healing

Rationale

Correct answer: b.

The client with leukemia has a high risk of infection because of the impaired immunity associated with the disease. High risk for cross contamination is incorrect because it presupposes that infection is present which can be transmitted. Risk for poor hygiene may exist but it is not the reason reducing the number of visitors and monitoring temperature is stressed. Risk of ineffective healing is not correct because it presupposes something to be healed and also hand washing, limiting visitors, and monitoring temperature do not directly affect healing.

4. When initiating care for a client in the emergency department with an estimated blood loss of 3 l from a chain saw injury, for which factor should the nurse assess first?
- Hypovolemia
 - Pain
 - Impaired cognition
 - Peripheral paresthasias

Rationale

Correct answer: a.

Hypovolemia is a potentially life threatening condition which can result from hemorrhage. Because it can lead to shock and is potentially life threatening, it is the priority

assessment because immediate intervention is needed. Pain level is important but not a life threatening issue. Impaired cognition and peripheral paresthasias are not pertinent.

5. Which information should the nurse give to a sickle cell client in regard to hand and foot syndrome?
- Without immediate treatment, necrosis and need for amputation can occur.
 - Incidence of hand and foot syndrome declines with age.
 - Prodromal signs of hand and foot disease are muscle spasms and mottling of the skin.
 - Episodes of hand and foot syndrome are self limiting.

Rationale

Correct answer: d.

Hand and foot syndrome refers to a self limiting vaso-occlusive episode characterized by pain and edema in the hands and feet. It does not progress to necrosis and amputation of an extremity and incidence does not decline with age. Muscle spasms and mottling of the skin are unrelated to hand and foot syndrome.

6. How should the nurse interpret sudden onset of paleness and symptoms of hypotension in clients with sickle cell disease?
- The client is bleeding.
 - A vaso-occlusive crisis is beginning.
 - The client is experiencing a sequestration crisis.
 - Systemic vasodilation has occurred.

Rationale

Correct answer: c.

Sudden onset of paleness and hypotension are signs of a sequestration crisis. These symptoms can indicate hemorrhage but in a client with known sickle cell disease, the more likely interpretation is sequestration crisis. Pain and edema are signs of vaso-occlusive crisis.

7. While doing health teaching with a client newly diagnosed with polycythemia vera, the client asks the nurse what causes blood clots to be such a problem with this disease. Which is the reason that should form the basis of the nurse's response?
- Viscosity is increased.
 - Blood volume is decreased.
 - Arterial diameter is narrowed.
 - Platelet activity is decreased.

Rationale

Correct answer: a.

Increased numbers of red blood cells increase the viscosity of the blood and slow blood flow. These changes support clot formation. Blood volume is not decreased; it is

increased because of the increased number of red blood cells. Arterial structure is unaffected by polycythemia vera. Platelet activity is not decreased. In many cases the number of platelets is increased concurrently with the erythrocytosis.

8. Which information should the nurse give to a client newly diagnosed with pernicious anemia?
 - a. Symptoms will begin to disappear once you begin eating a diet high in iron.
 - b. You should expect intermittent episodes of nausea and diaphoresis once therapy is started.
 - c. Injections of vitamin B12 will be required for the rest of your life.
 - d. It is important to avoid eating foods that cause increased peristalsis and loose stool.

Rationale

Correct answer: c.

Injections of vitamin B12 are required for the rest of the client's life because the problem is the inability to absorb the vitamin from the ileum and hence the GI tract must be bypassed in order to get the B12 into the system. In some cases oral vitamin B12 nasally administered vitamin B12 may also be prescribed. Eating a diet high in iron corrects symptoms of iron deficiency anemia. There are no side effects to B12 so nausea and diaphoresis do not occur. Degree of peristalsis and consistency of stool are unrelated to pernicious anemia.

9. During a home visit to a client with ITP who lives alone, which findings would suggest to the nurse that additional teaching related to self-care is required? Mark all that apply.
 - a. ___ A bottle of aspirin in on the counter with the client's other medications.
 - b. ___ There is an electric razor in the bathroom.
 - c. ___ There is no dental floss with the client's dental care equipment
 - d. ___ There is an appointment on the client's calendar with an oral surgeon.
 - e. ___ There are golf clubs in the entry hall.

Rationale

Correct answers: a and d.

The client with thrombopenia needs to avoid increasing the risk of bleeding. Therefore aspirin should not be taken and elective surgery including tooth extraction need to be avoided. Seeing aspirin in the client's home and an appointment with an oral surgeon indicates the need for the nurse to gather information about these findings and reinforce teaching regarding the risk of bleeding and its prevention.

An electric razor should be used because there is less risk of cutting oneself. No dental floss should be used and the toothbrush should be soft or a swab should be used

for mouth care. Contact sports should be avoided but sports like golfing, swimming and fishing are acceptable.

10. A client just diagnosed with thrombocytopenia related to a thiazide diuretic asks the nurse how long the condition will last. Which is the correct answer for the nurse to give?
 - a. 1– 2 weeks
 - b. 2– 4 weeks
 - c. 1– 6 months
 - d. It is unpredictable

Rationale

Correct answers: a.

Drug induced thrombocytopenia lasts 1–2 weeks after the drug is discontinued. Acute self limiting idiopathic thrombocytopenic purpura lasts less than months.

11. A client who has come to the clinic because of hypermenorrhea asks if this problem will make her anemic. The nurse's response should reflect understanding that the client is at risk for which type of anemia as a result of the hypermenorrhea? Mark all that apply.
 - a. ___ Acute hemorrhagic anemia
 - b. ___ Chronic hemorrhagic anemia
 - c. ___ Iron deficiency anemia
 - d. ___ Hemolytic anemia

Rationale

Correct answers: b and c.

Hypermenorrhea involves loss of blood gradually over time which is the defining characteristic of chronic hemorrhagic anemia. Acute hemorrhagic anemia is associated with sudden loss of blood volume. Iron deficiency anemia results from inadequate amounts of iron to meet the need for red blood cell production. The iron deficiency can stem from either too little dietary intake to meet normal need or chronic blood loss creating additional need. Hemolytic anemia results from destruction of red blood cells at a rate faster than which the bone marrow can replace them.

12. Which symptoms reported by a client 3 days after starting on Interferon alpha therapy for the blastic phase of chronic myelogenous leukemia are expected adverse effects of the medication?

Mark all that apply.

- a. ___ Depression
- b. ___ Chills
- c. ___ Joint pain
- d. ___ Ankle edema
- e. ___ Headache

Rationale

Correct answers: b, c, and e.

Chills, joint pain and headache as well as fever, malaise, and fatigue are adverse effects of interferon-alpha therapy

(continued)

which typically last about two weeks. Depression is a late toxic effect as are hepatitis, proteinuria, hypothyroidism, and psychosis. Edema is an adverse effect of Imatinib.

13. Which are the three major pathophysiological effects of leukemia that direct the plan of nursing care?
- ___ Infection
 - ___ Bleeding
 - ___ Neural excitability
 - ___ Anemia
 - ___ Decreased glomerular filtration
 - ___ Impaired myocardial perfusion

Rationale

Correct answers: a, b, and d.

Leukemia is a disease of the white blood cells which impairs their ability to generate a normal immune response to bacteria and other pathogens. This results in a markedly increased risk of infection. Because the uncontrolled proliferation of white blood cells overcrowds the bone marrow, production of red blood cells and lymphocytes is impaired resulting in anemia and risk for bleeding.

14. A child is scheduled for a bone marrow aspiration as part of the diagnostic evaluation for acute lymphocytic leukemia. The nurse's explanation of the procedure will be based on the knowledge that the procedure will be performed on which part of the body?
- Sternum
 - Scapula
 - Iliac crest
 - Sacrum

Rationale

Correct answer: c.

In a child, a bone marrow aspiration is performed on the iliac crest. In an adult it may be done on the iliac crest or the sternum.

15. Which is an appropriate nursing intervention for the client with a lymphocyte count of $19,000/\text{mm}^3$?
- Institution of DVT precautions
 - Institution of protective isolation
 - Institution of bleeding precautions
 - Institution of seizure precautions

Rationale

Correct answer: a.

Lymphocytes function in blood clotting. When the lymphocyte count falls below $20,000/\text{mm}^3$, there is a risk of life-threatening, spontaneous bleeding so bleeding precautions are instituted. Protective isolation is required for neutropenia because of the high risk of infection. Deep vein thrombosis and seizure precautions are not required because of a low lymphocyte count.

16. For which adverse effects must the nurse monitor a client with leukemia who is receiving Imatinib? Mark all that apply.
- ___ ascites
 - ___ hepatitis
 - ___ pulmonary edema
 - ___ hypothyroidism
 - ___ hyperparathyroidism

Rationale

Correct answers: a and c.

Fluid retention is a major adverse effect of Imatinib and it can be both sudden and severe. Therefore clients must be carefully monitored for ascites and pulmonary edema as well as pleural and pericardial effusions. Hepatitis and hypothyroidism are late toxic effects of interferon-alpha therapy. Hyperparathyroidism is unrelated.

17. As part of a community health education event, a nurse is speaking about sickle cell anemia. A question that is asked is, "How early can sickle cell disease be diagnosed?" Which is the correct answer for the nurse to give?
- Prenatal detection is possible.
 - It can be diagnosed within 48 hours of birth.
 - It can be diagnosed between 4 and 6 months of age.
 - It can be diagnosed whenever symptoms develop.

Rationale

Correct answer: a.

Sickle cell disease can be diagnosed prenatally by amniocentesis or chorionic villous sampling. Symptoms develop between 4 and 6 months of age when fetal hemoglobin is replaced by the adult hemoglobin which is sickled.

18. When planning care for a client with aplastic anemia, which nursing order should be included?
- Test urine and stool for occult blood.
 - Monitor for signs of pulmonary edema.
 - Encouraging flossing after each meal.
 - Prevent chilling.

Rationale

Correct answer: a.

Aplastic anemia is an impairment of red blood cell production. Because production of white blood cells and platelets is also affected the client is at risk for infection and bleeding. Testing urine and stool for occult blood is done to detect bleeding. Monitoring for pulmonary edema is essential if the client has heart failure but would not be part of a general care plan related to aplastic anemia. Dental flossing is contraindicated when a risk for bleeding exists. Chilling must be prevented for clients with cold-induced autoimmune anemia.

19. Which instruction should the nurse give to the parents of a child receiving out-client chemotherapy for acute lymphoblastic leukemia? Mark all that apply.
- ___ Launder the child's clothing and linens separately.
 - ___ Wear gloves when touching the child.
 - ___ Limit contact with the child to no more than 10 minutes/hour.
 - ___ Use a plastic mattress cover on the child's bed.
 - ___ Double flush the toilet after the child uses it.
 - ___ Use disposable eating utensils for the child.

Rationale

Correct answers: a, d, and e.

Cytotoxic chemicals are excreted for up to 48 hours after administration so precautions must be taken to protect the family from exposure. Clothing and linens need to be laundered separately; the mattress is covered with plastic to prevent it from absorbing excreted chemicals, and the toilet is double flushed after use. It is not necessary to wear gloves, limit contact to 10 minutes per hour, or use disposable dishes or other eating utensils.

20. Which direction would be given to the parent of a child with hemophilia?
- Administer prophylactic factor at bedtime.
 - Store factor in the refrigerator.
 - Give ibuprofen for joint pain.
 - Plan frequent rest periods throughout the day.

Rationale

Correct answer: b.

Factor must be stored in the refrigerator to be on hand in case of need. Prophylactic factor is given in the morning because of its short life. Ibuprofen is not given to a client with hemophilia because it is an NSAID and increases bleeding. Frequent rest periods are not needed by a child with hemophilia any more than by a child without hemophilia. The child with hemophilia needs to be protected from trauma which may start a bleed.

21. Which statement made by the parent of a child with a diagnosis of thalassemia minor indicates the need for further explanation about the disease?
- Being of Mediterranean descent put my child at risk for the disease.
 - My child will need lifelong treatment but will have a normal lifespan.
 - My child will be anemic but won't have symptoms that require treatment.
 - The problem is too few red blood cells are made and some get destroyed.

Rationale

Correct answer: b.

Thalassemia minor is generally asymptomatic and does not require treatment. It is an inherited disorder which most often affects persons of Mediterranean descent. The disease is characterized by decreased production of RBCs and chronic hemolytic anemia.

22. Which statement made by a client with sickle cell anemia indicates a correct understanding of an aspect of the disease?
- I inherited my disease from my father and his side of the family
 - Any children I have will also have the disease.
 - If I had my spleen removed, my symptoms would basically disappear.
 - My red blood cells only sickle when oxygen tension in my blood decreases.

Rationale

Correct answer: d.

The hemoglobin S red blood cell, which has normal oxygen-carrying capacity, forms a sickle shape under conditions of decreased oxygen tension in the blood. The sickled cells tend to clump and block small blood vessels thereby causing tissue hypoxia. Sickle cell anemia is inherited as an autosomal recessive disorder which means a defective gene had to be inherited from both the mother and the father. Therefore, if a woman with sickle cell anemia has a child with a man who does not have the disease and is not a carrier; the child will be a carrier but will not have the disease itself. Splenectomy does not relieve the symptoms of sickle cell disease; it relieves the symptoms of hereditary spherocytosis.

23. Increase in which food would most appropriately be among the nurse's recommendations for the diet of a client with vitamin B12 deficiency as a result of inadequate intake?
- Yellow vegetables
 - Red meats
 - Poultry
 - Dairy products

Rationale

Correct answer: d.

Dairy products are a good source of vitamin B12 along with organ meats, green leafy vegetables, dried beans, nuts, citrus fruits and Brewer's yeast.

24. When assessing a client with sickle cell disease, the nurse should be alert for signs of which chronic problems that are related to the disease? Mark all that apply.
- ___ Vision loss
 - ___ Gastrointestinal bleeding
 - ___ Leg ulcers

(continued)

- d. ___ Osteoporosis
- e. ___ Pulmonary hypertension

Rationale

Correct answers: a, c, and e.

Ocular problems such as retinal detachment and blindness occur as a result of repeated infarctions. Leg ulcers are common skin manifestations and pulmonary hypertension is a long term pulmonary complication. Gastrointestinal bleeding and osteoporosis are unrelated to sickle cell disease.

25. While reinforcing information about methods of preventing infection, the client with sickle cell disease asks the nurse why she is at risk for infection. Which fact should form the basis of the nurse's response?
- a. The lack of a functioning spleen increases the risk of infection.

- b. When the number of white blood cells is decreased, the risk of infection is increased.
- c. Repeated infarctions in various body tissues increase the risk of infection.
- d. Increased cardiac workload decreases the effectiveness of humoral immunity.

Rationale

Correct answer: a.

The spleen of a client with sickle cell anemia usually becomes nonfunctional by age 6 as a result of repeated infarctions. This leaves the client at increased risk of infection because the spleen plays a role in preventing bacterial infection. A decrease in white blood cells does increase the risk of infection but this is not the mechanism involved in sickle cell disease. Increased cardiac workload and humoral immunity are unrelated.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 3: Respiratory Problems

| | | | |
|------------------|-----|-------------------------------------|-----|
| Apnea of Infancy | 711 | Laryngeal Cancer | 721 |
| Asthma | 712 | Laryngotracheobronchitis | 705 |
| Atelectasis | 716 | Legionnaires' Disease | 708 |
| Bronchiectasis | 715 | Lung Cancer | 722 |
| Bronchiolitis | 706 | Pleural Effusion | 718 |
| Croup | 703 | Pneumonia | 707 |
| Cystic Fibrosis | 718 | Pneumothorax/Hemothorax | 720 |
| Emphysema | 714 | Reactive Airway Disease | 712 |
| Epiglottitis | 705 | Sudden Infant Death Syndrome (SIDS) | 711 |
| Flail Chest | 720 | Tonsillitis | 704 |
| Fractured Ribs | 719 | Tracheoesophageal Defect | 706 |
| Histoplasmosis | 717 | Tuberculosis | 709 |

PEDS CROUP

- Croup or acute spasmodic laryngitis is an upper respiratory tract infection characterized by laryngeal obstruction resulting from the spasm of the larynx.
- Incidence is high among children of age 6 months to 3 years.

Etiology:

- Viral parainfluenza types 1 and 2 viruses are the most common agents.

- Influenza virus
- RSV
- Adenovirus

Precipitating/risk factors:

- Anxiety
- Allergy

S&S:

- Barking cough and inspiratory stridor with supra sternal and inspiratory retraction

- Insidious onset with hoarse voice
- Hoarseness and anxiety
- Cool skin
- Afebrile

Dx:

- Chest X-ray shows subglottic narrowing

Rx:

- Epinephrine
- Aerosol
- Systemic steroids
- Cool-moist therapy

**Nursing Process Elements**

Alert: Preventing laryngeal spasm is the major nursing goal.

- Apply cool-moist treatment as ordered
- Provide clear fluids
- Provide calm, quiet environment to the child
- Keep the child calm

**Client teaching for self-care**

- Instruct the parent or caregiver to take the child to a steamy bathroom during acute distress at home
- If the spasm does not subside, then take the child into the emergency room (ER)

TONSILLITIS

- Tonsillitis is an infection or inflammation of the palatine tonsils.
- Tonsils filter and protect the respiratory tract from invasion by pathogens.
- Infections can be acute, recurrent, or chronic.

Etiology: Bacteria (often group A beta-hemolytic streptococcus) or virus spread by droplet nuclei.

Precipitating/risk factors:

Often occurs with pharyngitis; strep infections develop often in cold locations in-between the fall and spring; viral tonsillitis can affect those living in crowded conditions and lead to an epidemic; more common in children and young adults.

S&S:

- Tonsils are red and enlarged
- White exudates may be observed on tonsils
- Child has difficulty swallowing and breathing
- Mouth breathing
- Sore throat
- Enlarged, tender cervical lymph nodes
- Malaise

- Muscle aching
- Fever

**Assessment Alert****PEDS**

Assess adolescents for mononucleosis.

Dx: Based on symptoms and a visual assessment of the tonsils; throat cultures.

Rx: Provide supportive care; administer analgesics as ordered, acetaminophen for viral tonsillitis; treat symptoms, use humidification, and gargle with warm salt water; for bacterial tonsillitis: antibiotics are ordered such as penicillin, if child is allergic, erythromycin used. Tonsillectomy (See Chapter 18) for recurrent or chronic infections, when there is extensive hypertrophy that leads to difficult breathing and when a peritonsillar abscess closes off the pharynx.

**Assessment Alert**

Complications of streptococcal tonsillitis are otitis media, rheumatic fever, and acute glomerulonephritis so monitor closely for S&S.

**Nursing Process Elements****Assessment Alert**

Tonsillar material grows rapidly during childhood and reaches adult size during early childhood. Thus, the presence of enlarged tonsils does not always indicate tonsillitis.

- Inquire about previous tonsil infections
- Provide comfort
- Administer antibiotics and analgesics as ordered, acetaminophen relieves fever and throat pain
- Check with parents if any herbal medications were given and report to the physician
- Prepare parents and child for surgery if required and provide perioperative care as described in Chapter 18.

**Client teaching for self-care**

- Instruct to take antibiotic for 10 days
- Stress need for adequate rest

- Use warm salt water gargle to provide comfort
- Offer a diet with nonirritating cool fluids, soft, bland foods and ice chips to prevent dehydration

PEDS EPIGLOTTITIS

- Acute epiglottitis is a life-threatening bacterial infection, which causes progressive swelling of the epiglottis and surrounding tissue.
- It may lead to respiratory arrest.
- It affects children of 3–7 years of age

Etiology: H. influenza type B

Precipitating/risk factors:

- Upper respiratory infection
- Influenza

S&S: Epiglottitis is an upper airway obstruction; therefore, it is an inspiratory problem.

- Drooling
- Fever
- Tachycardia
- Labored respirations with retractions
- Dysphagia
- Muffled voice
- Irritability and restlessness
- Anxious appearing but quiet

Dx:

- Increased WBC
- Neck X-ray

Rx:

- Respiratory support
- Antibiotics
- Antipyretics
- Intubation if needed

Nursing Process Elements

Assessment Alert

Direct examination of the epiglottis is never done unless the anesthesiologist is ready to intubate the client because it may precipitate spasm and obstruction.

- Provide mist tent oxygen as ordered
- Suction as needed
- Administer antibiotics as ordered

Client teaching for self-care

Discuss measures to prevent further upper respiratory attacks.

PEDS LARYNGOTRACHEOBRONCHITIS

- Viral infection most common in children under 5 years of age.
- Infection of the larynx extends to trachea and bronchi if not treated
- Unlike croup onset is more gradual (Usually several days) and it takes longer to resolve.

Etiology: Parainfluenza virus

Precipitating/risk factors:

- Upper respiratory infection
- Fever

S&S:

Assessment Alert

Laryngotracheobronchitis is the most common cause of stridor in children.

- Inspiratory stridor, fever, barking cough, and coryza
- Tachycardia, tachypnea, and retractions

Dx:

- Chest X-ray

Rx:

- Epinephrine in acute cases
- Antibiotics if infection is present
- Oxygen therapy
- IV fluids if dehydrated

Nursing Process Elements

Nursing Intervention Alert

Providing respiratory support to minimize complications is the key nursing goal.

- Monitor VS, skin color, and respiratory status
- Maintain hydration
- Provide calm, quiet atmosphere
- Provide cool-moist vapor as ordered
- Provide emotional support

**Client teaching for self-care**

- Instruct the parent or caregiver to take the child into a steamy bathroom during acute distress at home
- Reassure the parent that vomiting large amounts of mucus posttherapy is normal

PEDS

TRACHEOESOPHAGEAL DEFECT

- Tracheoesophageal defect is a serious, congenital condition in which there is an abnormal connection between the trachea and the esophagus; the esophagus ends before reaching the stomach and/or the esophagus develops as a pouch connected to the trachea by a fistula.
- Classified by American Academy of Pediatrics as
 - Type A-esophageal atresia without fistula
 - Type B-esophageal atresia with tracheoesophageal fistula to proximal segment
 - Type C-esophageal atresia with fistula to distal segment
 - Type D-esophageal fistula with fistula to both segments
 - Type E-tracheoesophageal fistula without atresia
- It is associated with other anomalies affecting the heart, GU system, or anorectal areas

Etiology: Failure of embryonic trachea and esophagus to develop and separate correctly.

Risk Factors: Prematurity and polyhydramnios.

S&S:

- Excessive oral secretions
- Constant drooling
- Intolerance of feedings
- Regurgitation of feedings
- Periodic episodes of choking and cyanosis
- When fed, infant swallows but coughs, gags, and returns feeding through the nose and mouth
- Respiratory distress from aspiration of secretions
- Abdominal distention occurring soon after birth when air from the trachea enters esophagus and stomach through the fistula

**Assessment Alert**

Assess for symptoms immediately after birth. Delay in assessment and treatment may be fatal due to fluids and secretions entering lungs; may develop pneumonia.

Dx: X-ray taken with radiopaque catheter placed in esophagus to check for obstruction; standard chest X-ray shows a

dilated air-filled upper esophageal pouch and can demonstrate pneumonia; inability to pass a NG tube into stomach because it meets resistance; bronchoscopy visualizes fistula between trachea and esophagus; abdominal ultrasound; and an echocardiogram to check for cardiac abnormalities.

Rx:**Surgery:**

- Usually an emergency, is performed as soon as infant is stable.
- Involves ligation of fistulas and anastomosis of esophagus to stomach.
- Completed in one procedure if possible or done as a staged repair.

Supportive care until surgery; IV antibiotics; GT inserted before surgery to decompress stomach.

**Nursing Process Elements**

- Assess for symptoms immediately after birth
- Assess patency of esophagus before feeding or putting to breast
- Evaluate difficulty feeding, respiratory distress, excess drooling, choking, and coughing
- Assess lung sounds
- Use semi-Fowler's position to prevent reflux of gastric contents into trachea and to ease respiratory effort
- Monitor respiratory status closely
- Prevent aspiration
- Maintain fluid and electrolyte balance
- Administer IV fluids to prevent dehydration
- Provide emotional support and reassurance to parents
- Encourage parents to spend as much time with infant as possible
- Place in warm, humidified environment

**Client teaching for self-care**

- Involve parents in care of infant to facilitate bonding by means of touch and eye contact
- Offer information to parents about the defect, surgical repair, pre- and postoperative care and prognosis, and need for possible further surgery
- Teach parents how to administer gastrostomy feedings until esophagus heals

PEDS

BRONCHIOLITIS

- Bronchiolitis is a viral infection, which causes increased mucus production, decreased diameter of the bronchi, hyperinflation, and atelectasis.
- It affects infants of 2–8 months.

Etiology:

- Respiratory syncytial virus (Virus invades epithelial cells of nasopharynx and spreads to lower respiratory tract causing increased mucus production, decreased diameter of the bronchi, and hyperinflation.)

Precipitating/risk factors:

- Preterm
- Congenital cardiac anomaly
- Diabetes
- Immunocompromised infant

S&S:

- Toxic appearance
- Fatigue
- Air-hunger/nasal flaring
- Tachycardia and tachypnea, severe dyspnea
- Increased wheezing and grunt sound
- Intercostal retraction
- Prolonged expiratory phase
- Harsh cough
- Moist rales

Dx:

- Chest X-ray
- WBC count may be normal

Rx:

- RSV—immunoglobulins given monthly for the high-risk babies to prevent infection
- Synagis—given monthly to prevent infection
- Humidified oxygen therapy
- Bronchodilators such as albuterol
- Antiviral treatment such as ribavirin

**Nursing Process Elements****Assessment Alert**

Bronchiolitis is a lower respiratory tract infection; therefore, must monitor for expiratory problems

**Clinical Alert**

Prevention and maintenance of airway patency is the key nursing goal.

- Administer antibiotics as ordered to eradicate infection
- Administer antipyretic as ordered

- Increase fluid intake to loosen secretions
- Remove and control secretions
- Maintain a high humidity environment
- Administer humidified oxygen therapy.
- Offer small, frequent feedings

**Client teaching for self-care**

- Discuss with the parent the importance of high humidity environment (at home—take the child to the bathroom and open the hot water in a closed environment to provide humidity)
- Teach the parent the importance of getting the monthly synagis injection at the scheduled time

PNEUMONIA

- Pneumonia is an acute infection/inflammation of the lung parenchyma leading to consolidation of lung tissue as the alveoli fill with exudate that impairs gaseous exchange.
- Major pneumonias may be classified as community-acquired, hospital-acquired, aspiration, or pneumonias in an immunocompromised host.
- Community-acquired pneumonia (CAP) occurs in the community or within 48 hours of entering a hospital or other facility.
- Hospital-acquired pneumonia (HAP) has symptoms that occur more than 48 hours after admission to a hospital or other facility; also called nosocomial

Etiology: Pathogens (bacteria, viruses, mycobacteria, chlamydiae, mycoplasma, fungi, and parasites), irritants such as chemicals or aspirated material. Most common causes of bacterial pneumonia are *S. pneumoniae*, *S. aureus*, *E. coli*, *Pseudomonas aeruginosa*, and *H. influenzae*. Bacterial pneumonias are predominant during winter and early spring and mostly affect the elderly.

PEDS

Viruses are the most common cause of pneumonia in infants and children.

Precipitating/risk factors:

- Atelectasis/aspiration
- Chronic illness and debilitation such as lung cancer
- Abdominal or thoracic surgery
- Colds and viral respiratory infection
- COPD, asthma bronchiectasis, and cystic fibrosis
- Smoking and alcoholism
- Malnutrition
- Sickle cell disease
- Tracheostomy
- Exposure to noxious gases
- Immunosuppressive therapy

Assessment Alert

Elderly or debilitated clients, those receiving NGT feedings, as well as clients with an impaired gag reflex, poor oral hygiene, or decreased LOC are at high risk for aspiration pneumonia.

S&S:

Assessment Alert

S&S vary with type of pneumonia. Four cardinal S&S of bacterial pneumonia are cough, sputum production, pleuritic chest pain, and fever.

- Greenish to rusty-colored sputum
- Rapid, shallow respirations with expiratory grunt, nasal flaring, intercostal rib retraction, and use of accessory muscles of respiration
- Fever, chills, chest pain, and weakness
- Tachycardia, cyanosis, profuse perspiration, and abdominal distention

Dx:

- Chest X-ray (shows consolidation over affected area)
- Increased WBC
- Decreased PaO₂
- Sputum culture determines the specific organism
- VQ scan identifies early *Pneumocystis carinii* pneumonia

Rx:

- Antimicrobial treatment (varies according to organism)
- Supportive measures include
 - humidified oxygen;
 - high-calorie diet with increased fluid intake to 2–3 l/d;
 - bed rest as indicated;
 - analgesics to relieve pleuritic chest pain;
 - mechanical ventilation for respiratory failure.

Nursing Process Elements

- Assess for changes in temperature and pulse, frequency and severity of cough, amount and color of sputum, degree of dyspnea, and changes in chest assessment findings
- Facilitate adequate ventilation
 - Oxygen administration
 - Semi-Fowler's position
 - Turn and reposition clients who are immobilized
 - Administer analgesics to relieve pain associated with breathing (avoid morphine that can depress respirations; codeine is the choice of medication)

—Auscultate lung sounds and monitor ABGs

- Support removal of secretions
 - Deep breathing and coughing exercises, suction as needed, increase fluid intake to 2–3 l/d, expectorants as ordered, humidification of inhaled air, nebulizer treatment as ordered
 - Perform good oral hygiene after expectoration
- Provide adequate rest and pain relief
 - Limit physical activity
 - Limit visitors and conversation
 - Plan uninterrupted rest periods
 - Schedule nursing care in parts to ensure rest periods in-between
- Administer antibiotic, antipyretic medication as ordered; monitor client response to therapy and document
- Institute isolation precaution as per protocol
- Monitor for complications such as confusion from hypoxia, shock, respiratory failure, atelectasis, pleural effusion, and suprainfection

Nursing Intervention Alert

Nursing care focuses on facilitation of adequate ventilation, removal of secretions, comfort and rest, and medication administration.

Client teaching for self-care

- Antibiotic therapy regime and side effects to expect and/or report need to limit activity and obtain adequate rest
- Maintain increased fluid intake
- Continue with deep breathing and coughing exercises
- Importance of adequate nutrition
- Encourage annual influenza vaccine
- Need for reporting the S&S of upper respiratory tract infection to his/her health care provider especially when cystic fibrosis or immobility is a problem

LEGIONNAIRES' DISEASE

- Legionnaires disease is an acute bronchopneumonia in which the inflammation of the lung begins in the terminal bronchioles.
- It occurs epidemically or sporadically.
- The mortality is about 15%.

Etiology:

- *Legionella bacillus* (gram-negative) occurs in water and can be inhaled from aerosols in showers or water spray, or aspirated when drinking contaminated water. Exposure to

Legionella can occur in homes, workplace, hospitals, or other public places.

S&S:

Assessment Alert

Major symptom of Legionnaires' pneumonia is cough: initially nonproductive eventually progressing to grayish, nonpurulent, and blood-streaked sputum.

- Fever
- Generalized weakness
- Malaise
- Recurrent chills

Dx:

- Chest X-ray shows patchy, localized infiltration, which progress to multilobar consolidation
- Fluorescent testing for antibody titer
- Sputum, urine and blood sample studies

Rx:

- Oxygen therapy
- Antibiotic treatment: most antibiotics are effective including levofloxacin, ciprofloxacin, azithromycin, and erythromycin
- Antipyretics
- Inotropic agents

Nursing Process Elements

Assessment Alert

Maintenance of respiratory function is the key focus of nursing care. Closely monitor respiratory status, chest wall expansion, depth and pattern of respiration.

- Monitor VS including pulse oximetry and ABG values
- Provide mechanical ventilation as ordered
- Administer medication as prescribed

Client teaching for self-care

Teach the client S&S of *Legionella* infection

TUBERCULOSIS

Tuberculosis is an infectious, airborne, communicable disease primarily affecting the lung parenchyma.

Once inhaled, the organisms implant in the lung; start dividing slowly; and eventually lead to caseation (the conversion of necrotic tissue into a cheese-like material) and fibrosis. May be spread through lymph and circulatory system to kidney, bone, meninges, and lymph nodes.

Infection may be acute or chronic.

High-risk populations:

- People in inner-city neighborhoods
- People in over or densely populated areas
- Non-whites
- Socially and economically disadvantaged

Etiology:

- *Mycobacterium tuberculosis*

Precipitating/risk factors:

- Age 65 and over
- Overpopulation
- Immunocompromise
- Chemotherapy
- Radiation therapy
- HIV infection
- Malnutrition
- Leukemia
- Hodgkin's disease

S&S:

- Pulmonary symptoms
 - Productive cough, yellow mucoid sputum
 - Dyspnea
 - Pleuritic pain
 - Hemoptysis
 - Rales (crackles)
- Systemic symptoms
 - Fatigue
 - Weakness
 - Anorexia
 - Weight loss
 - Night sweats
 - Low-grade fever

Dx:

- Chest X-ray indicates presence and extent of disease process but cannot differentiate active or inactive tuberculosis
- PPD positive: area of induration of 10 mm or more after 48 hours. (Reading must be within 48–72 hours.)
- Sputum positive for acid-fast *Bacillus*
- Culture positive
- WBC and ESR increased.

Rx:

- Drug therapy
 - Antituberculosis: Initial treatment

—isoniazid (INH), rifampin (RIF), pyrazinamide, ethambutol, or streptomycin; daily dosing of all for 2 weeks. Subsequently, 6 weeks of twice weekly dosing and then 4 months of twice weekly doses of INH and RIF. Alternatively, daily dosing with all four for 8 weeks until drug resistance is ruled out, then 4 months of INH and RIF.

—INH preventative therapy (300 mg/d for 3–6 months) for persons with positive PPD and no clinical signs of disease who are at risk for progression of disease.

—Antibiotic: Streptomycin (usually for 9 months).

- Chest physiotherapy, postural drainage, and incentive spirometry
- Dietary changes, including high-carbohydrate, high-protein, vitamin B6, and vitamin C

Nursing Process Elements

- Maintain respiratory precautions. Client is not considered infectious 2–3 weeks after the initiation of medication
 - Teach the client methods to prevent spread of droplets when coughing
 - Client should be in a well-ventilated negative pressure room with door closed at all times
 - All visitors and staff should wear mask when in contact with client and discard before leaving the patient room
 - All specimens should be labeled AFB precautions.
 - Hand washing required after direct contact with the client
- Offer small frequent meals and nutritional supplement to promote nutritional intake.
- Weigh the client at least two times a week
- Prevent social isolation

Client teaching for self-care

- Prevent transmission of disease: cover mouth with tissue when coughing, sneezing, or laughing; dispose of used tissue safely in the garbage; and wash hand after coughing or sneezing
- Explain the medication regimen; prepare a sheet with medication name, dosage, time, and major side effects. This helps increase medication compliance
- Identify the signs of reoccurrence such as persistent cough, fever, weight loss; explain the importance of seeing a physician if these occur
- Reinforce the need for follow-up care including physical exam, sputum cultures, and chest X-ray
- Need for a high-protein, high-calorie, high-vitamin diet

PEDS Aspiration of Foreign Object in the Respiratory System:

- Aspiration of a foreign object in the respiratory system is a common problem among toddlers (children under 4 years of age).

- Symptoms and severity of symptoms depend on the type of object and its placement in the airway or the lung.

Precipitating/risk factors:

- Age: Toddler

S&S:

Assessment Alert

Symptoms depend on the type of object and its placement in the respiratory tract.

- If the object is in the upper airway: sudden onset of respiratory distress characterized by coughing, dyspnea, wheezing, stridor, and apnea
- If the object is in the lower airway: persistent respiratory infection/ pneumonia, cough, and mild respiratory distress

Dx:

- Chest X-ray
- Bronchoscopy
- Laryngoscopy

Rx:

- Immediate removal of the object if in the upper airway
- Surgical removal if it is the lower airway
- Symptomatic treatment such as antibiotics if there are signs of infection.

Clinical Alert

- If a foreign object is in the upper respiratory tract, it needs immediate removal; if the object is in the lower airway, it is less emergent.

Nursing Process Elements

Nursing Intervention Alert

Two major nursing responsibilities are to perform Heimlich maneuver and prevent further damage.

- Reassure the child and parent
- Administer humidified oxygen as ordered
- Administer antibiotics as ordered

Client teaching for self-care

- Teach the parents about age-related expected behaviors and age-appropriate safety precautions

PEDS

APNEA OF INFANCY

- Apnea is cessation of breathing.
 - Central apnea results from the lack of respiratory effort.
 - Obstructive apnea results from total airway obstruction.

Etiology:

- Prematurity
- Surgical therapy such as tonsillectomy

Precipitating/risk factors:

- Infection
- Anemia
- Hypoglycemia
- Delayed growth and development

S&S:

- Apneic spell
- Bradycardia
- Daytime sleepiness
- Loud snoring
- Night insomnia
- Mouth breathing
- Rapid onset with or without crying
- Polycythemia
- Cor pulmonale

Dx:

- CBC
- ABG

Rx:

- Symptomatic treatment
- Theophylline, caffeine, nasal CPAP, and intubation if needed
- Weight loss
- Tonsillectomy if enlarged and obstructive

**Nursing Process Elements****Nursing Intervention Alert**

Nursing care is based on etiology.

- Respiratory support
- Avoid stress
- Place client on constant observation
- Administer medication as ordered

PEDS

SUDDEN INFANT DEATH SYNDROME (SIDS)

- Sudden death of an infant that is unexpected by history and is without evidence of cause on postmortem examination.
- Incidence peaks at 3 months.
- Usually occurs during sleep.
- No evidence of struggle and death is silent.

Etiology: Unknown.**Precipitating/risk factors:**

- Preterm infants, twins, triplets, low birth weight
- Abnormalities in respiration, feeding, or other neurological symptoms

S&S:

Two- to three-month-old infant found cyanotic, apneic, and pulseless in the bed.

Dx:

- Autopsy

**Nursing Process Elements****Nursing Intervention Alert**

Support parent and family (parents tend to think it is their fault).

- Provide room to be alone if possible
- Let parent say good-bye to baby
- Allow parent to hold the baby
- Reinforce that death is not their fault
- Provide appropriate support, referrals, clergy, local SIDS program

**Client teaching for self-care:****Nursing Intervention Alert**

Teach prevention.

American Academy of Pediatrics Guidelines for Reducing SIDS Risk

- Always place a baby on his or her back during naps and at night; supine position decreases risk.

- Place babies on a firm sleep surface such as a safety-approved crib mattress that is covered with a fitted sheet.
- Do not smoke during pregnancy or near babies.
- Do not let a baby overheat during sleep.
- Always keep the head and face uncovered.
- Keep a baby's sleep area close to, but separate from, where parents and others sleep.
- Offer a clean, dry pacifier when placing a baby on his or her back to sleep. Do not reinsert it after the baby falls asleep.
- Reduce the chance that flat spot will develop on the baby's head by providing "tummy time" when the baby is awake and someone is watching.
- Do not use home respiratory or cardiac monitors to reduce SIDS risk.
- Keep soft objects, toys, sheepskins and loose bedding out of a baby's sleep area.
- Avoid products claiming to reduce SIDS risk.

PEDS REACTIVE AIRWAY DISEASE

- Reactive airway disease is a syndrome of wheezing and coughing that occurs in children when airways react to a stimulus with narrowing and mucus production.
- Precipitating factors include respiratory infection and inhalation of environmental pollutants.
- It may or may not lead to asthma; children with asthma in the family are at higher risk.

S&S: Rapid, shallow breathing; wheezing; dry cough; flaring nares; intercostal retractions.

Dx: Clinical presentation

Rx:

- Treat underlying problem
- Bronchodilators (aerosol or MDI)
- Steroids such as Predone or Orapred for several days to reduce inflammation in the airways.

Nursing Process Elements

- Assess for signs and symptoms of the problem
- Monitor response to therapy

Client teaching for self-care

- Avoid exposure to cigarette smoke, perfume, and other fumes
- Use only prescribed medications: do not give child OTC medications unless directed to do so by health care provider
- Contact health care provider if:
 - child does not smile, play, or show interest in normal activity for at least a few minutes out of 4 hours;
 - wheezing or difficulty breathing worsens;
 - child complains of tightness in the chest;

- breathing becomes markedly fast and shallow;
- baby cannot suck and breathe simultaneously or chokes when sucking;
- child cannot be calmed for at least a few minutes every hour;
- persistent coughing occurs after medication is taken.
- Call 911 if any of the following develops:
 - severe lethargy (child barely responds)
 - severe dyspnea
 - inspiratory grunting
 - cyanotic lips, gums, and nail beds
 - inability to speak while trying to breathe
 - apnea of more than 5-seconds duration

ASTHMA

- Asthma is increased bronchial reactivity in the lower respiratory tract to various stimuli, which produces episodic bronchospasm and airway obstruction and inflammation.
- It is the most common respiratory disease in children. In younger children, it affects twice as many boys as girls and evens out by adolescence.
- Immunologic/allergic reaction results in histamine production causing edema of the mucus membrane, spasm of the smooth muscle of bronchi and bronchioles, and accumulation of secretions.
- Asthma can be intrinsic (allergen is not obvious) or extrinsic (results from sensitivity to specific external allergens).

Etiology:

- Extrinsic asthma: exposure to pollens, animal dander, house dust or mold, feather pillows, silky materials, food additives.
- Intrinsic asthma: irritants, emotional stress, fatigue, endocrine changes, temperature and humidity changes, and exposure to noxious fumes.

Precipitating/risk factors:

- Allergen
- Upper airway infection
- Sudden change in temperature or weather
- Exercise, anxiety, excessive coughing, or laughing

S&S:

- Sudden dyspnea, wheezing, and tightness in the chest
- Coughing that produces thick, clear, or yellow sputum
- Tachypnea and use of accessory respiratory muscles
- Rapid pulse, profuse perspiration, hyperresonant lung fields, diminished breath sounds
- Barrel chest appearance from chronic air trapping
- Irritability from hypoxia

Dx:

- Physical examination
- Chest X-ray: hyperinflated lungs with air trapping and local atelectasis during attacks, normal during remission

- Sputum: presence of Cruschmann's spirals (casts of airways), eosinophils
- Skin testing for specific allergens may be necessary if the client lacks history of allergy

Rx:

- Treatment is usually tailored to individual client's need and focuses on identifying and avoiding predisposing factors. Desensitization of specific antigen may be helpful, but is not effective in persistent asthma.
- Emergency treatment: Oxygen therapy, corticosteroids, and bronchodilators such as subcutaneous epinephrine, IV theophylline, and inhaled agents such as metaproterenol, albuterol, and ipratropium
- Medication:
 - Bronchodilators
 - Beta-adrenergic agonists: metered dose inhaler—children will need spacers, nebulizer—for infants and toddlers, and rescue drugs for acute attacks.
 - Corticosteroids: oral for persistent wheezing, inhaled by MDI or nebulizer, IV in the hospital
 - Nonsteroidal anti-inflammatory agents: nedocromil, cromolyn sodium, and leukotriene inhibitors
 - Other commonly used medications are as follows:
 - Rapid-acting epinephrine
 - Aminophylline
 - Terbutaline
 - Theophylline
 - Corticosteroids

Step Approach to Asthma Management

Step 1 Long-term control: none

Rescue (Short-term control): short-acting bronchodilator (inhaled beta 2 agonist); if used more than biw; long-term control required.

Step 2 Long-term control: daily anti-inflammatory: low dose inhaled corticosteroid or cromolyn or nedocromil

Rescue: short-acting bronchodilator (inhaled beta 2 agonist); if used daily or with increased frequency, additional long-term therapy is needed.

Step 3 Long-term control: daily anti-inflammatory: medium dose inhaled corticosteroid or low to medium dose inhaled corticosteroid plus long-acting bronchodilator (inhaled or oral).

If needed, medium to high dose inhaled corticosteroid plus long-acting bronchodilator.

Rescue: short-acting bronchodilator (inhaled beta 2 agonist); if used daily or with increased frequency, improved long-term therapy is needed.

—High-dose inhaled corticosteroid plus long-acting inhaled bronchodilator or oral corticosteroid (2 mg/kg/d) and long-acting beta 2 agonist tablets.

—Rescue: inhaled short-acting beta 2 agonist

**Clinical Alert**

Status asthmaticus occurs when there is little or no response to treatment and symptoms persist.

**Nursing Process Elements****Nursing Intervention Alert**

During an acute attack, take appropriate measures to maintain airway and respiratory function, and relieve bronchoconstriction.

- Place the client on semi-Fowler's position
- Administer oxygen
- Encourage diaphragmatic breathing
- Administer medication and IV therapy as ordered
- Provide humidification and hydration to loosen secretions
- Monitor for respiratory distress
- Provide chest percussion and postural drainage once symptoms improve
- If the attack was caused by exertion, have the client sit down, rest, and sip warm water if not contraindicated
- For status asthmaticus, humidified oxygen to achieve full saturation; large, frequent doses of inhaled short-acting beta 2 agonists; continuous treatment with bronchodilators until clinical improvement or toxic side effects occur; subcutaneous epinephrine for those refractive to beta 2 agonists

**Clinical Alert**

Status asthmaticus unrelieved by epinephrine is a medical emergency. Noninvasive positive pressure ventilation is preferable to intubation and mechanical ventilation in its treatment.

**Client teaching for self-care**

- Prescribed medication
 - Take missed doses as soon as possible but do not double dose
 - If using inhaled bronchodilator and corticosteroid, use bronchodilator first and wait for 5 minutes before using the corticosteroid
 - Rinse mouth with water after inhaling corticosteroid to decrease risk of *Candida*
 - Contact physician if sore throat or mouth occur

- Don't discontinue cromolyn or nedocromil without consulting physician as exacerbation of symptoms may occur
- Use peak flow monitor to determine respiratory status
- Use of the oral inhaler
 - Remove cap and shake the inhaler
 - Hold the inhaler upside down
 - Breathe out as fully as possible
 - Open the mouth and tilt the head slightly back
 - Keep inhaler 2 in. away from the mouth
 - Firmly press the canister down into the mouth piece to release the medication
 - Slowly inhale through mouth
 - Hold breath for 10 seconds
 - Slowly breathe out through the nose
 - Wait for about 5 minutes. Repeat if needed
 - Cap and store the inhaler
 - Rinse mouth
 - Clean mouth piece periodically
- Breathing exercises
- How to control the asthma attack
 - Keep the nebulizer handy at all times
 - Do not take more than two or three inhalations every 4 hours.
 - Call the physician if the symptoms persist after two to three uses of the nebulizer.
- Explain that overuse of the inhaler can weaken response to medication and can also lead to cardiac arrest and death
- Stress the importance of preventing respiratory tract infection.
- Help the client to identify asthma triggers and explain how these triggers cause bronchospasm, airway edema, and mucus production.

Nursing Intervention Alert

Modification of environment such as providing good ventilation, removing plants and animals is the key to avoiding and reducing exposure to allergens.

- Refer the client to asthma support group as the American Lung Association.

EMPHYSEMA

- Emphysema is a chronic, irreversible, and abnormal enlargement and destruction of alveoli leading to loss of elastic recoil of the lung tissue resulting in the accumulation of sputum and the creation of large air pockets.
- Structural changes result in the accumulation of carbon dioxide, hypoxia, and ultimately respiratory acidosis.

Think Smart/Test Smart

The “arrow method” can be used to interpret arterial blood gas values and determine a client's acid–base balance.

- Place up or down arrows (depending on whether the client's lab values are higher or lower than normal) before the words/phrases pH, PaCO₂, and HCO₃⁻ and follow with an equals sign.
- Look at the direction of the arrows you have made: if the arrow before pH points down, write acidosis after the equals sign. If the arrow before pH points up, write alkalosis.
- Look at the arrow before PaCO₂. If it is pointing in the same direction as the pH arrow, write metabolic after the equals sign. If it is pointing in the opposite direction to the pH arrow, write respiratory after the equals sign.
- The two words to the left of the equals sign name the type of acid–base imbalance the client has.
- To determine if the client's body is trying to compensate for the problem, look at the arrows before PaCO₂ and HCO₃⁻; if they point the same way, compensatory effects are present; if they point in opposite directions, the imbalance is uncompensated.

↓pH ↓PaCO₂ ↓HCO₃⁻ = compensated metabolic acidosis

↓pH ↓PaCO₂ ↑HCO₃⁻ = uncompensated metabolic acidosis

↑pH ↑PaCO₂ ↑HCO₃⁻ = compensated metabolic alkalosis

↑pH ↑PaCO₂ ↓HCO₃⁻ = uncompensated metabolic alkalosis

↓pH ↑PaCO₂ ↑HCO₃⁻ = compensated respiratory acidosis

↓pH ↑PaCO₂ ↓HCO₃⁻ = compensated respiratory acidosis

↑pH ↓PaCO₂ ↓HCO₃⁻ = compensated respiratory alkalosis

↑pH ↓PaCO₂ ↑HCO₃⁻ = compensated respiratory alkalosis

- Most common respiratory cause of death in the United States.

Etiology:

- Congenital deficiency of alpha-antitrypsin
- Cigarette smoking

Precipitating/risk factors:

- Inhaled irritants
- Frequent upper respiratory tract infection
- Allergic factors

S&S:**Assessment Alert**

Onset is insidious with dyspnea as the predominant symptom

- Long-term respiratory disease symptoms: feeling of breathlessness, cough, sputum production, nasal flaring, use of accessory muscles, and dyspnea.
- Prolonged expiratory period with grunting, pursed lip breathing, and tachypnea
- Barrel chest, resonant to hyperresonant on percussion, and decreased breath sounds with prolonged expiration
- Anorexia and weight loss

Dx:

- Physical exam
- Health History
- Chest X-ray: flattened diaphragm, reduced vascular marking, and large air spaces
- Pulmonary function test
- Arterial blood gases: PaCO₂ is elevated and PaO₂ is decreased
- ECG: tall, symmetrical P waves
- CBC: increased RBC

Rx:

- Bronchodilators: aminophylline, albuterol, Isuprel, and theophylline
- Antimicrobials: tetracycline and ampicillin to treat bacterial infection
- Corticosteroids for inflammation

**Nursing Process Elements****Nursing Intervention Alert**

Oxygen to 2 l/min for hypoxia—clients with emphysema depend on hypoxia to drive respira-

tion because they become used to elevated levels of carbon dioxide which is the main drive to breathe in normal individuals. If a client with emphysema receives enough oxygen to eliminate hypoxia entirely, there is a risk of respiratory arrest because there is no impetus to breathe.

- Administer medication as ordered
- Institute measures to improve ventilation such as positioning the client in semi-to high-Fowler's position, and encouraging diaphragmatic breathing, productive coughing, and pursed-lip breathing
- Facilitate removal of secretions by increasing fluid intake and providing chest PT as ordered.
- Provide oral hygiene after chest PT

**Client teaching for self-care**

- Avoid precipitating/risk factors such as inhalation of irritants and exposure to sources of upper respiratory tract infection
- Importance of getting flu and pneumococcal vaccinations
- Use home humidifier at 30–50%
- Develop activity tolerance gradually starting with mild exercise and slowly increasing duration
- Avoid sudden changes of temperature, e.g., cover nose and mouth with scarf while going out
- Prevent frequent respiratory tract infection:
 - Avoid overcrowded areas
 - Report to physician any sign of respiratory tract infection such as change of sputum color.
- Encourage high-protein, high-calorie, increased vitamin diet

BRONCHIECTASIS

- Bronchiectasis is a chronic, irreversible condition marked by abnormal dilatation of bronchi and destruction of bronchial walls.
- It can occur throughout the tracheobronchial tree or can be confined to one segment or lobe but is usually bilateral involving basilar segments of the lower lobes.

Etiology/precipitating/risk factors:

- Immunologic disorders such as gammaglobulinemia
- Recurrent bacterial respiratory tract infections such as tuberculosis.
- Measles, pneumonia, pertussis, or influenza
- Obstruction by foreign body

S&S:

**Assessment Alert**

Chronic cough that produces copious, foul-smelling, mucopurulent secretion, possibly totaling several cupfuls daily is characteristic.

- Occasional wheezes
- Dyspnea
- Weight loss
- Clubbing
- Recurrent fever, chills, and other signs of infection

Dx:

- Bronchography: most reliable test, reveals the location and extent of the disease
- Chest X-ray: shows peribronchial thickening, areas of atelectasis, and scattered cystic changes
- Bronchoscopy: helps to identify the sources of secretions or the site of bleeding
- Sputum culture to identify infective organisms

Rx:

- IV antibiotics for 7–10 days
- Bronchodilators with postural drainage and chest PT
- Oxygen therapy
- Lobectomy

**Nursing Process Elements****Nursing Intervention Alert**

Warm, quiet environment and rest is very important for recovery.

- Administer antibiotics as ordered
- Perform chest PT as ordered, include postural drainage
- High-protein, high-carbohydrate diet
- Mouth care after chest PT

**Client teaching for self-care**

- Teach family members how to perform PT and postural drainage
- Discuss the importance of mouth care postpostural drainage

- Teach the client deep breathing and coughing exercises to promote good ventilation and removal of secretions
- Encourage the client to stop smoking
- Teach the client to properly dispose of secretions and other infection control measures
- Teach the client the importance of childhood vaccines in decreasing risk of this disease.

ATELECTASIS

- Atelectasis is collapse or airless condition of all or part of lung.
- It may be chronic or acute.

Etiology:

- Bronchial obstruction from intrabronchial or extra-bronchial cause that results in incomplete expansion of clusters of alveoli or lung segments

Precipitating/risk factors:

- Mucus plug, a common problem in smokers and clients with COPD, bronchiectasis, or cystic fibrosis
- Foreign body
- Bronchogenic carcinoma
- Inflammatory lung disease
- Oxygen toxicity
- Pulmonary edema
- Any condition that inhibits full lung expansion such as immobility or makes deep breathing painful such as thoracic surgery
- CNS depression from drug overdose

S&S:

**Assessment Alert**

Assessment findings may vary depending upon the cause and area involved.

- Dyspnea, possibly mild and subsiding without treatment if atelectasis involves only a small area of the lung; severe if massive collapse occurs.
- Cyanosis
- Decreased breath sounds
- Anxiety, diaphoresis, tachypnea, tachycardia, pain over the affected area, and elevated temperature
- Substernal or intercostal retraction

Dx:

- Chest X-ray shows lobar collapse with dense tissue and decreased size of affected lung. Extensive areas of

microatelectasis may exist without showing abnormalities on the client's chest X-ray.

- Bronchoscopy may or may not reveal obstruction
- PO₂ decreased.

Rx:

- Bronchoscopy
- Chest physiotherapy
- Antibiotics
- Symptomatic treatment
- Drug therapy includes
 - Bronchodilators such as Proventil
 - Mucolytic inhalation such as Mucomyst

Nursing Process Elements

Nursing Intervention Alert

Prevention of atelectasis in hospitalized clients is an important nursing responsibility.

- Prevention of predisposing factors is the key to preventing atelectasis
 - Turn and reposition the client every 1–2 hours while client is bedridden or immobile.
 - Use incentive spirometry
 - Encourage coughing and deep breathing every 1–2 hours as ordered
 - Provide suctioning as needed
 - For clients on mechanical ventilation, maintain tidal volume at 10–15 ml/kg of the client's body weight to ensure adequate lung expansion.
 - Monitor breath sounds and ventilatory status
 - Promote liquefaction and removal of secretions
 - Avoid large doses of sedative and opiates that depress the cough reflex
 - Encourage fluid intake

Client teaching for self-care

- Promote emotional support and reassurance; clients may be frightened by the limited breathing capacity
- Discuss the importance of using incentive spirometer: encourage client to use 10–20 times every hour while awake
- Teach breathing exercises, respiratory care, and postural drainage
- Encourage client to stop smoking

HISTOPLASMOSIS

- Histoplasmosis is a systemic fungal disease.
- Fungus is found in bird manure.
- Histoplasmosis is transmitted by inhalation of *Histoplasma capsulatum* contaminated dust.

Etiology: *Histoplasma capsulatum*.

Precipitating/risk factors:

- Inhalation of dust

S&S:

Assessment Alert

Symptoms of histoplasmosis are similar to tuberculosis and pneumonia.

- Cough
- Fever
- Pain in the joints
- Fatigue

Dx:

- Chest X-ray
- Skin test for histoplasmin

Rx:

- Antifungal agent such as amphotericin B
 - Watch for toxic effects such as anorexia, chills, fever, and renal failure
 - May give Benadryl before administration to minimize reaction to drug

Nursing Process Elements

Nursing Intervention Alert

Respiratory precautions similar to client with pneumonia are used.

- Support effective respiratory function
- Monitor renal function before and after medication administration
- Administer medication as ordered

Client teaching for self-care

- Side effects of and toxic reactions to the medication

- Respiratory precautions
- Prevention of recurrence by staying away from dust and birds

PEDS

CYSTIC FIBROSIS

- Cystic fibrosis is a chronic multisystem disorder primarily affecting the exocrine (mucus-producing) glands (pancreas, respiratory, gastrointestinal, and reproductive glands).
- It is inherited as an autosomal-recessive defect.
- It is the most common cause of lung disease in children.
- It occurs predominantly in whites as opposed to blacks or Asians

Etiology:

- Genetic predisposition (autosomal-recessive)
- Family history

S&S:

- Respiratory involvement: COPD including wheezing, chronic productive cough, dyspnea, barrel chest, cyanosis, clubbing, chronic infection
- Cardiovascular involvement: right-sided heart enlargement, CHF
- Pancreatic/gastrointestinal involvement: steatorrhea, weight loss, malnutrition, deficiencies of fat-soluble vitamins (A, D, E, K), neonatal history of meconium ileus. Loose, bulky, fatty stool, partial or complete intestinal obstruction known as distal intestinal obstruction syndrome (DIOS)
- Sweat gland involvement: parent reports salt taste when kissing the child, hyponatremia and hypochloremia.

Dx:

- Physical examination
- Sweat test indicates an increase in sodium and chloride in perspiration
- Absence or decrease of trypsin and an increase of fat in stool

Rx:

- Tailored to individual client's need; focuses on facilitating gas exchange and preventing respiratory infection
- Aerosol therapy
- Mist tent
- Breathing exercises
- Medication: bronchodilators, mucolytic agents and expectorants, and antibiotics

Nursing Process Elements

- Check for family history of cystic fibrosis
- Assess for S&S

Nursing Intervention Alert

Respiratory assessment for impaired gas exchange; good pulmonary hygiene to promote gas exchange, and prevention of respiratory infection are the priorities of care.

- Provide pulmonary hygiene to clear air passage:
 - Daily postural drainage with percussion and vibration between meals and HS
 - Avoid PD right before and right after meals
 - Follow PD with good oral hygiene and rest
 - Aerosol therapy as ordered
 - Maintain mist tent
- Encourage physical exercise
- Breathing exercises
- Administer bronchodilators, mucolytic agents, and expectorants as ordered
- Prevent respiratory infection; treat vigorously if present
- Maintain adequate nutrition
 - Provide high-calorie, high-protein, normal-fat diet
 - Administer water-soluble preparation for fat-soluble vitamins such as A, D, E, and K
 - Provide salt supplements during hot or febrile periods (soup, and sports drink, salty pretzels)
 - Administer pancreatic enzymes immediately with each meal and each snack. (Mix with cold sauce such as apple or pear sauce)
 - Increase intake of fluids with electrolytes (Gatorade, sports drink)
- Provide emotional support for the child and family
 - Allow verbalization of concerns and feelings
 - Encourage age appropriate independence
 - Suggest genetic counseling
 - Refer family to cystic fibrosis association

Client teaching for self-care

- Discuss the prescribed medication (refer to asthma teaching)
- Explain the importance of good pulmonary hygiene and preventing respiratory tract infection
- Review Dx, disease process, long-term implications, and chronic nature of the condition
- Review dietary instructions

PLEURAL EFFUSION

- Pleural effusion is the collection of excess fluid in the pleural space.

- Normally, pleural space contains a small amount of extra-cellular fluid that lubricates the pleural surface.
- Inadequate removal or excess production of pleural fluid results in pleural effusion.

Etiology: May result from various conditions.

Precipitating/risk factors:

- Heart disease
- Hepatic disease with ascites
- Kidney disease
- Pneumonia
- Tuberculosis
- Hypoalbuminemia
- Pulmonary edema
- Systemic infection
- Disseminated lupus
- Chest trauma

S&S:

- Dyspnea, dry cough
- Dullness over the affected area upon percussion
- Pleural friction rub
- Pleuritic pain that worsens with cough or deep breathing
- Tachycardia
- Tachypnea
- Decreased breath sounds

Dx:

- Chest X-ray reveals fluid collection in the dependent area
- With emphysema, cell analysis shows leukocytosis
- Fluid collected through thoracentesis may be tested for the following:
 - lupus antinuclear antibodies, analyzed for color, consistency, acid-fast *Bacillus*, fungal or bacterial cultures, triglycerides (to rule out chylothorax)
- Pleural biopsy may be particularly useful for confirming TB or cancer

Rx:

- Treatment of underlying cause is key
- Thoracentesis
- Drug therapy
 - Antibiotic therapy as indicated
 - Trypsin or streptokinase to decrease thickness of pus and dissolve fibrin clots
 - Closed chest drainage or open chest drainage

Nursing Process Elements

- Administer oxygen as ordered

Assessment Alert

Assess client for decreased breath sounds, a sign of plural effusion

Nursing Intervention Alert

Maintain client in high Fowler's position

- Provide chest tube care
- If the client has open drainage, provide postoperative dressing care
- Administer narcotic and pain reliever as ordered
- Assist with instillation of medication into pleural space

Nursing Intervention Alert

Reposition the client every 15 minutes to distribute drug which has been administered into the pleural space.

Client teaching for self-care

- Discuss and reassure regarding thoracentesis
- Encourage deep breathing and coughing exercise to promote lung expansion

FRACTURED RIBS

- Most commonly fractured ribs are —four to eight, which are protected by the least chest muscle.
- Most common chest injury from a blunt trauma.
- Displaced ribs may cause pleural and lung injury.

Etiology: MVA, accidents, and fight.

Precipitating/risk factors:

- Osteoporosis
- Calcium deficiency

S&S:

- Pain especially on inspiration
- Splitting with shallow respiration

Dx:

- Chest X-ray shows area of fracture
- ABG analysis: elevated PaCO₂ and decreased PaO₂

Rx:

- Pain management
 - Drug therapy for pain
 - Intercostal nerve block to relieve pain

**Nursing Process Elements****Nursing Intervention Alert**

Pain management and preventing complications are goals of care.

- Provide pain relief: administer ordered narcotic and monitor effect
- Position the client semi-Fowler's or Fowler's position
- Monitor client for complications
 - Lung injury
 - Pneumothorax
 - Hemothorax

**Client teaching for self-care**

- Teach side effects of narcotic analgesics

FAIL CHEST

- Fail chest is fracture of several ribs causing instability of the chest wall.
- Chest wall no longer provides the bony structure to maintain adequate ventilation.
- Flail portion of the chest wall moves in opposition to the rest of the chest wall.

Etiology:

- Trauma, sternal rib fracture with possible costochondral separations

Precipitating/risk factors:

- Long-term calcium deficiency

S&S:**Assessment Alert**

Paradoxical chest motion and acute respiratory symptoms are diagnostic signs of flail chest.

- Flail portion of the chest wall is sucked in on inspiration and bulges out on expiration
- Severe dyspnea; rapid, shallow breathing
- Cyanosis, tachycardia, hypotension

Dx:

- Chest X-ray
- ABG analysis:
 - PaO₂ decreased
 - PaCO₂ increased
 - pH decreased

Rx:

- Internal stabilization with a volume-cycled ventilator
- Pain reliever

**Nursing Process Elements****Nursing Intervention Alert**

Airway management and monitoring for signs of shock are critical interventions.

- Monitor VS
- Maintain an open airway
- Suction secretions as needed; note color, consistency, and amount
- Provide mechanical ventilator care
- Encourage turning and deep breathing

**Client teaching for self-care**

- Teach deep breathing technique.
- Importance of turning every 2 hours

PNEUMOTHORAX/HEMOTHORAX

- Pneumothorax
 - Loss of negative intrapleural pressure results in the collapse of the lung.
 - Spontaneous pneumothorax results from the rupture of a bleb.
 - Open pneumothorax occurs when an opening through the chest wall allows air to flow between the pleural space and the outside of the body.
 - Tension pneumothorax results from a buildup of air that can't escape in the pleural space

- Hemothorax
 - Blood accumulates in the pleural space resulting from rupture of pulmonary vessels.
 - Open pneumothorax can lead to hemothorax.

Etiology:

- Ruptured blebs
- Insertion of CVP
- Thoracic surgery
- Thoracentesis or closed pleural biopsy
- Penetrating chest injury
- MVA
- Transbronchial biopsy
- Tubercular lesion or malignant lesion that erodes into the pleural space.

S&S:**Assessment Alert**

Sudden, sharp pain in the chest that increases with respiration and diminished breath sounds unilaterally are diagnostic signs.

- In all types, the surface area for gas exchange is reduced, resulting in hypoxia and hypercapnia
- Dyspnea, tachypnea, subcutaneous emphysema, and cough
- Dullness on chest percussion.
- Weak, rapid pulse; anxiety; diaphoresis

Dx:

- Chest X-ray shows air or fluid collection in the pleural space, tracheal shift, and decreased chest expansion unilaterally.
- PaCO₂ elevated
- PaO₂ decreased
- Lung scan reveals V/Q ratio mismatch

Rx:

- Bed rest or activity as tolerated
- Chest tube to water seal drainage
- Occlusive dressing for open pneumothorax
- Incentive spirometry
- Oxygen therapy
- Analgesic therapy

**Nursing Process Elements**

- Monitor VS q 1 hour initially
- Maintain high-Fowler's position
- Maintain proper chest tube function

LARYNGEAL CANCER

- The majority of the laryngeal malignancies are squamous cell carcinomas.
- Types
 - Supraglottic (also called extrinsic laryngeal cancer): involves the epiglottis and false cords and is likely to produce no symptoms until advanced stages.
 - Glottic (also referred to as intrinsic laryngeal cancer): affects the true vocal cord; the most frequently occurring laryngeal cancer.
- Occurs most often in white men in middle or later life.

Etiology: Chronic irritation.

Risk/precipitating factors:

- Caused by cigarette smoking
- Excessive alcohol consumption
- Chronic laryngitis
- Vocal abuse
- Family history

S&S:**Assessment Alert**

Enlarged cervical lymph nodes are common to both types. Symptoms may vary based on the involvement.

Glottic

- Progressive hoarseness that lasts more than 2-weeks duration.

Supraglottic

- Burning while drinking citrus juices or hot liquids
- Localized throat pain
- Lump in the neck region causing dyspnea and dysphagia leading to weight loss
- Cough
- Hemoptysis
- Muffled voice

Dx:

- Laryngoscopy
- Flexible nasopharyngoscope
- CT scan or MRI

Rx:

- Radiation therapy
- Chemotherapy

- Partial laryngectomy: lesion on the true cord on one side removed along with adjoining tissue. Client is able to talk and has a normal airway postoperatively
- Total laryngectomy
- Radical neck dissection

Nursing Process Elements

- See care of the following interventions:
 - Radiation therapy
 - Chemotherapy
 - Laryngectomy
 - Radical neck dissection

LUNG CANCER

- Lung cancer usually develops within the wall or epithelium of the bronchial tree.
- It is the most common cause of cancer responsible for causing death in men and women.
- Prognosis is generally poor, but varies with cell type and extent of spread at the time of diagnosis.
- Types:
 - Squamous cell (epidermoid) carcinoma.
 - Adenocarcinoma, which involves lining of the lung wall.
 - Oat cell (small cell) carcinoma, cancer of the wall of the major bronchus, round or elongated cell.
 - Large cell (anaplastic) carcinoma, a bronchogenic undifferentiated large cell.
- Early metastasis occurs to other thoracic structures such as the hilar lymph nodes and mediastinum. Distant metastasis may involve the brain, liver, bone, and adrenal gland.

Etiology:

- Tobacco smoking: accounts for majority of lung cancers and is closely associated with all histologic types
- Genetic predisposition
- Exposure to carcinogenic industrial or air pollutions such as asbestos, uranium, coal dust, arsenic, and radioactive dust

S&S:

- With large cell cancer and adenocarcinoma, clients present with fever, weakness, weight loss, anorexia, shoulder pain, and other bone and joint pain.
- With small cell (Oat cell) and squamous cell carcinoma, clients present with respiratory symptoms such as smoker's cough, hoarseness, wheezing, dyspnea, hemoptysis, chest pain, flushing, diarrhea, cramps, skin lesions, and palpitations
- S&S of hypercalcemia, and S&S of Cushing's syndrome occur with squamous cell carcinoma
- Gynecomastia with large cell carcinoma

Dx:

- Chest X-ray shows advanced lesions
- Bronchoscopy can locate the tumor site and provide material for cytologic and histologic examination
- Needle biopsy detects peripheral tumors
- Tissue biopsy detects metastasis
- Thoracentesis allows chemical and cytologic examination
- Bone scan, computed tomography scan of the brain, liver function test, gallium scan of the liver, spleen, and bone to locate metastasis

Rx:

- Radiation: radiation therapy is usually recommended for early stage. Preoperative radiation therapy is used to reduce the size of the tumor to allow surgical resection. Prophylactic cranial irradiation may be used to prevent brain metastasis
- Chemotherapy:
 - A combination of fluoruracil, vincristine, and mitomycin induces remission of adenocarcinoma
 - For small cell carcinoma, a combination of cyclophosphamide, doxorubicin, and vincristine has proven effective
- Surgical intervention: surgery is the main intervention for squamous, adenocarcinoma, and large cell carcinoma

Nursing Process Elements

Nursing Intervention Alert

Eventless recovery from treatment and preventing complications are the goals of nursing care.

- Provide psychological support to the client and family
- Provide supportive care to the client

Assessment Alert

Disease is usually well developed by the time clients present with symptoms.

- Take measures to minimize complications and promote recovery from surgery, radiation, or chemotherapy
- Follow strict infection control protocol
- Treatment regime, the need for pulmonary hygiene and follow up
- Home oxygen therapy
- Prevention of respiratory infection
- Importance of medical treatment of upper respiratory tract infection

Client teaching for self-care

- Behavior/lifestyle modification especially toward smoking/avoidance of cigarette smoke

WORKSHEET

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Decreased breath sounds accompanied by pleuritic pain that worsens with coughing or deep breathing is consistent with a diagnosis of _____.
2. The diagnostic test that can identify early *Pneumocystis carinii* pneumonia is a ____.
3. *Legionella* bacteria are found in _____.
4. To minimize a client's reaction to amphotericin B, _____ may be given before the amphotericin B is administered.
5. Barking cough and inspiratory stridor are classic symptoms of _____.
6. A lung scan done on a client with a pneumothorax shows a _____.
7. A PPD must be read in _____ hours.
8. To decrease the risk of SIDS, infants should sleep in the _____ position.
9. TB is spread by _____.
10. An elderly confused client with an impaired gag reflex is at high risk for _____ pneumonia.
11. Clients with a pleural effusion should be placed in ____ position.
12. When using an inhaler, it should be held ____ inches away from the mouth.
13. To remove a foreign body from the lower airway, the _____ maneuver is performed.
14. The four cardinal S&S of bacterial pneumonia are _____, _____, _____, and _____.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|------------------|------------------|
| 1. With squamous cell carcinoma of the lung, the client needs to be monitored for Cushing's syndrome and hypocalcemia. | <u> </u> T | <u> </u> F |
| 2. A primary therapeutic goal for a child with bronchiolitis is maintaining a patent airway. | <u> </u> T | <u> </u> F |
| 3. Morphine is the drug of choice for the pleuritic chest pain that accompanies pneumonia. | <u> </u> T | <u> </u> F |
| 4. Epiglottitis is primarily a problem of expiration. | <u> </u> T | <u> </u> F |
| 5. The hilar lymph nodes are a site of early metastasis of lung cancer. | <u> </u> T | <u> </u> F |
| 6. The diet for a client with pneumonia should be high calorie with increased fluids. | <u> </u> T | <u> </u> F |
| 7. Trypsin is given to a client with a pleural effusion for the purpose of decreasing the viscosity of pus and dissolving fibrin clots. | <u> </u> T | <u> </u> F |
| 8. Removal of a foreign object from the lower airway is less of an emergency than removing one from the upper airway. | <u> </u> T | <u> </u> F |
| 9. Inspiratory pain, splinting, and shallow respirations are characteristically seen in clients with fractured ribs. | <u> </u> T | <u> </u> F |
| 10. Meeting resistance on trying to pass an N/G tube into the stomach is suggestive of a tracheal esophageal defect. | <u> </u> T | <u> </u> F |
| 11. The nurse should monitor clients with fractured ribs for pneumothorax. | <u> </u> T | <u> </u> F |
| 12. Paradoxical chest motion is characteristic of hemothorax. | <u> </u> T | <u> </u> F |
| 13. Excessive alcohol consumption is associated with the occurrence of laryngeal cancer. | <u> </u> T | <u> </u> F |
| 14. Putting an infant into a steamy bathroom at home can be an effective measure in the management of croup. | <u> </u> T | <u> </u> F |
| 15. Semi-Fowler's position for an infant with a T/E defect is important because it aids in expectoration of mucus. | <u> </u> T | <u> </u> F |
| 16. Bronchiolitis is an infection caused by gram-negative bacteria. | <u> </u> T | <u> </u> F |
| 17. Cough, which is initially non-productive and then produces grayish, blood streaked, nonpurulent sputum is characteristic of aspiration pneumonia. | <u> </u> T | <u> </u> F |
| 18. Sputum specimens from a client with TB should be labeled AFB precautions. | <u> </u> T | <u> </u> F |
| 19. Clients with TB should be in a positive pressure room with the door closed at all times. | <u> </u> T | <u> </u> F |
| 20. Prematurity is a risk factor for apnea of infancy. | <u> </u> T | <u> </u> F |
| 21. Preventing an infant from overheating during sleep reduces the risk of SIDS. | <u> </u> T | <u> </u> F |

| | | |
|---|------------------|------------------|
| 22. Sudden change in temperature can induce an asthma attack in susceptible persons. | <u> </u> T | <u> </u> F |
| 23. A goal of therapy during an acute asthma attack is the relief of bronchoconstriction. | <u> </u> T | <u> </u> F |
| 24. Increased RBC count is an expected finding in clients with pneumonia. | <u> </u> T | <u> </u> F |
| 25. Overuse of nebulized asthma medications increases the need for medication but presents no serious health risks. | <u> </u> T | <u> </u> F |
| 26. Corticosteroids are prescribed for asthma clients for their bronchodilating effect. | <u> </u> T | <u> </u> F |
| 27. Dyspnea is a prominent symptom of emphysema. | <u> </u> T | <u> </u> F |
| 28. Pursed-lip breathing improves ventilation. | <u> </u> T | <u> </u> F |
| 29. Bronchiectasis is typically unilateral. | <u> </u> T | <u> </u> F |
| 30. Mucous plugs, which are common in clients with COPD, can cause atelectasis. | <u> </u> T | <u> </u> F |
| 31. Clients with atelectasis have a decreased PaCO ₂ . | <u> </u> T | <u> </u> F |
| 32. Clients with atelectasis should be taught to use the incentive spirometer for 10–20 breaths per hour while awake. | <u> </u> T | <u> </u> F |
| 33. After postural drainage, mouth care is essential. | <u> </u> T | <u> </u> F |
| 34. Epiglottitis may lead to respiratory arrest. | <u> </u> T | <u> </u> F |
| 35. A congenital deficiency of alpha-antitrypsin predisposes to emphysema in adulthood. | <u> </u> T | <u> </u> F |

APPLICATION QUESTIONS

- Following insertion of a CVP line, a client suddenly complains of a sharp pain in the right chest that worsens on inspiration. Which assessment data would support the conclusion that the client had developed a pneumothorax?
 - Tracheal shift with unilateral decreased chest expansion
 - Increased PaCO₂ and decreased PaO₂
 - Crackles on affected side
 - Hyporesonance on affected side
- What advice should be given to a client's spouse who apologizes for his hoarse voice saying he has had the problem for almost a month and it just seems to get worse not better?
 - "Gargle with salt and warm water three to four times per day."
 - "If blood-streaked sputum develops, go to a clinic right away."
 - "Have it checked without delay."
 - "Rest your voice and drink a lot of fluid."
- Which would be the priority expected outcome when caring for an infant with croup?
 - Infant remains free of infection.
 - Infant takes clear fluids as prescribed.
 - Infant's temperature returns to normal within 24 hours of antibiotic therapy.
 - Infant remains free of laryngospasm.
- Which client would be most at risk for developing aspiration pneumonia?
 - An infant with a tracheoesophageal defect repair
 - An alert 10-year-old with cystic fibrosis

(continued)

- c. A 50-year-old with fractured ribs and a fractured leg from a MVA
 - d. A confused 75-year-old with a CVA
5. When teaching at a health fair, the nurse is asked if there is really a relationship between tobacco smoke and lung cancer. Which information should serve as the basis for the nurse's response?
- a. There is a relationship and it is between certain types of lung cancer and both smoking and being exposed to second-hand smoke.
 - b. Exposure to carcinogens such as asbestos and uranium account for a greater portion of lung cancer than does tobacco use.
 - c. Radon takes precedence over tobacco smoke as a factor responsible for lung cancer.
 - d. Tobacco smoking is associated with the majority of lung cancers of all types.
6. Management of an acute attack of asthma might include administration of which medications? Mark all that apply.
- a. Subcutaneous epinephrine
 - b. Inhaled albuterol
 - c. Oral corticosteroids
 - d. IV theophylline
 - e. Inhaled cromolyn sodium
7. When assessing a client with emphysema, which finding would the nurse conclude needed further investigation because it is not an expected characteristic of the disease?
- a. Pursed-lip breathing
 - b. Persistent productive cough
 - c. Grunting at the end of expiration
 - d. Prolonged expiration
8. Which laboratory results are consistent with long term COPD? Mark all that apply.
- a. Erythrocytosis
 - b. Hypoxemia
 - c. Hypercapnia
 - d. Leukopenia
9. When should a newborn be assessed for a T/E defect?
- a. Before the first feeding
 - b. After the first cry
 - c. As soon as meconium is passed
 - d. As soon as body temperature is stable
10. How should the nurse interpret the assessment finding that a client with bronchiectasis expectorated three cupfuls of foul-smelling mucopurulent secretions in the last 24 hours?
- a. A secondary infection has developed.
 - b. The disease process is resolving.
 - c. Client is exhibiting usual symptoms of the disease.
 - d. Chest physical therapy needs to be adjusted to client's need.
11. When teaching a client about prevention of Legionnaires' disease, instructions for avoiding contact with the infecting organisms should be based on which fact?
- a. *Legionella* is found in soil.
 - b. *Legionella* is found in water.
 - c. *Legionella* is found in bird feces.
 - d. *Legionella* is found in roach debris.
12. How should an infant awaiting repair of a T/E fistula be positioned?
- a. Side lying
 - b. Dorsal recumbent
 - c. Semi-Fowler's
 - d. Trendelenburg
13. How should the nurse interpret the finding of a "barrel chest" on examination of a client?
- a. Sign of long-term hypoxia
 - b. Sign of chronic air trapping
 - c. Sign of excess mucus production
 - d. Sign of congenital bronchospasm
14. When teaching about the prevention of SIDS, which is an appropriate guideline to be included?
- a. Always place a baby on the side during naps and at night.
 - b. Place babies on a soft sleep surface that is covered with a fitted sheet.
 - c. Do not smoke during pregnancy or near babies.
 - d. Do not let a baby get chilled during sleep.
15. Report of which activity would suggest the possibility of histoplasmosis in a client presenting with cough, fever, joint pain, and fatigue?
- a. Swallowing water from a hose
 - b. Eating rare meat
 - c. Cleaning dirt from a bird roost
 - d. Handling unwashed fruits
16. Which finding when a PPD is read 2 1/2 days after it is planted indicates a positive reaction?
- a. Reddened area 10 mm in diameter
 - b. Indurated area 12 mm in diameter
 - c. Blistered area 4 mm in diameter
 - d. Blanched area of at least 8 mm in diameter

17. The nurse should expect to include bed rest, a high-calorie diet, and extra fluids in the care plan for a client with which disorder?
- Cystic fibrosis
 - Emphysema
 - Pneumonia
 - Lung cancer
18. An infant with a T/E defect requires careful assessment for abnormalities affecting which other structure(s)?
- Brain
 - Kidneys
 - Liver
 - Lungs
19. Which is a characteristic assessment finding in clients with bacterial pneumonia?
- Increased PaO₂
 - Rust-colored sputum
 - Expiratory wheeze
 - Nonproductive cough
20. In what way are croup and laryngotracheobronchitis significantly similar?
- Client is afebrile with both.
 - Both are viral in origin.
 - Age range of susceptibility is the same.
 - Speed of onset is identical.
21. A client with histoplasmosis is receiving amphotericin B. Which S&S should the nurse interpret as a common toxic reaction to the drug?
- Jaundice
 - Tinnitus
 - Irritability
 - Fever
22. When assessing a client with a pleural effusion, which would be an expected finding?
- Expiratory wheeze
 - Productive cough
 - Decreased breath sounds
 - Stridor
23. Which would be the position of choice for a client with a pleural effusion?
- Side lying with affected side down
 - Side lying with affected side up
 - High-Fowler's position
 - Low-Fowler's position
24. When assessing a client with fractured ribs, which ABG values would be expected?
- PaO₂ 89 mm Hg, PaCO₂ 41 mm Hg
 - PaO₂ 101 mm Hg, PaCO₂ 50 mm Hg
 - PaO₂ 94 mm Hg, PaCO₂ 35 mm Hg
 - PaO₂ 76 mm Hg, PaCO₂ 48 mm Hg
25. On assessing a client brought into emergency following a motor vehicle accident, the nurse notes that an area of the lateral, right chest bulges on expiration and appears to be sucked in on inspiration. Which problem should the nurse suspect?
- Flail chest
 - Atelectasis
 - Pneumonia
 - Hemothorax
26. Which assessment data would support the conclusion that the client had likely developed a pneumothorax?
- Sudden sharp pain in the chest which increases on inspiration
 - Production of blood-streaked sputum
 - Stridor with diaphoresis
 - Prolonged inspiration with wet rales

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

Fill in the blanks spaces with the correct word. or phrase to complete each statement.

- Decreased breath sounds accompanied by pleuritic pain that worsens with coughing or deep breathing is consistent with a diagnosis of pleural effusion.

(continued)

2. The diagnostic test that can identify early *Pneumocystis carinii* pneumonia is a V/Q scan.
3. *Legionella* bacteria are found in water.
4. To minimize a client's reaction to amphotericin B, Benadryl may be given before the amphotericin B is administered.
5. Barking cough and inspiratory stridor are classic symptoms of laryngotracheobronchitis.
6. A lung scan done on a client with a pneumothorax shows a V/Q mismatch.
7. A PPD must be read in 48–72 hours.
8. To decrease the risk of SIDS, infants should sleep in the supine position.
9. TB is spread by droplets.
10. An elderly confused client with an impaired gag reflex is at high risk for aspiration pneumonia.
11. Clients with a pleural effusion should be placed in Fowler's position.
12. It is important to assess for and identify a T/E defect promptly because of the risk of pneumonia developing from fluids and secretions being aspirated into the lungs.
13. When using an inhaler, it should be held 2 in. away from the mouth.
14. To remove a foreign body from the lower airway, the Heimlich maneuver is performed.
15. The four cardinal S&S of bacterial pneumonia are cough, sputum production, pleuritic chest pain, and fever.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. With squamous cell carcinoma of the lung, the client needs to be monitored for Cushing's syndrome and hypocalcemia. *False*
The client needs to be monitored for Cushing's syndrome and hypercalcemia.
2. A primary therapeutic goal for a child with bronchiolitis is maintaining a patent airway. *True*
3. Morphine is the drug of choice for the pleuritic chest pain that accompanies pneumonia. *False*
Morphine can depress respirations; codeine is the drug of choice.
4. Epiglottitis is primarily a problem of expiration. *False*
It is an upper airway obstruction and therefore is an inspiratory problem.
5. The hilar lymph nodes are a site of early metastasis of lung cancer. *True*

6. The diet for a client with pneumonia should be high calorie with increased fluids. *True*
7. Trypsin is given to a client with a pleural effusion for the purpose of decreasing the viscosity of pus and dissolving fibrin clots. *True*
8. Removal of a foreign object from the lower airway is less of an emergency than removing one from the upper airway. *False*
The greater emergency is a foreign object in the lower airway because it is blocking the only passage for air to enter the lungs.
9. Inspiratory pain, splinting, and shallow respirations are characteristically seen in client's with fractured ribs. *True*
10. Meeting resistance on trying to pass an N/G tube into the stomach is suggestive of a tracheal esophageal defect. *True*
11. The nurse should monitor clients with fractured ribs for pneumothorax. *True*
12. Paradoxical chest motion is characteristic of hemothorax. *False*
Paradoxical chest movement is characteristic of flail chest.
13. Excessive alcohol consumption is associated with the occurrence of laryngeal cancer. *True*
14. Putting an infant into a steamy bathroom at home can be an effective measure in the management of croup. *True*
15. Semi-Fowler's position for an infant with a T/E defect is important because it aids in expectoration of mucus. *False*
It is important because it eases respiratory effort and prevents reflux of gastric contents into the trachea.
16. Bronchiolitis is an infection caused by gram-negative bacteria. *False*
Bronchiolitis is a viral infection.
17. Cough which is initially nonproductive and then produces grayish, blood-streaked, nonpurulent sputum is characteristic of aspiration pneumonia. *False*
It is characteristic of Legionnaires' disease.
18. Sputum specimens from a client with TB should be labeled AFB precautions. *True*
19. Clients with TB should be in a positive pressure room with the door closed at all times. *False*
The client with TB should be in a negative pressure room.
20. Prematurity is a risk factor for apnea of infancy. *True*
21. Preventing an infant from overheating during sleep reduces the risk of SIDS. *True*
22. Sudden change in temperature can induce an asthma attack in susceptible persons. *True*
23. A goal of therapy during an acute asthma attack is the relief of bronchoconstriction. *True*
24. Increased RBC count is an expected finding in clients with pneumonia. *False*
An increased RBC count is expected in chronic respiratory diseases such as emphysema which are characterized by hypoxia.
25. Over use of nebulized asthma medications increases the need for medication but presents no serious health risks. *False*
Overuse can weaken response to medications but can also lead to cardiac arrest.

(continued)

26. Corticosteroids are prescribed for asthma clients for their bronchodilating effect. *False*
Corticosteroids are given to clients with asthma for their anti-inflammatory effect.
27. Dyspnea is a prominent symptom of emphysema. *True*
28. Pursed-lip breathing improves ventilation. *True*
29. Bronchiectasis is typically unilateral. *False*
Bronchiectasis is typically bilateral affecting the basilar segments of the lower lobes of the lungs.
30. Mucous plugs, which are common in clients with COPD, can cause atelectasis. *True*
31. Clients with atelectasis have a decreased PaCO₂. *False*
Clients with atelectasis have a decreased PaO₂ because of the decrease in aerated lung tissue.
32. Clients with atelectasis should be taught to use the incentive spirometer for 10–20 breaths per hour while awake. *True*
33. After postural drainage, mouth care is essential. *True*
34. Epiglottitis may lead to respiratory arrest. *True*
35. A congenital deficiency of alpha-antitrypsin predisposes to emphysema in adulthood. *True*

APPLICATION ANSWERS

1. Following insertion of a CVP line, a client suddenly complains of a sharp pain in the right chest that worsens on inspiration. Which assessment data would support the conclusion that the client had developed a pneumothorax?
- Tracheal shift with unilateral decreased chest expansion
 - Increased PaCO₂ and decreased PO₂
 - Crackles on affected side
 - Hyporesonance on affected side

Rationale

Correct answer: a.

As air or fluid collects in the pleural space, the trachea is forced out of the midline toward the unaffected side. Simultaneous expansion of the lung and chest on the affected side is inhibited causing a unilateral decrease. Hypoxia and hypercapnia occur with pneumothorax so PaCO₂ is decreased with pneumothorax and O₂ is increased. No air is entering affected area so no breath sounds are heard. Hyperresonance occurs on affected side.

2. What advice should be given to a client's spouse who apologizes for his hoarse voice saying he has had the problem for almost a month and it just seems to get worse not better?
- "Gargle with salt and warm water three to four times per day."
 - "If blood-streaked sputum develops, go to a clinic right away."
 - "Have it checked without delay."
 - "Rest your voice and drink a lot of fluid."

Rationale

Correct answer: c.

Progressive hoarseness of more than 2-weeks duration is a symptom of glottic laryngeal cancer. Therefore, the client should be advised to see a physician right away. Telling the client to gargle or suggesting rest, although soothing, does not address the basic concern.

3. Which would be the priority expected outcome when caring for an infant with croup?
- Infant remains free of infection.
 - Infant takes clear fluids as prescribed.

- c. Infant's temperature returns to normal within 24 hours of antibiotic therapy.
- d. Infant remains free of laryngospasm.

Rationale

Correct answer: d.

Croup is a condition that results from acute obstruction at or just below the larynx. Laryngospasm, which is the spasmodic closure of the larynx produces the brassy or barking cough, hoarseness, and respiratory distress that are the S&S of croup and therefore must be prevented. Avoiding infection is a desirable goal but it is not the priority for this infant who already has experienced croup. Similarly, clear fluids are prescribed for infants with croup but laryngospasm that can block the airway is a greater priority than fluid intake. Infants with croup are typically afebrile and since croup is viral, not bacterial, in origin antibiotics are not needed.

- 4. Which client would be most at risk for developing aspiration pneumonia?
 - a. An infant with a tracheoesophageal defect repair
 - b. An alert 10-year old with cystic fibrosis
 - c. A 50-year old with fractured ribs and a fractured leg from a MVA
 - d. A confused 75-year old with a CVA

Rationale

Correct answer: d.

Confusion and impaired gag reflex are two of the major risk factors for aspiration pneumonia. Following a repair, an infant is not at particularly high risk for aspiration nor is an alert 10-year old with cystic fibrosis. A 50-year old with fractured ribs and a broken leg has some degree of immobility but no other risk factors.

- 5. When teaching at a health fair, the nurse is asked if there is really a relationship between tobacco smoke and lung cancer. Which information should serve as the basis for the nurse's response?
 - a. There is a relationship and it is between certain types of lung cancer and both smoking and being exposed to second-hand smoke.
 - b. Exposure to carcinogens such as asbestos and uranium account for a greater portion of lung cancer than does tobacco use.
 - c. Radon takes precedence over tobacco smoke as a factor responsible for lung cancer.
 - d. Tobacco smoking is associated with the majority of lung cancers of all types.

Rationale

Correct answer: d.

Tobacco smoking has been shown to be related to the development of all types of lung cancer, not just certain types. Second-hand smoke is also a risk factor as is expo-

sure to chemicals including asbestos, uranium, and radon but they do not account for more cases of lung cancer than tobacco use.

- 6. Management of an acute attack of asthma might include administration of which medications? Mark all that apply.
 - a. Subcutaneous epinephrine
 - b. Inhaled albuterol
 - c. Oral corticosteroids
 - d. IV theophylline
 - e. Inhaled cromolyn sodium

Rationale

Correct answers: a, b, and d.

Epinephrine stimulates the beta-2 adrenergic receptors on the respiratory smooth muscle resulting in bronchodilation. Albuterol is a short-acting, beta 2 agonist bronchodilator. Theophylline is a methylxanthine bronchodilator. Subcutaneous administration or inhalation yields a rapid onset of action. Oral corticosteroids are used for persistent wheezing not for emergency management of an acute attack. Cromolyn sodium is not used for acute attacks; it is a mast cell stabilizer whose effectiveness depends on regular use.

- 7. When assessing a client with emphysema, which finding would the nurse conclude needed further investigation because it is not an expected characteristic of the disease?
 - a. Pursed-lip breathing
 - b. Persistent productive cough
 - c. Grunting at the end of expiration
 - d. Prolonged expiration

Rationale

Correct answer: b.

Persistent productive cough is not a symptom of emphysema rather there is minimal cough and sputum production. Clients with emphysema automatically use pursed-lip breathing to facilitate exhalation, which is prolonged due to airway narrowing or collapse on expiration and ends with a grunt.

- 8. Which laboratory results are consistent with long-term COPD? Mark all that apply.
 - a. Erythrocytosis
 - b. Hypoxemia
 - c. Hypercapnia
 - d. Leukopenia

Rationale

Correct answers: a, b, and c.

COPD is characterized by a decrease in oxygen and increase in carbon dioxide so hypoxemia and hypercapnia

(continued)

are expected. Erythrocytosis or an increase in RBCs also occurs as a compensatory effort to maintain tissue oxygenation. It is frequently seen as PaO₂ levels fall below 55 mm Hg.

9. When should a newborn be assessed for a T/E defect?
 - a. Before the first feeding
 - b. After the first cry
 - c. As soon as meconium is passed
 - d. As soon as body temperature is stable

Rationale

Correct answer: a.

Assessment for T/E defect should be done immediately after birth and before the first feeding. Usually, sterile water is given first since the infant may swallow normally but suddenly coughs and struggles and fluid is aspirated or returned through the nose and mouth. Presence of frothy saliva in the mouth, difficulty handling secretions, or periods of unexplained cyanosis require that an infant be referred immediately for medical evaluation for T/E defect.

10. How should the nurse interpret the assessment finding that a client with bronchiectasis expectorated three cupfuls of foul-smelling mucopurulent secretions in the last 24 hours?
 - a. A secondary infection has developed.
 - b. The disease process is resolving.
 - c. Client is exhibiting usual symptoms of the disease
 - d. Chest physical therapy needs to be adjusted to client's need.

Rationale

Correct answer: c.

Bronchiectasis is characterized by a chronic cough with production of several cupfuls of foul-smelling mucopurulent sputum per day. Production of large amounts of this type of sputum does not indicate suprainfection, disease resolution or that chest physical therapy needs to be changed.

11. When teaching a client about prevention of Legionnaires' disease, instructions for avoiding contact with the infecting organisms should be based on which fact?
 - a. *Legionella* is found in soil.
 - b. *Legionella* is found in water.
 - c. *Legionella* is found in bird feces.
 - d. *Legionella* is found in roach debris.

Rationale

Correct answer: b.

Legionella bacillus is found in water; so a person can become infected by aspirating contaminated water or inhaling spray from a shower of contaminated water. Tetanus is found in soil and the organism causing histoplasmosis is found in bird feces.

12. How should an infant awaiting repair of a T/E fistula be positioned?
 - a. Side lying
 - b. Dorsal recumbent
 - c. Semi-Fowler's
 - d. Trendelenburg

Rationale

Correct answer: c.

An infant awaiting repair of a T/E fistula should be positioned in semi-Fowler's position to decrease the risk of stomach contents being regurgitated and entering the trachea. Side lying and dorsal recumbent positions do not contribute to the pull of gravity in preventing backflow of stomach contents into the esophagus and Trendelenburg position in which the head is lower than the body actually encourages the backflow.

13. How should the nurse interpret the finding of a "barrel chest" on examination of a client?
 - a. Sign of long-term hypoxia
 - b. Sign of chronic air trapping
 - c. Sign of excess mucus production
 - d. Sign of congenital bronchospasm

Rationale

Correct answer: b.

Barrel chest, a condition in which the anterior–posterior diameter of the chest is greater than normal results from hyperinflation due to chronic air trapping.

14. When teaching about the prevention of SIDS, which is an appropriate guideline to be included?
 - a. Always place a baby on the side during naps and at night.
 - b. Place babies on a soft sleep surface that is covered with a fitted sheet.
 - c. Do not smoke during pregnancy or near babies.
 - d. Do not let a baby get chilled during sleep.

Rationale

Correct answer: c.

Exposure of a fetus/infant to cigarette smoke is believed to increase the risk of SIDS. a, b, and d are not correct guidelines because babies should be placed on their back not on their sides to sleep; babies should sleep on firm not soft surfaces; and overheating, not chilling, predisposes to SIDS.

15. Report of which activity would suggest the possibility of histoplasmosis in a client presenting with cough, fever, joint pain, and fatigue?
 - a. Swallowing water from a hose
 - b. Eating rare meat
 - c. Cleaning dirt from a bird roost
 - d. Handling unwashed fruits

Rationale

Correct answer: c.

The causative organism of histoplasmosis is the fungus *Histoplasma capsulatum*, which is found in bird feces so cleaning a bird roost is a source of exposure. It is not passed person to person. Neither is it contracted by swallowing water, eating rare meat, or handling unwashed fruit.

16. Which finding when a PPD is read 2 1/2 days after it is planted indicates a positive reaction?
- Reddened area 10 mm in diameter
 - Indurated area 12 mm in diameter
 - Blistered area 4 mm in diameter
 - Blanched area of at least 8 mm in diameter

Rationale

Correct answer: b.

Ten mm or more of induration is highly significant for past or present infection with the tubercle bacillus. Erythema alone does not indicate a positive result. Blistering or blanching do not indicate a positive result.

17. The nurse should expect to include bed rest, a high-calorie diet, and extra fluids in the care plan for a client with which disorder?
- Cystic fibrosis
 - Emphysema
 - Pneumonia
 - Lung cancer

Rationale

Correct answer: c.

Bed rest, a high-calorie diet and extra fluids are essential parts of the therapeutic plan for the client with pneumonia. For cystic fibrosis, a high-calorie, high-protein, normal-fat diet is desirable but bed rest is not required; in fact, physical exercise is encouraged. For emphysema, a high-protein, high-calorie, vitamin-rich diet is encouraged; bed rest is not necessary. Clients with lung cancer need adequate nutrition but not bed rest.

18. An infant with a T/E defect requires careful assessment for abnormalities affecting which other structure(s)?
- Brain
 - Kidneys
 - Liver
 - Lungs

Rationale

Correct answer: b.

Associated anomalies with T/E defects involve GU, cardiovascular, vertebral, anorectal, and limb structures. Anomalies of the brain, liver, and lungs are not associated.

19. Which is a characteristic assessment finding in clients with bacterial pneumonia?
- Increased PaO₂
 - Rust-colored sputum
 - Expiratory wheeze
 - Nonproductive cough

Rationale

Correct answer: b.

Rust-colored sputum, pleuritic pain, cough, and fever are classic signs of bacterial pneumonia. PaO₂ is decreased secondary to consolidation in the lung. An expiratory wheeze is characteristic of asthma not pneumonia.

20. In what way are croup and laryngotracheobronchitis significantly similar?
- Client is afebrile with both.
 - Both are viral in origin.
 - Age range of susceptibility is the same.
 - Speed of onset is identical.

Rationale

Correct answer: b.

Both diseases are viral in origin. With croup, children are afebrile; with laryngotracheobronchitis, children have fever. Croup primarily affects children aged 6 months to 3 years and laryngotracheobronchitis affects children under 5 years of age. Onset of croup is sudden and onset of laryngotracheobronchitis is more gradual.

21. A client with histoplasmosis is receiving amphotericin B. Which S&S should the nurse interpret as a common toxic reaction to the drug?
- Jaundice
 - Tinnitus
 - Irritability
 - Fever

Rationale

Correct answer: d.

Toxic effects of amphotericin B include anorexia, chills, fever, and renal failure.

22. When assessing a client with a pleural effusion, which would be an expected finding?
- Expiratory wheeze
 - Productive cough
 - Decreased breath sounds
 - Stridor

Rationale

Correct answer: c.

Decreased breath sounds are a major finding associated with pleural effusion. Expiratory wheeze does not occur with pleural effusion; it occurs with asthma. Cough

(continued)

associated with pleural effusion is dry, not productive. Laryngotracheobronchitis is the most common cause of stridor in children.

23. Which would be the position of choice for a client with a pleural effusion?
- Side lying with affected side down
 - Side lying with affected side up
 - High-Fowler's position
 - Low-Fowler's position

Rationale

Correct answer: c.

High-fowler's position facilitates chest expansion and eases work of respiration.

24. When assessing a client with fractured ribs, which ABG values would be expected?
- PaO₂ 89 mm Hg, PaCO₂ 41 mm Hg
 - PaO₂ 101 mm Hg, PaCO₂ 50 mm Hg
 - PaO₂ 94 mm Hg, PaCO₂ 35 mm Hg
 - PaO₂ 76 mm Hg, PaCO₂ 48 mm Hg

Rationale

Correct answer: d.

Hypoxemia and Hypercapnia are expected. Hypoxemia is reflected in the PaO₂ (partial pressure of oxygen dissolved in the blood), the normal value of which is 80–100 mm Hg. Hypercapnia is reflected in the PaCO₂ whose normal range is 35–45 mm Hg.

25. On assessing a client brought into emergency following a motor vehicle accident, the nurse notes that an area of the lateral, right chest bulges on expiration and appears to be sucked in on inspiration. Which problem should the nurse suspect?

- Flail chest
- Atelectasis
- Pneumonia
- Hemothorax

Rationale

Correct answer: a.

Flail chest occurs when multiple contiguous ribs are fractured in more than one place resulting in free-floating rib pieces. This free-floating section is pulled in during inspiration and bulges outward during expiration (paradoxical movement) impeding both intake and outflow of air from the lungs. Paradoxical movement does not occur with atelectasis, pneumonia, or hemothorax. With atelectasis, there are decreased breath sounds over the affected area. With a large hemothorax, decreased chest movement on the affected side and decreased or absent breath sounds occur.

26. Which assessment data would support the conclusion that the client had likely developed a pneumothorax?
- Sudden, sharp pain in the chest that increases on inspiration
 - Production of blood-streaked sputum
 - Stridor with diaphoresis
 - Prolonged inspiration with wet rales

Rationale

Correct answer: a.

Sudden, sharp chest pain that increases on inspiration and unilaterally diminished breath sounds are classic signs of pneumothorax. Blood-streaked sputum, stridor, diaphoresis, prolonged inspiration, and wet rales are not S&S of pneumothorax.

Test Plan Category:

Physiological Integrity

MENINGITIS

- Meningitis is an acute inflammation of the meninges surrounding the brain and spinal cord.

Etiology: It is most often caused by a viral infection, but it can also be caused by a bacterial, amebic, or fungal infection. Bacterial infections are more life threatening.

Risk factors:

- Fall, winter, or early spring months
- Poor hand hygiene, sewage infected water, and individuals in crowded areas or dorms that have not been immunized against meningococcal, pneumococcal, Hib, and TB bacteria
- The disease may follow a viral infection occurring elsewhere in the body

PEDS

Bacterial meningitis is common in infancy and young children as the immature immune system is unable to isolate the infection in the body and it will spread to the meninges. With the advent and use of vaccines against *H. influenzae* and pneumococcal, the incidence of bacterial meningitis in children has decreased.

S&S:

- Severe headache
- High fever
- Lethargy, irritability, and muscular weakness
- Nausea, vomiting, stomach cramps, and diarrhea
- Stiff neck and nuchal rigidity
- Photophobia
- Decreased level of consciousness
- Rash
- Bulging fontanel
- High-pitched, moaning cry in infants
- Seizures—in 20% of cases
- Coma—rare, but carries poor prognosis

Assessment Alert

Distinction between meningitis and encephalitis needs to be made. Clients with meningitis have no abnormalities in brain function, but changes are common in clients with encephalitis.

PEDS

Assessment Alert

Any child who develops a purpuric rash along with symptoms of meningitis may have

meningococemia, a virulent form of meningitis. This child may develop disseminated intravascular coagulation. Meningococemia has a high mortality rate. Individuals who have been exposed to this child will need to contact their physicians for follow-up care.

Dx: Diagnosis is made from clinical S&S and diagnostic information. Positive Kernig's and Brudzinski signs correlate with meningitis. Most common diagnostic tools are spinal tap, to assess cerebrospinal fluid, and CT scan or MRI to assess for edema, hydrocephalus, or bleeding in the brain. Blood tests are used to assess for an infectious process and determine causative agent; skull X-rays may be done to assess for sinus infection.

Rx: Treatment depends upon type of meningitis. It is aimed at symptomatic relief, rest, and treating disease process. Prevention is the best cure.

- Drug therapy.
 - Diuretics—mannitol (Osmitol) or furosemide (Lasix) to decrease cerebral edema.
 - Antileptics—used to treat or prevent seizures. (See section “Seizures” for description of antileptic medication.)
 - Antibiotics—cephalosporin (cefotaxime [Claforan], ceftriaxone [Rocephin], cefuroxime [Ceftin], ceftizoxime [Cefizox], ceftazidime [Ceptaz]), ampicillin, or penicillin are used due to their ability to cross the blood–brain barrier and get to the infectious process in bacterial meningitis. Antibiotics are only used for bacterial infections.
- Hypothermia, acetaminophen (Tylenol), or aspirin.
- Codeine to treat severe headache, muscle, and joint pain.
- Sedatives to decrease irritability and restlessness.

Nursing Process Elements

Supportive therapy and prevention of secondary infection are treatment goals.

- Clear liquids and advance as tolerated. Nutritional supplements may be necessary. Monitor intake and output at least every 8 hours.
- Assess neurological status and for S&S of increasing intracranial pressure. Notify physician immediately if the pressure occurs.
- Provide intravenous fluids for administration of medication and fluid support.
- Provide pain medication as needed for headache, muscle, and joint pain.

- Monitor vital signs and give acetaminophen (Tylenol) or aspirin for fever as directed.
- Monitor for seizures and contact physician if occur.
- Keep room quiet and dim lights to allow for frequent rest periods throughout the day.
- Assist to position of comfort with head of bed slightly elevated.
- Increase fluids and offer nutritional supplements throughout the day.

Client teaching for self-care

- Stay away from individuals who are ill.
- Use good hand washing techniques at all times.
- Have your children immunized against Hib and tetanus.
- Drink plenty of liquids daily.
- Maintain high-protein, high-calorie diet to allow for recovery.
- Use range of motion and warm baths to ease stiff, sore muscles.
- Increase activity as tolerated.
- Get at least 8 hours sleep per night and rest during the day.
- Take your medication as directed and do not discontinue abruptly.
- To treat fever and headache, take acetaminophen (Tylenol) or aspirin every 4 hours as directed by your physician.
- Get immunized against meningococcal, TB, Hib, and pneumococcal bacteria particularly if you are planning on living in a crowded area or dorm.
- Follow up with your physician if S&S do not go away or if they increase in severity. Contact immediately for infants with bulging fontanels.

ENCEPHALITIS

- Encephalitis is an acute inflammation of the brain.
- Two forms of the disease occur:
 - Primary encephalitis: Infection begins in the brain and/or spinal cord. This form is more serious, but less common.
 - Secondary encephalitis: Infection begins in one part of the body and then invades the brain and/or spinal cord. This form is more common and usually less severe than primary encephalitis.

Etiology: Most often caused by a viral infection, but it can also be caused by a bacterial or parasitic infection.

Risk factors: Primary encephalitis may occur any time of the year. Secondary encephalitis is more common during the warm summer months. Outdoor activities, weakened immune system, and young or old age increase risk.

Precipitating factors: Persons outside during warm summer months, those that have not been immunized against chicken pox, measles, mumps, or rubella, individuals receiving cancer treatment, and individuals that have had an organ donation are most susceptible.

S&S:

- Headache
- Fever
- Lethargy, irritability, and muscular weakness
- Altered mental status
- Motor or sensory deficits
- Speech abnormalities
- Nausea and vomiting

- Stiff neck
- Ataxic gait
- Tremor or convulsions
- Confusion/sleepiness
- Bulging fontanel
- Milder cases may not have any S&S of the disease

Assessment Alert

Because encephalitis may be secondary, it is important to obtain clients' past medical history and previous illness prior to the new S&S to help determine type of encephalitis and treatment options. Distinction between meningitis and encephalitis needs to be made. Clients with meningitis have no abnormalities in brain function, but these are common in clients with encephalitis.

Dx: Most common diagnostic tools are the spinal tap to assess cerebrospinal fluid, EEG to assess brain wave activity, and CT scan or MRI to assess for edema or bleeding in the brain. A CT scan or MRI may be done before spinal tap to assess for increased intracranial pressure. Blood tests to assess for an infectious process and test for West Nile virus may also be done.

Rx: Treatment depends upon type of encephalitis. Antiviral medication is only given in severe cases of viral encephalitis

or for herpes encephalitis. Treatment is aimed at symptomatic relief and treating disease process. Prevention is the best cure.

- Drug therapy
 - Antiviral—acyclovir (Zovirax), ganciclovir (Cytovene), and vidarabine (Vira-A) to treat infection caused by herpes simplex virus.
 - Diuretics—mannitol (Osmitol) to decrease cerebral edema.
 - Corticosteroids—dexamethasone (Decadron) to decrease edema and inflammation of the brain and spinal cord.
 - Antileptics used to treat or prevent seizures. (See section “Seizures” for description of antileptic medication.)
 - Antibiotics may be prescribed for underlying bacterial infection.
 - Sedatives to decrease irritability and restlessness.

Nursing Process Elements

Supportive therapy and prevention of secondary infection are treatment goals.

- Provide airway management and respiratory support.
- Assess neurological status and for S&S of increasing intracranial pressure. Notify physician immediately if S&S occur.
- Provide intravenous fluids for administration of medication.
- Provide pain medication as needed for headache.
- Monitor vital signs and give acetaminophen (Tylenol) for fever as directed.
- Assist client with ambulation and activities of daily living as needed.

- Allow client time to answer and ask questions. If client has memory deficits, repeat teaching information as indicated.
- Assess need for physical, occupational, and/or speech therapy and refer as needed.
- Keep room quiet and allow for frequent rest periods throughout the day.
- Increase fluids and offer nutritional supplements throughout the day.
- Teach medication administration techniques for home therapy.

Client teaching for self-care

- If outside during early morning or at dusk, wear long sleeved shirts and long pants and use mosquito repellent with 10–30% DEET.
- Get rid of areas in your home that have standing water such as bird baths, drains, old tires, flower pots, and unused open containers that may hold water.
- Watch for signs of active viral disease—watch for sick or dying birds.
- Stay away from individuals that are ill if you have a weakened immune system.
- Have your children immunized against chicken pox, measles, mumps, and rubella.
- Drink plenty of liquids daily.
- Get at least 8 hours sleep per night and rest during the day.
- Take your medication as directed and do not discontinue abruptly.
- To treat fever and headache, take acetaminophen (Tylenol) every 4 hours as directed by your physician.

PEDS

REYE'S SYNDROME

- Reye syndrome is an acute encephalopathy with liver dysfunction
- The five stages of this syndrome are:
 - vomiting, lethargy, and drowsiness;
 - confusion, combativeness, and hyperactive reflexes;
 - decorticate posturing and coma;
 - decerebrate posturing; and
 - seizures, respiratory arrest, and death.

Etiology: Unknown

Risk Factors:

- Reye's syndrome usually followed by a viral infection such as varicella.
- It is associated with aspirin use.

S&S:

- Preceding viral infection
- Fever
- Decreasing level of consciousness with combativeness
- Vomiting
- Cerebral edema

Dx:

- Elevated liver enzymes
- Hypoglycemia
- Definitive diagnosis is based on liver biopsy

Rx: Supportive therapy aimed at reducing cerebral edema and maintaining body functions including respirations and coagulation. Outcome varies from full recovery to permanent

sequelae or death during the acute disease process. Drug therapy may include:

- corticosteroids and osmotic diuretics to reduce cerebral edema
- anticonvulsants
- vitamin K to aid coagulation

Nursing Process Elements

- Monitor level of consciousness
- Maintain fluid restrictions
- Monitor laboratory values

- Support respiratory function
- Provide physiologic support for the comatose child
- Provide emotional support to the family

Client teaching for self-care

- Teach parents to avoid aspirin in children, especially in relation to a viral infection
- Explain disease and medical treatment to the family
- Explain medical equipment in use with their child
- Rehabilitate on discharge

GUILLAIN–BARRÉ SYNDROME

- Guillain–Barré syndrome is an acute inflammatory polyneuropathy.
- Disease occurs in three stages:
 - 1–3 weeks of onset and deterioration of physical status
 - Plateau of a few days to weeks
 - Recovery period of 6 months to more than a year
- Demyelination occurs between nodes of Ranvier blocks transmission of impulses primarily in motor fibers.
- Recovery occurs in most cases as remyelination takes place; if axons are damaged recovery is slower or disease becomes chronic or recurrent.

Etiology: Autoimmune disease of unknown cause, which often develops few days after a bacterial or viral infection of the respiratory or GI tract.

Risk/precipitating factors: Bacterial or viral infection, surgery, transplant, immunization, other immune disorder such as Hodgkin's disease or AIDS

S&S:

- Varying degrees of symmetrical weakness and flaccid paralysis most often occurring in ascending progression starting with the feet and moving upward to the thorax, upper extremities, and face. Half of affected clients have respiratory insufficiency.
- Sensory involvement manifested as paresthesias (numbness, tingling, and hypersensitivity to touch) and pain are also common.
- Autonomic dysfunction: Labile blood pressure, tachycardia or bradycardia, dysrhythmias, flushing, sweating, urinary retention, and paralytic ileus

Assessment Alert

Facial nerve (fifth cranial) is often affected. Difficulty in swallowing, speaking, and breathing occur if 7th, 9th, and 10th cranial nerves are affected. There is no effect on the client's alertness or cognitive function.

Dx: History and clinical presentation, elevated CSF protein, and EMG studies

Rx: Supportive and designed to prevent complications

- Respiratory support (ventilator required by up to one third of clients because of respiratory failure)
- Corticosteroids to try and decrease autoimmune inflammation
- Plasmapheresis to remove antibodies, immunoglobulins, and other proteins during first 2 weeks; IVIG is also used
- Nutritional support because complete immobility causes rapid loss of muscle mass: tube feedings or if paralytic ileus is a problem, parenteral nutrition
- May have low dose anticoagulant therapy to prevent venous thrombosis
- Comprehensive plan for rehabilitation

Nursing Process Elements

- Assess for and intervene for sensory deprivation as it is a major potential problem

- Monitor motor, sensory, and cranial nerve status
- Monitor vital capacity, tidal volume, or minute volume: mechanical ventilation is initiated when tidal volume falls below a predetermined level usually 1.0–1.5 l for an average sized adult
- Monitor weight
- Monitor for signs of complications: venous thrombosis, pulmonary embolism, atelectasis, and pneumonia are common
- Maintain range of motion
- Prevent skin breakdown
- Institute bowel program
- Provide care for bladder: indwelling catheter or intermittent catheterization
- Provide meaningful stimulation and regular communication
- Include client in care decisions as cognition is not impaired

MULTIPLE SCLEROSIS

- Multiple sclerosis is a chronic, progressive, and degenerative disorder that affects the central nervous system (CNS).
- It is an autoimmune disorder characterized by exacerbations and remissions causing deterioration of the myelin sheath of the brain and spinal cord with resultant characteristic plaque formation and scarring throughout the CNS.
- Four main patterns:
 - Relapsing remitting—clearly defined relapses followed by periods of remission. Exacerbations appear suddenly, last for weeks or months, and gradually disappear.
 - Primary progressive—disease progression with a gradual decline, with temporary minor improvement.
 - Secondary progressive—continuous deterioration with or without sudden relapses, plateaus, or minor remissions.
 - Progressive relapsing—progressive from onset with sudden episodes of acute relapses with or without full recovery.

Etiology: Unknown.

Risk factors: First, second, and third degree relatives of individuals with multiple sclerosis, people of Northern European descent, and individuals living in temperate climates. Many bacteria and viruses have been thought to be a trigger of the disease.

Precipitating factors: Emotional distress, excessive fatigue, pregnancy, physical injury, and infection.

S&S:

- Unsteady gait or lack of coordination
- Tremor
- Sensation of electric shock radiating down spine with movement of head
- Dizziness

- Paresthesias in one or more limbs on one side of the body or the lower half of the body
- Vertigo, tinnitus, or decreased hearing
- Partial or complete loss of vision, blurred vision, or diplopia
- Fatigue
- Spastic bladder with urinary frequency, urgency, dribbling, and incontinence or hypotonic bladder with urinary retention.
- Erectile dysfunction
- Decreased libido
- Forgetfulness and difficulty concentrating
- Slurred speech
- Paralysis
- Muscle stiffness or spasticity

Assessment Alert

S&S such as slurred speech, muscle weakness, paralysis, dizziness, and visual disturbances can mimic persons having a transient ischemic attack (TIA) or cerebrovascular accident (CVA). Careful differentiation between MS, CVA, and TIA is critical.

Dx: No definitive diagnosis, thus based on past medical history, clinical manifestations, and diagnostic studies. MRI to assess for multiple lesions or scarring over time, spinal tap to test CSF for abnormal levels of white blood cells or proteins, evoked responses to check for delayed nerve conduction.

Rx: No cure for MS. Treatment aimed at symptomatic relief and treating disease process.

- Corticosteroids to reduce inflammation and shorten duration of exacerbations

- Muscle relaxants to treat muscle spasticity, stiffness, and spasms
- Bladder control treatments
 - Cholinergics—bethanechol (Urecholine), neostigmine (Prostigmin) to treat urinary retention from a flaccid bladder.
 - Anticholinergics—probanthine (Pro-Banthine), oxybutynin (Ditropan) to treat urinary urgency, frequency from spastic bladder.
- Immunomodulators
 - Beta interferons—Betaseron, Avonex, Rebif to help fight viral infection, regulate the immune system, and decrease exacerbations. Betaseron and Rebif are given subcutaneously. Avonex is given intramuscularly.
 - Glatiramer acetate (Copaxone) subcutaneously once weekly as an alternative to Beta interferons to help block the immune system's attack on the myelin sheath.
- Immunosuppressants given intravenously every 3 months for clients with more severe attacks or rapidly advancing disease not responding to other treatments.

Clinical Caution

Immunosuppressants and immunomodulators may cause serious birth defects or miscarriage. It is, therefore, not used for women who are pregnant or plan to become pregnant. Corticosteroids must not be discontinued abruptly.

- Physical and occupational therapy to increase strength and teach use of assistive devices.
- Plasmapheresis to help restore neurologic function in clients not responding to high-dose corticosteroid therapy.

- Surgery (neurectomy, rhizotomy, cordotomy) to decrease muscle spasticity. Thalamotomy or deep brain stimulation to treat tremors.
- Intrathecal baclofen (Lioresal) pump or electrical stimulation to treat spasticity.
- Counseling—individual or group therapy to help client and family cope with MS and relieve emotional stress.

Nursing Process Elements

- Assess for S&S of acute exacerbation or progression of disease.
- Assess activities of daily living and need for referral for physical and/or occupational therapy.
- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.
- Assess urinary and bowel patterns. Teach urinary catheter care or self-catheterization techniques (see SCCI) to client and caregiver.

Client teaching for self-care

- Take medication as prescribed.
- Do not discontinue medications abruptly.
- Follow a high-protein, high-fiber diet to help maintain dietary needs and prevent constipation.
- Get adequate rest.
- Avoid extreme heat such as hot tubs and saunas especially if alone.
- Avoid factors that may increase risk for exacerbation such as crowded areas, temperate climates, pregnancy, or infection.
- Seek health care provider if you become ill and before taking any OTC medications.

MYASTHENIA GRAVIS

- Myasthenia gravis is a chronic, autoimmune neuromuscular disorder characterized by fluctuating muscular weakness of voluntary muscle groups.
 - It can occur at any age. Peak age is in the fourth to fifth decade of life for females and sixth to seventh decades in males.
 - It is more common in females with a 3:2 ratio. Ocular myasthenia gravis is higher in males.
- Common voluntary muscle groups affected include facial, chewing, eye, swallowing, and shoulder and hip muscles.

- Acetylcholine receptor antibodies are produced and block the target receptors with a resultant decrease in available acetylcholine receptors available at the postsynaptic membrane.

Etiology: Unknown; however, there is increasing evidence that the thymus might play an important role.

Risk factors: Other autoimmune disorders such as systemic lupus erythematosus (SLE), and rheumatoid arthritis (RA), extrathymic tumors, hyperthermia, hyperthyroidism, and medications such as aminoglycosides, polymyxins and

D-penicillamine, alpha-interferon, and botulinum toxin have been associated with myasthenia gravis.

Precipitating factors: Exposure to bright sunlight, viral illness, surgery, immunization, emotional stress, menstruation, and physical factors might trigger or worsen the exacerbations.

S&S:

- Specific muscle weakness that increases as the day progresses
- Ocular disturbance such as ptosis and diplopia
 - Ptosis may be unilateral or bilateral and may shift from eye to eye
- Difficulty swallowing, chewing, and talking
- Fatigability showing incremental weakness following same motor movements
- Difficulty taking a deep breath
- Weak cough
- Shortness of breath
- Unstable gait
- Impaired speech

Dx: May be delayed for 1–2 years due to commonality of muscular weakness. Laboratory tests include: anti-AChR antibodies assay, thyroid function test, antinuclear antibody test, and rheumatoid factor to test for myasthenia gravis and rule out other disorders; MRI or CT to rule out lesions or thymoma; anticholinesterase test using edrophonium chloride (Tensilon), and electromyography (EMG).

Rx: There is no cure for myasthenia gravis. Common treatments include medication, plasmapheresis, and thymectomy.

- Corticosteroids (Prednisone) to suppress the abnormal action of the immune system.
- Anticholinesterase agents, pyridostigmine bromide (Mestinon), neostigmine bromide (Prostigmin) to allow acetylcholine to remain at the neuromuscular junction longer.
- Immunosuppressants azathioprine (Imuran) and cyclosporine (Gengraf, Neoral, Sandimmune) to depress the immune system. Used when corticosteroids fail. Effect is delayed four to 8 months; symptoms may recur when discontinued.
- Immunoglobulins (IVIG) sometimes used to decrease the production of abnormal antibodies.

Clinical Caution

Immunosuppressants may cause serious birth defects or miscarriage, therefore, they are not used for women who are pregnant or plan to become pregnant. Corticosteroids must not be discontinued abruptly. Do not mix azathioprine with other drugs.

- Plasmapheresis to remove anti-AChR antibodies from the circulation. It is reserved for myasthenic crisis and refractory cases. Improvement is noted in a couple of days, but does not last for more than 2 months.
- Thymectomy
- Physical and occupational therapy, speech therapy to assist with swallowing, chewing, speech, and assist with ADLs and IADLs.

Nursing Process Elements

- Assess for S&S of acute exacerbation or progression of disease.
- Assess airway patency, strength of cough, respiratory rate and effort, mental status, and cardiac status.
- Pace activities throughout the day to allow for rest periods in between. Complete major care activities in the morning when the client is usually stronger.
- Elevate head and shoulders close to 90 degrees for all meals.
- Utilize mechanical soft diet during periods of dysphagia, and thicken clear fluids to avoid aspiration.
- Assess activities of daily living and need for referral for physical, occupational, and/or speech therapy.
- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.

Client teaching for self-care

- Take medication as prescribed.
- Record the response after each dose of pyridostigmine during the initial period of medication treatment.
- Keep medications with you at all times; keep in carry-on luggage when traveling.
- Avoid the use of D-penicillamine, alpha-interferon, and botulinum toxin.
- Do not discontinue medications abruptly.
- Seek immediate medical attention if difficulty breathing or swallowing occurs.
- Follow a healthful diet utilizing a variety of foods that chew easily. Eat slowly and rest between bites.
- Sit upright in a chair and lean forward when eating.
- Do not complete a large amount of activity prior to meals.
- Get adequate rest, and space activities throughout the day.
- Wear a medical identification bracelet.
- Wear low-heeled shoes that are comfortable and have nonskid soles.
- Use a walker or cane if you have an unsteady gait.
- Sit in a chair that has armrests to assist you when you get up.

PARKINSON'S DISEASE

- Parkinson's disease is a chronic, progressive disease in which nerve cells in the midbrain, called the substantia nigra, die or are impaired.
- A loss of 70–80% of these dopamine-producing neurons occurs before development of symptoms.

Etiology: Causes are not specifically known. Contributing factors include a combination of genetic factors and environmental exposures.

Precipitating factors: Environmental insults such as pesticides or illicit drug use, progression of age. Usually develops in individuals older than 60 years of age.

S&S:

- Resting tremor
- Rigidity or stiffness
- Slowness of movement (bradykinesia), or shuffling gait
- Postural instability
- Muffled speech
- Stiff facial appearance (mask-like appearance)
- Small, cramped handwriting
- Initially, symptoms may be on only one side of the body

Assessment Alert

Some of the S&S are similar to common manifestations of the aging process, particularly in clients with arthritis. Medication-induced parkinsonism may occur with use of antipsychotics, metoclopramide, reserpine, tetrabenazine, and some calcium-channel blockers. The parkinsonism usually resolves within weeks to months after discontinuation of the medication. Careful differentiation between arthritis, parkinsonism and Parkinson's disease is critical.

Dx: Diagnosis is usually based on clinical presenting symptoms. Presentation of two or more of the above S&S, particularly with a resting tremor, and a unilateral onset are utilized to help distinguish between Parkinson's disease and parkinsonism. An MRI may be useful in distinguishing true Parkinson's disease from other neurodegenerative disorders.

Rx: Currently, there is no cure for Parkinson's disease or treatment that is able to slow or stop the progression of the disease. Treatment is aimed at symptomatic relief and treating disease process.

- Symmetrel (amantadine) to reduce fatigue, tremor, and bradykinesia.
- Eldepryl (selegiline HCL) to inhibit the action of monoamine oxidase B, the enzyme that breaks down dopamine, thereby prolonging the action of dopamine in the brain.

- Anticholinergics—biperiden HCL (Akineton), benztropine mesylate (Cogentin), procyclidine (Kemadrin), trihexyphenidyl (Artane), orphenadrine (Norflex) to help reduce tremor or rigidity.
- Levodopa preparations—to reduce slowness, stiffness, and tremor
 - Standard preparations: levodopa/carbidopa (Sinemet or Atamet)
 - Extended release preparations: levodopa/carbidopa (Sinemet CR), levodopa/benserazide (Madopar HBS)
- Dopamine agonists—bromocriptine (Parlodel), pergolide (Permax), ropinirole (Requip), and pramipexole (Mirapex) to stimulate dopamine receptors.

Clinical Caution

Sleepiness, drowsiness, or sedation may be significant in some individuals taking dopamine agonists and may interfere with activities such as driving.

- Physical and occupational therapy to increase strength and teach use of assistive devices.
- Surgery (pallidotomy) to decrease tremor, bradykinesia, rigidity, and dyskinesia.
- Deep brain stimulation procedures—thalamic stimulation, VIM DBS, pallidal stimulation, subthalamic nucleus stimulation to reduce tremor, rigidity, and bradykinesia, gait disorder.

Nursing Process Elements

- Assess for S&S of progression of disease.
- Assess activities of daily living and need for referral for physical and/or occupational therapy.
- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.

Client teaching for self-care

- Take medication as prescribed.
- Do not discontinue medications abruptly.
- Follow a high-calorie, high-fiber diet and increase fluids to help maintain dietary needs and prevent constipation.
- Teach purposeful movements and concentrating on gait when walking.
- Teach diaphragmatic breathing and taking deep breaths before speaking to facilitate communication.
- Seek health care provider if you become ill and before taking any OTC medications.

AMYOTROPHIC LATERAL SCLEROSIS

- It is also called Lou Gehrig's disease
- Degeneration of upper and lower motor neurons occurs causing weakness and paralysis
- Amyotrophic lateral sclerosis is chronic and rapidly progressive with survival about 5 years from time of diagnosis.

Etiology: Unknown; theories include autoimmune reaction, defect in metabolism of the neurotransmitter glutamate, and cell damage from free radicals. Autosomal dominant gene present in about 1 in 10 cases.

S&S: It typically begins with weakness and atrophy of the skeletal muscles of the upper body due to damage to lower motor neuron manifest as decline in ability to perform fine motor skills and dropping things. Muscle fasciculations and fibrillations, decreased tendon reflex, muscle cramping, and generalized fatigue occur. As upper motor neurons degenerate, hyperactive reflexes, jaw clonus, tongue fasciculations, and a positive Babinski reflex present. With involvement of muscles of neck and throat, difficulty articulating words and difficulty swallowing occur. Ultimately, generalized paralysis including the respiratory muscles occurs and death from pneumonia and respiratory failure results.

Dx: There is no definitive diagnostic test; it is a diagnosis of exclusion. Muscle biopsy documents source of muscle weakness and EMG documents denervation of muscle, fibrillation, and fasciculation.

Rx: There is no cure; symptom relief is goal; tube feedings to maintain nutrition when needed.

Riluzole (Rilutek) used for its apparent neuroprotective effect and ability to prolong life by several months.

Nursing Process Elements

- Promote good nutrition.
- Balance activity and rest.
- Promote adequate sleep.
- Prevent complications.
- Support client's functional abilities encouraging use of self-help devices as needed.
- Support families' coping and refer to services such as Hospice and area support groups.

Client teaching for self-care

- Sit up to eat or drink.
- Tuck chin in toward neck when eating to aid swallowing.
- If cough is weak, suction mouth to clear as needed.

Nursing Intervention Alert

Facilitate client/family decision about the use of ventilator support. This decision should be made before a respiratory crisis occurs.

ALZHEIMER'S DISEASE

- Alzheimer's disease is the most common cause of severe intellectual deterioration and extreme physical degeneration in the elderly population.
- One in 10 individuals older than age 65 and about half of older adults aged 85 and older have AD.
- *Amyloid plaques* and *neurofibrillary tangles* are found in the brains of AD victims.

Etiology: Unknown

Risk factors: Age, family history

S&S:

- Memory loss (short-term memory first)
- Difficulty performing tasks
- Difficulties with language (forget words, cannot name objects) and communication
- Disorientation to place and time
- Impaired judgment
- Personality changes, delusions, paranoia, and hallucinations

Dx: Based on symptoms and rule out of other causes for dementia with physical and psychiatric examination, laboratory tests, and brain scan

Rx: No cure; drug therapy may improve symptoms and lessen behavioral problems.

Nursing Process Elements

- Provide for safety
- Provide consistency in daily routine

- Provide for socialization
- Use reality orientation
- Maximize independence with ADLs; break down tasks into short simple tasks

Educate the Caregiver on the following points:

- Provide literature, for example, *The 36 Hour Day*
- Teach importance of caregiver support group, and importance of respite for caregiver
- Teach therapeutic modalities including therapeutic touch, validation therapy, and reminiscence

CEREBROVASCULAR ACCIDENT (CVA)

- Cerebrovascular accident is an inadequate blood supply to the brain due to ischemia or hemorrhage with resultant decreased oxygen supply and death of brain cells.
- It may also be classified as a brain attack or stroke.

Etiology: Atherosclerosis, venous thrombosis, embolic and small vessel diseases, hypercoagulopathies, and genetic predisposition.

Precipitating factors: Hypertension, diabetes mellitus, sickle cell disease, obesity, hyperlipidemia, hypercholesterolemia, hypercoagulability, heavy alcohol consumption, smoking, oral contraceptive use, heart disease, physical inactivity, and atrial fibrillation. Nonmodifiable risk factors include African American ethnicity, increasing age, and male gender. Persons with a previous transient ischemic attack (TIA) are at increased risk for developing a CVA.

S&S: Dependent upon which area of the brain affected.

- Right side of brain
 - Left side of body is affected.
 - Right side of face is affected.
 - Vision problem: left homonymous hemianopsia (loss of vision in the left half of the visual field in both eyes)
 - Memory loss
 - Problems recognizing faces
 - Gets lost easily
 - Short attention span
 - Concrete thinking
 - Left hemiplegia
 - Left hemiparesis
 - Altered sensation on left side
 - Impulsive, inquisitive, uninhibited, and socially inappropriate behavior
 - Verbal outbursts
 - Left-sided neglect of body

- Impaired time and judgment
- Overestimation of own abilities with poor judgment regarding safety
- Left side of brain
 - Right side of body is affected
 - Left side of face is affected
 - Right homonymous hemianopsia (loss of vision in the right half of the visual field in both eyes)
 - Memory impaired for verbal and auditory stimuli
 - Poor naming ability
 - Right hemiplegia
 - Right hemiparesis
 - Altered sensation on right side
 - Speech/language impairment (aphasia): auditory speech interpretation, word selection, and motor aspects (articulation) of speech
 - Reading comprehension impaired
 - Agraphia (inability to write)
 - Slow, cautious behavior
 - Easily frustrated
 - Disorganized in approach to new problems
 - Depression and anxiety
 - Impaired comprehension of language and mathematics concepts, difficulty telling left from right

Dx: Usually based on clinical presenting symptoms, client history, and diagnostic tests. A CT is the primary diagnostic tool used to differentiate type of stroke, indicate size and location of the lesion, and guide treatment modality. MRI—to determine extent of brain injury, angiography for carotid artery imaging, transcranial Doppler (TCD)—to measure velocity of blood flow and assess for vasospasm in cerebral arteries. An EEG may be done to show brain wave activity and differentiate hemorrhagic from ischemic stroke. A lumbar puncture may be done if subarachnoid hemorrhage is suspected and CT is not definitive.

Assessment Alert

Differentiation between ischemic and hemorrhagic stroke is imperative so that emergency treatment can begin immediately. A thorough review of client history to determine exact time of S&S will help facilitate expedient care. Emergency medication “clotbusters” must be given within 3 hours after the symptoms of an ischemic stroke began. The use of clotbusters is contraindicated in a hemorrhagic stroke.

Rx: Determined by type of stroke. Treatment is aimed at restoring blood flow to the brain, preventing further brain damage, and reducing disability.

- Drug therapy
 - The following are utilized only for ischemic stroke.
 - Recombinant tissue plasminogen activator (tPA), streptokinase, or urokinase to break down clots.
 - Anticoagulant therapy—warfarin (Coumadin), heparin, or low molecular weight heparin to increase time for blood to coagulate.
 - Acetylsalicylic acid (aspirin), ticlopidine (Ticlid), clopidogrel (Plavix), and dipyridamole (Persantine) to inhibit platelet aggregation.
 - Calcium channel blockers—nimodipine (Nimotop) to decrease and/or prevent vasospasm in hemorrhagic stroke.
 - Antiseizure medication if seizure has occurred.
 - Aspirin or acetaminophen (Tylenol) for treatment of hyperthermia.
- Surgical treatment to remove cerebral hematoma due to hemorrhagic stroke. May include clipping, wrapping, or inserting microcoil in a ruptured cerebral aneurysm.

Clinical Caution

The tPA must be given within 3 hours of initial symptoms of ischemic stroke. Candidacy for use of drug therapy must be determined before beginning treatment. Contraindications include uncontrolled blood pressure (>185/110 mm Hg on repeated measurements), a history of brain hemorrhage, abnormal coagulation factors, and a history of major surgery during the previous 14 days.

- Physical and occupational therapy to increase strength, teach use of assistive devices, memory, and cognitive exercises.
- Speech therapy for swallowing and speech difficulties.

Nursing Process Elements

- Assess for S&S of progression of disease.
- Cardiac/respiratory assessment and support during acute phase.
- Oral hygiene, swallowing assessment, and assessment for pocketing of food while client is eating.
- Oral and endotracheal suctioning.
- Monitor for aspiration pneumonia; keep head of bed elevated during and after feedings.
- Prevention of deep vein thrombosis—provide range of motion exercises, utilize compression stockings, and assess lower extremities.
- Assist with activities of daily living, turn client every 2 hours, and assist with ambulation. Keep high-top tennis shoes on client's feet; do not pull on affected limbs.
- Monitor urinary and bowel function.
- Assist family to understand the client's behavior.
- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.
- Adaptations of care for left hemisphere damage
 - Speak slowly to allow time for processing
 - Use simple, short, one- or two-word phrases and commands.
 - Gesture and demonstrate along with using words to convey meaning.
 - Repeat often.
 - Use large print and other visual input.
 - Use music to provide information.
 - Help family to understand the communication impairment and how to circumvent it; including fact that comprehension is unimpaired.
- Adaptations of care for right hemisphere damage
 - Decrease environmental sensory stimuli
 - Move and speak slowly around client.
 - Use auditory and visual input together to communicate.
 - State names of objects as they are touched.
 - Break tasks into small steps.
 - Orient the client frequently.
 - Provide reminders for activities.
 - Take precautions in regard to client safety.
 - Prepare family members for behavior changes and for inability to recognize faces.

Client teaching for self-care

- Take medication as prescribed.
- Do not discontinue medications abruptly.
- Follow a high-calorie, high-fiber diet and increase fluids to help maintain dietary needs and prevent constipation. Take stool softeners as prescribed and indicated.
- Teach family members/caregivers to speak slowly and give ample time for client to respond. Use communication board as needed.
- Remove clothes from unaffected side first, followed by affected side. Dress affected side before unaffected side.
- Use assistive devices as taught by therapists.
- Continue with exercises taught by physical, occupational, and speech therapy.
- Follow up with home care and rehabilitation team as ordered.
- Remove unnecessary items from table when eating to avoid spills. Use assistive equipment to assist with eating. Allow client to feed self as much as possible.

CEREBRAL ANEURYSM

- Cerebral aneurysm is an area of a blood vessel in the brain that weakens over time and begins to bulge like a balloon.
- Over time the area can become weaker. Increased pressure exerted in the vessel increases the likelihood that the vessel may rupture.
- The aneurysm may not rupture, but may cause S&S due to the pressure exerted on brain tissue and cranial nerves.

Etiology: Uncontrolled blood pressure, head injury or trauma, and congenital due to weakness in the circle of Willis.

Risk factors: May occur at any age, but more common in adults than children. Occur slightly more often in women than men.

Precipitating factors: High blood pressure, arteriosclerosis/atherosclerosis in the brain, arteriovenous malformation (AVM), injury or trauma to the head, habitual use of cocaine, and genetics.

S&S:

- Sudden, severe headache often classified as “the worst headache ever”
- Nausea and/or vomiting
- Sensitivity to light
- Weakness on one side of the body
- Dizziness or loss of consciousness
- Diplopia
- Neck pain
- Drowsiness or difficulty awakening

nausea, vomiting, and sensitivity to light can mimic persons with a migraine headache. S&S such as weakness or paralysis on one side of the body, loss of consciousness, drowsiness, nausea, vomiting, and dizziness can mimic persons having a brain attack (stroke, cerebral vascular accident or CVA). Careful differentiation between aneurysm, migraine, and CVA is critical.

Dx: Based on past medical history, clinical manifestations, and diagnostic studies. CT most common procedure used—to assess for bleeding into brain tissue; lumbar puncture to test for blood and other elements in the cerebrospinal fluid; angiogram to assess for circulation of blood flow in the brain.

Rx: Ruptured cerebral aneurysm treatment aimed at restoring deteriorating vital signs and decreasing intracranial pressure. Surgical intervention to clip the aneurysm and prevent rebleeding is usually required and done within the first 3 days unless the client is unstable. For clients at high risk for surgery or for clients that have an aneurysm that has not ruptured a microcoil thrombosis or balloon embolization may be performed.

- Bed rest
- Hypertensive-hypervolemic therapy to increase pressure on the bleeding vessels in the brain and “thin” the blood to assure adequate blood supply to the brain and decrease vasospasm in cerebral vessels.
 - Vasoconstricting agents—dopamine (Intropin) and phenylephrine.
 - Volume expansion using crystalloid or colloid solutions.

Assessment Alert

Emergency treatment needs to begin as soon as possible. S&S such as severe headache with

- Calcium channel blocker—nimodipine (Nimotop) to prevent and treat vasospasms.
- Stool softeners to keep client from straining with stool.
- Diuretics such as mannitol (Osmitol) or furosemide (Lasix) to reduce fluid overload and increased ICP.
- Respiratory and cardiac support as indicated.
- Hyperthermia—acetaminophen (Tylenol) and/or use of a cooling blanket.
- Rehabilitation therapy dependent on client's prognosis, overall health, and effects from cerebral bleed.
 - Physical and occupational therapy to increase strength and teach use of assistive devices.
 - Speech therapy to improve speech and swallowing.
 - Counseling—individual or group therapy to help client and family cope with any lasting debilitating effects and relieve emotional stress.
- Provide oral hygiene every 2 hours for clients on ventilatory support to prevent skin breakdown and keep mucous membranes moist.
- Provide active and passive range of motion to prevent muscle wasting and rigidity.
- Elevate the head of the body and keep head and neck in alignment and avoid hip flexion to prevent increases in ICP.
- Administer nutritional support with use of enteral or parenteral feeding.
- Monitor urine output to assess for possible syndrome of inappropriate antidiuretic hormone (SIADH) and fluid retention.
- Turn client every 2 hours to prevent skin breakdown.
- Assess activities of daily living and need for referral for physical and/or occupational therapy.
- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.

Nursing Process Elements

- Primary assessment: Focus on respiratory, cardiac, and neurologic status.
- Assess respiratory status and need for ventilatory/oxygen support.
- Maintain airway patency and suction as needed.
- Monitor ICP.
- Monitor Glasgow Coma Scale (GCS) and level of consciousness (LOC) and notify primary physician immediately for any decreased LOC or decrease in GCS.
- If client has had surgical intervention, monitor dressing for amount, color, and consistency or drainage. Report any serous drainage with “halo” on gauze and/or positive for glucose immediately to physician.

Client teaching for self-care

- Stop or avoid smoking.
- Control blood pressure and take antihypertensive medication as directed.
- Maintain weight within normal limits for age and height.
- Avoid use of cocaine.
- Follow therapy exercises as prescribed by physical, occupational, and speech therapy.
- Report any sudden, severe headache, diplopia, hemiparesis, or hemiplegia to primary physician immediately.
- Get adequate rest.

HEADACHE

- Primary headaches: These are not symptoms of another known disease, they include: migraine, cluster, tension headaches
- Secondary headaches: These are symptoms of a known disease such as meningitis, brain tumor, and aneurysm.
- Migraine and cluster headaches are also classified as vascular headaches.

MIGRAINE HEADACHE

- Develops in teen to young adult years
- Occurs predominantly in women
- Episodic, lasts hours to days

Etiology: Hereditary pattern evident but precise cause unknown. Believed to be related to vasoconstriction followed by vasodilatation and neurogenic inflammation of cerebral blood vessels causing release of serotonin.

Risk/Precipitating Factors: Stress and hormone changes

S&S: May be an aura 10–30 minutes before acute attack: lights dancing in front of the eyes, photophobia, confusion, or sensorimotor symptoms; pain predominant on one side of the head and increases in severity as attack proceeds; may be accompanied by nausea, vomiting, fatigue, and irritability

Dx: History and clinical presentation

Rx:

Prevention:

- Pharmacological
 - beta blockers: Inhibit vasodilation of cerebral vessels and the reuptake of serotonin
 - Tricyclic antidepressants: block uptake of catecholamines and serotonin
 - Diuretics: prevent fluid retention
- Biofeedback
- Relaxation techniques

Symptom management:

- Triptans—cause vasoconstriction by binding to serotonin receptors on cranial arteries.
- Ergot alkaloids—cause vasoconstriction
- Antiemetics for nausea and vomiting
- Nonopioid analgesics

**Nursing Process Elements**

- Determine how client manages headaches including use of OTC medications
- Encourage client to keep a headache diary and record occurrence of headaches and surrounding events such as amount of sleep, foods eaten, activities, etc. to help identify triggering factors.

**Client teaching for self-care**

- Correct use of preventative and symptom relief medications: preventative drugs must be taken on schedule without missed doses to be effective. Take drugs for symptomatic relief as soon as aura or symptom occurs.
- Avoidance of identified triggering factors: common triggers are nitrates, nitrites, alcohol, monosodium glutamate, and high salt intake with fluid retention, nicotine.
- Once headache starts, rest in a quiet, darkened room
- Referrals as appropriate to dietician and/or support groups

**Clinical Alert**

Women with migraines should not take oral contraceptives because these have been found to increase migraine occurrence.

CLUSTER HEADACHE

- Occurs in clusters over periods of a week to a year with remissions between clusters.
- Lasts minutes to a few hours
- Severe neurologic pain syndrome

Etiology: Similar to migraine

Risk/precipitating factors: Alcohol and nitrates

S&S: Deep, throbbing, often one-sided pain starting under the orbit of the eye and spreading to head and neck; may be accompanied by tearing, flushing, nasal stuffiness, sweating, swelling of temporal blood vessels; no aura

Rx: Opioid analgesics

**Nursing Process Elements**

Similar to migraine

TENSION HEADACHE

Etiology: Tension and anxiety

S&S: Dull, constant pain, usually bilateral and involving neck and shoulders; contracted head and neck muscles; no aura; not affected by activity

Rx: Nonopioid analgesics, amitriptyline (Elavil), relaxation exercises

**Client teaching for self-care**

- Help client identify sources of stress
- Encourage use of stress management and relaxation strategies

SEIZURES

- A seizure is a temporary brain dysfunction caused by aberrant electrical activity in the brain.
- About 30% seizure incidences begin in childhood. Next area of increased incidence occurs in individuals older than 65 years of age.
- One seizure alone does not constitute having a seizure disorder.

- International Classification of Seizure Disorders classifies seizures into the following categories:
 - Generalized seizures: bilaterally, symmetrically, and without local onset
 - Absence seizures (brief loss of consciousness, staring, unresponsiveness), myoclonic seizures (brief jerking of a muscle group which may cause falling), clonic

seizures (rhythmic jerking of muscles), tonic seizures (rigidity of all muscles) tonic–clonic seizures (rigidity of muscles followed by rhythmic jerking sometimes accompanied by tongue biting and urinary and fecal incontinence), and atonic seizures (brief loss of muscle tone which may cause falling).

—Partial seizures

- Simple partial seizures without impairment of consciousness (focal twitching of an extremity, halt in speech, visual phenomena like seeing lights, feeling of fear or doom)
- Complex partial seizures with impairment of consciousness
 - Simple partial seizures (automatic behavior such as lip smacking, chewing or picking at clothes) with progression to impairment of consciousness
 - Impairment of consciousness at onset

—Unclassified: inadequate or incomplete data

- Status epilepticus: A seizure that does not stop or rapidly occurring seizures without a break in between for recovery. Status epilepticus is a medical emergency requiring immediate treatment to prevent harm and brain damage.

Etiology: Usually not identifiable. The seizure may be caused by underlying physiologic or psychogenic processes.

Precipitating factors: Hypoxia during birth, head injury, Alzheimer's, cerebral bleeding, cerebrovascular accident, hypoparathyroidism, hypocalcemia, hypoglycemia, hypomagnesemia, hypernatremia, hyponatremia, brain malformations, brain tumor, maternal drug use, prescription drugs, alcohol withdrawal, cerebral edema, fever, infection, congenital conditions, cardiac arrhythmia, syncope, and stressful psychological experiences.

S&S: Dependent upon location of abnormal electrical activity in the brain. (See types of seizures above.)

- Convulsions on one side of the body, one area of the body, or entire body
- Loss of consciousness
- Inability to speak or respond
- Staring
- Pleasant or unpleasant sense of smell
- Confusion or altered consciousness
- Loss of bowel or bladder control
- Numbness or tingling in specific body area
- Abnormal movements
- Twitching of eyelids and facial muscles
- Abruptly stopping activity; may fall to the ground

Assessment Alert

In older clients, “Senior moments” characterized by blank stares, temporary confusion or even

short gaps in conversation may actually be signs of a seizure disorder.

Dx: Based on client history, eyewitness account of the occurrence, and diagnostic studies. Blood test to determine levels of electrolytes, glucose, white blood cells, and red blood cells; liver and kidney function tests; EEG to assess electrical activity in the brain; CT scan or MRI to assess for cerebral abnormalities, and an EKG to assess cardiac rhythm.

Assessment Alert

Testing is usually done after the client has experienced at least two unprovoked seizures. Many times once the underlying cause of the seizure is corrected, no further seizures will occur. Thus, it is imperative to get an accurate and complete client history to help determine diagnosis and treatment options. If the client experiences a seizure, it is important to note the length of the seizure, symptoms, what the person was doing before the seizure, and whether there were any lasting effects afterward.

Rx: Dependent upon type of seizure and whether there is any underlying physiology or psychogenic processes.

- Anticonvulsant medication dependent upon type of seizure. Lowest possible dose with fewest side effects that stops all seizures is the goal of treatment.
- Medication used for generalized tonic–clonic and partial seizures
 - carbamazepine (Tegretol), divalproex (Depakote), lamotrigine (Lamictal), gabapentin (Neurontin), felbamate (Felbatol), phenytoin (Dilantin), tiagabine (Gabitril), topiramate (Topamax), zonisamide (Zonegran), valproic acid (Depakene) phenobarbital, levetiracetam (Keppra), oxcarbazepine (Trileptal), and primidone (Mysoline).
- Medication used for absence and myoclonic seizures
 - clonazepam (Klonopin), divalproex (Depakote), phenobarbital, valproic acid (Depakene), or ethosuximide (Zarontin).
- Medication used to stop a seizure that has occurred or for status epilepticus
 - fosphenytoin, lorazepam (Ativan), diazepam (Valium) or midazolam (Versed).

Clinical Caution

Many anticonvulsant medications are harmful to pregnant and lactating women. It is imperative that female clients are made aware of this and pregnancy status determined before beginning treatment therapy to assist in which medication to use. Medication may need to be changed during pregnancy or lactation but only on orders from the physician.

- Surgery—cutting of the nerves in the corpus callosum to decrease seizures that occur in several areas and spread to other parts of the brain.
- Correction of the underlying cause of the seizures—correcting fluid and electrolyte levels, removing tumor, decreasing stress, decreasing cerebral edema, decreasing fever, correcting cardiac arrhythmia, and removing alcohol from client's diet.
- Electrical stimulation of the vagus nerve to reduce number of partial seizures.

Nursing Process Elements

- Protect the client from injury
 - Pad siderails
 - Remove objects close to client
 - Loosen clothing around neck
 - Do not restrain client

- Do not place anything in the mouth
- Keep oxygen and suction equipment nearby
- Do not leave client alone until fully conscious and can move about on own again.
- Keep the room quiet and decrease stimuli.
- Allow for periods of rest, especially after client experiences a seizure.
- Administer anticonvulsant medication as ordered. Do not administer other medications at the same time as anticonvulsant medication unless directed by physician.
- Notify physician when client experiences a seizure.

Client teaching for self-care

- Take medication as directed at the same time every day.
- Do not discontinue medication.
- Do not take your anticonvulsant with any other medication unless directed by your physician.
- Do not drink alcoholic beverages.
- Do not swim alone.
- Do not engage in activities that may result in a loss of consciousness.
- Get plenty of sleep every day.
- Always wear a Medic Alert bracelet.
- Follow up with laboratory work as directed by your physician.
- Exercise or walk as often as possible.
- Decrease stress at work and home as much as possible.
- Do not operate heavy machinery or power tools.
- Do not drive a vehicle until you have been free of seizures for at least 6 months to 1 year. Many states prohibit driving for at least this amount of time.

FEBRILE CONVULSIONS

Etiology: It is one of the most common neurologic problems seen in children. It is usually a symptom of an infectious process. The most common infection associated with febrile convulsions is otitis media.

Risk factors:

- Age between 3 months and 3 years
- Boys more often than girls
- Familial tendency

S&S:

- Rise in temperature, usually above 101.
- Sudden onset of tonic-clonic seizure

Dx: Diagnosis is usually based on the presence of an infectious process and temperature elevation. An EEG may be performed at a later date to rule out underlying neurologic pathology.

Rx: Usually the seizure has ended prior to reaching medical help. Treatment is aimed at the underlying infection and preventing future temperature elevations.

**Nursing Process Elements**

- Antipyretics such as acetaminophen. Aspirin is not used because of the danger of Reye's syndrome
- Remove excessive clothing
- Maintain cool room temperature
- Tepid bath or sponge: Pat the child dry; do not rub
- Do not cause the child to shiver as that will raise temperature
- Offer cool clear liquids

**Client teaching for self-care**

- Teach parents how to take the child's temperature
- Explain temperature reducing methods
- Remind parents that children that have had febrile convulsion are at risk of additional febrile convulsions; so temperatures should be treated immediately.
- Explain to parents that there is rarely permanent sequelae from a febrile convulsion

CEREBRAL PALSY

- Nonprogressive brain dysfunction
- Leads to disorders involving movement, muscle tone and coordination
- Classified by clinical characteristics
 - Spastic: Hypertonic muscles, develops contractures, scissoring of legs
 - Athetoid: Also called dyskinetic. Slow, wormlike movements, involuntary movements of extremities
 - Ataxic: Muscles and reflexes hypotonic. Coordination difficulty
 - Mixed: Combination of types of cerebral palsy
- May affect one side of the body (hemiplegia), or all four extremities (quadriplegia).

Etiology: Cerebral injury occurring during the fetal or neonatal period. Asphyxia and intrauterine infections, birth injuries and intracranial hemorrhage. The type of cerebral palsy is dependent upon the area of the brain affected

Risk factors: Prematurity, kernicterus, and low Apgar scores

S&S:

- Failure to meet expected development milestones
- Excessive or diminished muscle tone
- Feeding difficulties
- Seizures may be present
- Mental retardation may accompany CP
- Visual and auditory deficits may be present

Dx: Based on clinical findings with CT and MRI

Rx: Early recognition with interventions designed to promote normal growth and development

- Mobility aids such as bracing, crutches, walkers, and wheelchairs as needed
- Anticonvulsants if needed
- Surgical release of contractures may be necessary

- Intrathecal baclofen infusions may be used to reduce spasticity

**Nursing Process Elements**

- Multidisciplinary approach individualized to the needs of the child.
- Early intervention such as passive range of motion exercises can reduce the development of contractures and promote muscle development.
- The child will need assistance with daily hygiene and other self-care activities. The skin will be prone to breakdown in the area of bony prominences. Bracing can also contribute to skin breakdown.
- Nutritional support may be necessary if facial involvement makes chewing and swallowing difficult. This support can range from adaptation of feeding methods and the use of high-calorie foods or the insertion of a gastrostomy tube.
- Speech therapy may be necessary to improve communication. Use of computer assisted communication may be necessary for the more severely involved child.
- The child may be at greater risk for aspiration due to involvement of the oral muscles. Whenever possible, the child should be fed in an upright position.
- Emotional support for the child and family throughout the life of the child. Identify and refer to appropriate community resources.

**Client teaching for self-care**

- Teach the parents means of promoting growth and development by identifying areas of delay and developing a plan that will promote development in that area

- Teach the parents how to apply the braces and means of protecting the underlying skin. Provide information that will assist the parents in early recognition of skin breakdown
- Work with the parents on developing feeding methods that safely promote growth.
- Teach the parents how to administer the medications as well as side effects of the medications their child is receiving.
- The parents may need guidance in adapting safety equipment, toys and other devices for their child.

HYDROCEPHALUS

- Hydrocephalus is an accumulation of cerebral spinal fluid in the ventricles of the brain
- If untreated or treatment is unsuccessful, hydrocephalus will lead to brain damage and could cause eventual herniation of the brain stem through the foramen magnum and death

Etiology:

- May be congenital or acquired.
- May be due to an obstruction of the CSF flow preventing the normal reabsorption of the CSF by the subarachnoid spaces. Termed “noncommunicating hydrocephalus,” this form may be caused by tumors, hemorrhage, infection or structural abnormalities.
- Impaired absorption by the subarachnoid spaces, this form is called “communicating hydrocephalus” and is less common than the noncommunicating form
- Accumulation of CSF in the ventricles leads to compression of the surrounding brain tissue and if the sutures are not closed, to an enlarging head circumference.

Risk factors:

- Associated with spina bifida cystica (meningoceles and myelomeningoceles) defects due to structural abnormalities. May be apparent at birth or may not be symptomatic until the sac is closed surgically.
- Intracranial hemorrhage, especially in the premature, meningitis, and brain tumors.

S&S: Symptoms will be dependent upon the age of the child and whether the sutures have closed.

- In the young infant:
 - Increasing head circumference
 - Bulging fontanels
 - Thin scalp with fine appearing hair and obvious scalp veins
 - Setting sun sign, white sclera showing above the iris
 - Shrill, high-pitched cry
- In the older child:
 - Headaches, initially early morning
 - Vomiting without nausea, initially early morning
 - Papilledema

- In all children:
 - Varying degrees of irritability, lethargy progressing to mental slowness

Dx:

- Hydrocephalus may be diagnosed in utero. The earlier the diagnosis and surgical intervention, the greater will be the preservation of brain function.
- CT and MRI

Rx:

Surgery aimed at re-establishing the CSF flow by removing the obstruction (tumor) or by providing an alternate route to CSF reabsorption (shunt)

- Shunts involve a small tube with a one-direction valve taking CSF from the ventricles to a distant site. The CSF fluid is reabsorbed by the body into the blood stream
- Two types of shunts are commonly used
 - Ventriculoatrial shunt: CSF is directed from the ventricle into the atrium of the heart. The advantage to this type of shunt is there is little risk of the distal tip becoming clogged. The disadvantages of this shunt include the need for revisions to allow for the child's growth and the risk that if infection occurs, endocarditis may result.
 - Ventriculoperitoneal shunt: The distal tip of this shunt is in the peritoneal cavity. Extra tubing can be placed in the abdomen to allow for growth and there is no risk of endocarditis with this type of shunt. However, the fatty omentum frequently occludes the distal tip requiring revision.

Nursing Process Elements

Preoperative care

- Measure daily head circumference.
- Promote nutrition. Refeed if the child vomits as vomiting may temporarily relieve the intracranial pressure.
- Elevate the head as it may reduce headaches by reducing the contents of the skull. Medication may be required but care should be taken not to depress the mental status

Postoperative care

- Position the child's head according to medical orders and on nonsurgical side. Elevation of the head may cause the shunt to reduce the intracranial volume too rapidly.
- Monitor for signs of intracranial infection

**Client teaching for self-care**

- Parents should be aware that the return of symptoms of increased intracranial pressure may indicate that the shunt is not functioning.

- If brain damage has occurred, information should be provided about promoting growth and development as well as community resources available for the child with mental retardation.
- Children who have recurrent neurosurgical procedures have an increased risk of developing latex allergies. Parents should be taught to avoid exposure to latex products including pacifiers and toys.

HEAD INJURY

- Head injury refers to injury to scalp, cranium, and/or brain
- Motor vehicle accidents are the most common cause followed by alcohol and drug ingestion, assaults, and sports related accidents
- Major concern: amount of damage to brain

SKULL FRACTURE

- Break in the bone of the cranium; occurs due to trauma; may be associated cerebral edema and other complications or may result in no further injury
- Linear or simple—crack in bone; may be asymptomatic; no treatment required
- Comminuted—bone is broken or crushed into small pieces
- Depressed—bone fragments are depressed inward into brain tissue
 - Open if dura is torn
 - Closed if dura is intact
 - Requires immediate surgical intervention to prevent brain damage
- Basilar—break at base of skull
 - May result in CSF drainage from the nose or ear
 - Treated with antibiotics because of the risk of meningitis
- Depressed—surgery usually within 24 hours to raise bone, remove fragments, close dura if possible. Cranioplasty with insertion of acrylic bone immediately or if cerebral edema or infection is a problem, in 3–6 months. Dexamethasone given for cerebral edema and prophylactic antibiotics for 24–48 hours postoperatively.
- Basilar—if dura is torn and CSF leaking continues for more than 7–10 days the time in which most dural tears close, craniotomy to repair the tear may be necessary. Prophylactic antibiotics are given whenever there is a suspected CSF leak.

**Nursing Process Elements**

Dx: Skull fracture is visualized by CT or MRI. Basilar is difficult to see if dura is torn and may have CSF leaking from nose (rhinorrhea) or ear (otorrhea), periorbital ecchymoses “Raccoon eyes”; ecchymosis over the mastoid; air in frontal sinuses on CT.

Rx: The treatment varies with type and location

- Linear—no treatment just close monitoring for underlying brain injury

- Assess for signs of a torn dura: CSF leaking from nose or ears. All drainage is tested for glucose; CSF is positive for glucose.
- If dura is known to be torn,
 - instruct clients to refrain from activities such as coughing, sneezing, nose blowing, and the Valsalva maneuver that increase ICP. Monitor for signs of encephalitis or meningitis.
 - keep head of bed flat or elevated to no more than 30 degrees as per physician's order.
 - all procedures involving entry into the ear canal or nasal cavity are avoided.

BRAIN INJURY

- **Concussion**—transient, neurologic dysfunction occurring as a result of head injury
- **Contusion**—area of brain tissue into which bleeding has occurred as a result of trauma that causes the brain to strike the inside of the skull
- **Coup injury**—injury of the brain tissue directly underneath the site of trauma
- **Contra-coup injury**—injury of the brain tissue on the opposite side of the brain from where the injury occurred as a result of trauma causing the brain to move back and forth within the skull.

Etiology: Falls, child abuse, motor vehicle accidents, and other trauma

S&S:

Concussion

- **Mild:** No loss of consciousness, confusion and disorientation may occur but clear in seconds or minutes, dizziness, spots before the eyes, recovery is complete
- **Severe:** Loss of consciousness lasting less than 24 hours, headache, vomiting, irritability; recovery of consciousness usually associated with brief period of confusion/disorientation; amnesia for injury and immediately preceding events, bulging fontanel in infants younger than 18 months, vomiting

Contusion

- More severe S&S than concussion. Loss of consciousness with stupor and confusion and focal neurological deficits including seizures reflecting area of brain that is damaged. Ipsilateral pupil changes, weak pulse, shallow respirations, incontinence, and cerebral edema may also occur.

Dx: History, neurological examination, CT or MRI to rule out underlying injury such as hematoma

Rx: Prevention or management of cerebral edema is of primary importance as well as prevention or reduction of brain compression. Surgical intervention may be required. Contusion: dexamethasone to reduce cerebral edema. Supportive care is based on symptoms.

Nursing Process Elements

- Monitor neurologic status. This may include the Glasgow Coma Scale and:
 - vital signs including blood pressure,
 - level of consciousness,
 - strength/ability to move all extremities,
 - pupil reactions, and
 - headache, dizziness, vomiting, confusion, and weakness.
- Limit fluid intake to reduce the development of cerebral edema
- Monitor for drainage that suggests basilar skull fracture
- Monitor pain but analgesics and sedatives are not recommended as their use may mask a decreasing level of consciousness
- Monitor for seizures and be prepared to respond should they occur
- Provide physiologic support for the comatose client
- Instruct the client with a concussion to resume ADLs slowly and progressively

Client teaching for self-care

- All children should wear protective equipment when involved in activities which can cause head injury including bicycle riding and skateboarding
- If the child is to be discharged and monitored at home, teach the parents to awaken the child several times during the night to assess level of consciousness.
- Explain to the parents symptoms they might note that would require immediate notification of the physician.
- Many children will experience a postconcussion syndrome that can include forgetfulness, behavioral changes, and learning difficulties that may last for several months.

EPIDURAL HEMATOMA

- Epidural hematoma is bleeding, usually arterial, into the epidural space, which is between the skull and the dura.
- It creates pressure on the brain and clots rapidly.
- It is a medical emergency.

Etiology: Often associated with fracture of the temporoparietal bones

S&S: Decreasing level of consciousness 1 or even 2 days after initial return to being alert and lucid following injury.

Headache, vomiting, and same side pupil (ipsilateral) dilation. If brain stem herniation occurs due to pressure of the hematoma, contralateral (opposite-side) motor paralysis with increased tendon reflexes, positive Babinski sign, coma, and decerebrate posturing develop.

Dx: Emergency CT to determine location of hematoma and amount of cerebral edema.

Rx: Immediate surgical evacuation; in some cases, craniotomy necessary to top hemorrhaging.

SUBDURAL HEMATOMA

- Subdural hematoma is venous bleeding into the subdural space, which is between the dura and the arachnoid.
- It develops more slowly than arterial hematomas.
- Types:
 - Acute: symptomatic within 48 hours of initial injury
 - Subacute: symptomatic 2 days to 2 weeks after injury
 - Chronic: symptomatic 2 weeks to months after injury

S&S:

- Acute and subacute: Increased intracranial pressure, headache, drowsiness, and confusion that insidiously worsen; ipsilateral pupil dilation.
- Chronic: headache, variable LOC, personality changes, and motor weakness.

Dx: CT scan

Rx: Small hematomas reabsorb; larger clots may require repeated subdural taps to remove the clot or surgical evacuation.

Nursing Process Elements

- Immobilize clients with head trauma until coexistent spinal cord injury has been ruled out.

- Priority assessment is airway: check rate and depth of respirations.
- Assess LOC
- Monitor for VS changes indicative of increasing intracranial pressure: increasing systolic pressure causing widened pulse pressure and decreasing respiratory rate.
- Obtain description of accident.
- Ask about client's use of drugs and alcohol.
- Perform baseline neurological assessment: check PERRLA and lifts and grips.
- Inspect nose and ears for blood or cerebrospinal fluid.
- If alert, ask if client lost consciousness at time of accident
- Monitor neurological status every 2 hours using Glasgow Coma Scale; report change from baseline.
- Monitor VS every 2 hours.
- Administer medications to control cerebral edema.
- Control environmental stimuli to prevent increase in ICP.
- Maintain side lying position to keep airway patent.
- Monitor ABGs because hypoxia and hypercarbia can potentiate an increase in ICP.
- Change position every 2 hours to prevent pooling of secretions and skin breakdown.

BRAIN TUMOR

- Brain tumor is a tumor located anywhere in the brain.
- Primary tumors originate in the brain or spinal cord and rarely spread elsewhere in the body.
- Secondary brain tumors may metastasize to the brain from other tumors in the body.
- Brain tumors can be benign or malignant.

Etiology: Unknown, family history may increase predisposition.

Precipitating factors: Exposure to radiation, formaldehyde, vinyl chloride, or acrylonitrile (textiles and plastics) at work, family history of gliomas, increasing age, and being male. Secondary tumors may arise from a primary lesion elsewhere in the body and spread or metastasize to the brain.

S&S: Dependent upon tumor size, type, and location

- Headache that may awaken the client
- Problems with balance

- Muscle weakness
- Aphasia
- Memory problems
- Nausea or vomiting
- Changes in hearing, vision, or speech
- Paresthesias in arms or legs
- Seizures
- Mood or personality changes

Dx: Usually based on clinical presenting symptoms, client history, complete neurological examination, and diagnostic tests. A CT scan to determine the location of the lesion. MRI and PET to determine location of the lesion; useful in detecting smaller lesions that may not be evident on other studies. Angiography to determine blood flow and localize the tumor. Endocrine studies may be done to detect pituitary adenoma. A biopsy for histology testing is the most accurate way to diagnose a brain tumor.

Assessment Alert

Many of the S&S are due to increasing intracranial pressure caused by the growing tumor. An accurate baseline neurological assessment is critical when determining any change in level of consciousness with increasing intracranial pressure. Immediate action should be taken in case of any decreasing level of consciousness.

Rx: A combination of therapies may be used and is determined by tumor type, location, and stage.

- Surgery is preferred treatment for removal of brain tumor.
- Chemotherapy may be given intravenously, orally, intrathecally, or via a wafer implanted during surgery.
 - Chemotherapeutic agents are limited due to their difficulty in crossing the blood–brain barrier. Many malignant tumors break down the barrier increasing the likelihood that chemotherapeutic agents will cross to the tumor and be more effective.
- Radiation therapy using X-rays, gamma rays or protons, or radiation seeds implanted during surgery. Follows surgery or is used when surgery is not an option.
- Corticosteroids such as dexamethasone (Decadron), prednisone, or methyl-prednisolone (Solu-Medrol) may be

administered to decrease cerebral edema and increasing intracranial pressure that may occur after surgery and/or radiation therapy.

- Anticonvulsant medication may be utilized if the client experiences seizures.
- Antiemetics may be given to decrease nausea the client may experience after radiation and chemotherapy treatments.
- Physical therapy may be used to increase strength and balance.
- Occupational therapy may be used to manage activities of daily living and teach use of assistive devices.
- Speech therapy may be used to assist with speaking, swallowing, and cognition.

Nursing Process Elements

- Assess for S&S of infection after surgical interventions.
- Assess for changes in level of consciousness, and complete a thorough neurological assessment.
- Allow for periods of rest. Treatments can be very taxing.
- Administer pain medication as ordered and indicated.
- Assess for nausea and administer antiemetics as needed.
- For radiation treatments, assess areas surrounding treatment for increased redness and skin breakdown.
- Implement seizure precautions for clients experiencing seizures.
- Assess need for referral for social services, physical, occupational, or speech therapy.
- Allow ample time for client to answer questions.

Client teaching for self-care

- Your hair will grow back in a few months. Use a wig, scarf or hat to keep head from becoming sunburned.
- Do not wash off marks made for radiation therapy.
- Do not operate heavy machinery or a vehicle if you have experienced seizures.
- Allow client ample time to answer questions and use communication board if indicated.
- Allow client to perform as much of own care as possible.
- Follow up with therapy as ordered.
- Take oral chemotherapy as directed.
- Take antiemetics half an hour before radiation or chemotherapy treatments.
- Get plenty of rest.
- Drink plenty of fluids and eat high-protein, high-calorie foods.

PEDS **NEUROBLASTOMA**

- Solid, malignant tumor arising from the neural crest cells or adrenal glands.
- Tumor may originate in the sympathetic nervous system from the base of the neck to the tailbone.

Etiology: Not specifically known. Occasionally found in children with neurofibromatosis.

Precipitating factors: Usually found by the age of two. Boys are at slightly increased risk over girls.

S&S:

- Pain in the abdomen
- Dark circles under the eyes
- Hypertension
- Weakness/paralysis or fatigue
- Lump in abdomen, neck, or chest
- Bone pain
- Bulging eyes
- Breathing difficulties in infants
- Easy bruising
- Uncontrolled eye movements
- Edema of legs, feet, ankles or scrotum
- Petechiae
- Severe diarrhea
- Jerky muscle movements/ataxia
- Fever
- Shortness of breath

Assessment Alert

Clinical differentiation can be difficult because neuroblastoma can mimic so many other disease processes. By the time the diagnosis is made, many times the disease has already spread. Careful attention to presenting S&S is critical in assisting with diagnosis.

Dx: Usually based on clinical presenting symptoms and diagnostic studies. Twenty-four-hour urine test to check for elevated levels of catecholamines. Blood chemistry to check for elevated levels of dopamine and norepinephrine. CT scan, MRI, or ultrasound to assess for tumor size and location. Neurological examination to assess neurologic function, mental status, and reflexes. Bone marrow aspiration or biopsy to assess for tissue and chromosomal changes, and test for the presence of antigens.

Rx: Prognosis and treatment are dependent on age of the child at diagnosis, stage of the cancer, tumor location, and histology. Treatment is also affected by the rate of tumor cell growth, number of chromosomes in tumor cells, pattern of tumor cells, tumor differentiation, and how many copies have been made.

- Surgery to remove all or most of the tumor cells. A biopsy may be indicated if the entire tumor cannot be removed.
- External radiation therapy to kill cancer cells. Internal radiation using needles seeds, wires, or catheters placed directly into or near the tumor cells to kill the tumor.
- Chemotherapy—daunorubicin, cyclophosphamide, carboplatin, and etoposide to stop the growth of cancer cells.
- Bone marrow transplantation may be used following aggressive chemotherapy.
- Dopamine agonists—bromocriptine (Parlodel), pergolide (Permax), ropinirole (Requip), and pramipexole (Mirapex) to stimulate dopamine receptors.

Nursing Process Elements

- Assess need for referral for counseling.
- Teach medication administration techniques for home therapy.
- Assess need for nutritional support.
- Maintain accurate record of intake and output and weight. Weigh all diapers and assess for increased diarrhea.
- Assess surgical site for S&S of infection.
- Assess vital signs/blood pressure every 4 hours and PRN.
- Assess abdomen for presence of lumps.
- Do not palpate abdomen on clients with adrenal tumors.

Client teaching for self-care

- Take medication as prescribed.
- Do not discontinue medications abruptly.
- Follow a high-calorie, high-protein diet and increase fluids to help maintain dietary needs.
- Seek health care provider if child becomes ill, has difficulty breathing, or if increased nausea and vomiting occur due to treatment.
- Keep a record of how well the child tolerated treatment modalities.
- Maintain record of child's daily weight.
- Do not wash off radiation markers from skin.
- Apply sunscreen if outside and watch for increased redness and dryness at the site of therapy.

PEDS

MENTAL RETARDATION

Mental retardation is a cognitive dysfunction that dates from the developmental period (prenatal or postnatal) and results with difficulty in function and adaptability. Mental retardation is measured on the intelligence quotient below 70 or 75 when normal IQ is considered 100. IQ is a measure of mental age divided by chronologic age.

Etiology: Selected chromosomal anomalies such as Down's syndrome, and fragile X syndrome, periods of hypoxia, and infections have all been associated with mental retardation.

Risk factors: Prenatal factors include infection and alcohol and drug abuse. Poor nutrition and hypoxia are risk factors in both the prenatal and postnatal periods.

S&S:

- Diagnosis may be made at birth secondary to select characteristics as in Down's syndrome or microcephaly or after delays occur in development
- Parents are often the first to recognize that the child's development differs from normal
- Development follows the same pattern as the normal child but at a slower pace
- Degree of mental retardation is determined by IQ scores which are used educationally to determine the optimal learning environment
 - Mild MR ranges from 50 to 75 and the child usually reaches the mental age of 8–12 years. This child may be classified as educable and may be main streamed for some classes while receiving additional help for other subjects
 - Moderate MR ranges on the IQ scale from 35 to 50, reaching a mental age of 3–7 years. This child may be classified educationally as trainable and will require supervision throughout life

—Severe MR has an IQ of 20–35 and the child will attain a mental age of a 2–3-year old. The child will learn to walk and have limited speech requiring lifelong support and supervision

—Profound MR has an IQ of less than 20. The child will need custodial care and educational goals will be aimed at basic skills of eating and use of extremities

Dx: Chromosomal studies, IQ tests, CT scans and MRIs may be ordered

Rx: Medical care will be directed toward diagnosis and supportive care. Seizures may accompany MR and anticonvulsants may be indicated. Genetic counseling may be included in selected situations.

**Nursing Process Elements**

- Emotional support to the family during the diagnostic period and throughout the life of the child
- Meeting the needs of the child such as innovative feeding techniques for the child who has a poor suck and swallow

**Client teaching for self-care**

- Explain about the diagnostic procedures
- Provide information about supporting growth and development
- Instruct parents about anticonvulsant therapy and management during a seizure if needed
- Refer to community resources to provide support to the family

PEDS

NEURAL TUBE DEFECTS

Neural tube defects are congenital defects affecting the spinal canal including the vertebrae and spinal cord. The defects can occur anywhere along the spinal canal but are most frequent in the sacral area

There are several types of neural tube defects with varying degrees of involvement:

- Spina bifida occulta: In this form of neural tube defect, the posterior vertebral bodies fail to completely form. The individual may be symptom free. The defect may be an incidental finding on an X-ray.

- Spina bifida cystica: In addition to the bony vertebral defect, there is a herniation of spinal material through the defect. There are two primary forms of Spina bifida cystica:

—Meningocele: In the milder form, the meninges protrude through the bony defect. This form will display a saclike protrusion over the spine, which may be covered by skin or only by the thin meninges. The individual may display weakness below the defect. Without intact skin, meningitis is a risk.

—Myelomeningocele: In this severe form of spina bifida cystica, the protrusion contains not only the meninges and CSF but also the spinal cord (or more frequently the cauda equina). Blood supply to the nerves will be impaired resulting in permanent nerve damage. The child will be paralyzed from that point down.

Etiology: Unknown

OB

Risk factors: Folic acid deficiency during early pregnancy has been associated with neural tube defects. It is recommended that all pregnant women and women who want to become pregnant take a folic acid supplement.

S&S:

- Spina bifida occulta may display a tuft of hair or a dimple at the site or be nonapparent.
- Spina bifida cystica is obvious defect present at birth.
 - Sac-like protrusion over lower spine. The sac may be covered with intact skin or by a thin membrane.
 - Weakness or paralysis of lower extremities.
 - Neurogenic bladder and bowel.
 - Hydrocephalus may be present at birth or develop after closure of the meningocele/myelomeningocele

Dx: An alpha-fetoprotein blood test run on the pregnant woman may yield high levels which may indicate neural tube defects. The finding can be confirmed by ultrasound. Further radiologic studies will differentiate the defects. Testing of neurologic function will determine the level of damage.

Rx: No treatment is required for spina bifida occulta. The child with meningocele/myelomeningocele will have surgery to repair the defect. A shunt device will be placed.

- For meningocele/myelomeningocele, surgical repair will be performed within 48 hours of birth to reduce the risk of infection.
- A shunt device may be needed to control the hydrocephalus.
- Bracing and other mobility assistive devices will be added as the child grows.

Nursing Process Elements

Preoperative care

- Position the child to protect the sac. This usually requires a prone position

- A nonadherent dressing may be applied to protect the sac from contamination.
- Avoid powdering the diaper area as the powder may contaminate the sac.
- Monitor bladder function. The child may dribble continuously placing skin integrity at risk or may not spontaneously void at all. The nurse may need to crede the bladder.
- Monitor bowel function. In the preoperative period, care must be taken that stool does not contaminate the meningocele sac.
- Provide normal infant nutrition. Position the infant during feedings to protect the sac.
- Monitor for infection including signs of meningitis
- Measure head circumference daily
- Provide emotional support to the parents. Infant may be transferred shortly after birth from the birth hospital and separated from mother. Encourage parental visits and include them in the care of their newborn.

Postoperative care

- Sterile dressings over surgical site
- Continue to monitor bladder and bowel function
- Promote nutrition for healing
- Measure head circumference daily
- Monitor for infection including signs of meningitis

Client teaching for self-care

- Prepare the parents for eventual discharge and normal infant care.
- Teach the parents to monitor and manage bladder and bowel function.
- Provide information on skin care focusing on paralysis.
- Provide information on promoting growth and development.
- Teach parents to monitor for signs of infection and hydrocephalus.
- As child grows, provide information to parents on using bracing and other assistive devices.
- Teach parents to avoid exposure to latex products including pacifiers and toys because children who have recurrent neurosurgical procedures have an increased risk of developing latex allergies.

SPINAL CORD INJURY

- Above C3 injuries are generally fatal.
- Above C4 respiratory failure is common.
- *Complete transection of the cord*—complete loss of sensory and motor function below level of injury.

- *Incomplete transection*—some spinal cord tracts are intact so there is some sensory or motor function below the level of injury.

- *Tetraplegia* (formerly quadriplegia)—loss of function in arms, legs, trunk, bowel, and bladder due to a cervical cord injury.
- *Quadripareisis*—weakness of both upper and lower extremities.
- *Paraplegia*—loss of function in legs, bowel, and bladder resulting from a thoracic, lumbar, or sacral cord injury.
- *Paraparesis*—weakness of lower extremities.
- *Level of injury*—lowest neurologic segment with normal sensory and motor function.

Etiology:

- Hyperflexion injury
 - Head and neck are forced into hyperflexion as in a head on motor vehicle accident.
 - Usually affects C5-C6
- Hyperextension injury
 - Head and neck are forced back and downward as in rear end motor vehicle accidents and falls striking the chin
 - Middle to lower cervical spine most often affected
 - Damage is often major
- Compression injury
 - Results from extreme vertical force as in being hit on top of the head or forceful landing on the feet or buttocks
 - Cervical and thoracolumbar spine most often affected
- Rotational injury
 - Extreme lateral flexion or twisting of the head

Clinical Alert

Many SCIs involve more than one direction of force so often mixed injuries occur.

- Penetrating injury
 - Direct contact of an object such as a bullet or knife with the spinal cord
 - Low-impact (low-speed) injury results in damage localized at site of impact; high-impact (high-speed) injury as from a gunshot results in widespread damage.
- Primary injury
 - Results from initial damage to the cord and is irreversible
 - Types:
 - Cord concussion
 - Occurs due to severe jarring or squeezing as in many sports injuries
 - No structural injury to cord
 - May cause 1–2-day loss of sensory and motor function
 - Function returns spontaneously

- Cord contusion
 - Bleeding into cord occurs causing swelling and bruising
 - Effect depends on overall perfusion of cord and extent of inflammatory response
 - Often caused by compression
- Cord laceration
 - Tear in cord causes permanent injury
- Cord transection
 - May be complete or incomplete
 - Function lost below level of injury
- Vascular injury
 - Causes decreased perfusion and ischemia
 - If ischemia loses, cell death will occur
- Secondary injury
 - Begins within minutes of the initial injury and results from it.
 - Can destroy full thickness of cord and extend injury both above and below the site of injury.

Risk/precipitating factors: Age: greater frequency among young (16–30 years); sex: males four times as likely to sustain an SCI; alcohol use

S&S: Depend primarily on amount and level of injury to the cord

- *Spinal shock*
 - It is temporary suppression of reflexes below level of injury (spinal reflexes do not require connection to the brain as functions like sensation and voluntary movement do)
 - Spinal shock occurs in all SCI clients
 - Reappearance of spinal reflexes indicates end of period of spinal shock
- *Neurogenic shock*
 - Neurogenic shock is a hemodynamic instability secondary to the loss of neuroconnection between the brain and the sympathetic nervous system
 - It occurs with injuries to cervical or high thoracic spine
 - S&S are hypotension caused by venous pooling in lower extremities and splanchnic circulation
 - Bradycardia occurs due to unopposed parasympathetic stimulation
 - Warm, dry skin occurs due to peripheral vasodilation
 - Neurogenic shock gradually resolves over 10–14 days

Assessment Alert

When assessing a trauma victim and trying to differentiate between hypovolemic shock and neurogenic shock, consider that bradycardia occurs with neurogenic shock and tachycardia is typical of hypovolemic shock.

Syndromes of incomplete transection

- *Central cord syndrome*: frequently occurs with cervical hyperextension injury
 - Motor weakness, which is more pronounced in arms than legs
 - Variable degree of sensory impairment but always more pronounced in arms than legs
 - Possible effect on bowel and bladder function
 - Tends to improve over time
- Anterior cord syndrome
 - Frequently occurs due to damage to the anterior spinal artery or from pressure of a tumor or a herniated disc
 - Loss of strength, pain perception, and temperature perception below the level of injury
 - Can sense position, vibration and light touch
- Posterior cord syndrome
 - Rare
 - Position and vibration sense lost
 - Movement, pain, and temperature sense are lost.
- Brown–Séguard syndrome
 - Occurs with a penetrating injury involving half the cord
 - Motor ability, touch, vibration, and pressure sense lost on side of injury; loss of pain and temperature sense on side opposite the injury
- Conus medullaris syndrome
 - Injury at L1–2 level frequently due to vertebral fracture of disc herniation
 - Urinary retention, loss of anal sphincter tone, constipation, impotence, slight motor weakness, loss of sensation in perineum, parts of thighs, and buttocks
- Cauda equina syndrome
 - Asymmetrical weakness, numbness, and pain along the nerve roots, sometimes neurogenic bladder and bowel dysfunction

It is rare that any of these syndromes occur just as described; most often injuries result in a combination of syndromes.

Assessment Alert

There is greater potential for some recovery of function with incomplete transection of the cord but it is not possible to differentiate complete from incomplete until after the period of spinal shock is over.

Respiratory symptoms

- Paralysis of muscles of respiration; if injury above C3, respirations cease.

- C3 to C4 injuries result in decreased inspiratory volumes because the diaphragm and some intercostals muscles are innervated from nerves at this level.
- C5 to T1 injury results in hypoventilation as a result of weak intercostals and accessory muscle strength with reduced vital capacity and inspiratory force. Inability to clear secretions occurs because of inability to take a deep breath and impaired use of abdominal muscles.
- Below T1, buildup of secretions is the major problem.

Bladder, bowel, and sexual symptoms

- Micturition reflex center, the spinal defecation reflex center, and the sexual reflex center (controls erection and labial–clitoral engorgement and vaginal lubrication) are located at S2 and S4 levels
- Injury above these reflex centers results in:
 - Spastic automatic bladder with voluntary control of urination lost; no perception of bladder fullness or urge to void; incontinence with the bladder often not fully emptying.
 - Loss of voluntary control over the anal sphincter, which is flaccid during spinal shock and then becomes spastic; no sense of rectal fullness and no urge to defecate; defecation may occur if the reflex arc is stimulated.
 - Loss of sexual response to psychological stimuli but able to respond reflexively to direct stimulation of the genitals and surrounding areas.
- Injury below these reflex centers results in:
 - An autonomous, flaccid bladder with urinary retention and overflow common.
 - Flaccid bowel and anal sphincter with both constipation and incontinence
 - Loss of reflex erections, engorgement and lubrication but can respond to psychologic stimuli
- Ejaculation is rare with spinal cord injury.

Dx: Neurological examination; X-rays, MRI, CT scan, and myelography

Rx:

- Immediate immobilization with a rigid cervical collar and backboard; cardiorespiratory support.
- Mechanical ventilation required for injury above C3; mechanical ventilation required at least during acute phase for C3 and C4 injury but ultimately may breathe independently for at least short intervals; temporary mechanical ventilation may be required for clients with middle to lower cervical injury who can initiate and maintain breathing but can need assistance in compensating for decreased tidal volume and difficulty maintaining a clear airway.
- IV fluids along with inotropic and chronotropic agents are administered to counteract hypotension of neurogenic shock and maintain systolic BP between 85 and 90 mm Hg to ensure good perfusion of the cord and decrease secondary injury.

- Pharmacological treatment:
 - Methylprednisolone (Solu-Medrol) in first 8 hours after injury; not given later than 8 hours
 - Anticoagulant prophylaxis
 - Muscle relaxants to control spasticity
 - Histamine 2 receptor antagonist or proton pump inhibitor to protect against gastric ulcers
- Decompression and stabilization
 - Nonsurgical: immobilization and traction
 - Cervical tongs (Crutchfield) with a prescribed amount of weight to provide pull and realign vertebrae.
 - Halo device for cervical skeletal fixation; may be used similarly to tongs or attached to a body vest which allows the client to be ambulatory and shortens hospitalization.
 - Bedrest may initially stabilize thoracolumbar injuries; injuries at this level cannot be stabilized with traction so braces, corsets or other devices may be used; surgical repair is needed for unstable fractures.
 - Surgical treatment
 - Remove bony fragments; relieve cord compression, correct alignment by means of screws, plates, rods, or wiring to improve stability, or to treat a penetrating wound.

Surgery is immediate if realignment is not possible in any other way or if there is unrelieved compression.

As soon as client is stable and alignment and cord compression are not problems, mobilization and rehabilitation are begun.

Assessment Alert

Motor and sensory function is assessed before and after the addition of each weight used for traction.

Complications:

- Autonomic hyperreflexia (previously dysreflexia)
 - Emergency that can result in stroke, blindness, or death
 - Over response of the sympathetic nervous system because below the injury it is shut off from inhibitory control of centers in the brain
 - Occurs with injuries at T6 or above after period of spinal shock is over
 - Stimuli initiating the response include: bladder distention (most common cause), bowel distention, local pressure or irritation in groin, sacral or penile areas, tight clothing, urethral catheterization or digital or other stimulation of anus, abdominal or pelvic stimulation as from sexual activity, menses, UTI, cholecystitis, gastritis, cold, heat, and drafts.

- Sympathetic stimulus from below area of injury causes vasoconstriction and paroxysmal hypertension; this in turn leads to bradycardia and vasodilation above level of injury in an unsuccessful attempt to lower BP.
- Pounding headache, nausea, nasal stuffiness, and blurred vision often accompany the hypertension.
- Below injury, skin is pale or mottled, cool and has goosebumps due to profound vasoconstriction; above injury, skin is flushed and diaphoretic due to the vasodilation.

- Pneumonia
- DVT
- Pain muscular, visceral, or neuropathic
 - Neuropathic pain is burning, sharp, or shooting above, below, or at level of injury
 - Often more responsive to treatment with antidepressants or anticonvulsants than to analgesics
- Spasticity
 - Develops when stage of spinal shock is over
 - May be sustained (tonic) or intermittent (clonic)
 - Spasticity may worsen with other stresses such as UTI
 - Degree of spasticity stabilizes in about 24 months after injury
- Altered thermoregulation
 - Injury at or above T6 results in an inability to sweat or shiver below injury
- Adynamic ileus
 - Result of loss of autonomic innervation to gut
 - NG tube for gastric distention
 - Resolves in 3 days to a week
- Gastric ulcers
 - Secondary to stress and steroids
 - Prophylactic medications to decrease gastric acid
 - Monitor for bloody or coffee ground vomitus or aspirate; tarry stools
- Orthostatic hypotension
- UTI
- Renal calculi
- Osteoporosis

Nursing Process Elements

Immediate Care

- First priority: immobilize spinal cord: neck securely immobilized and lower spine aligned
- Log roll or lift.
- Ensure a patent airway
- Assess rate and depth of respirations
- Obtain baseline neurological status (see Chapter 9)

Continuing Care

- Maintain effective respiration
 - Position for ease of respiration—breathing may be easiest in supine position because when sitting, the abdomen protrudes and the flaccid intercostals muscles collapse inward on inspiration decreasing chest capacity; as muscles become spastic over ensuing months, the chest stops collapsing on inspiration. Use of an abdominal binder may facilitate breathing in the sitting position.
 - Facilitate clearing of secretions: with injuries below T1 this is the major respiratory problem; secretions build up.
 - Guide in use of incentive spirometer every 1–2 hours while awake
 - Thin secretions with humidity and good fluid intake
 - Monitor oxygen saturation and administer supplemental oxygen PRN
 - Turn clients every 2 hours. If spine not yet stable, a specialty bed is used
 - Use assisted cough techniques to promote airway clearance:
 - Manual assist: place hands above umbilicus and below the xiphoid; press strongly inward and upward as the client exhales
 - Mechanical assist—use of a machine, which delivers a deep breath with positive pressure and then applies negative pressure to simulate a cough.

**Assessment Alert**

A moist, nonproductive cough indicates inadequate airway clearance.

- Chest PT, for example, percussion and postural drainage as ordered.
- Suction clients with tracheostomies PRN

**Nursing Intervention Alert**

Clients with high cervical injuries can develop bradycardia, which sometimes progresses to asystole when being suctioned or moved. If it occurs during suctioning, manually ventilate and provide supplemental oxygen during the procedure.

- Assess and intervene for autonomic dysreflexia
 - Close monitoring essential: if hypertension occurs, elevate head of bed to 90 degrees.
 - If bowel is impacted, manually remove feces.
 - Respond immediately to autonomic hyperreflexia.
 - Elevate head of bed to Fowler's position if possible.

- Loosen clothing and any constricting equipment, for example, compression stockings or devices.
- Monitor BP and pulse every 2–5 minutes.
- Check for bladder distention. If catheterized, check for blocks, replace catheter PRN; if not, catheterize stat; instill anesthetic gel before catheterizing as per agency policy.
- If condition persists: check for bowel distention. Apply Nupercaine or similar local anesthetic to rectal area; check response; remove stool as needed. If there is no resolution, administer vasodilators such as nifedipine or captopril as per order; assess for sources of irritation; change position; and send a urine specimen for C&S.

**Clinical Alert**

Autonomic dysreflexia can result in CVA if untreated.

- DVT prophylaxis for 3 months after injury
 - Position without pressure behind knee and to prevent edema from gravity to decrease risk of DVT; limit tactile stimulation and change position every 2 hours keeping joints in a functional position to combat spasticity and maintain rehabilitation potential.
 - Put joints through regular ROM exercise at least four times per day to prevent DVT and prevent contractures from spasticity.
 - Use compression devices such as stocking or pneumatic sleeves.
 - Administer anticoagulant prophylaxis as ordered.

**Assessment Alert**

Client cannot feel calf pain or tenderness and so warmth, erythema, and edema are the warning signs of DVT. Low-grade fever may also present. Bedside duplex ultrasound can assist in diagnosis.

- Promote effective urinary elimination
 - Maintain indwelling catheter initially to prevent overdistention of bladder and allow close monitoring of output.
 - Subsequently implement an individualized bladder management program.
 - Intermittent catheterization (IC)
 - Most common type of management
 - Catheterize every 3–4 hours using aseptic technique (clean technique used when client goes home)
 - Volume of urine at any catheterization should not exceed 400 ml for women or 500 ml for men; if volume is consistently greater then reinsert indwelling

catheter and try IC again later. If it is consistently less than 400–500 ml, gradually lengthen time between IC with goal to stabilize at a 4–6 hour interval. If volume of greater than 400–500 ml occurs at anytime, shorten the length of time between catheterizations.

- Valsalva and Crede (compression of bladder by manually pushing on the lower abdomen) maneuver voiding
 - Initiates voiding when injury is to the UMN but bladder emptying is often incomplete and incontinence results.
 - Reflexive voiding
 - With lower motor neuron injury, the micturition reflex may be triggered by tapping the suprapubic area, pulling on pubic hair, or stroking the inner thigh. Initially this method is used with IC, when reflexive voiding occurs, residual urine is checked. Once residual drops to less than 100ml then IC may be eliminated.
 - Suprapubic catheter if none of the above is effective.
- Monitor for UTI: hematuria, clouding of urine, foul smell, increased sediment, mucus, chills, fever, and autonomic hyperreflexia).
- Institute a bowel program to prevent constipation.
 - Determine what client's bowel habits were before injury.
 - Set a consistent time for bowel elimination, ideally 30 minutes after a meal to take advantage of the gastrocolic reflex and as close to preinjury pattern as possible.
 - Establish a proper balance of fiber and fluids; clients are usually begun with 5–25 g of fiber daily.
 - Administer stool softeners or bulk formers as ordered.
 - Provide privacy.
 - Do a digital rectal examination to check for fecal impaction using anesthetic ointment if injury is at or above T6 to decrease the risk of autonomic hyperreflexia.
 - Administer stimulant suppository if ordered; using anesthetic ointment as above.
 - Place client in sitting position or, if not possible, left side lying position.
 - May apply pressure manually or with a binder to the abdomen to facilitate defecation.
 - 20–30 minutes after giving the suppository, may digitally stimulate reflex defecation in clients with UMN injury by moving a gloved, lubricated, finger in circular motion inside the rectum (anesthetic ointment

used as above); if LMN injury, no reflex stimulation is possible, so feces is manually removed.

Nursing Intervention Alert

Frequency and consistency of stool is the guide to the development of an effective bowel program.

- Maintain skin integrity
 - See pressure ulcers in Chapter 29
 - Skin assessment twice daily by self or other
 - For clients with SCI, relieve pressure with weight shifts every 15–20 minutes when sitting up.
 - Use of a wheel chair pillow.
- Promote effective coping
- Accept and support client through stages of grief.
- Provide information according to what client desires.
- Give client a sense of control by offering choices, involving in care and making as many decisions as possible.
- If client is unable to speak, provide alternate form of communication.
- Set limits as needed.
- Use a nonjudgmental approach.

Client teaching for self-care

- Relationship of injury to sensory motor function
- Expected functional outcomes
- Use/care of stabilization devices
- Respiratory support strategies
- Signs of respiratory infection: fever, cough, sputum change, noisy breathing.
- Bladder care
- Signs of UTI
- ROM
- Moving and positioning techniques
- Skin care regimen
- Sexual function
- Autonomic hyperreflexia
- Coping strategies
- Resources

SPINAL CORD TUMOR

- Spinal cord tumors may be primary or metastatic tumors
 - They most commonly occur in the thoracic spine
 - Primary tumors are often benign but cause motor or sensory defects because they compress the cord
 - Metastatic tumors erode the vertebrae and increase the risk of fracture and spine instability
- Etiology:** Common sources of metastatic tumors are the lungs, breast, and prostate.

S&S: Mild to severe pain is usually the first symptom; either localized or radicular (along the spinal nerve root path); weakness, sensory and motor loss develop and bladder, bowel, or sexual problems may also occur. The exact symptoms depend on level of lesion.

Dx: MRI

Rx:

- Corticosteroids, usually dexamethasone (Decadron), to decrease edema and, therefore, decrease cord compression; surgical removal of primary tumors; surgery to

decompress cord and debulk the tumor for metastatic lesions; radiation for palliation when surgical excision is impossible.

- Immobilization if spine is unstable

Nursing Process Elements

Nursing care varies according to whether tumor is primary or metastatic; the medical treatment plan; and functional deficits.

TRIGEMINAL NEURALGIA

- Trigeminal neuralgia is a disorder affecting one or more branches of the fifth cranial nerve (trigeminal)
- It is chronic with exacerbations and remissions; over time exacerbations become longer and remissions shorter.

Etiology: Unknown but vascular compression of the nerve root, trauma, pressure from a tumor, or dental infection are theorized to contribute.

Risk/precipitating factors: Age and sex—more common in middle aged and older women

S&S: Abrupt onset, unilateral, and paroxysmal pain along the nerve pathway—usually the maxillary and/or mandibular branch of the nerve, lasting from a few seconds to a few minutes. Pain described as intense, piercing, burning; no motor or sensory defects occur. Often a pain trigger can be identified by the client such as a draft of air, brushing teeth, talking, smiling, chewing, or touching the face.

Dx: Based on classic pain pattern and exclusion of other causes

Rx:

- Pharmacological: Anticonvulsant medications such as carbamazepine (Tegretol which inhibits pain impulses)
- Surgery for refractory disease:
 - Neurodestructive procedures, done through the skin, usually result in almost immediate pain relief but cause partial facial numbness and sometimes loss of innervation to the cornea. Recurrence is common.
 - Stereotactic radiosurgery (Gamma knife) irradiates trigeminal nerve resulting in pain relief in 4–6 weeks; facial sensation remains intact.

—Microvascular decompression involves cutting away the compressing blood vessel by visualizing the nerve by means of a craniotomy

Nursing Process Elements

- Assist client in identifying pain triggers and identifying methods of avoiding or minimizing them
- Assess nutrition because of risk of less than body requirements as a result of pain interfering with eating.

Client teaching for self-care

- Take medications on a strict schedule to maintain optimal blood levels.
- Take analgesics as soon as pain starts to maximize their effectiveness.
- Use relaxation techniques and imagery to aid in pain control.
- Eat small, frequent meals composed of soft, nutritious foods or nutritional supplements chewing on unaffected side to minimize pain and increase caloric intake.
- Monitor weight weekly; report weight loss
- If oral care is painful, use soft swabs, mouthwashes or a water-based system
- Rinse mouth after eating to remove food particles and cleanse breath.
- See dentist every 6 months.

BELLS PALSY

- Bells Palsy is a disorder of cranial nerve VII (facial nerve)
- Most common in men and women aged 20–60
- Recovery is generally complete in a few weeks but may take up to a year

Etiology: Herpes simplex virus

S&S: Rapid weakening of muscles of one side of face sometimes preceded by a feeling of facial stiffness or pain behind the ear, inability to blink or close eyelid, constant tearing, decreased taste, difficulty swallowing. Increased sensitivity to sound on affected side

Dx: History and presentation; a diagnosis of exclusion

Rx: Corticosteroids, antiviral medications

Complications: Corneal abrasions, permanent facial weakness

Nursing Process Elements

- Nursing Intervention Goals: prevent eye injury; prevent aspiration and related respiratory problems
- Ease anxiety by reassuring client that condition is temporary

Client teaching for self-care

- Use artificial tears
- Patch or tape eyelid shut at night and when outdoors.
- Eat and drink only when upright; eat foods with consistency that is easiest to swallow.
- Perform facial exercises as nerve function begins to return to help regain muscle tone.

WORKSHEET

MATCHING QUESTIONS

Match the following:

Column A

- ___ concussion
- ___ cerebrospinal rhinorrhea
- ___ beta interferons
- ___ subdural hematoma
- ___ cerebral aneurysm
- ___ hemiparesis
- ___ tonic seizure
- ___ carbamazepine
- ___ coup injury

Column B

- tumor of the neural crest cells or adrenal gland
- drug used to decrease cerebral edema
- venous bleeding into space between dura and arachnoid
- sign of brain contusion
- transient, neurologic dysfunction occurring as a result of head injury
- injury of brain tissue directly underneath the site of trauma
- drug used for seizures
- associated with cocaine use
- immunomodulators used in treatment of multiple sclerosis

(continued)

- | | |
|------------------------------------|---|
| 10. ___ bradykinesia | j. slowness of movement seen in Parkinson's disease |
| 11. ___ ipsilateral pupil dilation | k. used in management of Guillain–Barré syndrome |
| 12. ___ neuroblastoma | l. surgical procedure used in management of myasthenia gravis |
| 13. ___ lorazepam | m. paralysis of half the body |
| 14. ___ myoclonic seizure | n. drug used for status epilepticus |
| 15. ___ hemiplegia | o. sign of a tear in the dura |
| 16. ___ thymectomy | p. weakness on one side of the body |
| 17. ___ dexamethasone | q. abnormal sensation |
| 18. ___ plasmapheresis | r. brief jerking of a muscle group |
| 19. ___ paresthesia | s. impairment of motor or sensory function of lower extremities |
| 20. ___ paraplegia | t. rigidity of all muscles |

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------------|-------------|
| 1. A major difference between meningitis and encephalitis is that brain function is normal with meningitis and abnormal with encephalitis. | <u> </u> | <u> </u> |
| 2. For clients with meningitis, the room should be kept quiet and lights dimmed to allow for frequent rest periods throughout the day. | <u> </u> | <u> </u> |
| 3. Long term memory loss is an early sign of Alzheimer's disease. | <u> </u> | <u> </u> |
| 4. The priority intervention for a client who has sustained head trauma is immobilization because of the risk that damage to the spinal cord has also occurred. | <u> </u> | <u> </u> |
| 5. One seizure alone does not constitute having a seizure disorder. | <u> </u> | <u> </u> |
| 6. Pallidotomy is performed on selected clients with Parkinson's disease to decrease muscle stiffness and increase mobility. | <u> </u> | <u> </u> |
| 7. A subacute, subdural hematoma becomes symptomatic 24–48 hours after injury. | <u> </u> | <u> </u> |
| 8. Rhinorrhea consisting of clear fluid is suggestive of a tear in the dura in a client with a basilar skull fracture. | <u> </u> | <u> </u> |
| 9. Decadron decreases spinal cord compression by decreasing inflammation and, therefore, decreasing edema. | <u> </u> | <u> </u> |

| | | |
|---|------------------|------------------|
| 10. It is not possible to differentiate complete from incomplete transection of the spinal cord until the period of spinal shock is over; thus it is impossible to estimate recovery potential until this time. | <u> </u> T | <u> </u> F |
| 11. Methylprednisolone (Solu-Medrol) when given for SCI cannot be given later than the first 4 hours after injury. | <u> </u> T | <u> </u> F |
| 12. Clients with SCI must be monitored for tarry stools because of the risk of gastric bleeding. | <u> </u> T | <u> </u> F |
| 13. Breathing is generally easiest when clients with a recent SCI are in an upright sitting position. | <u> </u> T | <u> </u> F |
| 14. Bells palsy is a disorder of cranial nerve V. | <u> </u> T | <u> </u> F |
| 15. A symptom of hydrocephalus in an older child is vomiting without nausea. | <u> </u> T | <u> </u> F |
| 16. The client with meningitis is best positioned flat with a small pillow. | <u> </u> T | <u> </u> F |
| 17. A child who has a febrile convulsion is at risk for having a seizure from another type of environmental stimulus at another time. | <u> </u> T | <u> </u> F |
| 18. Teaching the parents of a child with cerebral palsy how to care for the skin underlying the braces is essential. | <u> </u> T | <u> </u> F |
| 19. For a client with a fractured skull the bed should be flat or no higher than 30 degrees if ordered. | <u> </u> T | <u> </u> F |
| 20. Symptoms of postconcussion syndrome include forgetfulness, changes in behavior, and learning problems. | <u> </u> T | <u> </u> F |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

- The most commonly used test for the diagnosis of meningitis is the _____.
- When caring for a client with a subdural hematoma the nurse would monitor neurological status every 2 hours using the _____.
- The neurological disorder characterized by progressive ascending sensory and motor defects is _____.
- Treatment with tPA must be given within _____ hours of initial symptoms of ischemic stroke.
- A fracture at the base of the skull is called a _____ fracture.
- Deep, throbbing, one-sided head pain starting under the orbit of the eye and spreading to the head and neck are symptoms of a _____ headache.
- A decline in fine motor skills is an early symptom of _____.

(continued)

8. In the treatment of a client with myasthenia gravis, the class of drug used when corticosteroids fail is the _____.
9. The tremor characteristic of Parkinson's disease is a _____ tremor.
10. Sleepiness, drowsiness, and sedation are side effects of the _____ used in the treatment of Parkinson's disease.

APPLICATION QUESTIONS

1. A client with Guillain–Barré syndrome has an order for low dose anticoagulation. Which finding best indicates that this treatment is having the desired effect on this client?
 - a. Client reports of paresthesias have decreased.
 - b. Client's blood pressure is stable.
 - c. Client's cerebrospinal fluid is clear.
 - d. Client is free of S&S of thromboembolism.
2. Which characteristic must an antibiotic have in order to be used in the treatment of meningitis?
 - a. Low protein binding in the bloodstream
 - b. Ability to cross the blood–brain barrier
 - c. Effectiveness against gram-negative organisms
 - d. Resistance to neurotransmitter effects.
3. A client with encephalitis has an order for a diuretic. Which assessment data would provide the best evidence of the drug having its desired effect related to the disease process?
 - a. Fever returns to normal.
 - b. DTRs are intact.
 - c. Seizure activity is absent.
 - d. ICP decreases.
4. Which assessment findings would the nurse expect when admitting a client with a diagnosis of bacterial meningitis? Mark all that apply.
 - a. High fever
 - b. Nausea and vomiting
 - c. Stomach cramps
 - d. Diarrhea
 - e. Nuchal rigidity
 - f. Photophobia
5. Which nursing order should be included in the plan of care for a 2-year old with an adrenal neuroblastoma?
 - a. Palpate abdomen for increased distention daily.
 - b. Weigh all diapers.
 - c. Limit fluids to 1000 cc/24 hours.
 - d. Provide a high-carbohydrate, low-protein diet.
6. Occurrence of which symptom best differentiates between mild and severe concussion?
 - a. Loss of consciousness
 - b. Tremor
 - c. Unstable gait
 - d. Impaired speech
7. A client with a seizure disorder whose disease is well controlled with medication tells the nurse she is trying to get pregnant. Which would be the most appropriate response for the nurse to make?
 - a. You should see your neurologist as soon as you get a positive pregnancy test because you may need to discontinue your seizure medications.
 - b. Be sure to see your neurologist if you should have a seizure once you are pregnant because you may need increased doses of medication.
 - c. You should see your neurologist now because some seizure medications are harmful during pregnancy.
 - d. You should see your gynecologist to determine if you can get pregnant because seizure drugs can cause changes in the uterus that prevent pregnancy.
8. A child is admitted to the hospital with symptoms of meningitis and a purpuric rash. Until the diagnosis is confirmed, the child should be:
 - a. entertained to prevent boredom.
 - b. placed in contact and respiratory isolation
 - c. kept in a well-lit room to be observed for cyanosis.
 - d. encouraged to drink fluids to counteract dehydration.

9. The nurse in the physician's office completes the nursing history on a 6-month-old infant. Which statement by the mother would make the nurse suspect cerebral palsy?
 - a. I've noticed my baby often crosses his eyes.
 - b. My baby is on schedule with his development.
 - c. My baby often crosses his legs when I pick him up.
 - d. When I feed my baby, he often pushes the food back out of his mouth.
10. A newborn has been admitted to the pediatric hospital with a large, high myelomeningocele. The child displays paralysis of the lower extremities. To monitor for a common associated defect, the nurse will
 - a. monitor cardiac function.
 - b. measure intake and output
 - c. do daily head circumferences.
 - d. measure abdominal circumferences.
11. When a mother of a child with a viral illness asks the nurse what she should do when her child runs a fever, the nurse would recommend:
 - a. placing the child in a bathtub of cold water.
 - b. giving the child acetaminophen according to the label directions.
 - c. giving the child baby aspirin according to the label directions.
 - d. bringing the child to the emergency room if the child's temperature was over 99 °F
12. When comparing the development of a mentally retarded child to a normal child, the nurse would note
 - a. the development patterns will be exactly the same.
 - b. the pattern of development for the mentally retarded child is unpredictable.
 - c. the development of the mentally retarded child follows the same pattern as the normal child does except at a slower pace.
 - d. the normal child develops cephalocaudally, the mentally retarded child develops in the reverse pattern.
13. A child is admitted to the hospital unit after a car accident in which his/her head struck the windshield. The child is alert and oriented. While cleaning up the child's lacerations, the nurse notes serosanguineous drainage from the right ear. The nurse would suspect
 - a. ruptured ear drum.
 - b. basilar skull fracture.
 - c. depressed skull fracture.
 - d. linear skull fracture.
14. A newborn is admitted to the pediatric hospital with a meningocele. In which position would the nurse place the infant during the preoperative period?
 - a. Prone
 - b. Supine
 - c. High Fowler's
 - d. Semi-Fowler's
15. An infant has had a meningocele repair. After surgery, the mother is at the baby's crib and asks the nurse: "When will my baby start moving his legs?" The nurse's best response would be based on the knowledge that:
 - a. damage to the spinal cord is permanent.
 - b. no one knows if the baby will regain leg use or not.
 - c. it takes several weeks after surgery for the swelling to go down.
 - d. the baby will gain movement following the insertion of a shunt for hydrocephalus.
16. Which direction would be included when teaching a client with multiple sclerosis?
 - a. Use strict aseptic technique for self-catheterization.
 - b. Report slurred speech to the health care provider.
 - c. Eat a high-protein, low-fiber diet.
 - d. Avoid extremes of heat such as hot tubs or saunas if alone.
17. When caring for a client with an upper motor neuron spinal cord injury, on what basis would the nurse conclude that the period of spinal shock is over?
 - a. Client is hemodynamically stable.
 - b. Client's spinal reflexes have returned.
 - c. Client experiences an episode of autonomic hyperreflexia.
 - d. Client sweats above the level of injury.
18. What direction regarding nutrition should the nurse give to a client with trigeminal neuralgia?
 - a. Drink large amounts of clear fluids each day.
 - b. Eat three meals per day taking an analgesic a half hour before each.
 - c. Stick to a full liquid diet until pain is relieved.
 - d. Use unaffected side of mouth to manage food and chew.
19. Which assessment findings would be expected in a client with Brown-Séquard syndrome resulting from a stab wound? Mark all that apply.
 - a. ipsilateral loss of pain perception
 - b. ipsilateral paralysis

(continued)

- c. ipsilateral vasomotor loss
 d. contralateral loss of position sense
 e. contralateral temperature sensation
 f. contralateral paralysis
20. Which is a priority concern when planning teaching for a client with Bell's palsy?
 a. Exercises to combat facial weakness
 b. Precautions to prevent spread to others
 c. Eye care to prevent corneal abrasion
 d. Nutritional requirements to support healing.
21. For which client would planned reflexive bladder emptying be a possibility?
 a. A client with an upper motor neuron injury
 b. A client with a lower motor neuron injury
 c. A client with Brown-Séguard syndrome
 d. A client with anterior cord syndrome
22. What is the first action the nurse should take when a client with a cervical SCI develops hypertension, bradycardia, a throbbing headache, blurred vision and marked diaphoresis above the level of the injury?
 a. Notify the physician.
 b. Raise the head of the bed to Fowler's position.
 c. Check for bladder distention.
 d. Remove restrictive clothing.
23. Why is it important to determine the exact time that the S&S developed in a client who presents at the emergency room with a stroke?
 a. Diagnostic laboratory values change during the first 8 hours after stroke.
 b. The tPA therapy if appropriate, must be given within the first 3 hours after the onset of symptoms.
 c. Differentiation between ischemic and hemorrhagic stroke is not possible once 4 hours have elapsed.
 d. Size of the lesion cannot be determined for at least 48 hours.
24. Flaccid paralysis would be an expected assessment finding in which client?
 a. A client with an upper motor neuron injury
 b. A client with a lower motor neuron injury
 c. A client with Brown-Séguard syndrome
 d. A client with anterior cord syndrome
25. Which nursing order should be part of the plan of care for a client with SCI?
 a. Assess skin every morning.
 b. Monitor for calf pain.
 c. Use a gloved finger to stimulate bowel elimination 30 minutes after arising in the morning.
 d. Have client shift weight every 15–20 minutes when sitting up.

ANSWERS & RATIONALES

MATCHING ANSWERS

Column A

1. e concussion
2. o cerebrospinal rhinorrhea
3. i Beta interferons
4. c subdural hematoma
5. h cerebral aneurysm
6. p hemiparesis
7. t tonic seizure
8. g carbamazepine

Column B

- a. tumor of the neural crest cells or adrenal gland
- b. drug used to decrease cerebral edema
- c. venous bleeding into space between dura and arachnoid
- d. sign of brain contusion
- e. transient, neurologic dysfunction occurring as a result of head injury
- f. injury of brain tissue directly underneath the site of trauma
- g. drug used for seizures
- h. associated with cocaine use

- | | |
|---|---|
| 9. <u>f</u> coup injury | i. immunomodulators used in treatment of multiple sclerosis |
| 10. <u>j</u> bradykinesia | j. slowness of movement seen in Parkinson's disease |
| 11. <u>d</u> ipsilateral pupil dilation | k. used in management of guillain–barré syndrome |
| 12. <u>a</u> neuroblastoma | l. surgical procedure used in management of myasthenia gravis |
| 13. <u>n</u> lorazepam | m. paralysis of half the body |
| 14. <u>r</u> myoclonic seizure | n. drug used for status epilepticus |
| 15. <u>m</u> hemiplegia | o. sign of a tear in the dura |
| 16. <u>l</u> thymectomy | p. weakness on one side of the body |
| 17. <u>b</u> Dexamethasone | q. abnormal sensation |
| 18. <u>k</u> plasmapheresis | r. brief jerking of a muscle group |
| 19. <u>q</u> paresthesia | s. impairment of motor or sensory function of lower extremities |
| 20. <u>s</u> paraplegia | t. rigidity of all muscles |

TRUE & FALSE ANSWERS

1. A major difference between meningitis and encephalitis is that brain function is normal with meningitis and abnormal with encephalitis. *True*
2. For clients with meningitis, the room should be kept quiet and lights dimmed to allow for frequent rest periods throughout the day. *True*
3. Long term memory loss is an early sign of Alzheimer's disease. *False*
Short-term memory is an early symptom.
4. The priority intervention for a client who has sustained head trauma is immobilization because of the risk that damage to the spinal cord has also occurred. *True*
5. One seizure alone does not constitute having a seizure disorder. *True*
6. Pallidotomy is performed on selected clients with Parkinson's disease to decrease muscle stiffness and increase mobility. *False.*
It is performed to decrease tremor.
7. A subacute, subdural hematoma becomes symptomatic 24–48 hours after injury. *False*
An acute subdural hematoma becomes symptomatic 24–48 hours after injury; a subacute hematoma becomes symptomatic 2 days to 2 weeks after injury.

(continued)

8. Rhinorrhea consisting of clear fluid is suggestive of a tear in the dura in a client with a basilar skull fracture. *True*
9. Decadron decreases spinal cord compression by decreasing inflammation and, therefore, decreasing edema. *True*
10. It is not possible to differentiate complete from incomplete transection of the spinal cord until the period of spinal shock is over; thus it is impossible to estimate recovery potential until this time. *True*
11. Methylprednisolone (Solu-Medrol) when given for SCI cannot be given later than the first 4 hours after injury.
False
It must be given within the first 8 hours after injury.
12. Clients with SCI must be monitored for tarry stools because of the risk of gastric bleeding. *True*
13. Breathing is generally easiest when clients with a recent SCI are in an upright sitting position. *False*
Breathing is often easiest in the supine position because the flaccid intercostals muscles collapses inward on inspiration thereby decreasing chest capacity.
14. Bell's palsy is a disorder of cranial nerve V. *False.*
Bell's palsy affects cranial nerve VII, the facial nerve. Trigeminal neuralgia affects cranial nerve V.
15. A symptom of hydrocephalus in an older child is vomiting without nausea. *True*
16. The client with meningitis is best positioned flat with a small pillow. *False*
The client is best positioned with the head slightly elevated.
17. A child who has a febrile convulsion is at risk for having a seizure from another type of environmental stimulus at another time. *False*
A child who has a febrile seizure is likely to have another seizure if he/she develops another fever so fevers must be treated promptly. The child is not at greater risk for any other type of seizure.
18. Teaching the parents of a child with cerebral palsy how to care for the skin underlying the braces is essential. *True*
19. For a client with a fractured skull the bed should be flat or no higher than 30 degrees if ordered. *True*
20. Symptoms of postconcussion syndrome include forgetfulness, changes in behavior, and learning problems. *True*

ANSWERS FOR FILL IN THE BLANKS

1. The most commonly used test for the diagnosis of meningitis is the spinal tap.
2. When caring for a client with a subdural hematoma the nurse would monitor neurological status every 2 hours using the Glasgow Coma Scale.
3. The neurological disorder characterized by progressive ascending sensory and motor defects is Guillain-Barré syndrome.
4. Treatment with tPA must be given within 3 hours of initial symptoms of ischemic stroke.
5. A fracture at the base of the skull is called a basilar fracture.

6. Deep, throbbing, one-sided head pain starting under the orbit of the eye and spreading to the head and neck are symptoms of a cluster headache.
7. A decline in fine motor skills is an early symptom of amyotrophic lateral sclerosis.
8. In the treatment of a client with myasthenia gravis, the class of drug used when corticosteroids fail is the immunosuppressants.
9. The tremor characteristic of Parkinson's disease is a resting tremor.
10. Sleepiness, drowsiness, and sedation are side effects of the dopamine agonists used in the treatment of Parkinson's disease.

APPLICATION ANSWERS

1. A client with Guillain–Barré syndrome has an order for low dose anticoagulation. Which finding best indicates that this treatment is having the desired effect on this client?
 - a. Client reports of paresthesias have decreased.
 - b. Client's blood pressure is stable.
 - c. Client's cerebrospinal fluid is clear.
 - d. Client is free of S&S of thromboembolism.

Rationale

Correct answer: d.

Clients with Guillain–Barré syndrome receive low dose anticoagulation because of the risk for thromboembolism secondary to immobility. Therefore, the desired effect of the treatment is that the client remains free of thromboembolism. This is indicated by absence of the S&S of the disorder. Anticoagulation is not given for paresthesias or unstable blood pressure, neither does it affect the spinal fluid.

2. Which characteristic must an antibiotic have in order to be used in the treatment of meningitis?
 - a. Low protein binding in the bloodstream
 - b. Ability to cross the blood–brain barrier
 - c. Effectiveness against gram-negative organisms
 - d. Resistance to neurotransmitter effects

Rationale

Correct answer: b.

Antibiotics must be able to cross the blood–brain barrier in order to reach the infective organisms. Not all organisms causing meningitis are gram negative and so this is not a characteristic that must apply to all antibiotics used to treat it. Low protein binding in the blood and resist-

ance to neurotransmitter effects are irrelevant to the ability of an antibiotic to combat meningitis.

3. A client with encephalitis has an order for a diuretic. Which assessment data would provide the best evidence of the drug having its desired effect related to the disease process?
 - a. Fever returns to normal.
 - b. DTRs are intact.
 - c. Seizure activity is absent.
 - d. ICP decreases.

Rationale

Correct answer: d.

A diuretic such as Osmitol or Furosemide is prescribed for clients with meningitis to decrease cerebral edema. The best measure of cerebral edema is intracranial pressure (ICP).

4. Which assessment findings would the nurse expect when admitting a client with a diagnosis of bacterial meningitis? Mark all that apply.
 - a. High fever
 - b. Nausea and vomiting
 - c. Stomach cramps
 - d. Diarrhea
 - e. Nuchal rigidity
 - f. Photophobia

Rationale

Correct answer: all.

In addition to the S&S listed, rash, lethargy, irritability, muscular weakness, seizures and decreased level of consciousness, even coma also occurs. In infants a bulging fontanel and high-pitched moaning may also be present.

(continued)

5. Which nursing order should be included in the plan of care for a 2-year old with an adrenal neuroblastoma?
- Palpate abdomen for increased distention daily.
 - Weigh all diapers.
 - Limit fluids to 1000 cc/24 hours.
 - Provide a high-carbohydrate, low-protein diet.

Rationale

Correct answer: b.

All diapers should be weighed as part of monitoring output. The abdomen is not palpated when an adrenal tumor is present. Fluids are encouraged not limited. Diet is high calorie and high protein.

6. Occurrence of which symptom best differentiates between mild and severe concussion?
- Loss of consciousness
 - Tremor
 - Unstable gait
 - Impaired speech

Rationale

Correct answer: a.

Loss of consciousness does not occur with a mild concussion.

7. A client with a seizure disorder whose disease is well controlled with medication tells the nurse she is trying to get pregnant. Which would be the most appropriate response for the nurse to make?
- You should see your neurologist as soon as you get a positive pregnancy test because you may need to discontinue your seizure medications.
 - Be sure to see your neurologist if you should have a seizure once you are pregnant because you may need increased doses of medication.
 - You should see your neurologist now because some seizure medications are harmful during pregnancy.
 - You should see your gynecologist to determine if you can get pregnant because seizure drugs can cause changes in the uterus that prevent pregnancy.

Rationale

Correct answer: c.

Some seizure medications are harmful to the fetus/infant when taken by pregnant or lactating women so the client's neurologist should be consulted prior to her getting pregnant. Pregnancy may require a change in seizure medication but it does not require drug therapy to be discontinued. Seeing a neurologist only if a seizure occurs during pregnancy does not protect the fetus from possible untoward effects of prescribed drugs. Anticonvulsants do not affect the uterus.

8. A child is admitted to the hospital with symptoms of meningitis and a purpuric rash. Until the diagnosis is confirmed, the child should be:
- entertained to prevent boredom.
 - placed in contact and respiratory isolation
 - kept in a well-lit room to be observed for cyanosis.
 - encouraged to drink fluids to counteract dehydration.

Rationale

Correct answer: b.

Until meningococcal meningitis has been ruled out, the child should be placed on isolation. Photophobia is a common symptom of meningitis so a well-lit room will add to the discomfort. The child will probably be placed on fluid restrictions to reduce cerebral edema.

9. The nurse in the physician's office completes the nursing history on a 6-month-old infant. Which statement by the mother would make the nurse suspect cerebral palsy?
- I've noticed my baby often crosses his eyes.
 - My baby is on schedule with his development.
 - My baby often crosses his legs when I pick him up.
 - When I feed my baby, he often pushes the food back out of his mouth.

Rationale

Correct answer: c.

Children with spastic cerebral palsy often display "scissoring" of the legs. Babies with cerebral palsy are often described as delayed in development. The tongue thrust is a normal feeding mechanism of infancy and pseudostrabismus (cross eyes) is a sign of immaturity.

10. A newborn has been admitted to the pediatric hospital with a large, high myelomeningocele. The child displays paralysis of the lower extremities. To monitor for a common associated defect, the nurse will
- monitor cardiac function.
 - measure intake and output.
 - do daily head circumferences.
 - measure abdominal circumferences.

Rationale

Correct answer: c.

A large percentage of infants with myelomeningoceles also develop hydrocephalus. Daily head circumferences may indicate hydrocephalus.

11. When a mother of a child with a viral illness asks the nurse what she should do when her child runs a fever, the nurse would recommend
- placing the child in a bathtub of cold water.
 - giving the child acetaminophen according to the label directions.

- c. giving the child baby aspirin according to the label directions.
- d. bringing the child to the emergency room if the child's temperature was over 99°F.

Rationale

Correct answer: b.

Never give a child with a viral illness aspirin as it is associated with Reye's syndrome. Cold water would bring the child's temperature down too fast and could cause seizures. A fever of 99°F is not considered serious.

12. When comparing the development of a mentally retarded child to a normal child, the nurse would note:
- a. the development patterns will be exactly the same.
 - b. the pattern of development for the mentally retarded child is unpredictable.
 - c. the development of the mentally retarded child follows the same pattern as the normal child does except at a slower pace.
 - d. the normal child develops cephalocaudally, the mentally retarded child develops in the reverse pattern.

Rationale

Correct answer: c.

The pattern is the same but the mentally retarded child develops at a slower rate.

13. A child is admitted to the hospital unit after a car accident in which his/her head struck the windshield. The child is alert and oriented. While cleaning up the child's lacerations, the nurse notes serosanguineous drainage from the right ear. The nurse would suspect:
- a. ruptured eardrum.
 - b. basilar skull fracture.
 - c. depressed skull fracture.
 - d. linear skull fracture.

Rationale

Correct answer: b.

The bloody drainage could be cerebrospinal fluid, an indication of a basilar skull fracture.

14. A newborn is admitted to the pediatric hospital with a meningocele. In which position would the nurse place the infant during the preoperative period?
- a. Prone
 - b. Supine
 - c. High Fowler's
 - d. Semi-Fowler's

Rationale

Correct answer: a

The child is placed in a position to protect the sac. All other positions would put pressure on the sac.

15. An infant has had a meningocele repair. After surgery, the mother is at the baby's crib and asks the nurse: "When will my baby start moving his legs?" The nurse's best response would be based on the knowledge that:
- a. damage to the spinal cord is permanent.
 - b. no one knows if the baby will regain leg use or not.
 - c. it takes several weeks after surgery for the swelling to go down.
 - d. the baby will gain movement following the insertion of a shunt for hydrocephalus.

Rationale

Correct answer: a.

Damage to the spinal cord that has occurred during the fetal period is permanent. The paralysis will not change because the sac has been removed.

16. Which direction would be included when teaching a client with multiple sclerosis?
- a. Use strict aseptic technique for self-catheterization.
 - b. Report slurred speech to the health care provider.
 - c. Eat a high-protein, low-fiber diet.
 - d. Avoid extremes of heat such as hot tubs or saunas if alone.

Rationale

Correct answer: d.

Client should avoid exposure to extreme heat when alone. Self-catheterization in the home is done using clean, not sterile technique. Slurred speech is a symptom of multiple sclerosis. The diet for a client with MS should be high protein, high fiber. Fiber is needed to facilitate bowel function.

17. When caring for a client with an upper motor neuron spinal cord injury, on what basis would the nurse conclude that the period of spinal shock is over?
- a. Client is hemodynamically stable.
 - b. Client's spinal reflexes have returned.
 - c. Client experiences an episode of autonomic hyperreflexia.
 - d. Client sweats above the level of injury.

Rationale

Correct answer: b.

Resolution of spinal shock is indicated by a return of spinal reflexes. Hemodynamic instability is associated with autonomic hyperreflexia, which is a condition that results from over response of the sympathetic nervous system because below the injury is shut off from inhibitory control of centers in the brain

(continued)

18. What direction regarding nutrition should the nurse give to a client with trigeminal neuralgia?
- Drink large amounts of clear fluids each day.
 - Eat three meals per day taking an analgesic a half hour before each.
 - Stick to a full liquid diet until pain is relieved.
 - Use unaffected side of mouth to manage food and chew.

Rationale

Correct answer: d.

The client should be encouraged to eat soft, nutritious foods using the unaffected side of the mouth to hold and move food and chew. Drinking large amounts of clear fluids per day would not be a good suggestion because fluids are hard to manage using only one half of the mouth and clear fluids are not nutrient rich. Since eating can be painful anything the client eats should contribute significantly to meeting nutritional needs. A full liquid diet is not desirable because of the difficulty managing liquids.

19. Which assessment findings would be expected in a client with Brown-Séquier syndrome resulting from a stab wound? Mark all that apply.
- ipsilateral loss of pain perception
 - ipsilateral paralysis
 - ipsilateral vasomotor loss
 - contralateral loss of position sense
 - contralateral temperature sensation
 - contralateral paralysis

Rationale

Correct answers: b, c, and e.

Paralysis and loss of position sense, and vasomotor control occur on the same side as the lesion (ipsilateral). Loss of pain and temperature sensation is contralateral, that is, it occurs on the side opposite the lesion. This is because the nerve fibers that carry the sensations of pain and temperature immediately cross over and ascend on the other side of the cord.

20. Which is a priority concern when planning teaching for a client with Bell's palsy?
- Exercises to combat facial weakness
 - Precautions to prevent spread to others
 - Eye care to prevent corneal abrasion
 - Nutritional requirements to support healing.

Rationale

Correct answer: c.

Inability to blink or close the eye on the affected side creates risk of corneal abrasion. Client is taught to use artificial tears and to wear a patch when outdoors to prevent particles from entering the eye and to prevent drying and exposure to the environment. At night the client is

instructed to wear an eye patch or tape the lid shut. Exercises may be done to strengthen facial muscles but preserving eyesight is the priority. Bell's palsy is caused by the Herpes simplex virus, which the majority of people in the population are already exposed to. Nutrition does not play a significant role in treatment of the disease.

21. For which client would planned reflexive bladder emptying be a possibility?
- A client with an upper motor neuron injury
 - A client with a lower motor neuron injury
 - A client with Brown-Séquier syndrome
 - A client with anterior cord syndrome

Rationale

Correct answer: a.

Upper motor neuron lesions result in a loss of brain control over the lower motor neurons. Initially an UMN injury causes muscles to be flaccid and hyporeflexic but reflex arcs gradually become reactive resulting in spasticity of the muscles in response to muscle stretch or autonomic or noxious stimuli. With a lower motor neuron injury, impulses from the cord do not reach the peripheral nerves, which innervate muscles. The result is flaccid weakness or paralysis, loss of reflexes, and atrophy of the involved muscle. Brown-Séquier syndrome occurs with a penetrating injury involving half the cord. It involves loss of motor ability, touch, vibration, and pressure sense on side of injury; and loss of pain and temperature sense on the side opposite injury. Anterior cord syndrome is frequently due to damage to the anterior spinal artery or from pressure of a tumor or a herniated disc. It involves loss of strength, pain perception, and temperature perception below the level of injury.

22. What is the first action the nurse should take when a client with a cervical SCI develops hypertension, bradycardia, a throbbing headache, blurred vision and marked diaphoresis above the level of the injury?
- Notify the physician.
 - Raise the head of the bed to Fowler's position.
 - Check for bladder distention.
 - Remove restrictive clothing.

Rationale

Correct answer: b.

Hypertension, bradycardia, a throbbing headache, blurred vision, and marked diaphoresis above the level of the injury are S&S of autonomic hyperreflexia, which is a medical emergency. The nurse's first action when autonomic hyperreflexia occurs is to raise the head of the bed to 45 degrees to lower pressure in cranial arteries. The physician is notified because this is a medical emergency. The bladder is checked for distention because this along with bowel distention are the most common causes of autonomic hyper-

reflexia. Restrictive clothing is removed because autonomic hyperreflexia can be caused by a variety of stimuli which include heat and pain.

23. Why is it important to determine the exact time that the S&S developed in a client who presents at the emergency room with a stroke?
- Diagnostic laboratory values change during the first 8 hours after stroke.
 - The tPA therapy if appropriate, must be given within the first 3 hours after the onset of symptoms.
 - Differentiation between ischemic and hemorrhagic stroke is not possible once 4 hours have elapsed.
 - Size of the lesion cannot be determined for at least 48 hours.

Rationale

Correct answer: b.

Ischemic strokes can be treated with “clot buster” drugs such as tPA but treatment must be given within the first 3 hours after symptoms occur. Therefore it is important to determine the exact time of symptoms in order to know if clot buster treatment is possible. CT scans are used to differentiate hemorrhagic from ischemic strokes and to determine the size and location of the lesion.

24. Flaccid paralysis would be an expected assessment finding in which client?
- A client with an upper motor neuron injury
 - A client with a lower motor neuron injury
 - A client with Brown–Séguard syndrome
 - A client with anterior cord syndrome

Rationale

Correct answer: b.

With a lower motor neuron injury, impulses from the cord do not reach the peripheral nerves, which innervate muscles. The result is flaccid weakness or paralysis, loss of reflexes, and atrophy of the involved muscle. Upper motor neuron lesions result in a loss of brain control over

the lower motor neurons. Initially an UMN injury causes muscles to be flaccid and hyporeflexic but reflex arcs gradually become reactive resulting in spasticity of the muscles in response to muscle stretch or autonomic or noxious stimuli. Brown–Séguard syndrome occurs with a penetrating injury involving half the cord. It involves loss of motor ability, touch, vibration, and pressure sense on side of injury; and loss of pain and temperature sense on the side opposite injury. Anterior cord syndrome is frequently due to damage to the anterior spinal artery or from pressure of a tumor or a herniated disc. It involves loss of strength, pain perception, and temperature perception below the level of injury. Senses of position, vibration, and light touch remain intact. Both of these two syndromes can involve either upper or lower motor neurons and, therefore, can result in either flaccid or spastic paralysis.

25. Which nursing order should be part of the plan of care for a client with SCI?
- Assess skin every morning.
 - Monitor for calf pain.
 - Use a gloved finger to stimulate bowel elimination 30 minutes after arising in the morning.
 - Have client shift weight every 15–20 minutes when sitting up.

Rationale

Correct answer: d.

Clients with SCI are at risk for skin breakdown. An important preventative measure is weight shifting every 15–20 minutes when sitting up. Clients’ skin should be assessed to ensure early detection and treatment of any skin problems but it must be checked twice a day; once per day is not sufficient. Clients would not be monitored for calf pain because they are unable to feel pain. A gloved finger moved in a circular motion within the rectum may be used to stimulate defecation 20–30 minutes after administration of a suppository to a client with an UMN injury. It is not a routine aspect of care; the finger must be lubricated and an anesthetic ointment applied in accord with agency policy.

Think Smart/Test Smart

As you review the care of clients with eye and ear disorders, keep in mind that safety is always a particular concern for these clients. Not only does the nurse have to institute safety measures when giving direct care to the client but the nurse also has an important role in teaching about safety measures applicable to daily life. Examples of the latter include teaching clients with loss of peripheral vision to turn the whole head in order to look to the sides and informing clients with a hearing deficit about devices such as fire alarms that use light rather than sound to alert to a problem.

EYE PROBLEMS

CATARACTS

- Cataract is the clouding or opacity of the lens resulting in blurred vision and leading ultimately to the loss of vision.

- It is the leading preventable cause of blindness in United States.

Etiology:

- Senile cataract—associated with aging

- Congenital cataract—present at birth, may be due to maternal exposure to rubella in the first trimester
- Traumatic cataract—resulting from trauma such as a contusion or a penetrating injury
- Secondary cataract—resulting from other eye or systemic diseases such as uveitis, diabetes mellitus, and sarcoidosis
- Also associated with ultraviolet radiation and medications such as phenothiazines, corticosteroids, and certain chemotherapeutic agents

S&S:

- Gradual painless blurring and loss of vision
- Glare at night when driving is often the first symptom
- Improved vision with pupil dilation
- Inability to discriminate hues
- Cloudy white opacity behind pupil

Dx: Direct visualization with an ophthalmoscope

Rx: Monitoring with surgical removal and lens implantation at the point at which cataract interferes with the client's daily activities

**Nursing Process Elements**

For care of clients having cataract surgery, see Chapter 18. For those not having surgery, recognize that the ability to read, drive, see family members' faces clearly, cook, sew, or to perform any other activities that require clear eyesight may be compromised.

**Client teaching for self-care**

- Keep eyeglasses or contact lens prescription up-to-date
- Have plenty of lighting in your home—incandescent, not fluorescent—to reduce glare
- Reduce glare by wearing sunglasses outside, having windows with sheer curtains, tinted glass, or adjustable shades
- Explain availability and use of appropriate vision aids such as magnifiers, clear sheets of yellow plastic to reduce glare and make print darker for easier reading, overlays for check writing, large print materials, stove dials with raised markings, telephones that have large buttons with raised numbers, etc. Stress that all aids are not right for everyone

RETINAL DETACHMENT

- Retinal detachment refers to the painless separation of the outer and inner layers of the retina.
- It may be sudden or gradual.

Etiology: Myopic degeneration, trauma, inflammation, and bleeding from a retinal blood vessel.

S&S:

- Floating spots before the eyes
- Flashes of light

- Loss of vision in affected area
- If sudden and extensive, the sensation is of a curtain being lowered over the eye; if the macula involved, blindness results

Dx: Ophthalmoscopic examination shows the tear and its location

Rx:

- If the vision is impaired, surgery is done to reattach retina
- Small areas or holes are sealed with laser or cryopexy (cold)

**Nursing Process Elements**

See Chapter 18 for perioperative care

After laser therapy

- Ensure that the client has someone to drive him or her home

**Client teaching for self-care**

- Expect sensitivity to light so wear dark glasses and avoid direct light exposure
- There are no activity restrictions

MACULAR DEGENERATION

Macular degeneration is a chronic, degenerative disease of the aging retina that occurs in neovascular (exudative or wet) and nonneovascular (dry) forms.

- Wet form: In this, a sudden proliferation of new, fragile blood vessels that leak and cause damage occurs in the normally avascular macula; it may result in rapid loss of central vision over days or weeks.
- Dry form: Macular thins or atrophies and functions poorly.

Etiology Unknown:

S&S: Blurred vision, distortion, loss of central vision, and decreased ability to distinguish color

Dx: Missing areas and distorted, wavy lines seen on the Amsler grid; fluorescein angiography confirms neovascularization

Rx:

Dry form: No effective treatment

Wet form: No restoration of vision but additional loss prevented by laser or photodynamic therapy (PDT), which consists of IV verteporfin activated by low-level laser light

**Clinical Alert**

Drusen (subretinal hyaline deposits) indicate risk of age-related macular degeneration (AMD); if seen on ophthalmic examination of persons above the age of 55 years. An antioxidant plus zinc supplement is recommended.

Nursing Process Elements

- Assess how change in vision has affected lifestyle
- Explain that vision loss is permanent but total loss is rare
- Refer to state agencies such as Bureau for Vocational Rehabilitation if retraining is needed

Client teaching for self-care

- Use of Amsler grid to determine progressive visual change: Check each eye daily with glasses on
- Use an object in the living area such as a doorframe or clock to check vision daily
- Report to ophthalmologist if new or enlarged areas of distortion occur
- Maximize vision by using incandescent light, 75–100-watt bulbs with light rays directed at the area to be seen, and other visual aids such as magnifiers, overlays, etc.

GLAUCOMA

- Glaucoma is an eye disorder characterized by an intraocular pressure (IOP) too high for the health of the eye, optic nerve damage, and loss of peripheral vision, which, if untreated, can cause blindness.
- It is controllable but not curable.
- In glaucoma, lost vision cannot be restored.
- There are two major forms of glaucoma: open-angle, which forms 90% of all cases, and angle-closure.

Etiology: Normal IOP which reflects balance between formation and drainage of aqueous humor is 10–21 mm Hg. Cause of elevation to damage-causing levels is most often unknown; can occur as a result of another eye problem and is then called secondary glaucoma.

S&S:

Open-angle

- No early signs and symptoms are seen; slow, progressive peripheral vision loss occurs later
- IOP over 24 mm Hg
- Tunnel vision
- Persistent dull brow pain
- Inability to detect color changes
- Difficulty adjusting to darkness
- Cupping of the optic disc on ophthalmic examination.

Acute angle-closure

- Severe eye pain often with N&V (nausea and vomiting)
- Decreased vision with halos around lights
- Enlarged, fixed pupil
- Erythematous conjunctiva
- IOP severely elevated (may be 50 mm Hg or over)

- Permanent blindness occurs if IOP remains severely elevated for 24–48 hours

Dx: Tonometry to determine IOP, tonography to check resistance in outflow channels, ophthalmoscopy to assess optic disc, perimetry to check visual fields, and gonioscopy to check for abnormalities in the angle (where iris, ciliary body, and cornea meet) of the eye

Rx: The goal is to lower and maintain IOP at a level that does not cause vision loss. First line Rx is with medications to either increase outflow of aqueous humor (prostaglandin agonists) or decrease its production (beta-adrenergic blockers and carbonic anhydrase inhibitors) or both (alpha-adrenergic agonists). If control is not achieved with medications, argon-laser trabeculoplasty or surgical trabeculotomy to create new drainage channels for aqueous humor is done. Medications are usually still needed after surgery to control IOP.

Acute angle-closure is a medical emergency due to potential loss of vision if IOP is not lowered. Management may require IV carbonic anhydrase inhibitors in combination with osmotic agents along with topical beta blockers and miotics. Topical steroids may be given to minimize tissue damage. If due to a nonreversible cause, laser peripheral iridotomy or surgical peripheral iridectomy is done to create a permanent opening between the anterior and posterior chambers of the eye.

Nursing Process Elements

- For care of client having surgery for glaucoma, see Chapter 18
- Assess client's understanding of the disease specifically its chronicity, need for treatment to prevent further loss of vision, and the fact that once vision is lost it cannot be restored

Assessment Alert

If client has been previously diagnosed, determine what medications are used and the frequency of their use; compare with the list of prescribed medications and note differences.

- Approach client from front and not from side
- If approaching from a direction out of line of vision, call out a greeting to avoid startling client

Client teaching for self-care

The client should be taught the following:

- how to administer prescribed eye drops
- importance of adherence to prescribed medication regime for a lifetime if loss of vision is to be avoided
- importance of keeping a reserve bottle of eye drops on hand and of carrying eye drops on one's person when traveling

- need for regular follow-up care to determine effectiveness of treatment
- need to avoid heavy lifting, isometric exercises, straining at stool, and wearing tight collars, all of which can increase IOP
- importance of taking the required safety precautions related to vision changes from medications or the disease: blurring, delayed dark adaptation, and loss of peripheral vision
 - Turn head to look to sides to make up for loss of peripheral vision
 - Remove small objects from frequently traveled paths
 - Have good lighting in all rooms
 - Use night lights
 - Wait for eyes to adjust before walking in dark areas
 - Avoid driving at night

Practice Alert

Persons with a family history of glaucoma should have an eye examination with IOP measurement every 2 years after the age of 40 years.

CONJUNCTIVITIS

Conjunctivitis is the inflammation or infection of the conjunctiva.

Etiology: It may be caused due to allergies, exposure to irritants, bacteria, or viruses.

S&S: Itching, burning, photophobia, foreign-body sensation, tearing or drainage, and hyperemia or redness

Rx: Antibiotic eye drops for bacterial; anti-allergy drops, corticosteroid drops, and vasoconstrictors may be used for allergic; avoidance of irritants and allergens

Nursing Process Elements

- Use cool compresses and refrigerated eye drops to reduce itching and soreness
- Wear sunglasses or a wide-brimmed hat and use window shades to reduce the effects of photophobia
- Do not rub eyes; replace with substitute action such as rubbing chin if necessary
- Avoid perfumed soaps and make up
- Prevent transmission and reoccurrence if infective:
 - Avoid touching the infected eye
 - Wash hands before and after doing compresses or instilling medications

- Use disposable tissues to wipe drainage; dispose of in proper container; wash hands
- When cleansing face, wash uninfected eye, infected eye; then rinse cloth and continue
- Keep washcloth and towel separate from those of other people
- Launder washcloth, towel, and pillowcase separately from others
- If eye drops are needed in both eyes for another problem, use two bottles—one for each eye, clearly labeled for each

KERATITIS

Keratitis refers to the inflammation or infection of the cornea; it is called corneal ulcer if a microorganism is involved.

Etiology: Exposure or microorganisms (bacteria, viruses, fungi, amoebae); herpes simplex virus 1 is major cause.

S&S:

Exposure keratitis: dry, scratchy, foreign-body sensation; red, swollen conjunctiva; small erosions on lower half of cornea

Microbial keratitis: epiphora, decreased visual acuity, photophobia, iridescent vision, mucopurulent discharge, pain

Rx: Varies with cause.

Exposure keratitis: ocular lubricant, eye patch or soft contact lens if necessary; eyelid sutured shut is final measure

Microbial keratitis: anti-infective drops. Severity of ulcer determines the frequency of administration of ophthalmic drops. Frequency may be as often as every hour. If two drops must be given every hour, one is administered on the hour and the second on the half hour

Nursing Process Elements

- Assess for precipitating events: eye injury, travel, and use of homemade contact lens cleaning solution

Practice Alert

Prevent exposure keratitis by instilling ocular lubricants at least every 8 hours in susceptible clients; apply eye patch PRN.

- Institute measures to maximize vision, decrease glare, and ease photophobia

EAR PROBLEMS

HEARING LOSS

- **Conductive hearing loss:** Results from any obstruction to the passage of sound waves through the external ear canal to the bones of the middle ear.
- **Sensorineural hearing loss:** Sensory hearing loss results from lesions in the cochlea; neural loss results from lesions in the cochlear nerve or higher auditory pathways. Symptoms along with deafness can include distortion of sound, unusual difficulty hearing in the presence of background noise, impaired discrimination (can hear people talk but do not know what is being said), difficulty localizing sound, intolerance for even low noises, tinnitus, and vertigo. Sounds of high frequency are affected first.
- **Mixed hearing loss:** Combination of conductive and sensorineural hearing loss.

Etiology:

Sudden loss (most often from trauma): Risk of sensorineural hearing loss exists with all ear surgeries, head injuries, blast trauma or barotraumas.

Progressive loss: Ototoxic drugs such as aminoglycoside antibiotics, salicylates, quinine, and loop diuretics (e.g., furosemide and ethacrynic acid), exposure to noise, and infections.

Clinical Alert

All clients with meningitis should have their hearing tested immediately on recovery. Meningitis is one of the most common causes of severe bilateral deafness in infants and children.

Dx:

- Tuning fork tests: allow differentiation between conductive and sensorineural hearing loss
- **Rinne Test**—A sounded tuning fork is held beside the head just in front of the ear and the client is asked to say when the sound is no longer heard. The base of the tuning fork is then placed against the mastoid process. If sound is not heard the client is Rinne-positive, which means that air conduction is better than bone conduction and the client either has normal hearing or a sensorineural hearing loss; if sound is heard, the client is Rinne-negative meaning that bone conduction is better than air conduction and the client has a conductive hearing loss.
 - **Weber's Test**—A sounded tuning fork is placed in the middle of the client's forehead or vertex; the client is asked if

the sound is heard, is it louder in one ear, and if so, which one? In case of conductive hearing loss, sound is heard loudest in the ear with the greatest loss while in sensorineural loss, sound is heard loudest in the least affected ear.

Audiometry

- **Pure-tone audiometry** is an indicator of sensorineural function; it is a part of any hearing assessment particularly if surgery is being considered to improve hearing.
- **Speech audiometry** is an indicator of the client's ability to discriminate speech; it is important in assessing suitability for surgery and hearing aids.

PROBLEMS OF THE EXTERNAL EAR

Wax Buildup

Etiology: Excessive production or change in consistency.

S&S: Hearing loss which may be sudden is chief; pain and irritation may also occur

Rx: Removal with a curette or by ear irrigation; wax may need to be softened first

Dx: Otoscope examination

Nursing Process Elements

To irrigate an ear, a stream of fluid is directed up and back along the posterior wall of the external auditory canal so it gets behind the wax or other detriment and washes it back toward the entrance of the canal.

Practice Alert

A stream of water under great pressure aimed directly at the eardrum can perforate it.

Otitis Externa

Otitis externa refers to the inflammation of the skin of the external auditory canal and the surface of the tympanic membrane.

Etiology: Infection either primary or spread from middle ear through a perforated eardrum, eczema, or allergy to eardrops.

Risk factors: Hot, humid climates, moisture in the ear canal, and exposure to irritants which lead to scratching the ear

S&S: Acute: red, swollen meatus weeping freely and very painful; in less acute cases, ear is tender to touch and glands in front of or behind the ear may be enlarged

Rx: Analgesics and local heat application to control pain; steroid drops to control inflammation; antibiotic drops to combat infection; canal may need to be cleansed

Clinical Alert

Antibiotic drops must be given with great care if a perforation exists because some antibiotics may be ototoxic if they enter the middle ear.

Nursing Process Elements

Assessment Alert

Hearing loss is usually not a significant symptom of otitis externa unless it is secondary to middle-ear infection.

Client teaching for self-care

Prevention of external otitis

- Keep ears dry—wear ear plugs when showering, washing hair, or swimming
- Never poke anything in the ears
- Avoid cosmetic products such as hair dyes and sprays, which can cause irritation or itching
- Seek health care at earliest sign of itching or discomfort

Otomycosis

It is a fungal infection of the ear; key characteristic is finding of white to brown or black masses of material like wet paper in the ear. It may occur as a complication of antibiotic treatment of external otitis.

Rx: Cleansing and a local fungicide, e.g., nystatin or clotrimazole for at least 3 weeks

PERFORATED TYMPANIC MEMBRANE

Etiology: Puncture by a foreign object such as a match or a hair pin, blow on the external ear, or compression of air in the external ear as from a shotgun blast.

S&S: Pain and discharge. If due to infection, pain is relieved on perforation; if due to trauma, pain occurs at the moment of perforation but does not persist

Rx: “Less is better”—sterile dressing over ear, antibiotic–steroid eardrops if infection likely. Complicated cases may require surgical repair

Nursing Process Elements

Assessment Alert

Clients with trauma to the ear must be assessed for signs of damage to the facial nerve and for dizziness, nystagmus, and sensorineural hearing loss as any of these indicate the need for surgical exploration of the ear via tympanotomy. If there is recent trauma, consider that clear fluid drainage may be cerebrospinal fluid and be a symptom of a skull fracture.

Client teaching for self-care

- Keep ear canal dry during healing
- Avoid vigorous nose blowing which can disrupt healing
- Contact health care provider if signs of infection such as fever, pain, drainage, or warmth occur

Clinical Alert

Never irrigate an ear when there is the possibility of a perforated tympanic membrane.

PROBLEMS OF THE MIDDLE EAR

PEDS

Otitis Media

Acute or chronic infection of the lining of the middle ear, common in children, nearly always preceded by an upper respiratory infection (URI).

Etiology: Infection can spread up into middle ear via the Eustachian tube in which case the tube becomes blocked and air is reabsorbed and replaced with exudates or the infection can spread from the external ear via a perforation of the eardrum. Most commonly due to *Streptococcus pneumoniae* or *H. influenzae*.

S&S:

- Sharp, stabbing pain in ear itself
- Hearing loss with fluid accumulation in the middle ear, discharge and lessening of pain if perforation of the tympanic membrane occurs
- Tinnitus, dizziness, fever, and malaise may also occur
- In infants and young children, discharge from the ear may be the first sign; or fever and acting not well may be present; in all cases, screaming, especially at night, rolling the head on the pillow, or putting the hand up to the ear suggest need for ear examination

**Assessment Alert**

Progressive conductive hearing loss is best indicator of progressing otitis media; return of hearing indicates resolving of the infection.

Normal: hear whisper at 8 m

Moderate hearing loss: hear whisper at 2 m

Great hearing loss: whisper can just be heard

Severe hearing loss: conversational voice heard only at 1–2 m

Rx: The goal is return of normal hearing. Analgesics or local heat for pain relief; decongestant nose drops and oral medications, mucolytics, and inhalations to reestablish Eustachian tube function; amoxicillin or other antibiotic if deemed indicated

**Clinical Alert**

Once the middle ear has drained either through perforation or myringotomy, pain should decrease. If pain persists or worsens, it indicates progression of disease and requires intervention.

Chronic Otitis Media

Chronic otitis media can be suppurative or nonsuppurative. Nonsuppurative is known as secretory otitis media, otitis media with effusion or “glue ear”—fluid is in middle ear without acute inflammation—is the most frequent cause of acquired hearing loss in childhood.

**Assessment Alert**

Signs of hearing loss vary with child's age: Under the age of 3 years, it may manifest as delayed

speech and language development, for example, by 12 months, a child should be able to localize familiar sounds and by the age of 2 years, to understand simple commands and put spoken words together; older children may appear as inattentive and uncooperative.

Rx: Insertion of small plastic tubes through incisions in the eardrums (myringotomy) to ventilate the middle ear and bypass Eustachian tube function; they are not drainage tubes. Tubes are slowly extruded over several months

PROBLEMS OF THE INNER EAR**Otosclerosis**

Otosclerosis is the overgrowth of a spongy bone around the oval window and stapes footplate resulting in progressive conductive hearing loss because the resulting fixation prohibits transmission of sound waves to the cochlea. It is often bilateral, is common in young adult females, and shows familial disposition.

S&S: Progressive hearing loss, sometimes tinnitus

**Assessment Alert**

Paracusis (ability to hear better in a noisy environment) is characteristic of early otosclerosis. Reason for this is that the client hears background noises less clearly while others hear it well and raise their speaking voices to overcome it. This louder speech without hearing background noise enables the person with otosclerosis to hear better than others.

Rx: Stapedectomy with insertion of a prosthesis to restore mobility of the ossicles (see Chapter 18).

Meniere's Disease

Etiology: Usually idiopathic.

S&S: Recurrent episodes (20 minutes to several hours) of spontaneous rotary vertigo, fluctuating hearing loss, tinnitus, and a feeling of fullness in the ear, often accompanied by nausea, vomiting, and sweating and sometimes loss of consciousness. After acute symptoms subside, balance is poor and client feels unwell for up to 24 hours

Rx: Low-salt diet, betahistine hydrochloride and a mild diuretic given to reduce number and severity of attacks;

vestibular sedative such as prochlorperazine to abort acute attacks. Surgery may be done in refractory cases.

Nursing Process Elements

Help the client identify precipitating events or forewarning of attacks

Client teaching for self-care

- Aim to reduce severity of attacks by taking medication as prescribed when attack starts and lying down on the unaf-

ected side in a quiet, darkened room and avoiding sudden movements and activities including reading

- Try to prevent attacks by avoiding exposure to loud sounds, bright light including sunlight, rapid jerky movements, bending at the waist, or twisting the head, all of which predispose to vertigo
- Encourage avoidance of nicotine, caffeine, and decongestants all of which have a vasoconstrictive effect
- Avoid fatigue and stress
- Use a white-noise machine to mask tinnitus PRN

WORKSHEETS

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|------------------|------------------|
| 1. The one symptom of a retinal detachment is the sensation of a curtain being pulled down over the eye. | <u> </u> T | <u> </u> F |
| 2. Tonometry is done to check for abnormalities in the angle of the eye. | <u> </u> T | <u> </u> F |
| 3. Prostaglandin agonists work to lower IOP by increasing outflow of aqueous humor. | <u> </u> T | <u> </u> F |
| 4. Following surgery for glaucoma, topical eye medications are no longer required. | <u> </u> T | <u> </u> F |
| 5. Retinal detachment is a painless event. | <u> </u> T | <u> </u> F |
| 6. Hearing loss is commonly associated with external-ear infection. | <u> </u> T | <u> </u> F |
| 7. Progressive hearing loss particularly in young adult females is suggestive of otosclerosis. | <u> </u> T | <u> </u> F |
| 8. Vertigo due to ear disease is usually accompanied by other signs of ear disease such as hearing loss or tinnitus as opposed to signs of central nervous system dysfunction. | <u> </u> T | <u> </u> F |
| 9. Signs of hearing loss vary with a child's age. | <u> </u> T | <u> </u> F |
| 10. Fluid in the middle ear without acute inflammation is the most common cause of acquired hearing loss in childhood. | <u> </u> T | <u> </u> F |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Blindness can result if IOP is elevated to 50 mm Hg or more for _____ to _____ hours.
2. An ear is never irrigated when there is the possibility of _____.
3. Persons with a family history of glaucoma should have IOP measured every 2 years after the age of _____.
4. Antibiotic eardrops must be used carefully and selectively when the eardrum is perforated because some antibiotic drops may be _____ if they enter the middle ear.
5. Wavy lines seen on an Amsler grid are symptomatic of _____.

MATCHING QUESTIONS

Match the following:

- | | |
|---------------------------------------|--|
| 1. _____ Acute angle-closure glaucoma | a. Glare at night when driving is often first symptom |
| 2. _____ Meniere's disease | b. Sudden hearing loss |
| 3. _____ Retinal detachment | c. Persistent dull brow pain, slow dark adaptation |
| 4. _____ Otosclerosis | d. Masses of white to brown wet paper-like material in ear |
| 5. _____ Cataracts | e. Sharp, stabbing pain in ear |
| 6. _____ Macular degeneration | f. N&V, enlarged fixed pupil |
| 7. _____ Otitis media | g. Moving spots in front of the eyes |
| 8. _____ Otomycosis | h. Recurrent episodes of vertigo |
| 9. _____ Open-angle glaucoma | i. Paracusis |
| 10. _____ Ear wax buildup | j. Distorted vision with central loss |

APPLICATION QUESTIONS

1. Which are the risk factors for infection of the external ear? (Select all that apply.)
 - a. Hot, humid environment
 - b. Moisture in the ear canal
 - c. Upper respiratory infection
 - d. Scratching the ear
 - e. Change in altitude and air pressure

(continued)

2. How should the nurse interpret persistent pain in a client with a middle-ear infection whose tympanic membrane has ruptured?
 - a. Expected since drainage takes 24–48 hours to occur
 - b. Expected because of the trauma of the perforation
 - c. Disease is progressing since pain should decrease immediately with rupture
 - d. Secondary infection has occurred as a result of the break in the membrane
3. Clients with ear trauma must be assessed for which of the following problems? (Select all that apply.)
 - a. Facial nerve damage
 - b. Sensorineural hearing loss
 - c. Dizziness
 - d. Nystagmus
4. When assessing the effectiveness of prochlorperazine therapy for a client with Meniere's disease which data is the most important for the nurse to obtain?
 - a. the number of attacks per week
 - b. the length of time between attacks
 - c. the duration of an attack
 - d. the perceived severity of an attack
5. Which information would be correct to give to the parents of a child having myringotomy tubes inserted for the treatment of chronic otitis media?
 - a. Tubes will come out by themselves in a few months
 - b. Small amounts of drainage from the tubes will occur, especially in the morning
 - c. Tubes cause periodic discomfort, which is treated with acetaminophen
 - d. Prophylactic antibiotics are needed while the tubes are in place
6. Which is the best indicator that an acute middle-ear infection is resolving?
 - a. Tinnitus disappears
 - b. Drainage thins
 - c. Hearing improves
 - d. Pain dulls
7. A mother tells the nurse at a Health Fair that her 5-month old has been screaming at night and tossing his head back and forth on the pillow for the last few nights. Which type of examination would the nurse suggest for the infant?
 - a. Dental examination
 - b. Ear examination
 - c. Throat examination
 - d. Neurological examination
8. The daughter of an elderly client keeping an appointment for an eye examination asks the nurse how cataracts are diagnosed. Which is an accurate reply?
 - a. "Cataracts are seen with an ophthalmoscope."
 - b. "Decreased central vision is diagnostic of cataracts."
 - c. "Cataracts are visualized using fluorescein dye."
 - d. "MRIs of the head are used to make the diagnosis."
9. For which disease would the nurse would plan to evaluate the ability of a client to use an Amsler grid?
 - a. Glaucoma
 - b. Macular degeneration
 - c. Retinal detachment
 - d. Uveitis
10. Which finding indicates a risk for AMD?
 - a. Decreased visual fields
 - b. Sluggish pupillary response to light
 - c. Presence of drusen
 - d. IOP measurement of 22
11. A client tells the nurse that the eye doctor said the pressure in her right eye was 19 and asks if this is normal. Which is the most appropriate answer?
 - a. "19 is within the normal range of 10–21."
 - b. "19 is low but not dangerously so."
 - c. "19 is borderline high and needs monitoring."
 - d. "19 is high and treatment is needed."
12. Which are characteristic assessment findings in a client with acute closed-angle glaucoma? (Select all that apply.)
 - a. persistent dull brow pain
 - b. inability to detect color changes
 - c. severe eye pain
 - d. N&V
 - e. decreased vision with halos around lights
 - f. difficulty adjusting to darkness
 - g. enlarged, fixed pupil
 - h. erythematous conjunctiva
13. Which is an appropriate answer to a client who asks "When do cataracts get removed"?
 - a. "When they reach a diameter of 3 mm or more."
 - b. "When they have turned from light gray to milky white in color."
 - c. "When they have a distinct capsule around them."
 - d. "When they interfere with daily activities."

14. Reports of floating spots before the eyes, flashes of light, and loss of an area of vision as part of the client's description of the reason for seeking health care should be interpreted by the nurse as possible signs of which problem?
- acute glaucoma
 - wet macular degeneration
 - corneal abrasion
 - retinal detachment
15. Which statement made by a client with conjunctivitis indicates the need for further teaching?
- "I will not touch the affected eye unnecessarily."
 - "I will instill prescribed eye drops at room temperature."
 - "I will wash the infected eye after the uninfected eye."
 - "I will use disposable tissues to wipe drainage from my eye."
16. What advice is appropriate for the nurse to give to a client who complains of problems with tinnitus?
- "You can block it with a white noise machine."
 - "A radio set at low volume will help."
 - "Wearing ear plugs is a very effective solution."
 - "Obtaining a hearing aid can help."
17. When caring for a client at risk for exposure keratitis, how often should the nurse plan to instill ophthalmic lubricant drops?
- Once a day
 - Every 12 hours
 - Every 8 hours
 - Every 4 hours
18. Which of the following activities should be avoided by a client with Meniere's disease? (Select all that apply.)
- Sun bathing
 - Attending a rock concert
 - Bending at the knees to pick a spoon off the floor
 - Turning the body to look to the left
 - Traveling by plane
 - Drinking coffee
19. Which measure would the nurse recommend for a client who needs to reduce glare?
- Use of fluorescent lighting in the home
 - Use of 60-watt bulb in a lamp directly aimed at the reading surface
 - Use of a hand-held magnifier
 - Use of a yellow plastic overlay for reading
20. After laser therapy for a small retinal tear, the client complains of sensitivity to light. Which is an appropriate response by the nurse?
- "This sometimes occurs. If it continues over the next 8 hours you will need to be checked."
 - "This is normal. Let me review some things you can do to avoid exposure to direct light."
 - "Apply cool compresses; if you do not have relief in 2 hours, call me back."
 - "You need to come in right away to check for abnormal swelling in your eye."

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- The one symptom of a retinal detachment is the sensation of a curtain being pulled down over the eye. *False*
This is the symptom that is experienced if the detachment is sudden and extensive; symptoms of smaller, slower detachments include floating spots before the eyes, flashes of light, and blind spots.
- Tonometry is done to check for abnormalities in the angle of the eye. *False*
Tonometry measures intraocular pressure (IOP).

(continued)

3. Prostaglandin agonists work to lower IOP by increasing outflow of aqueous humor. *True*
4. Following surgery for glaucoma, topical eye medications are no longer required. *False*
In most cases, medication is still needed to keep IOP in a safe range.
5. Retinal detachment is a painless event. *True*
6. Hearing loss is commonly associated with external-ear infection. *False*
Hearing loss generally occurs with external otitis only if it is secondary to a middle-ear infection.
7. Progressive hearing loss particularly in young adult females is suggestive of otosclerosis. *True*
8. Vertigo due to ear disease is usually accompanied by other signs of ear disease such as hearing loss or tinnitus as opposed to signs of central nervous system dysfunction. *True*
9. Signs of hearing loss vary with a child's age. *True*
10. Fluid in the middle ear without acute inflammation is the most common cause of acquired hearing loss in childhood. *True*

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Blindness can result if IOP is elevated to 50 mm Hg or more for 24 to 48 hours.
2. An ear is never irrigated when there is the possibility of tympanic membrane perforation.
3. Persons with a family history of glaucoma should have IOP measured every 2 years after the age of 40.
4. Antibiotic eardrops must be used carefully and selectively when the eardrum is perforated because some antibiotic drops may be ototoxic if they enter the middle ear.
5. Wavy lines seen on an Amsler grid are symptomatic of macular degeneration.

MATCHING ANSWERS

Match the following:

- | | |
|--|--|
| 1. <u>f</u> Acute angle-closure glaucoma | a. Glare at night when driving is often first symptom |
| 2. <u>h</u> Meniere's disease | b. Sudden hearing loss |
| 3. <u>g</u> Retinal detachment | c. Persistent dull brow pain, slow dark adaptation |
| 4. <u>i</u> Otosclerosis | d. Masses of white to brown wet paper-like material in ear |

- | | |
|------------------------------------|---------------------------------------|
| 5. <u> a </u> Cataracts | e. Sharp, stabbing pain in ear |
| 6. <u> j </u> Macular degeneration | f. N&V, enlarged fixed pupil |
| 7. <u> e </u> Otitis media | g. Moving spots in front of the eyes |
| 8. <u> d </u> Otomycosis | h. Recurrent episodes of vertigo |
| 9. <u> c </u> Open-angle glaucoma | i. Paracusis |
| 10. <u> b </u> Ear wax buildup | j. Distorted vision with central loss |

APPLICATION ANSWERS

1. Which are the risk factors for infection of the external ear? (Select all that apply.)
- Hot, humid environment
 - Moisture in the ear canal
 - Upper respiratory infection
 - Scratching the ear
 - Change in altitude and air pressure

Rationale

Correct answers: a, b, and d.

Microorganisms tend to thrive in warm, moist environments and scratching the ear increases the likelihood of breaking the skin and introducing pathogens. URIs and changes in altitude and air pressure affect the middle ear.

2. How should the nurse interpret persistent pain in a client with a middle-ear infection whose tympanic membrane has ruptured?
- Expected since drainage takes 24–48 hours to occur
 - Expected because of the trauma of the perforation
 - Disease is progressing since pain should decrease immediately with rupture
 - Secondary infection has occurred as a result of the break in the membrane

Rationale

Correct answer: c.

Rupture should result in immediate relief of pain. Persistent or worsening pain needs to be reported because intervention is required. Drainage can occur as soon as the membrane is perforated. Pain is not experienced from the perforation itself. Secondary infection takes time to develop and therefore persistent pain is not consistent with this occurrence.

3. Clients with ear trauma must be assessed for which of the following problems? (Select all that apply.)
- Facial nerve damage
 - Sensorineural hearing loss
 - Dizziness
 - Nystagmus

Rationale

Correct answers: a, b, c, and d.

Because of its location close to the ear, facial nerve damage is a risk when ear trauma occurs. Sensorineural hearing loss can occur due to damage to the cochlear. Dizziness also can result from inner ear damage and nystagmus, which is an involuntary, rapid, rhythmic movement of the eyeball, can result from damage to the labyrinth of inner ear.

4. When assessing the effectiveness of prochlorperazine therapy for a client with Meniere's disease which data is the most important for the nurse to obtain?
- the number of attacks per week
 - the length of time between attacks
 - the duration of an attack
 - the perceived severity of an attack

Rationale

Correct answer: c.

Prochlorperazine, a vestibular sedative, is designed to abort acute attacks. It does not reduce the number, frequency, or severity of attacks.

5. Which information would be correct to give to the parents of a child having myringotomy tubes inserted for the treatment of chronic otitis media?
- Tubes will remain in place until removed by the physician

(continued)

- b. Small amounts of drainage from the tubes will occur, especially in the morning
- c. Tubes cause periodic discomfort, which is treated with acetaminophen
- d. Prophylactic antibiotics are needed while the tubes are in place

Rationale

Correct answer: a.

Tubes are slowly extruded over a few months. Small amounts of drainage, especially in the morning, are not expected; tubes do not cause discomfort and prophylactic antibiotics are not given.

- 6. Which is the best indicator that an acute middle-ear infection is resolving?
 - a. Tinnitus disappears
 - b. Drainage thins
 - c. Hearing improves
 - d. Pain dulls

Rationale

Correct answer: c.

Progressive hearing loss indicates progressive infection; return of hearing indicates resolution of the infection. Tinnitus may or may not occur with middle-ear infection. Pain is sharp and stabbing—it disappears with perforation of the tympanic membrane or with the resolution of the infection; it does not become dull. Drainage occurs only if the tympanic membrane ruptures.

- 7. A mother tells the nurse at a Health Fair that her 5-month old has been screaming at night and tossing his head back and forth on the pillow for the last few nights. Which type of examination would the nurse suggest for the infant?
 - a. Dental examination
 - b. Ear examination
 - c. Throat examination
 - d. Neurological examination

Rationale

Correct answer: b.

The symptoms described are classic signs of an earache so an ear examination would be the first type of examination suggested.

- 8. The daughter of an elderly client keeping an appointment for an eye examination asks the nurse how cataracts are diagnosed. Which is an accurate reply?
 - a. "Cataracts are seen with an ophthalmoscope."
 - b. "Decreased central vision is diagnostic of cataracts."
 - c. "Cataracts are visualized using fluorescein dye."
 - d. "MRIs of the head are used to make the diagnosis."

Rationale

Correct answer: a.

Cataracts can be directly visualized with an ophthalmoscope. Decreased central vision is the major symptom of macula degeneration. Fluorescein dye is used to detect corneal abrasions when placed on the surface of the eye and when given IV is used to illuminate the blood vessels of the retina.

- 9. The nurse would plan to evaluate the ability of a client with which disease, to use an Amsler grid?
 - a. Glaucoma
 - b. Macular degeneration
 - c. Retinal detachment
 - d. Uveitis

Rationale

Correct answer: b.

The Amsler grid allows areas of blindness and distortion to be identified; it is used by the client with AMD daily to monitor disease progression. The Amsler grid is not used by clients with the other disorders.

- 10. Which finding indicates a risk for AMD?
 - a. Decreased visual fields
 - b. Sluggish pupillary response to light
 - c. Presence of drusen
 - d. IOP measurement of 22

Rationale

Correct answer: c.

Drusen are subretinal hyaline deposits that are risk factors for AMD. Decreased visual fields can occur from a wide variety of problems including visual problems such as retinitis pigmentosa and central nervous system problems such as pituitary adenomas. Sluggish pupillary response to light accompanies a large variety of neuro-ophthalmic disorder and can also be caused by Addison's disease or diabetes mellitus. Increased IOP is associated with glaucoma.

- 11. A client tells the nurse that the eye doctor said the pressure in her right eye was 19 and asks if this is normal. Which is the most appropriate answer?
 - a. "19 is within the normal range of 10–21."
 - b. "19 is low but not dangerously so."
 - c. "19 is borderline high and needs monitoring."
 - d. "19 is high and treatment is needed."

Rationale

Correct answer: a.

IOP normally ranges between 10 and 21.

- 12. Which are characteristic assessment findings in a client with acute closed-angle glaucoma? (Select all that apply.)
 - a. persistent dull brow pain
 - b. inability to detect color changes

- c. severe eye pain
- d. N&V
- e. decreased vision with halos around lights
- f. difficulty adjusting to darkness
- g. enlarged, fixed pupil
- h. erythematous conjunctiva

Rationale

Correct answers: c, d, e, g, and h.

Persistent dull brow pain, inability to detect color changes, and difficulty adjusting to darkness are all signs/symptoms of chronic open-angle glaucoma.

13. Which is an appropriate answer to a client who asks “When do cataracts get removed?”
- a. “When they reach a diameter of 3 mm or more.”
 - b. “When they have turned from light gray to milky white in color.”
 - c. “When they have a distinct capsule around them.”
 - d. “When they interfere with daily activities.”

Rationale

Correct answer: d.

In the past, it was believed that cataracts had to ripen before they could be removed; current practice is they are removed when the client reports significant interference with daily activities. Size, color, and distinct capsule are all irrelevant.

14. Reports of floating spots before the eyes, flashes of light, and loss of an area of vision as part of the client’s description of the reason for seeking health care should be interpreted by the nurse as possible signs of which problem?
- a. acute glaucoma
 - b. wet macular degeneration
 - c. corneal abrasion
 - d. retinal detachment

Rationale

Correct answer: d.

Floating spots before the eyes, flashes of light, and loss of an area of vision are indicative of retinal detachment. With a large detachment, the client may experience a “curtain being pulled” effect on vision. Acute glaucoma is characterized by severe pain and elevated IOP; macular degeneration whether wet or dry is characterized by loss of central vision; corneal abrasion is characterized by tearing, pain, and a foreign-body sensation in the eye.

15. Which statement made by a client with conjunctivitis indicates the need for further teaching?
- a. “I will not touch the affected eye unnecessarily.”
 - b. “I will instill prescribed eye drops at room temperature.”

- c. “I will wash the infected eye after the uninfected eye.”
- d. “I will use disposable tissues to wipe drainage from my eye.”

Rationale

Correct answer: b.

Eye drops should be cool for comfort. If the client says they will be instilled at room temperature then he or she needs to be instructed to cool them.

16. What advice is appropriate for the nurse to give to a client who complains of problems with tinnitus?
- a. “You can block it with a white noise machine.”
 - b. “A radio set at low volume will help.”
 - c. “Wearing ear plugs is a very effective solution.”
 - d. “Obtaining a hearing aid can help.”

Rationale

Correct answer: a.

Tinnitus can be blocked with a white noise machine. A radio or TV will not help; ear plugs will not help since the source of the sound is internal not external; and a hearing aid does not help either.

17. When caring for a client at risk for exposure keratitis, how often should the nurse plan to instill ophthalmic lubricant drops?
- a. Once a day
 - b. Every 12 hours
 - c. Every 8 hours
 - d. Every 4 hours

Rationale

Correct answer: c.

Ophthalmic lubricant drops need to be instilled at least every 8 hours.

18. Which of the following activities should be avoided by a client with Meniere’s disease? (Select all that apply.)
- a. Sun bathing
 - b. Attending a rock concert
 - c. Bending at the knees to pick a spoon off the floor
 - d. Turning the body to look to the left
 - e. Traveling by plane
 - f. Drinking coffee

Rationale

Correct answers: a, b, and f.

Clients with Meniere’s disease need to avoid exposure to bright light, loud noise, caffeine, and nicotine. They should also avoid sudden, jerky movements, bending at the waist, and twisty movements of the head.

(continued)

19. Which measure would the nurse recommend for a client who needs to reduce glare?
- a. Use of fluorescent lighting in the home
 - b. Use of 60-watt bulb in a lamp directly aimed at the reading surface
 - c. Use of a hand-held magnifier
 - d. Use of a yellow plastic overlay for reading

Rationale

Correct answer: d.

Fluorescent lights create glare so incandescent are better. Use of a 75–100-watt bulb aimed at what is to be read and/or use of a hand magnifier can facilitate reading but does not affect glare per se.

20. After laser therapy for a small retinal tear, the client complains of sensitivity to light. Which is an appropriate response by the nurse?

- a. “This sometimes occurs. If it continues over the next 8 hours you will need to be checked.”
- b. “This is normal. Let me review some things you can do to avoid exposure to direct light.”
- c. “Apply cool compresses; if you do not have relief in 2 hours, call me back.”
- d. “You need to come in right away to check for abnormal swelling in your eye.”

Rationale

Correct answer: b.

There is light sensitivity after laser therapy and sunglasses should be worn and window shades used for comfort.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 6: Musculoskeletal Problems

| | | | |
|------------------------------------|-----|--|-----|
| Developmental Dysplasia of the Hip | 809 | Osteogenesis Imperfecta | 810 |

FRACTURES

A fracture is a break in the bone. Types of fractures are:

- Linear—fracture line is parallel to the bone's axis
- Longitudinal—fracture line extends in a longitudinal direction along the bone's axis
- Oblique—fracture line crosses the bone at a 45-degree angle to the bone's axis
- Spiral—fracture line crosses the bone at an oblique angle creating the spiral pattern; typically occurs in long bones

- Transverse—fracture forms a right angle with the bone's axis

Etiology: Trauma; pathological conditions that weaken the bone (osteoporosis, bone tumors, metabolic disease)

S&S:

- Pain and joint tenderness
- Pallor
- Pulse loss distal to fracture
- Deformity
- Swelling
- Discoloration
- Crepitus

Open fractures can present with

- blood loss and
- hypovolemic shock.

Dx: Anteroposterior and lateral X-rays; angiography may be done if vascular compromise is noted.

Rx: Emergent treatment includes splinting above and below the fracture, applying ice or a cold pack, elevating the limb to reduce swelling and pain. Severe fractures may require the application of pressure to stop bleeding and fluid replacement. Following diagnosis, there will be application of a splint, cast, or traction to immobilize the fracture.

Complications:

- Compartment syndrome
- Fat emboli

Nursing Process Elements

- Assess neurovascular status
- Administer analgesics
- Maintain proper body alignment
- Provide pin care, if in skeletal traction

- Reposition frequently if on bed rest due to traction
- Assist with range of motion exercises
- Encourage deep breathing and coughing if on bed rest due to traction
- Monitor for S&S of fat emboli
- Monitor for S&S of compartment syndrome (increased pain in limb, skin color changes, absent pulse, edema distal to injury, pain with passive muscle stretching, sensory changes)
- Encourage fluids to prevent constipation and urinary stasis

Client teaching for self-care

- S&S of impaired circulation to be reported
- Keep cast dry, if appropriate
- Do not insert foreign objects into cast
- Encourage ambulation as permitted

See Chapter 16 for discussion of casts and traction.

Think Smart/Test Smart

Almost all clients with a musculoskeletal problem have some degree of immobility. The immobility may be the result of the disease process itself, a result of the treatment required, or a result of the client's reaction to the symptoms or the treatment i.e., clients limit activity because of discomfort or fear. This means there is a risk of one or more effects of immobility and so preventative measures must be a part of every plan of care. Be sure to recognize that the degree of risk will vary with the client's problem as will the specific risk. For example, a client with rheumatoid arthritis does not have the same risk as a client with paraplegia.

HIP FRACTURE

Fracture of the proximal femur may be intracapsular (within hip joint and capsule), extracapsular, or intertrochanteric (outside the hip joint and capsule to an area approximately 5 cm below the lesser trochanter), and subtrochanteric (below the lesser trochanter).

Etiology: Falls

Risk factors:

- Osteoporosis
- Advanced age
- Female and Caucasian

- Decreased estrogen levels
- Prior hip fractures
- Alzheimer's dementia
- Institutional residence
- Sedentary lifestyle

S&S:

- Severe pain at fracture site
- Inability to move leg
- Shortening and external rotation of leg

Clinical Alert

Hospital stay of the elderly is often complicated and long with hip fracture being the leading cause of morbidity and mortality.

Dx: X-ray

Rx: Conservative management with traction or surgical repair.

Complications:

- Thromboembolism
- Pneumonia
- Alteration in skin integrity
- Voiding dysfunction

Nursing Process Elements

- Provide pain management

Client teaching for self-care

- Perform neurovascular assessment
- Maintain hip precautions (avoid hip flexion beyond 60 degrees, avoid adduction beyond midline, maintain weight bearing status per MD orders)
- Follow medication regime for pain management, anticoagulants, and/or treatment of osteoporosis
- Practice hip precautions (avoid hip flexion beyond 90 degrees for up to 2 months, avoid adduction past midline for up to 2 months)
- Monitor S&S of complications for thromboembolism, pneumonia, and infection
- Use adaptive or assistive devices
- Restrict weight bearing while ambulating
- Prevent falls
- Have sufficient dietary intake of calcium and vitamin D

SPRAINS

A sprain is a complete or incomplete tear of supporting ligaments surrounding a joint.

Etiology: Sharp twist to the joint

S&S:

- Localized pain
- Swelling
- Ecchymosis
- Decreased use of the joint several hours after injury

Dx: X-rays are performed to rule out fracture

Rx: Immobilize the joint and control pain and swelling

Nursing Process Elements

- Immobilize joint with splint or soft cast
- Administer analgesic or nonsteroidal anti-inflammatory drug
- Apply heat

Client teaching for self-care

- Elevate joint for 48–72 hours
- Apply heat
- Apply ice periodically for the initial 24–48 hours following the injury
- Apply elastic wrapping

DISLOCATION

Dislocation is a displaced joint causing loss of contact of the articulating surfaces.

Etiology: Congenital abnormality, trauma, disease of surrounding joint tissue.

S&S:

- Deformity around joint
- Altered length of the extremity
- Impaired joint mobility
- Point tenderness or extreme pain

Assessment Alert

Dislocation occurs at the joints of the shoulder, elbow, wrist, digits, hips, knees, ankles, and feet.

Dx: X-ray, client history, and clinical examination

Rx: Reduction of the dislocation should be performed immediately. Closed reduction occurs when manual traction is applied with the client either under local or generalized anesthesia. Open reduction may be required to repair ligaments, use of wire fixation of the joint, or for skeletal traction.

Complications: Tissue damage and vascular impairment if reduction is not done immediately.

Nursing Process Elements

- Apply ice to relieve pain until reduction is attempted
- Splint the extremity as it lies even though angle may be awkward and not normal body alignment
- Keep emergency resuscitation equipment nearby when client receives IV morphine sulfate or diazepam during reduction of dislocation
- Immobilize joint

Client teaching for self-care

S&S of neurovascular compromise (numbness, pain, cyanosis, coldness of extremity)

STRAIN

- A strain is an injury to a muscle or tendon.
- The common sites of strain are the back and hamstring.

Etiology: Twisting or pulling of muscle

S&S:

- Rapid swelling
- Ecchymosis after several days
- Muscle tenderness

Assessment Alert

A chronic strain will have the client complaining generalized tenderness, stiffness, and soreness of the injured muscle or tendon.

Dx: X-ray to rule out fracture and injury to ligaments.

Rx: Immobilize; control pain and swelling.

Complications: Muscle rupture if strain is severe.

Nursing Process Elements

- Apply ice to relieve pain
- Splint the extremity
- Elevate the limb
- Administer analgesic and/or muscle relaxant as needed

Client teaching for self-care

- Maintain a healthy, well-balanced diet to keep muscles strong.
- Maintain a healthy weight.
- Practice safety measures to help prevent falls (for example, keep stairways, walkways, yards, and driveways free of clutter, and salt or sand icy patches in the winter).
- Do stretching exercises daily.
- Warm up and stretch before participating in any sports or exercise.
- Wear protective equipment when playing.
- Avoid exercising or playing sports when tired or in pain.
- Run on even surfaces.

OSTEOMYELITIS

- Osteomyelitis is an acute or chronic bone infection caused by bacteria
- It can cause tissue necrosis, breakdown of bone structure, and decalcification

Etiology: Combination of trauma and acute infection. Most common organisms are *Staphylococcus aureus* as well as *Streptococcus pyogenes*, *Pneumococcus*, *Pseudomonas aeruginosa*, *Escherichia coli*, and *Proteus vulgaris*.

Risk factors:

- Hematoma
- Local site of infection

S&S:**Localized symptoms:**

- Sudden pain
- Tenderness
- Heat
- Swelling
- Restricted movement
- Drainage from a sinus tract

**Assessment Alert****PEDS**

Occurs more commonly in children than adults and most often in boys. In children the most common sites are the upper or lower ends of the tibia, humerus, and radius. In adults the most common locations are the pelvis and vertebrae.

Dx: X-rays, bone scans, CBC, blood cultures, bone lesion aspiration, or biopsy.

Rx: Large dose intravenous penicillinase-resistant penicillin (nafcillin, oxacillin); immobilization of the bone; analgesics; intravenous fluids; local wound care.

Complications:

- Chronic osteomyelitis
- Local spread of infection
- Reduced function of limb or joint
- Amputation

**Nursing Process Elements**

- Practice strict aseptic technique when doing wound care
- Administer intravenous fluids
- Assess vital signs every 4 hours
- Administer analgesics
- Provide a balanced diet that is high in calcium, vitamin D, and protein
- Provide preventative skin care if client is on bed rest
- Take care of cast and/or traction if the affected bone has been immobilized
- Provide safety measures as needed depending on level of immobility

**Client teaching for self-care**

- Explain the disease process to both client and family
- Teach medication regime, including side effects and when to contact health care provider
- Educate about management of wound care
- Tell S&S of a recurring infection

OSTEOPOROSIS

Thinning of bone tissue with loss of density over time

Risk factors:

- Insufficient calcium intake or impaired absorption of calcium
- Menopause
- Smoking
- Heavy alcohol consumption
- Amenorrhea
- Use of steroids or anticonvulsants

S&S:

- No symptoms in early stage of disease
- Fractures of vertebrae, wrists, or hips
- Low back pain
- Neck pain

- Bone pain or tenderness
- Loss of height over time
- Stooped posture

**Assessment Alert**

Most common in menopausal women

Dx: Bone marrow density testing

Rx: Bisphosphonates, such as alendronate (Fossumax) and risedronate (Actenol); raloxifene (Evista); hormone replacement therapy; calcitonin, such as Miacalcin (nasal spray) and Calcimar (injectable)

Complications:

- Compression fractures of the spine
- Hip and wrist fractures

**Nursing Process Elements**

- Check skin daily for signs of possible fracture (redness, warmth, and pain)
- Provide a balanced diet high in vitamin D, calcium, and protein
- Administer analgesics as needed
- Apply heat to relieve pain

**Client teaching for self-care**

- Encourage exercise that includes weight-bearing and resistance
- Diet that includes adequate amounts of calcium (e.g., low-fat milk, yogurt, cheese, tofu, and salmon) and protein
- Supplemental calcium 1200 mg per day
- Supplemental vitamin D 400–800 IU per day
- Smoking cessation

OSTEOARTHRITIS

Degeneration of the joint cartilage and formation of reactive new subchondral bone which causes joint deformity and pain on motion.

Etiology: Cause is unknown

Risk factors:

- Metabolic conditions such as acromegaly
- Injury
- Inflammatory disorders

S&S:

- Gradual and subtle onset of joint pain that is worse after exercise and relieved by rest
- Joint swelling
- Limited movement
- Morning stiffness
- Grating of the joint with motion

Dx: Physical examination, X-ray

Rx: Medications for pain relief and inflammation include aspirin, phenylbutazone, indomethacin, ketorolac, ibuprofen (Motrin, Advil, Nuprin), naproxen (Aleve, Naprosyn, Naprelan, Anaprox) propoxyphene, hydrochloride, rofecoxib, and intra-articular injections of corticosteroids; surgical procedures for clients with disabilities and severe pain include arthroplasty (replacement of a deteriorated joint with a prosthesis),

arthrodesis (surgical fusion of bones), and osteotomy (excision of bone to change alignment and relieve stress).

**Nursing Process Elements**

- Promote adequate rest, particularly following activities
- Encourage client to perform gentle range of motion exercise
- Provide emotional support
- For the hands, apply hot soaks and paraffin dips as ordered
- Check for redness and irritation of the skin, if client is wearing a cervical collar.
- Administer prescribed medications for pain, spasms, and inflammation

**Client teaching for self-care**

- Maintain proper body alignment to avoid excessive stress on joints
- Install safety devices at home, if appropriate
- Avoid over exertion and plan for adequate rest throughout the day
- Tell about side effects of medications and when to contact health care provider
- Advise weight loss, if appropriate

RHEUMATOID ARTHRITIS

Chronic, systemic disease that causes inflammation of the joints and surrounding tissues

Etiology: Unknown; considered an autoimmune disease

S&S:

- Fatigue
- Morning stiffness lasting more than 1 hour
- Generalized muscle aches
- Loss of appetite
- Weakness
- Joint pain

Assessment Alert

Joint destruction starts 1–2 years after the appearance of the disease.

Dx: Joint X-rays; rheumatoid factor test; erythrocyte sedimentation rate; CBC (low hematocrit and platelet count); C-reactive protein; synovial fluid analysis

Rx: Disease-modifying antirheumatic drugs (DMARD): Methotrexate (Rheumatrex), leflunomide (Arava), gold thiomalate (Myochrysine), aurothioglucose (Solganal), auranofin (Ridaura); anti-inflammatory agents: aspirin and non-steroidal anti-inflammatory agents; COX-2 inhibitors; anti-malarial drugs such as hydroxychloroquine (Plaquenil) and sulfasalazine (Azulfidine); tumor necrosis factor (TNF) inhibitors such as etanercept (Enbrel), infliximab (Remicade), and adalimumab (Humira); corticosteroids; immunosup-

pressive agents such as azathioprine (Imuran), cyclophosphamide (Cytoxan)

Nursing Process Elements

- Administer appropriate medication
- Apply heat to relax muscles and relieve pain
- Apply ice pack during acute episodes
- Provide splints to rest inflamed joints
- Encourage diversionary activities
- Provide range of motion to maintain function of joints

Client teaching for self-care

- Disease process
- Need for 8–10 hours of sleep per night
- Importance of maintaining treatment regime
- Medications, their adverse effects and when to contact health care provider

PEDS

JUVENILE RHEUMATOID ARTHRITIS

- Juvenile rheumatoid arthritis (JRA) is a chronic inflammation of the synovium with joint effusion
- JRA is also known as juvenile idiopathic arthritis
- There are three types of JRA
 - Pauciarticular: affects four or fewer joints
 - Polyarticular: affects five or more joints
 - Systemic onset: affects at least one joint but causes inflammation of internal organs as well.

Etiology: Unknown; considered an autoimmune process

S&S:

- Joint pain
- Swollen joint(s)
- Limping
- Stiffness when waking
- Fever
- Rash

Dx: Diagnosis is by exclusion; plain X-rays. Laboratory tests most often performed include complete blood count (CBC), erythrocyte sedimentation, rheumatoid factor, antinuclear antibody (ANA), blood culture, bone marrow examination, and bone scan.

Rx: Nonsteroidal anti-inflammatory drugs (naproxen, ibuprofen, tolmetin), methotrexate, tumor necrosis factor inhibition drugs (etanercept), slow-acting antirheumatic drugs (sulfasalazine, hydroxychloroquine, gold, D-penicillamine); physical therapy

Nursing Process Elements

- Pain management
- Encourage a well-balanced diet
- Promote maintaining a normal life style, such as attending school and getting adequate rest
- Encourage compliance with health care regime (medication, physical therapy, use of assistive devices)

Assessment Alert

Emotional and behavioral function is not linked to the severity of the child's disability but to maternal depression and parental distress over the child's condition.

Client teaching for self-care

- Participate in a support group
- Follow the prescribed therapeutic regime (medication, physical therapy, application of heat)
- Incorporate physical therapy and exercise into favorite play activities

SYSTEMIC LUPUS ERYTHEMATOSUS

- Systemic lupus erythematosus is a chronic, inflammatory autoimmune disorder
- It may affect the skin, joints, and kidneys
- It can be fatal
- Recurring remissions and exacerbations most often occur in Spring and Summer

Etiology: Mechanism is not known; it is speculated that following an infection with an organism that is similar to a particular protein in the body, the protein is at a later date mistaken for the original organism and destroyed by the body's natural defenses.

Risk factors:

- Genetic predisposition
- Stress
- Streptococcal or virus infections
- Exposure to sunlight or ultraviolet light
- Immunizations
- Pregnancy
- Abnormal estrogen metabolism
- Medications, such as procainamide, hydralazine, anti-convulsants, penicillins, sulfa drugs, and oral contraceptives

S&S: The most common are:

- Facial erythema (butterfly rash)
- Nonerosive arthritis
- Photosensitivity

Other symptoms include

- Aching
- Malaise
- Fatigue
- Low-grade or spiking fever
- Chills
- Anorexia
- Weight loss
- Lymph node enlargement
- Abdominal pain
- Nausea and vomiting
- Diarrhea or constipation
- Irregular menstrual periods or amenorrhea
- Discoid rash
- Oral or nasopharyngeal ulcerations
- Pleuritis
- Psychoses
- Patchy alopecia

Assessment Alert

Most prevalent among Asians and African-Americans.

Dx: Blood tests for ANA, antideoxyribonucleic and lupus erythematosus cell

Rx: Mild disease requires little to no management. Nonsteroidal anti-inflammatory drugs and aspirin are used to manage arthritis symptoms. Skin lesions are treated topically with corticosteroids as well as with oral antimalarial (hydroxychloroquine) medication. Corticosteroids are the treatment of choice for systemic symptoms.

Complications:

- Infection
- Kidney failure
- Thrombocytopenia
- Hemolytic anemia
- Myocarditis
- Seizures

Nursing Process Elements

- Monitor for bleeding by checking urine, stool, gums, and skin for bruising
- Monitor weight and intake and output
- Monitor vital signs, particularly for hypertension
- Provide a balanced diet
- Apply heat packs to relieve joint pain and stiffness
- Monitor for neurological changes, such as personality change, paranoid or psychotic behavior, ptosis or diplopia

Client teaching for self-care

- Encourage client to get adequate rest
- Perform range of motion and maintain proper body alignment
- Explain the need for prescribed medications and side effects and when to contact health care provider
- For photosensitivity wear protective clothing (long sleeves, hat, slacks, and sunglasses) and sun-screen containing para-aminobenzoic acid

GOUT

Gout is a chronic, systemic, metabolic inflammatory disease.

Etiology:

- Buildup of uric acid in the blood which leads to deposit of urate crystals in joints and soft tissues
- Primary gout due to a genetic error in purine metabolism.

Risk factors:

- Diet high in rich food (e.g., red meat, cream sauces, and red wine)
- Kidneys unable to filter uric acid from blood

S&S: Joint symptoms—base of large toe most often affected

- Swelling
- Pain
- Stiffness
- Redness

Assessment Alert

Most common in menopausal women

Dx: Synovial fluid contains uric acid crystals, elevated serum uric acid

Rx: NSAID (e.g., naproxen) and indomethacin. Cortisone may be injected into the joint.

Assessment Alert

There may not be an elevation of uric acid during an acute attack.

Client teaching for self-care

- Dietary restriction for alcohol and foods high in purine (e.g., scallops, sardines, red wine, cream sauces, and sweet breads)
- Increased intake of fluids, such as water
- Pain control
- Rest for affected joints during acute episodes
- Weight control measures if needed

MULTIPLE MYELOMA

- Multiple myeloma is a cancer of the plasma cells in the bone marrow
- It infiltrates the bone to produce osteolytic lesions throughout the skeleton
- The late stages of the disease will have infiltration of internal organs
- Prognosis is poor

Etiology: Cause is unknown

S&S:

- Severe back pain that increases with exercise
- Achiness
- Joint swelling and tenderness
- Fever
- Malaise
- Paresthesia
- Pathologic fractures

Advanced disease symptoms

- Anemia

- Weight loss
- Thoracic deformities
- Height loss

Assessment Alert

Early diagnosis and treatment may prolong life by 3–5 years.

Dx: Bone marrow biopsy, serum protein electrophoresis, bone X-rays, CBC (low hematocrit, RBCs, platelets, and WBCs), serum chemistry profile (high calcium and total protein)

Rx: Goal of treatment is to relieve symptoms, since there is no permanent cure. Chemotherapy and localized radiation therapy. Combinations of chemotherapy include melphalan and prednisone or vincristine, doxorubicin, and dexamethasone. Treatment of hypercalcemia would include hydration, diuretic, corticosteroids, oral phosphate, and IV mithramycin.

Complications:

- Renal failure
- Increased susceptibility to infection
- Paralysis
- Pathological fractures

**Nursing Process Elements**

- Observe for S&S of infection
- Monitor intake and output (daily output should not be less than 1500 cc)
- Reposition every 2 hours if on bed rest

- Administer analgesics as ordered
- Assist with passive range of motion exercises
- Encourage respiratory hygiene activities, such as deep breathing and coughing
- Provide emotional support for client and family
- Refer to appropriate community resource, such as the Leukemia Society of America

**Client teaching for self-care**

- Drink 3–4 liters of fluids daily
- Encourage exercise to minimize bone demineralization
- Use of assistive devices when ambulating to prevent falling

OSTEOGENIC SARCOMA

- Osteogenic sarcoma is a malignant bone tumor which occurs during periods of rapid growth in adolescence
- It is also known as osteosarcoma

Etiology: Cause is unknown

Risk factors:

- Family history
- Repeated trauma to an area of long bone
- Exposure to ionizing radiation for the treatment of other cancers
- History of retinoblastoma

S&S:

- Bone pain
- Tenderness, swelling, or redness at site of bone pain
- Pathological fracture
- Limping

Dx: X-ray, CT scan, open biopsy at time of surgery for definitive diagnosis

Rx: Limb-saving surgery, but amputation may be necessary for a permanent cure. Chemotherapy includes high dose

methotrexate with leucovorin, doxorubicin (Adriamycin), cisplatin, carboplatin (Paraplatin), cyclophosphamide (Cytosan), and ifosfamide (Ifex).

Complications:

- Lung metastasis
- Effects of chemotherapy

**Nursing Process Elements**

- Emotional support
- Referral to a cancer support group
- Administering analgesics
- Postoperative care including monitoring for infection, pain management, neurovascular assessment, monitoring for DVT

**Client teaching for self-care**

- Use of assistive devices and/or prosthesis
- Compliance with medical regime

EWING'S SARCOMA

- Bone tumor occurring in the marrow of the femur, tibia, ulna, humerus, vertebrae, scapula, ribs, and skull.
- Second most common bone tumor in children and adolescents. Occurs in persons less than 30 years of age.

Etiology:

Primitive neuroectodermal tumor

S&S:

- Pain, initially intermittent and then becomes intense
- Intermittent fever
- Mild anemia
- Leukocytosis
- Increased sedimentation rate

- Increased serum lactic dehydrogenase level
- Weight loss
- Palpable mass that grows rapidly with tense, tender local swelling

Dx: X-ray, CT scan, MRI

Rx: Combination of radiation and combination chemotherapy (vincristine, actinomycin D and cyclophosphamide or ifosfamide, VP-16, and Adriamycin); surgical amputation is only performed when necessary.

Nursing Process Elements

- Skin assessment for signs of reaction to radiation therapy
- Administer chemotherapy agents
- Monitor for S&S of reaction to chemotherapy
- Monitor for S&S of infection
- Encourage food and fluid intake to maintain nutritional health
- Encourage the use of loose clothing during radiation therapy

Client teaching for self-care

- Preparation for diagnostic tests, such as bone marrow aspiration
- Preventative skin care while receiving radiation therapy, such as wearing loose clothing, protecting skin from sunlight, avoiding heating pads or ice packs
- Management of dry and/or moist desquamation of skin from radiation therapy
- Side effects of chemotherapy, such as hair loss, nausea, vomiting, peripheral neuropathy, and cardiotoxicity
- Encouraging a normal lifestyle, including physical activities

INTERVERTEBRAL DISC DISEASE

- Intervertebral disc disease is also known as degenerative disc disease
- It is a degeneration of the spine due to dehydration of the intervertebral disc
- It is a common disorder of the lower spine

Etiology: Aging process results in loss of gelatinous mucoid material of the nucleus pulposus due to loss of water content which is replaced by fibrocartilage.

S&S:

- Low back pain radiating to hips

Dx: Spinal X-ray, myelography, CT scan, and MRI

Rx: Anti-inflammatory medications such as nonsteroidal anti-inflammatory drugs, physical therapy, and spinal injections. Surgery may be beneficial to some clients not receiving adequate pain relief

Complications:

- Bone spurs that can pinch or put pressure on the nearby nerve roots or spinal canal

Nursing Process Elements

- Neurovascular assessment
- Application of corset or back brace

Client teaching for self-care

- Notify health care provider if pain increases or there is loss of sensation to extremities
- Apply corset or back brace
- Reduce weight, if appropriate

HERNIATED NUCLEUS PULPOSUS

- In herniated nucleus pulposus, all or part of the nucleus pulposus leaks out from the intervertebral disc
- It is also known as herniated disc

Etiology: May be the result of trauma, strain, or intervertebral disc degeneration

S&S:

- Severe low back pain radiating to buttocks, legs, and feet
- Increase in pain with Valsalva maneuver, sneezing, coughing, bending

- Possible motor and sensory loss
- Weakness and atrophy of leg muscles

Dx: Straight leg raising test (posterior leg pain without back pain), Lasègue's test (with thigh and knee flexed at a 90-degree angle there is resistance and pain with either absence or decrease of ankle and deep tendon reflexes), CT scan, MRI, and myelography

Rx: Conservative treatment with bed rest, pelvic traction, application of heat; aspirin, corticosteroids, muscle relaxants (diazepam, methocarbamol), and analgesic (hydrocodone with APAP); chemonucleolysis (injection of chymopapain (enzyme) into herniated disc to dissolve nucleus pulposus (an alternative to laminectomy); surgical management such as, microdiscectomy, laminectomy, and/or spinal fusion

Complications:

- Deterioration of neurological status

Nursing Process Elements

- Assess neurological status
- Maintain antiembolism stockings
- Encourage fluids
- Provide skin care
- Administer analgesics and/or muscle relaxants
- Provide emotional support

Client teaching for self-care

- Physical therapy exercises as appropriate
- Proper body mechanics
- Proper weight
- Adverse reactions to medications (analgesics, muscle relaxants)

PEDS

SCOLIOSIS

- Scoliosis is a descriptive term referring to the curve of the spine

Risk factors:

Congenital spinal deformities, genetic conditions, neuromuscular disease, cerebral palsy, spina bifida, muscular dystrophy, and tumors.

S&S:

- Shoulders are at different heights
- Head is not centered directly over pelvis
- One hip appears higher than the other
- Sides of rib cage are at different heights
- Uneven waist
- Skin over spine may have dimples, hairy patches, or color changes
- Body leans to one side

Dx: Adam's Forward Test; confirmed by X-ray, CT scan, and MRI

Rx: Nonsurgical treatment includes observation and braces (Boston & Wilmington, Thoracolumbosacral orthosis (TLSO), Milwaukee brace, Charleston nighttime bending brace); surgery

Nursing Process Elements

- Preoperative
 - NPO prior to surgery
 - Instruction on log rolling
- Postoperative
 - Monitor neurovascular status of extremities
 - Pain management
 - Monitor skin integrity
 - Monitor intake and output
 - Perform abdominal assessment

Clinical Alert

Common postoperative complications of spinal fusion include spinal cord injury, hypotension from blood loss, wound infection, and implanted hardware complications.

Client teaching for self-care

- Application of molded plastic brace

PEDS

LEGG-CALVÉ-PERTHES DISEASE

Legg-Calvé-Perthes disease is a self-limiting juvenile idiopathic avascular necrosis of the femoral head

Etiology: Lack of blood supply to the bone

Risk factors: Trauma, lupus, kidney and liver disease, sickle cell anemia, and blood clotting disorders

S&S:

- Limping, becomes pronounced with activities
- Pain in hip, the entire thigh, or knee joint
- Limited range of motion

Dx: X-ray, MRI

Rx: Nonsurgical management for up to 4 years using abduction brace, leg cast, leather harness sling, and restricted

weight-bearing on affected leg; surgical reconstruction would return the child to normal activities within 4 months

**Nursing Process Elements**

- Referral for medical evaluation
- Maintaining corrective appliance/device chosen for conservative (nonsurgical) therapy

**Client teaching for self-care**

- Provide activities to meet creative needs of child while maintaining restrictive activity

PEDS

DEVELOPMENTAL DYSPLASIA OF THE HIP

Developmental dysplasia is an abnormal formation of the hip joint resulting in the femoral head not being stable in the acetabulum.

Etiology: Unknown

Risk factors: Familial tendency, crowding of the fetus inside the uterus (large birth weight, oligohydramnios)

S&S: Asymmetrical thigh and buttock skin folds or creases

- Legs may appear a different length
- Hip may have decreased motion
- Toddler or child may walk with a limp or altered gait

Dx: Physical examination, hip ultrasound

Rx: Pavlik harness (soft dynamic brace that maintains the hip in flexion and abduction); Spica cast

**Nursing Process Elements**

- Teach parents to apply and maintain the reduction device
- Provide cast care, if appropriate
- Monitor skin for alteration in skin integrity

**Client teaching for self-care**

- Apply reduction device
- Provide activities and/or distraction appropriate to the child's age
- Provide cast care, if appropriate

PEDS

SLIPPED FEMORAL CAPITAL EPIPHYSIS (COAX VARA)

- Slipped femoral capital epiphysis is an unusual disorder of the adolescent hip occurring during growth spurts
- The ball of the upper femur slips backward

Etiology: Weakness of the growth plate

Risk factors: Obesity, physical architecture and orientation, pubertal hormone changes, minor fall, or trauma

S&S:

- Hip or knee pain for several weeks
- Intermittent limp
- Unable to bear weight on affected leg, if severe
- Affected leg turned outward
- Affected leg may appear shorter
- Loss of range of motion in affected leg

Dx: X-ray

Rx: Surgical stabilization of femoral head

Nursing Process Elements

- Maintain cast or traction as appropriate
- Provide cast care, if appropriate

Assessment Alert

Slipped femoral capital epiphysis can be associated with endocrine disorders, renal osteodystrophy, and radiation therapy.

Client teaching for self-care

- Cast care

PEDS

OSTEOGENESIS IMPERFECTA

- Osteogenesis imperfecta causes bones to break easily.
- It is the most common osteoporosis syndrome in children.
- There are five types with type I being the least severe.

Etiology: Genetic disorder affecting the body's production of collagen

Risk factors: Hereditary (autosomal dominant)

S&S:

- Bone fragility, deformity, or fracture
- Blue sclera
- Hearing loss
- Dentinogenesis imperfecta (hypoplastic discolored teeth)

Dx: Physical examination, family history, bone density testing, X-ray, skin biopsy for collagen testing

Rx: Supportive therapy to prevent positional contractures/deformities, muscle weakness, osteoporosis, and malalignment of lower extremities.

Nursing Process Elements

- Gently handle the infant with slow movements of the extremities

- Maintain Immobilization of fractures
- Refer to Osteogenesis Imperfecta Foundation

Assessment Alert

Children with new or healing fractures should be screened for osteogenesis imperfecta rather than immediately assuming child abuse.

Client teaching for self-care

- Gentle handling of the infant with slow movements of the extremities, never hold by the ankles when changing diaper
- Recognition of a fracture and how to transport child to emergency room
- Referral for genetic counseling

PEDS

TIBIAL TORSION

- It is the twisting of the tibia.
- As the tibia lengthens the unnatural twisting is resolved.

Etiology: In utero development

Risk factors: Genetic

S&S:

- Toes turn inward
- Stumbling or tripping when walking

Dx: Prenatal ultrasonography, assessment at birth

Rx: Surgery will be done if the child is 8–10 years old and has a severe twisting of the tibia causing ambulation problems.

Nursing Process Elements

- Cast care
- Skin assessment

Client teaching for self-care

- Provide cast care
- Encourage normal growth and development activities

PEDS

MUSCULAR DYSTROPHY

- Muscular dystrophy (MD) is a group of familial disorders.
- Progressive weakness and degeneration of the skeletal muscles that control movement may lead to disability and deformity.
- This is a general diagnosis for several types of muscle diseases: Duchenne's (most common), Emery–Dreifuss, Becker's, Limb-girdle, Congenital, Facioscapulohumeral, Distal Welander, and Myotonic.
- Children rarely live past 25 years of age.

Etiology: Genetically determined

S&S:

- Progressive muscle wasting, weakness, and eventual loss of function
- Delayed development of basic muscle skills and coordination in children (Duchenne's MD)
- Obesity
- Joint contractures
- Intellectual impairment (occurs in a few of the types of MD)

Dx: Clinical presentation, muscle biopsy, electromyography, and serum muscle enzyme levels

Rx: Treatment varies on the basis of the type of MD

Duchenne's: Physical therapy, orthoses, braces, wheelchair, spinal fusion, release of contractures, and respiratory exercises.

Becker's: Surgical release of contractures, maintain ambulation

Limb-girdle: Physical therapy

Facioscapulohumeral: Physical therapy, orthoses, maintain ambulation and use wheelchair for distances, surgical stabilization of scapula, arthrodesis of scapula to ribs

Myotonic: Aspiration precautions, tube feeding might be needed for decreased esophageal motility, cataract surgery, medication for somnolence

Nursing Process Elements

- Administer steroids and immunosuppressants
- Refer to genetic counseling
- Encourage ambulation
- Provide assistive devices, such as a lift

Client teaching for self-care

- Knowledge of S&S and complications of MD
- Prevention of complications associated with immobility
- Transfer techniques to and from wheel-chair

WORKSHEET

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. Describe three hip precautions that should be taught to a client following a total hip replacement.

A. _____

B. _____

C. _____

(continued)

2. List five localized symptoms of osteomyelitis.

- A. _____
- B. _____
- C. _____
- D. _____
- E. _____

3. Identify four risk factors for osteoporosis.

- A. _____
- B. _____
- C. _____
- D. _____

4. Explain the difference between a sprain and a strain of an extremity.

5. Describe limitation of range of motion.

6. Identify three specific diseases or injuries that can result in limitation of range of motion.

- A. _____
- B. _____
- C. _____

7. Describe four nursing interventions to prevent the occurrence of complications related to immobility.

- A. _____
- B. _____
- C. _____
- D. _____

MATCHING QUESTIONS

Match the following.

Problem

- 1. _____ Sprain
- 2. _____ Dislocation
- 3. _____ Crepitation
- 4. _____ Strain

Cause

- a. Grating joint sounds
- b. Twisting injury to a muscle
- c. Tear of a ligament
- d. Loss of contact between bony articulating surfaces

Disease Process

5. ____ Gout
6. ____ Legg-Calvé-Perthes
7. ____ Lyme Disease
8. ____ Osteogenesis imperfecta
9. ____ Tibial torsion

Etiology

- e. Lack of blood supply to the bones
- f. Develops in utero
- g. Build up of uric acid in the joints
- h. *Borrelia burgdorferi* transmitted to humans by ticks
- i. Genetic disorder affecting production of collagen

MATCHING QUESTIONS

Match the following.

Diagnostic Test

1. ____ Elevated serum uric acid
2. ____ Adam's forward test
3. ____ Bone marrow biopsy
4. ____ Open biopsy at time of surgery
5. ____ Lasègue's test
6. ____ Antinuclear antibody

Disease Process

- a. Osteosarcoma
- b. Systemic lupus erythematosus
- c. Scoliosis
- d. Herniated nucleus pulposus
- e. Gout
- f. Multiple myeloma

Match the following.

Type of Fracture

1. ____ Transverse
2. ____ Longitudinal
3. ____ Spiral
4. ____ Linear
5. ____ Oblique

Definition of Fracture

- a. Fracture line crosses bone at a 45-degree angle to bone's axis
- b. Fracture forms a right angle with bone's axis
- c. Fracture line is parallel to bone's axis
- d. Fracture line crosses bone at an oblique pattern
- e. Fracture line extends along bone's axis

Match the following.

Diagnostic test

1. ____ Gallium scan
2. ____ Arthrogram
3. ____ Bone scan
4. ____ Arthrocentesis

Definition

- a. Visualization of bone or joint using a radioisotope
- b. Removal of fluid from the joint
- c. Visualization of inflammatory areas using a radioactive medium
- d. Visualization of the joints using a radiopaque dye

MATCHING QUESTIONS

Match the following.

Immobility Complication

1. _____ Decreased peristalsis
2. _____ Decreased hydration of dermis
3. _____ Loss of detrusor tone
4. _____ Decreased vital capacity
5. _____ Osteoporosis
6. _____ Orthostatic hypotension
7. _____ Negative nitrogen balance

Body System

- a. Cardiovascular
- b. Gastrointestinal
- c. Integument
- d. Metabolic
- e. Musculoskeletal
- f. Respiratory
- g. Urinary tract

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all False statements in the space provided.

- | | | |
|--|-------|-------|
| 1. Maintaining proper body alignment is an important part of teaching for the client with osteoarthritis because it prevents excessive strain on the joints. | _____ | _____ |
| | T | F |
| 2. Ewing's sarcoma is the second most common bone tumor in children. | _____ | _____ |
| | T | F |
| 3. A complication of a muscle strain is muscle rupture. | _____ | _____ |
| | T | F |
| 4. Joint pain can be the result of injury, arthritis, infection, gout, and medication. | _____ | _____ |
| | T | F |
| 5. Trauma and demineralization are the only causes of bone pain. | _____ | _____ |
| | T | F |
| 6. Both kidney stones and kidney dysfunction are complications of gout. | _____ | _____ |
| | T | F |
| 7. A diagnostic sign of a herniated disc is pain that is relieved by the Valsalva maneuver. | _____ | _____ |
| | T | F |
| 8. The importance of 8–10 hours of sleep per night should be stressed to the client with rheumatoid arthritis. | _____ | _____ |
| | T | F |
| 9. Aspiration precautions should be included in the plan of care for a child with myotonic muscular dystrophy. | _____ | _____ |
| | T | F |
| 10. Care must be taken not to conclude an infant is a victim of child abuse before the possibility of osteogenesis imperfecta has been ruled out. | _____ | _____ |
| | T | F |
| 11. Surgery for tibial torsion needs to be scheduled before the infant begins to walk. | _____ | _____ |
| | T | F |
| 12. Ewing's sarcoma is a bone cancer of the lower extremities which affects children, teens, and young adults. | _____ | _____ |
| | T | F |

APPLICATION QUESTIONS

1. Which complaint would be expected when reviewing the health history of a client with rheumatoid arthritis?
 - a. Rash over the nose and cheeks
 - b. Joint stiffness for 1–2 hours on arising
 - c. Reddened edematous joints
 - d. Intolerance of vegetable protein
2. Which topic would be included in the teaching plan for a client with gout?
 - a. Need to include foods high in purine in the daily diet
 - b. Importance of restricting use of alcohol
 - c. Necessity of limiting fluid intake
 - d. Benefits of decreasing intake of dairy products
3. Which factors are associated with an increased risk of osteoporosis? Mark all that apply.
 - a. Menopause
 - b. Anticonvulsant medications
 - c. Smoking
 - d. Obesity
 - e. Early menarche
 - f. Prolonged use of NSAIDs
4. Which intervention would appropriately be included in the care plan of a client experiencing an acute episode of rheumatoid arthritis?
 - a. Guide the client in active exercises for the affected joints twice a day.
 - b. Apply ice packs to affected joints.
 - c. Maintain affected joints in a hyperextended position.
 - d. Assist the client to weight bear on affected joints for at least 15 minutes tid.
5. A complaint of a joint “grating when moved” should be interpreted by the nurse as consistent with which condition?
 - a. Rheumatoid arthritis
 - b. Osteoarthritis
 - c. Osteomyelitis
 - d. Osteoporosis
6. Which statement made by a client who has a fractured hip indicates understanding of “hip precautions”?
 - a. “I can’t fully extend my leg at the hip for 1 month.”
 - b. “I won’t be able to cross my knees for at least 12 weeks.”
 - c. “I can put weight on the affected leg as long as it doesn’t cause pain.”
 - d. “I can flex my hip but not more than 90 degrees for up to 2 months.”
7. Which finding would be expected when assessing a client with a herniated nucleus pulposus?
 - a. Anterior leg pain when flexing and extending the knee
 - b. Decreased deep tendon reflexes when the leg is rapidly raised and lowered
 - c. Relief of low back pain when thigh and knee are flexed at a 90-degree angle
 - d. Posterior leg pain without back pain when straight legs are raised
8. Nonsurgical management of Legg-Calvé-Perthes disease involves maintaining the affected leg in which position?
 - a. abduction
 - b. adduction
 - c. flexion
 - d. hyperextension
9. Which instructions would the nurse include when teaching self-care to a client with osteoporosis? Mark all that apply.
 - a. Stop smoking
 - b. Take 1200 mg of supplemental calcium daily
 - c. Take 400–800 IU of supplemental vitamin D daily
 - d. Do weight bearing and resistance exercises daily
 - e. Make certain your diet is not deficient in calcium or protein
10. Which statement made by a client indicates a correct understanding of systemic lupus erythematosus?
 - a. Sunlight can help clear skin lesions that develop.
 - b. Exacerbations are most likely to occur in the winter and spring.
 - c. Pulmonary function tests are needed annually because of frequent lung involvement.
 - d. Blood pressure needs monitoring because of the risk of hypertension.
11. Emergent treatment of a simple long bone fracture includes which measure?
 - a. Application of heat
 - b. Positioning the limb in a dependent position

(continued)

- c. Splinting above and below the fracture
 - d. Application of a pressure bandage
12. A client being treated for intervertebral disc disease calls to report that he has no feeling in his left leg. Which is an appropriate response for the nurse to make?
 - a. "This is a common symptom of your disease; no treatment is needed."
 - b. "Most likely it's not a problem but let's schedule an appointment for a checkup when it's convenient for you."
 - c. "I will tell the doctor and have him call you this afternoon."
 - d. "You need to be checked; come in right away."
 13. Monitoring for signs of a fat embolus is of particular importance when caring for a client with which problem?
 - a. Degenerative disc disease
 - b. Systemic lupus erythematosus
 - c. Osteogenesis imperfecta
 - d. Femoral fracture
 14. Emergent care for a client with a dislocation includes which intervention?
 - a. Putting the joint through passive range of motion
 - b. Splinting the joint in the dislocated position
 - c. Keeping the area warm
 - d. Providing tactile stimulation distal to the affected joint
 15. Which statement made by a client being treated for a badly sprained ankle indicates a need for further explanation of self-care during the first 2 days after injury?
 - a. "I will keep my foot elevated."
 - b. "I will apply ice periodically."
 - c. "I will keep my ankle wrapped in an elastic bandage."
 - d. "I will bear full weight on my injured leg for no more than 15 minutes at a time."
 16. Which goal related to fluid balance for a client with multiple myeloma would be appropriate?
 - a. Daily output should be at least 1000 ml.
 - b. Daily output should be at least 1500 ml.
 - c. Daily intake should not exceed 2000 ml.
 - d. Daily intake should not exceed 2500 ml.
 17. Which client presenting with a limp would be at the greatest risk for osteogenic sarcoma?
 - a. A 72-year-old man
 - b. A 46-year-old woman
 - c. A 16-year-old boy
 - d. A 7-year-old girl
 18. A client presents with a dislocated wrist. The hand on the affected side is cold and blue. How should the nurse interpret these findings?
 - a. Bleeding into the soft tissues has occurred
 - b. Neurovascular compromise exists
 - c. Lymphatic channels are blocked
 - d. A bone fracture coexists
 19. When planning care for a client with a fractured hip, the nurse would plan to monitor for which common complications?
 - a. Urinary tract infection
 - b. Pneumonia
 - c. Candidiasis
 - d. Herniated nucleus pulposus
 - e. Thromboembolism
 20. Hip precautions would be part of the plan of care for a client with which disorder?
 - a. Osteogenesis imperfecta
 - b. Tibial torsion
 - c. Juvenile rheumatoid arthritis
 - d. Hip fracture
 21. The teaching plan for the parents of an infant with which problem would include the instruction "Never hold by the ankles when changing the diaper"?
 - a. Muscular dystrophy
 - b. Osteomyelitis
 - c. Club foot
 - d. Osteogenesis imperfecta
 22. Which statement made by the relative of a child with muscular dystrophy indicates understanding of at least one aspect of the disease?
 - a. "I'm relieved that this is a noninherited, developmental defect."
 - b. "There may be some disability but at least there is a normal life expectancy."
 - c. "If intellectual impairment was not always a part of the disease, it would be easier to deal with."
 - d. "It will be very hard watching as the muscle wasting and loss of function occur."
 23. Which client has risk factors and/or signs most characteristic of Ewing's sarcoma?
 - a. A 24-year old with a rapidly growing mass palpable on the tibia
 - b. A 40-year old with a history of retinoblastoma
 - c. A 55-year old with severe back pain that increases with exercise
 - d. A 73-year old with multiple pathological fractures

24. What findings on physical examination of a client brought into Emergency are consistent with a fractured hip?
- Lengthening and internal rotation of the affected leg
 - Lengthening and external rotation of the affected leg
 - Shortening and internal rotation of the affected leg
 - Shortening and external rotation of the affected leg
25. When monitoring a client for compartment syndrome, which question should be included in the assessment?
- “Does it hurt when you flex the muscle of your arm?”
 - “Has the pain increased in your arm?”
 - “Has the swelling increased near your shoulder?”
 - “Is there a red line going down your arm?”
26. Foods such as scallops, red wine, and gravies should be restricted in the diet of clients with which disease?
- Rheumatoid arthritis
 - Systemic lupus erythematosus
 - Gout
 - Muscular dystrophy

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

1. Describe three hip precautions that should be taught to a client following a total hip replacement.

- _____
- _____
- _____

Answers may include: Do not cross legs, do not adduct operative leg beyond midline of body, avoid flexing hips more than 90 degrees when rising from chair or bed, avoid turning affected leg inward, use high seated chairs, use raised toilet seat, do not flex hip to put on clothing.

2. List five localized symptoms of osteomyelitis.

- _____
- _____
- _____
- _____
- _____

Answers may include: Sudden pain, tenderness, heat, swelling, restricted movement or drainage from a sinus tract.

3. Identify four risk factors for osteoporosis.

- _____
- _____
- _____
- _____

Answers may include: Insufficient calcium intake, menopause, smoking, heavy alcohol consumption, amenorrhea, use of steroids, and use of anticonvulsants.

4. Explain the difference between a sprain and a strain of an extremity.

- _____
- _____
- _____

Answer: A sprain can be either a complete or incomplete tear of supporting ligaments surrounding a joint. A strain is an injury to a muscle or tendon.

(continued)

5. Describe limitation of range of motion.

Answer: There is a decrease in the normal distance and direction through which a joint can move.

6. Identify three specific diseases or injuries that can result in limitation of range of motion.

A. _____

B. _____

C. _____

Answers may include arthritis, cerebral palsy, dislocation, fracture, or spondylosis.

7. Describe four nursing interventions to prevent the occurrence of complications related to immobility.

A. _____

B. _____

C. _____

D. _____

Answers may include: Range of motion, monitor for dehydration, monitor serum electrolytes (sodium, potassium, chloride, calcium), assess for DVT, apply compressive stockings (TEDS) or device (SCD), encourage deep breathing and use of incentive spirometry, administer calcium and phosphorous supplements, monitor for infection, monitor bowel function, administer stool softener, encourage foods high in fiber, assess vulnerable body surfaces for changes in skin integrity, reposition at least every 2 hours, provide a pressure relief surface that is appropriate for client.

MATCHING ANSWERS

Problem

- 1. c Sprain
- 2. d Dislocation
- 3. a Crepitation
- 4. b Strain

Cause

- a. Grating joint sounds
- b. Twisting injury to a muscle
- c. Tear of a ligament
- d. Loss of contact between bony articulating surfaces

Disease Process

- 5. g Gout
- 6. e Legg-Calvé-Perthes
- 7. h Lyme Disease
- 8. i Osteogenesis imperfecta
- 9. f Tibial torsion

Etiology

- e. Lack of blood supply to the bones
- f. Develops during utero
- g. Build up of uric acid in the joints
- h. *Borrelia burgdorferi* transmitted to humans by ticks
- i. Genetic disorder affecting production of collagen

MATCHING ANSWERS**Diagnostic Test**

1. e Elevated serum uric acid
2. c Adam's Forward Test
3. f Bone marrow biopsy
4. a Open biopsy at time of surgery
5. d LeSegue's Test
6. b Antinuclear antibody

Type of Fracture

1. b Transverse
2. e Longitudinal
3. d Spiral
4. c Linear
5. a Oblique

Diagnostic test

1. c Gallium scan
2. d Arthrogram
3. a Bone scan
4. b Arthrocentesis

Disease Process

- a. Osteosarcoma
- b. Systemic lupus erythematosus
- c. Scoliosis
- d. Herniated nucleus pulposus
- e. Gout
- f. Multiple Myeloma

Definition of Fracture

- a. Fracture line crosses bone at a 45-degree angle to bone's axis
- b. Fracture forms a right angle with bone's axis
- c. Fracture line is parallel to bone's axis
- d. Fracture line crosses bone at an oblique pattern
- e. Fracture line extends along bone's axis

Definition

- a. Visualization of bone or joint using a radioisotope
- b. Removal of fluid from the joint
- c. Visualization of inflammatory areas using a radioactive medium
- d. Visualization of the joints using a radiopaque dye

MATCHING ANSWERS

Immobility Complication

1. b Decreased peristalsis
2. c Decreased hydration of dermis
3. g Loss of detrusor tone
4. f Decreased vital capacity
5. e Osteoporosis
6. a Orthostatic hypotension
7. d Negative nitrogen balance

Body System

- a. Cardiovascular
- b. Gastrointestinal
- c. Integument
- d. Metabolic
- e. Musculoskeletal
- f. Respiratory
- g. Urinary Tract

TRUE & FALSE ANSWERS

1. Maintaining proper body alignment is an important part of teaching for the client with osteoarthritis because it prevents excessive strain on the joints. *True*
2. Ewing's sarcoma is the second most common bone tumor in children. *True*
3. A complication of a muscle strain is muscle rupture. *True*
4. Joint pain can be the result of injury, arthritis, infection, gout, and medication. *False*
Medication is not a cause of joint pain.
5. Trauma and demineralization are the only causes of bone pain. *False*
Bone pain has many etiologies, which include trauma, demineralization, overuse, infection, malignancy, disruption of blood supply and leukemia.
6. Both kidney stones and kidney dysfunction are complications of gout. *True*
7. A diagnostic sign of a herniated disc is pain that is relieved by the Valsalva maneuver. *False*
With a herniated disc, pain increases with the Valsalva maneuver, coughing, sneezing, or bending.
8. The importance of 8-10 hours of sleep per night should be stressed to the client with rheumatoid arthritis. *True*
9. Aspiration precautions should be included in the plan of care for a child with myotonic muscular dystrophy. *True*
10. Care must be taken not to conclude an infant is a victim of child abuse before the possibility of osteogenesis imperfecta has been ruled out. *True*
11. Surgery for tibial torsion needs to be scheduled before the infant begins to walk. *False*
Surgery for tibial torsion is done between 8 and 10 years of age if twisting is severe and creates problems with ambulation.
12. Ewing's sarcoma is a bone cancer of the lower extremities which affects children, teens and young adults. *False*
Ewing's sarcoma affects persons under age 30 but can occur in the marrow of the femur, tibia, ulna, humerus, vertebrae, scapula, ribs, or skull.

APPLICATION ANSWERS

1. Which complaint would be expected when reviewing the health history of a client with rheumatoid arthritis?
 - a. Rash over the nose and cheeks
 - b. Joint stiffness for 1–2 hours on arising
 - c. Reddened edematous joints
 - d. Intolerance of vegetable protein

Rationale

Correct answer: b.

Joint stiffness for more than 1 hour on arising in the morning is characteristic of rheumatoid arthritis. Rash over the nose and cheeks is a symptom of systemic lupus erythematosus. Reddened erythematous joints are signs of gout. Intolerance to vegetable protein is unrelated to a musculoskeletal disorder.

2. Which topic would be included in the teaching plan for a client with gout?
 - a. Need to include foods high in purine in the daily diet
 - b. Importance of restricting use of alcohol
 - c. Necessity of limiting fluid intake
 - d. Benefits of decreasing intake of dairy products

Rationale

Correct answer: b.

Alcohol restriction is an essential treatment measure for clients with gout. Clients with gout need to limit intake of high purine foods, not to increase it; and increase fluid intake to aid renal filtration of uric acid from the blood. Dairy products do not have to be decreased.

3. Which factors are associated with an increased risk of osteoporosis? Mark all that apply.
 - a. Menopause
 - b. Anticonvulsant medications
 - c. Smoking
 - d. Obesity
 - e. Early menarche
 - f. Prolonged use of NSAIDs

Rationale

Correct answers: a, b, and c.

Menopause, anticonvulsant medications and smoking are all associated with an increased risk for osteoporosis. Obesity, early menarche and prolonged use of NSAIDs are not known to be related to the development of osteoporosis.

4. Which intervention would appropriately be included in the care plan of a client experiencing an acute episode of rheumatoid arthritis?
 - a. Guide the client in active exercises for the affected joints twice a day.

- b. Apply ice packs to affected joints.
- c. Maintain affected joints in a hyperextended position.
- d. Assist the client to weight bear on affected joints for at least 15 minutes tid.

Rationale

Correct answer: b.

Ice helps reduce inflammation and relieve pain during acute episodes; heat is used to relax muscles and relieve pain at other times. During acute episodes affected joints are splinted for rest; they are not exercised; used to bear weight; nor placed in a hyperextended position.

5. A complaint of a joint “grating when moved” should be interpreted by the nurse as consistent with which condition?
 - a. Rheumatoid arthritis
 - b. Osteoarthritis
 - c. Osteomyelitis
 - d. Osteoporosis

Rationale

Correct answer: b.

A major symptom of osteoarthritis is grating of the affected joint with motion. Joint pain and morning stiffness are characteristic of rheumatoid arthritis. Restricted movement is a sign of osteomyelitis. Bone pain or tenderness are characteristic of osteoporosis.

6. Which statement made by a client who has a fractured hip indicates understanding of “hip precautions”?
 - a. “I can’t fully extend my leg at the hip for 1 month.”
 - b. “I won’t be able to cross my knees for at least 12 weeks.”
 - c. “I can put weight on the affected leg as long as it doesn’t cause pain.”
 - d. “I can flex my hip but not more than 90 degrees for up to 2 months.”

Rationale

Correct answer: d.

Hip flexion of more than 90 degrees must be avoided for up to 2 months. Adduction past the midline must be avoided for up to 2 months so the knees cannot be crossed for 2 months. Weight bearing is restricted and doctor’s orders regarding extent of restriction need to be followed. There is no restriction on extending the leg.

7. Which finding would be expected when assessing a client with a herniated nucleus pulposus?
 - a. Anterior leg pain when flexing and extending the knee

(continued)

- b. Decreased deep tendon reflexes when the leg is rapidly raised and lowered.
- c. Relief of low back pain when thigh and knee are flexed at a 90-degree angle
- d. Posterior leg pain without back pain when straight legs are raised

Rationale

Correct answer: d.

A positive straight leg raising test (posterior leg pain without back pain) is diagnostic of herniated nucleus pulposus.

A positive Lasègue's test (with thigh and knee flexed at a 90-degree angle, there is resistance and pain with ankle and DTRs either decreased or absent) is also indicative of herniated nucleus pulposus.

8. Nonsurgical management of Legg-Calvé-Perthes disease involves maintaining the affected leg in which position?
- a. abduction
 - b. adduction
 - c. flexion
 - d. hyperextension

Rationale

Correct answer: a.

An abduction brace or leg cast can be used.

9. Which instructions would the nurse include when teaching self-care to a client with osteoporosis? Mark all that apply.
- a. Stop smoking.
 - b. Take 1200 mg of supplemental calcium daily.
 - c. Take 400–800 IU of supplemental vitamin D daily
 - d. Do weight bearing and resistance exercises daily
 - e. Make certain your diet is not deficient in calcium or protein

Rationale

Correct answer: All of the above.

10. Which statement made by a client indicates a correct understanding of systemic lupus erythematosus?
- a. Sunlight can help clear skin lesions that develop.
 - b. Exacerbations are most likely to occur in the winter and spring.
 - c. Pulmonary function tests are needed annually because of frequent lung involvement.
 - d. Blood pressure needs monitoring because of the risk of hypertension.

Rationale

Correct answer: d.

There is a risk of hypertension with lupus erythematosus so blood pressure monitoring is needed. Sunlight can

exacerbate the disease not help clear skin lesions. Exacerbations occur most often in the spring or summer.

Pleuritis can be a symptom of the disease but monitoring with annual pulmonary function tests is not part of the medical routine.

11. Emergent treatment of a simple long bone fracture includes which measure?
- a. Application of heat
 - b. Positioning the limb in a dependent position.
 - c. Splinting above and below the fracture
 - d. Application of a pressure bandage

Rationale

Correct answer: c.

Above and below the fracture is stabilized to prevent movement of the bone segments and further damage. Cold not heat is applied immediately and the limb is elevated not lowered. A pressure bandage would not be used for a simple fracture.

12. A client being treated for intervertebral disc disease calls to report that he has no feeling in his left leg. Which is an appropriate response for the nurse to make?
- a. "This is a common symptom of your disease; no treatment is needed."
 - b. "Most likely it's not a problem but let's schedule an appointment for a checkup when it's convenient for you."
 - c. "I will tell the doctor and have him call you this afternoon."
 - d. "You need to be checked; come in right away."

Rationale

Correct answer: d.

Loss of sensation indicates pressure on a nerve and it needs to be treated immediately to prevent permanent damage.

13. Monitoring for signs of a fat embolus is of particular importance when caring for a client with which problem?
- a. Degenerative disc disease
 - b. Systemic lupus erythematosus
 - c. Osteogenesis imperfecta
 - d. Femoral fracture

Rationale

Correct answer: d.

Fat embolism is a risk associated with a break in a long bone. Degenerative disc disease places the client at risk for compression damage to nerves; risks associated with SLE include infection, kidney failure, myocarditis, seizures, hemolytic anemia, and thrombocytopenia.

14. Emergent care for a client with a dislocation includes which intervention?
- Putting joint through passive range of motion
 - Splinting the joint in the dislocated position
 - Keeping the area warm
 - Providing tactile stimulation distal to the affected joint

Rationale

Correct answer: b.

The joint would be splinted in the dislocated position until controlled reduction is possible. Cold, not heat, is applied initially to reduce swelling. The joint is immobilized not moved through a ROM. Tactile stimulation distal to the affected joint serves no purpose.

15. Which statement made by a client being treated for a badly sprained ankle indicates a need for further explanation of self-care during the first 2 days after injury?
- “I will keep my foot elevated.”
 - “I will apply ice periodically.”
 - “I will keep my ankle wrapped in an elastic bandage.”
 - “I will bear full weight on my injured leg for no more than 15 minutes at a time.”

Rationale

Correct answer: d.

Weight bearing is contraindicated or restricted. The foot should be elevated, ice applied periodically for the first 1–2 days and an elastic bandage applied.

16. Which goal related to fluid balance for a client with multiple myeloma would be appropriate?
- Daily output should be at least 1000 ml.
 - Daily output should be at least 1500 ml.
 - Daily intake should not exceed 2000 ml.
 - Daily intake should not exceed 2500 ml.

Rationale

Correct answer: b.

Renal failure is a complication of the disease. Intake is not restricted rather 3–4 liters per day is encouraged since hypercalcemia which occurs with this disease is treated with hydration.

17. Which client presenting with a limp would be at the greatest risk for osteogenic sarcoma?
- A 72-year-old man
 - A 46-year-old woman
 - A 16-year-old boy
 - A 7-year-old girl

Rationale

Correct answer: c.

Osteogenic sarcoma occurs during periods of rapid growth in adolescents.

18. A client presents with a dislocated wrist. The hand on the affected side is cold and blue. How should the nurse interpret these findings?
- Bleeding into the soft tissues has occurred.
 - Neurovascular compromise exists.
 - Lymphatic channels are blocked.
 - A bone fracture coexists.

Rationale

Correct answer: b.

Symptoms of neurovascular damage include numbness, pain, cyanosis, and coldness of an extremity. Bleeding does not typically occur with a dislocation; lymphatic blockage does not cause cyanosis; and coldness and blue color are not specific signs indicative of a fracture.

19. When planning care for a client with a fractured hip, the nurse would plan to monitor for which common complications?
- Urinary tract infection
 - Pneumonia
 - Candidiasis
 - Herniated nucleus pulposus
 - Thromboembolism

Rationale

Correct answers: b and e.

Pneumonia and thromboembolism are complications related to immobility and are significant risks in clients with fractured hips. Urinary tract infection and candidiasis may occur but clients with fractured hips are not at particular risk for them. Herniated nucleus pulposus is a problem of the intervertebral discs that may be the result of degeneration or trauma to the spine.

20. Hip precautions would be part of the plan of care for a client with which disorder?
- Osteogenesis imperfecta
 - Tibial torsion
 - Juvenile rheumatoid arthritis
 - Hip fracture

Rationale

Correct answer: d.

Hip precautions—no hip flexion beyond zero degrees, no adduction beyond the midline, and weight bearing restriction as prescribed—are part of the plan of care for the client with a fractured hip. Osteogenesis imperfecta requires

(continued)

careful handling to avoid breaking bones. There are no special positioning precautions for JRA or tibial torsion.

21. The teaching plan for the parents of an infant with which problem would include the instruction “Never hold by the ankles when changing the diaper”?
- Muscular dystrophy
 - Osteomyelitis
 - Club foot
 - Osteogenesis imperfecta

Rationale

Correct answer: d.

Holding the infant by the ankles to change the diaper is contraindicated in osteogenesis imperfecta because of the ease with which any stress can cause a bone to break. Holding by the ankles is not contraindicated by any of the other disorders.

22. Which statement made by the relative of a child with muscular dystrophy indicates understanding of at least one aspect of the disease?
- “I’m relieved that this is a noninherited, developmental defect.”
 - “There may be some disability but at least there is a normal life expectancy.”
 - “If intellectual impairment was not always a part of the disease, it would be easier to deal with.”
 - “It will be very hard watching as the muscle wasting and loss of function occur.”

Rationale

Correct answer: d.

Muscle wasting, weakness, and loss of function are characteristic of muscular dystrophy. Muscular dystrophy is an inherited disorder, with a shortened life expectancy. Intellectual impairment occurs with a few forms of MD but not with all.

23. Which client has risk factors and/or signs most characteristic of Ewing’s sarcoma?
- A 24-year-old with a rapidly growing mass palpable on the tibia
 - A 40-year-old with a history of retinoblastoma
 - A 55-year-old with severe back pain that increases with exercise
 - A 73-year-old with multiple pathological fractures

Rationale

Correct answer: a.

Ewing’s sarcoma is a disease of those under 30 years of age and is characterized by a rapidly growing mass on the affected bone with tense, tender local swelling. History of

retinoblastoma is a risk factor for osteogenic sarcoma. Back pain that increases with exercise is characteristic of multiple myeloma. Pathological fractures are associated with multiple myeloma.

24. What findings on physical examination of a client brought into Emergency are consistent with a fractured hip?
- Lengthening and internal rotation of the affected leg
 - Lengthening and external rotation of the affected leg
 - Shortening and internal rotation of the affected leg
 - Shortening and external rotation of the affected leg

Rationale

Correct answer: d.

The leg shortens and externally rotates when the hip fracture allows the femur to move up and it is no longer held in position within the acetabulum.

25. When monitoring a client for compartment syndrome, which question should be included in the assessment?
- “Does it hurt when you flex the muscle of your arm?”
 - “Has the pain increased in your arm?”
 - “Has the swelling increased near your shoulder?”
 - “Is there a red line going down your arm?”

Rationale

Correct answer: b.

A sign of compartment syndrome is increased pain in the extremity. Other signs are pain on passive muscle stretching of the part and edema distal to the site of injury. A red line down the arm is indicative of infection.

26. Foods such as scallops, red wine, and gravies should be restricted in the diet of clients with which disease?
- Rheumatoid arthritis
 - Systemic lupus erythematosus
 - Gout
 - Muscular dystrophy

Rationale

Correct answer: c.

Foods high in purines should be avoided because primary gout is caused by a genetic error in purine metabolism the end result of which is the over production or retention of uric acid. There are no dietary restrictions for any of the other diseases.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 7: Gastrointestinal Problems

| | | | |
|--------------------------|-----|-----------------------------------|-----|
| ▶ Abdominal Hernias | 841 | ▶ Gastroesophageal Reflux Disease | 828 |
| ▶ Appendicitis | 840 | ▶ Hemorrhoids | 842 |
| ▶ Bowel Obstruction | 839 | ▶ Hiatal Hernia | 830 |
| ▶ Celiac Disease | 836 | ▶ Hirschsprung's Disease | 843 |
| ▶ Cleft Lip/Cleft Palate | 826 | ▶ Imperforate Anus | 844 |
| ▶ Colic | 835 | ▶ Inflammatory Bowel Disease | 837 |
| ▶ Colorectal Cancer | 842 | ▶ Intussusception | 838 |
| ▶ Diverticular Disease | 841 | ▶ Jaw Fracture | 827 |
| ▶ Esophageal Cancer | 829 | ▶ Oral Cancer | 827 |
| ▶ Failure To Thrive | 834 | ▶ Peptic Ulcer Disease | 831 |
| ▶ Gastritis | 830 | ▶ Peritonitis | 840 |
| ▶ Gastroenteritis | 832 | ▶ Pyloric Stenosis | 833 |

FACIAL/ORAL PROBLEMS

PEDS CLEFT LIP/CLEFT PALATE

- Cleft lip and cleft palate refer to facial malformations that evolve during embryonic development, resulting in nonunion of the bones and tissues of the lip and palate.
- Cleft lip and cleft palate may occur independently or together.
- There may be a combination of defects and degrees of involvement.
- Facial defects are noticeable at birth.

Etiology: Cleft lip occurs when the medial nasal and maxillary processes fail to form. Cleft palate occurs when the bone and tissue of the primary palatal shelves or processes fail to fuse, causing a communication between the mouth and nose.

Precipitating factors: Combination of genetic and environmental factors; cleft palate is found mostly in girls and cleft lip alone or together with cleft palate is found mostly in boys; maternal smoking during the first trimester may contribute to the development of these defects.

S&S:

- Incompletely formed lip
- Opening in roof of the mouth can be palpated
- Unilateral or bilateral cleft lip
- With cleft palate, milk or formula escapes through the nose
- Abdominal distention due to swallowing air
- Slow weight gain

Dx: Visual assessment of defects at birth and by palpation; ultrasound to identify cleft lip or cleft palate in utero; MRI to detect the extent of the abnormality; evaluation of the infant's ability to suck, swallow and breathe; a genetic evaluation to determine reoccurrence

Rx: Modification of feeding technique with adaptive devices (nipples) to ensure growth; extra-and intraoral prosthesis used before surgery to aid in feeding and speech and to prevent maxillary collapse; cleft lip is usually corrected before cleft palate; immediate repair focuses on the first few weeks after birth; repair of cleft palate is at about eighteen months. Surgery offers optimal cosmetic and functional results; scheduled when the infant is without any infections (respiratory, oral, or systemic), surgical treatments begin early and continue into adolescence; scheduling depends on the severity of the cleft.

Chiloplasty used for correction of a cleft lip; the involvement of a multidisciplinary team is needed: pediatrician,

plastic surgeon, orthodontist, audiologist, speech therapist, prosthodontist, and psychiatrist

Assessment Alert

When taking temperature, avoid the oral route.

Nursing Process Elements

- Provide emotional support to parents as they experience the emotional reactions to the infant's appearance
- Offer information to provide a better understanding about the infant's deformity, that the infant is normal and that surgery will correct the problem
- If sucking is ineffective use a cross-cut soft nipple or other specially adapted nipples
- When the infant is unable to suck, use a syringe with a rubber tip to place the formula into the mouth
- Hold the infant's head upright when feeding, to prevent aspiration
- Make the infant burp often, this helps prevent regurgitation and aspiration
- Monitor feeding-tube function if the infant cannot feed orally
- Postoperative nursing
 - Assess respiratory status
 - Monitor vital signs
 - Check weight periodically to evaluate adequate nutritional intake
 - Clean suture line to prevent infection
 - Use a gentle restraint to prevent the infant from placing hands on its mouth
 - Position infant so that rubbing of lip is prevented
 - Use wrist restraints after cleft-lip repair and elbow restraints following cleft-palate repair to prevent the child from putting anything into the mouth
 - Use a rubber-tipped asepto syringe to feed after cleft-lip repair
 - Following cleft-palate repair, limit the child to fluids, which the child can drink from a cup
 - Do not use eating utensils or straws to prevent traumatizing the palate repair
 - Avoid any activity that might strain the suture line, including crying, in the postoperative period

Nursing Intervention Alert

The infant requires stimulation after surgery to provide distraction, to prevent reaching for the mouth and to decrease crying which increases tension on the suture line. Provide age-appropriate toys and music; encourage the parents to hold, cuddle, and comfort the infant.

Client teaching for self-care

- Teach parents that cleft lip or palate interferes with the ability to suck and feeding is difficult
- Encourage family to participate in both physical and emotional care
- Teach feeding methods: to feed small amounts, slowly and for a short time, to hold the infant upright and to burp often
- Review the need to observe for respiratory difficulty and aspiration
- Monitor for weight gain
- Prepare for discharge home by allowing time for parents to practice feeding
- Answer parents' questions about care and initiate referrals to the American Cleft Palate Association

JAW FRACTURE

- Jaw fracture includes broken jaw, trauma to the mandible, and also possible trauma to the maxillary bones, teeth, face, and mouth framework.

Etiology: Caused by a direct blow to the jaw; related to a motor vehicle accident, assault, a sport or recreation injury; a powerful blow may also injure the cervical spine.

Precipitating factors: Males are 3 times more prone to jaw fracture; ages 20–29 years form a common group with this injury.

S&S:

- Difficulty in breathing
- Pain
- Edema
- Bleeding
- Bruising
- Difficulty in opening mouth
- Temporary problem during talking and eating

Assessment Alert

Monitor general condition for shock; check neurovascular status.

Dx: Assessment of symptoms; X-rays to determine the type of fracture and position of any bone fragments; MRI

Rx: The goal is to reduce the fracture and restore function—apply ice to reduce edema and pain; use analgesics; wire jaws together to keep bones in place; surgery involves repositioning and reconstruction of the jaw and insertion of a rigid plate fixation with screws into the bone to stabilize fracture

Clinical Alert

The following complications are medical emergencies that may accompany a fractured jaw and need immediate attention: airway obstruction, cervical spine injury, or hemorrhage.

Nursing Process Elements

- Monitor for increased respiratory effort
- Address concerns about body image
- Evaluate neurovascular status
- Treat pain with analgesics
- Help clear secretions from oropharynx
- Keep wire cutter nearby

Client teaching for self-care

- Offer guidelines for mouth care and feeding
- Instruct client with wired jaw or postsurgery to follow a liquid diet, not to chew, and to use protein drinks
- Teach to call physician for: difficult breathing, severe jaw pain not relieved by medication, elevated temperature, and loose wires
- Provide wire cutters for client's use

ORAL CANCER

- The most commonly occurring oral cancers are squamous cell carcinomas.

- Oral cancer may occur anywhere in mouth: lips, palate, floor, etc., but tongue is the most common site.
- Metastasis from the tongue is especially rapid because of lymph and blood supply.

Etiology: Precise cause unknown.

Risk factors: Smoking and alcohol use linked to all but tongue cancers.

Leukoplakia are white lesions appearing on the oral mucosa. More common in men, and those over the age of 60 years, one type linked to heavy smoking, also cheek or lip biting or friction from dentures. Associated with increased cancer risk only if occur on the floor of mouth.

Erythroplakia are red, velvety lesions associated with cancer risk. Biopsy recommended.

S&S: Single asymptomatic lesion like a painless, nonhealing ulcer, often unnoticed by client

Dx: Biopsy is definitive. Ultrasonography or CT scans may be done to evaluate masses

Rx: Depends on size and stage.

- Early: radiation or surgery; highly curable with radiation if confined to mucosa
- More invasive: both surgery and radiation.
- Late: palliative

Surgery often includes neck dissection because of early metastasis to cervical nodes

Nursing Process Elements

Assess and manage side effects of treatment

- Surgery: Airway, chewing, swallowing, or speech problems
- Radiation: stomatitis, xerostomia, dental decay, change/loss of taste

(See section on radiation Rx.)

Client teaching for self-care

Following oral surgery instruct the client to:

- Follow program of mouth care carefully to help prevent infection and tooth decay. Use sterile water, dilute peroxide, and saline and/or bicarbonate solution as prescribed; no commercial mouth washes until healed
- Select foods of a consistency which is easiest to swallow and least uncomfortable
- Avoid damage to healing tissues: Eat slowly, avoid very hot or cold foods; do not use a fork or other potentially traumatic utensil
- Take nutritional supplements as needed to maintain weight and balanced nutrition
- Rinse mouth as directed after eating

GASTROESOPHAGEAL REFLUX DISEASE

- Gastroesophageal reflux disease (GERD) refers to a relapsing, chronic disorder in which gastric and duodenal contents move back into the lower esophagus resulting in a break in the mucosa and inflammation.
- In the long term, this can result in the development of Barrett's epithelium, which is more resistant to acid but has a significant malignant potential.
- Ulceration and hemorrhage as well as fibrosis and esophageal stricture can also occur.

Etiology: Inappropriate relaxation of the lower esophageal sphincter (LES), possibly delayed gastric emptying.

Precipitating factors: Ingestion of foods that lower LES pressure (fatty foods, chocolate, alcohol, caffeine containing cola, coffee, and tea); nicotine; drugs such as calcium channel blockers, theophylline, maybe NSAIDs; elevated estrogen or progesterone levels; conditions such as obesity or pregnancy that elevate intra-abdominal pressure.

S&S:

- Heartburn—substernal or retrosternal burning pain that may radiate to the back or jaw
- Regurgitation, belching, flatulence, and difficult or painful swallowing in severe cases
- Nocturnal cough, wheezing, or hoarseness

Assessment Alert

The heartburn of reflux can mimic angina. Careful differentiation between reflux and cardiac disease is critical.

Dx: Often based on symptoms. 24-hour pH monitoring is the gold standard, endoscopy to check mucosal damage; biopsy to check for Barrett's epithelium or cancer; manometry to check muscle and sphincter function

Rx: Drug therapy to neutralize acid and/or suppress its secretion

Antacids or alginates (Gaviscon) and histamine 2 (H₂) receptor antagonists for mild symptoms; proton pump inhibitors (PPIs) (once a day, 15–20 minutes before breakfast) for severe cases

Surgery (fundoplication) to reinforce the LES may be done in severe, refractive cases

Nursing Process Elements

- Assess for S&S
- Obtain baseline weight to determine need for weight loss
- Support efforts to lose weight and/or stop smoking

Assessment Alert

Clients generally do not report heartburn unless specifically asked or symptoms are very severe. It is important to ask specifically and explore the use of OTC remedies.

Client teaching for self-care

Teach the client to

- take medication as prescribed
- follow a low-fat, adequate-protein diet; fatty foods delay gastric emptying
- avoid foods that lower LES pressure or that consistently cause heartburn
- eat four to six small meals daily to avoid gastric distention, to eat slowly and chew thoroughly
- sit up for 1–2 hours after meals
- avoid eating or drinking for at least 3 hours before bedtime; evening snacking makes problem worse
- elevate head of bed 6–8 inches with foam wedge to discourage reflux secondary to the recumbent position
- lose weight if needed
- stop smoking
- avoid factors that increase intra-abdominal pressure: constrictive clothing, straining, weight lifting, and working bent over

ESOPHAGEAL CANCER

- Esophageal cancer is a rare but aggressive form of cancer. It is almost never diagnosed early.
- There are two distinct types:
 - Squamous cell esophageal cancer, which occurs predominantly in African-American men and arises in the middle and lower third of the esophagus.
 - Adenocarcinoma esophageal cancer, which primarily affects Caucasian men and arises in the distal third of the esophagus.

Etiology: Unknown.

Risk factors:

- Squamous cell: Tobacco use, heavy alcohol use, dietary nitrates, deficient intake of fresh fruits and vegetables, vitamin deficiency, mucosal irritants, African-American ethnicity, male sex.
- Adenocarcinoma: Barrett's epithelium (age 10–20 years, Caucasian ethnicity, male sex).

S&S: Typically asymptomatic until advanced

- Progressive dysphagia is the most common symptom; client often automatically eliminates difficult-to-swallow foods from the diet and is unaware of the problem until diet is predominantly liquid
- Vague sense of substernal discomfort or feeling of fullness after eating only a small amount may occur
- Halitosis, anorexia, weight loss, and emaciation in later stages of disease
- N&V occurs if esophagus completely obstructed
- Cough if tracheoesophageal fistula or other tracheal involvement occurs
- Steady, boring pain on swallowing and/or hoarseness if mediastinum involved

Dx: X-ray esophagram with barium swallow indicates mass present; esophagoscopy with biopsy determines the specific pathology. Workup for metastasis

Rx: Varies with tumor location, client condition, and stage of disease

- Resection of the esophagus to eliminate obstruction and restore swallowing
- Radiation pre- or postoperatively or for palliation when surgery not feasible
- Endoscopic laser destruction of the tumor, which requires repeated treatments but has no undesirable systemic effects and is unaffected by tumor location in the esophagus
- Prosthetic intubation—pliable tube inserted in esophagus to keep it open and/or bypass a tracheoesophageal (T/E) fistula
- Gastrostomy to maintain nutrition

Nursing Process Elements

- Assess for S&S with particular attention to nutritional status
- Monitor I&O
- Provide care as described under esophageal resection for clients having surgery
- Provide care as described under radiation therapy for clients having radiation
- For clients having laser palliation:
 - Explain that a temporary increase in dysphagia and discomfort is expected

- Begin oral diet a few days after last treatment
- Monitor for complications: aspiration, bleeding, and perforation of esophagus

HIATAL HERNIA

Hiatal hernia refers to the movement of the distal esophagus and a part of the stomach up through the esophageal hiatus (opening) in the diaphragm into the thoracic cavity. It is called

- sliding hernia if the gastroesophageal junction is above the diaphragm and part of the stomach slides up into the thorax when the client lies down and slides back into the abdomen on standing.
- paraesophageal hernia if the junction remains below the diaphragm but a section of the gastric fundus and greater curvature rolls up into the thorax forming a pouch.

Etiology: May be a congenitally enlarged opening.

Risk factors: Weakening of the diaphragmatic muscle, aging, trauma, surgery, prolonged increased intra-abdominal pressure from obesity, tumors, ascites, pregnancy, and strenuous activity.

S&S:

- Most hiatal hernias are asymptomatic
- S&S that occur with sliding hernias, are due to chronic reflux so are the same as in GERD
- With paraesophageal hernias, S&S are due to distention and obstruction so heartburn and chest pain are common. Occult bleeding secondary to rubbing of the mucosal surfaces of the herniated portion of the stomach also occurs

Assessment Alert

Occult bleeding associated with a hiatal hernia can lead to iron-deficiency anemia. Be sure to assess for related S&S.

Complications: Paraesophageal hernia—obstruction, strangulation, acute volvulus, regurgitation with tracheal aspiration

Dx: Visualized on barium swallow; mostly found during workup for GERD

Rx:

- Medical—Treat reflux as described under GERD
- Surgical—Only effective Rx for paraesophageal hernias. Hernia and its sac is reduced and the widened hiatus is

partially closed; a fundoplication antireflux procedure may also be done

Nursing Process Elements

Same as for the client with GERD

Nursing Intervention Alert

Warn client not to take alcohol for pain relief because it lowers LES pressure and worsens the problem.

GASTRITIS

Gastritis refers to the inflammation of the stomach mucosa.

- It may be acute or chronic, diffuse or localized.
- Acute gastritis is self-limiting and is characterized by superficial ulcerations, which heal with time.
- Hemorrhagic type may be a result of the use of NSAIDs or due to stress.

Acute Gastritis

Etiology: Injury to the gastric mucosa from chemical, thermal, or bacterial factors, which include drugs such as NSAIDs, steroids, digitalis; large amounts of irritating foods such as tea, coffee, spices; very hot, rough, or bacterially contaminated foods; alcohol; radiation exposure. Also occurs in association with severe physiologic stress.

S&S:

- Often asymptomatic
- When symptomatic: epigastric pain, abdominal tenderness, N&V, eructation. If hemorrhagic gastritis: hematemesis, melena, decreased HCT, increased BUN

Dx: Endoscopy or biopsy

Rx: Only when symptomatic

- Eliminate precipitating factor
- Treat symptoms: NPO during acute symptoms progressing to bland diet as tolerated, antiemetics, antacids, and H₂-antagonist to decrease irritating gastric secretions; fluid and blood replacement, NG lavage PRN for hemorrhagic type

Nursing Process Elements

- Assess for S&S using PQRS format
- Pay particular attention to

- pain
- use of alcohol
- following of prescription
- use of OTC and herbal drugs
- usual diet and any changes in eating habits
- appetite and weight
- signs of dehydration
- Monitor electrolyte values
- Monitor emesis for signs of bleeding
- Discourage cigarette smoking because nicotine increases gastric acidity

Client teaching for self-care

In case of acute gastritis:

- Avoid risk factors: drugs such as NSAIDs, steroids, digitalis; large amounts of irritating foods such as tea, coffee, spices; very hot, rough, or bacterially contaminated foods; alcohol; radiation exposure; nicotine because it increases gastric activity
- Handle, store, and prepare food properly
- Follow directions for taking medications
- Read OTC drug labels or ask pharmacist to check for ASA content in medicines
- Change to nonirritating foods and flavorings in the daily diet and limit alcoholic beverages
- Participate in a stop smoking program

Chronic Gastritis

In case of chronic gastritis, gastric mucosa atrophies, parietal and chief cells disappear, secretions decrease, and digestion becomes impaired.

Etiology:

- Type A: autoimmune associated with pernicious anemia.
- Type B: associated with *Helicobacter pylori* infection.

S&S:

- Mimic peptic ulcer disease or gastric cancer with epigastric fullness, burning or pain, N&V, and flatulence, especially after a large meal
- Anorexia, weight loss, and symptoms of anemia can also develop

Dx: Endoscopy and biopsy

Rx: Only when symptomatic

- Lifestyle changes to eliminate contributing factors
- Antibiotic therapy for *H. pylori* infection
- Bland diet and antacids
- Cobalamin injections for pernicious anemia

Nursing Process Elements

Assess for S&S, also for signs of developing B-12 deficiency associated with pernicious anemia, such as glossitis and stomatitis

Nursing Intervention Alert

Gastric cancer occurs more commonly in those with chronic gastritis than in the general population. Teaching the client about the importance of regular medical follow-up is important.

PEPTIC ULCER DISEASE

Peptic ulcer disease (PUD) is a break in the mucosa of any area of GI tract exposed to gastric secretions containing acid and pepsin. Thus, peptic ulcers can occur in lower esophagus, stomach, duodenum or any part of GI tract surgically connected to stomach

Duodenal or Gastric Ulcers

Etiology: Most cases are related to mucosal injury secondary to *H. pylori* infection, though only a small percent of people with *H. pylori* infection develop ulcers. Remaining cases are a result of mucosal injury secondary to chronic NSAID use.

Risk factors: Smoking: as amount and duration of smoking increases, so does risk. Alcohol has no proven role nor do diet, stress, or excess acid production.

S&S:

- Pain:
 - Gastric ulcer: Dull epigastric pain near midline, unrelied by antacids or food
 - Duodenal ulcer: Gnawing, burning or aching, midline epigastric pain sometimes with radiation around costal border to back, 1–3 hours after meals and at night (12pm–3am), lasting 30 minutes to 2 hours, often relieved by food or antacid
- Early satiety with gastric ulcer
- Dyspepsia, i.e., fullness, vague nausea, bloating/distention, anorexia, and weight loss

Assessment Alert

GERI

S&S of PUD are often atypical in the elderly. Pain may be absent or poorly localized and similar to that associated with angina, gall bladder disease, or dysphagia.

Dx: Suggested by history, confirmed by endoscopy, presence of *H. pylori* confirmed by biopsy or serology test

Clinical Alert

Serology test can confirm presence of *H. pylori* but cannot be used to monitor therapeutic results because it remains positive for an indefinite period of time.

Rx:

- Antibiotics to eliminate *H. pylori* infection
- H₂ receptor antagonists or proton pump inhibitors to decrease gastric acid production
- Antacids to decrease irritation from gastric acid and permit healing; used predominantly for symptomatic relief; aluminum hydroxide preparations preferred
- Mucosal protective agents
 - sucralfate coats mucous membrane and ulcer crater providing a barrier against gastric acid
 - GERI** Misoprostol, synthetic prostaglandin analog, used preventatively in high-risk older clients who need NSAIDS

Clinical Alert **OB**

Misoprostol can cause abortion so it is not used for women of child-bearing age.

- Surgery primarily for complications though selective vagotomy may be done to decrease HCl production
- Diet: Restrict foods that cause distress

Complications:

- Hemorrhage from damage to a large blood vessel
- Peritonitis secondary to perforation and release of contaminated GI contents into peritoneal cavity
- Obstruction (partial or total) as a result of edema in narrow pyloric area
- Gastric cancer

GERI Most complications occur in elderly. Elderly more likely to be colonized with *H. pylori*, more frequently use NSAIDS, often have dyspepsia making diagnosis more difficult, and less often seek treatment.

Nursing Process Elements

- Assess S&S with particular attention to pain, signs of GI bleeding including occult blood in feces, changes in Hgb, HCT, and RBC count, weight gain or loss
- Obtain history of medication use with focus on ulcerogenic drugs especially ASA and NSAIDs, alcohol use, smoking, and dietary habits
- Refer to smoking cessation program if needed

Client teaching for self-care

Provide the following instructions to the client:

- Adhere to prescribed drug regimen. This includes continuing to take all medications even if pain or other S&S are relieved
- Do not take antacids at the same time as other anti-ulcer medications such as H₂ blockers because the antacids decrease absorption of the other drugs by a significant amount
- Never abruptly discontinue anti-ulcer medications because of risk of severe acid rebound
- Substitute acetaminophen for ASA or other NSAIDs for routine pain or fever management
- Use good eating habits:
 - Avoid foods that cause discomfort
 - Avoid overeating
 - Eat slowly and chew thoroughly
 - Avoid snacking at bedtime because it increases nighttime acid secretion
- Use alcohol in moderation if at all; do not drink on an empty stomach because of irritating effect on the mucosa
- Obtain adequate rest
- Engage in stress-reducing activities

GASTROENTERITIS

- Gastroenteritis refers to an inflammation of the stomach and small intestine.
- The most common causative agents of gastroenteritis are bacteria and viruses, and then parasites or toxins.
 - Bacteria: *Escherichia coli*, *Salmonella*, *Staphylococcus aureus*, and *Shigella*.
 - Parasites: *Ascaris*, *enterobius*, and *trichomonas*.
 - Viruses: Norwalk, retrovirus, adenoviruses, echoviruses, and coxsackievirus.
 - Toxins: Poisonous plants, lead, mercury, arsenic, and toadstools.

Etiology: Tissue damage and inflammation lead to the release of exotoxins that cause a secretion of electrolytes and

water into the intestine; as a result, diarrhea and fluid loss occur.

Precipitating factors: Ingestion of feces-contaminated food and water; food borne viral infections caused by feces-contaminated shellfish; the use of antibiotics which decrease normal intestinal flora that usually protects the bowel from pathogens; travelers to countries with poor sanitation are prone to gastroenteritis or traveler's diarrhea; not washing hands before handling food and after using the bathroom.

Assessment Alert

PEDS

GERI

Those at greatest risk are infants, the elderly, and debilitated clients, due to immature or impaired immune systems.

S&S:

- Diarrhea, mild to severe
- Anorexia, N&V
- Excessive vomiting may lead to metabolic alkalosis due to loss of hydrochloric acid from the stomach
- Malaise
- Abdominal distention, pain, cramps
- Borborygmi
- Electrolyte imbalances such as hypokalemia, hyponatremia
- Fever
- Headache

Dx: Laboratory tests such as HCT (decreased due to dehydration and hypovolemia), creatinine, and BUN; assessment of electrolyte values and acid–base balance; tests to identify the causative agent such as Gram stain, stool culture, blood culture, and ELISA to specifically identify *Clostridium difficile*; endoscopic examinations show an inflamed, edematous bowel mucosa

Assessment Alert

Complications include shock, dehydration, and renal failure.

Rx: Acute gastroenteritis resolves quickly; if client is severely ill, medications are prescribed, antibiotics are used if cause is bacterial (obtain a stool culture first), occasionally antidiarrheals used to increase comfort and decrease fluid loss or cathartics may be used to remove toxins from the bowel and

antiemetics for severe vomiting; supportive measures as bed rest, nutritional supplements, increasing fluids and a bland diet; electrolytes are replaced; IV fluids are administered if necessary, as glucose in normal saline or lactated ringers solution

Nursing Process Elements

- When client can tolerate fluids, offer ginger ale, lemonade, or broth to replace fluids and electrolytes
- Ask about recent travel and antibiotic therapy
- Wash hands thoroughly after administering care to prevent spread of infection
- Plan care so that the client has uninterrupted periods of rest to improve resistance and conserve strength
- Administer IV fluids as ordered
- If food poisoning is the cause, contact the public health department to find source of the problem

Client teaching for self-care

- Teach to wash hands before handling food and after using the bathroom
- Instruct to clean cooking utensils well
- Teach to identify foods that need immediate refrigeration as dairy products, meats, and fresh fish
- Teach client to avoid raw meat
- Instruct to cook meat well to prevent salmonellosis or staphylococcal food poisoning
- Teach about the cause, symptoms, and treatments of gastroenteritis
- Inform clients who travel to drink only bottled water, not to use ice in their drinks, and to avoid raw fruits and vegetables

PEDS

PYLORIC STENOSIS

- Pyloric stenosis is a hypertrophy (thickening) of the circular muscles surrounding the pylorus resulting in stenosis and obstruction.

Etiology: Exact cause unknown; develops during infant's first weeks of life; hypertrophy and hyperplasia cause the circular muscles of the pylorus to enlarge, resulting in narrowing of the pyloric canal between the stomach and duodenum; later, inflammation and edema add to constriction of the lumen and to obstruction.

Precipitating factors: May be familial or acquired; more common in Caucasians; affects males more than females; associated with anorectal abnormalities and intestinal malrotation.

Assessment Alert

Most often seen in full term first-born male infants.

S&S:

- Vomiting (usually stale milk), 30–60 minutes after feeding, becomes forceful and projectile
- Visible peristalsis
- Infant is irritable, hungry, and without weight gain
- Few, small stools
- Distended upper abdomen
- Dehydration—poor skin turgor, sunken fontanel, lethargy
- Palpable olive-shaped mass in the epigastrium
- Development of alkalosis and hyperbilirubinemia

Assessment Alert

Infants are at high risk for dehydration due to fluid deficit and altered nutrition as a result of vomiting.

Dx: Ultrasound to confirm diagnosis, Upper GI to rule out any other cause of vomiting; evaluation of laboratory values to detect anemia and metabolic alkalosis, increased blood urea nitrogen and/or decreased sodium, potassium, and chloride levels

Rx: Correct fluid and electrolyte imbalances; surgery: a pyloromyotomy (Fredet-Ramstedt procedure) performed to enlarge the pyloric outlet or opening of the obstruction to allow for passage of fluids and food; may use laparoscopic surgery which involves a shorter surgical time and an earlier feeding and discharge time

Assessment Alert

Complications that may occur postoperatively: wound dehiscence, continued pyloric obstruction, and gastroesophageal reflux.

Nursing Process Elements

- Monitor vital signs, daily weights, I&O, urine specific gravity
- Assess vomiting episodes and assess for aspiration

- Evaluate for fluid and electrolyte imbalances
- Restoration of hydration
- Evaluate NG tube function, type and amount of drainage
- Assess parent's anxiety and offer reassurance about problem
- Postoperative care:
 - Promote rest and comfort
 - Prevent infection
 - Maintain IV fluids and I&O
 - Encourage parents to remain with infant and to participate with care

Client teaching for self-care

- Encourage parents to hold child and provide pacifier for comfort
- Instruct family to monitor intake of food and fluids and vomiting episodes
- Inform parents about pre- and postoperative interventions
- Offer discharge instructions to parents: check incision for redness and drainage, when temperature is elevated call the physician, give written instructions about feedings, to fold diaper off incision site to prevent infection, give analgesics as acetaminophen as ordered, warn parents that some postsurgery vomiting may occur.
- Provide resources for parents to contact for any questions about infant's needs

PEDS

FAILURE TO THRIVE

- Failure to thrive (FTT) refers to growth failure.
- It is the inability to utilize or obtain enough food, resulting in poor growth patterns.
- It represents a continual deceleration on the growth curve.

Etiology: Organic FTT caused by the presence of a major disease, inorganic FTT caused by many psychosocial factors. Mixed FTT may also occur.

Precipitating factors: Presence of a disease such as AIDS, congenital heart defects, metabolic disorders, esophageal reflux, or a neurological abnormality; psychosocial problems as parent's misunderstanding of the infant/child's nutritional requirements, disturbances in the parent-child relationship, poverty, or immature parents.

S&S:

- Weight and/or height falls below the fifth percentile for child's age
- Developmental milestones are not achieved
- Slow social, lingual, and motor development
- Irregular sleep patterns

- Weakness
- Limited smiling
- Absence of appropriate stranger anxiety

Dx: Health and dietary history; physical examination and diagnostic tests to rule out major illnesses; developmental screening; evaluation of growth patterns; family assessment; evidence of growth retardation

Assessment Alert

It is normal for American-Asian children to be lower than the fifth percentile on growth charts.

Rx: Reversal of malnutrition; adequate nutrition to increase calorie intake; treat psychosocial problems with a multidisciplinary team; multivitamins and minerals

Nursing Process Elements

- Assess parent and child behavior during feeding; how child is held, eye-to-eye contact, sensitivity to child's needs
- Provide feedings by consistent nursing staff, to learn child's feeding behavior
- Take initial height and weight and weigh daily
- Evaluate when hungry and when hunger is met
- Record food intake
- Use a structured feeding schedule
- Provide quiet nonstimulating surroundings
- Offer appropriate developmental stimulation
- Arrange home care visits, contact social agencies for financial assistance to family

Client teaching for self-care

- Give instruction and guidance about meeting child's nutritional needs
- Demonstrate feeding techniques to parent
- Encourage parents to hold, touch, and cuddle when feeding infant
- Teach to maintain scheduled, quiet meal times
- Suggest that parents eat with the child or that the child eat with others can be more enjoyable for the child
- Instruct parent to create eye contact when feeding infant or child
- Teach to offer foods first and liquids later, liquids have fewer calories and create a feeling of fullness
- Instruct to limit junk food in a child's diet

PEDS

COLIC

- Colic is a disorder characterized by periods of excessively loud crying associated with proxysmal abdominal cramping and pain.

Etiology: Unknown, possibly swallowing air during feeding; newer theory suggests an association with CNS maturation; there is no apparent medical reason for crying; infant does gain weight and thrives.

Precipitating factors: Feeding too fast; swallowing large amounts of air; generally present in infants under 3 months; may be a symptom of cow's milk allergy or allergy to something in mother's diet.

S&S:

- Continuous loud crying for hours
- Infant may draw up legs to chest
- Clenched hands
- Distended abdomen
- Symptoms may resemble intestinal obstruction
- Refuses breast or bottle
- Usually occurs in late afternoon or early evening
- When crying stops, see exhaustion and/or passage of gas or stool

Assessment Alert

Assess for abuse; parents become frustrated when caring for difficult infants.

Dx: Based on symptoms, infant is inconsolable

Rx: No medical treatment; outgrow problem; sometimes use drugs as antispasmodics, sedatives, and antiflatulents may be useful; if breast-feeding mother notes certain foods in her diet cause increased crying, these foods should be eliminated; if cow's milk is a problem, trial use of another formula; burping to relieve air in GI tract

Nursing Process Elements

- Support parent's every effort to comfort infant; listen attentively and offer suggestions
- Observe feeding process, relationship between feeding and crying, diet type, and amount of burping
- Evaluate colic episodes
- Reduce stimuli, provide soothing music, and respond to crying
- Swaddle and hold

- Place infant in crib or bassinet on back if all efforts fail, will eventually fall asleep

Client teaching for self-care

- Explain to parents that although crying is stressful, colic disappears in about 3 months and leaves no long-term effects
- Hold and rock infant, give rhythmic movement using either infant swing or front baby carrier
- Reduce stimuli, no loud noises, provide quiet, soothing environment
- Massage abdomen, try pacifier or warm bath to relieve discomfort
- Feed small amounts and burp often
- Try bottle with collapsible bag to prevent sucking air
- Change formula, or mother's diet if necessary

CELIAC DISEASE

- Celiac disease is a chronic malabsorption syndrome.
- It involves inability to digest gliadin, formed from the breakdown of gluten, a protein found in wheat, rye, oats, and barley.
- It is also called gluten-induced enteropathy or celiac sprue.

Etiology: Malabsorption develops when a child or adult is unable to absorb and digest nutrients; celiac disease, lactose intolerance, and short bowel syndrome are examples of malabsorption. Specific cause is unknown; ingestion of gluten causes an immune response that damages the small intestine villi, resulting in malabsorption; affects fat metabolism.

Precipitating factors: Genetic and environmental influences or immune factors; more common in Caucasians; affects young children and adults; present more often in females; untreated celiac disease can develop into associated lactose intolerance due to intestinal mucosa lesions.

S&S:

- Distended abdomen and wasted extremities
- Steatorrhea, foul-smelling stools
- Irritability
- Anemia
- Extreme malaise
- Anorexia

Dx: Measurement of stool fecal fat; assessment of failure to thrive; jejunal biopsy to evaluate changes in the intestinal mucosa; serologic testing for IgA endomysial antibodies and IgA and IgG antigliadin antibodies for diagnosis and for evaluation of compliance to diet; CBC to evaluate anemia, prothrombin time to check for vitamin K deficiency

Rx: Gluten-free, high-calorie, high-protein diet: the elimination of wheat, rye, oats, and barley from the diet; limited fat in diet; use corn and rice as wheat substitutes; vitamins, minerals, and also iron and folic acid for anemia; vitamin K if prothrombin time is prolonged; corticosteroids if modified diet is not successful, used to reduce the inflammatory response

Clinical Alert

Noncompliance with diet results in risk for relapse, retarded growth, anemia, and development of gastrointestinal cancers when an adult.

Nursing Process Elements

- Continuing support to parents, provide information about celiac disease and about dietary restrictions
- Observe for normal growth patterns after treatment
- Evaluate stools: should be soft and formed
- Reinforcement needed for school age children and adolescents to maintain their diet since they are influenced by peers to try other foods
- Arrange for home care

Assessment Alert

Celiac crisis, a sudden buildup of glutamine, which destroys the intestinal mucosa cells and causes severe watery diarrhea and vomiting results in a quick onset of dehydration and metabolic acidosis, which is treated with IV fluids and electrolytes and corticosteroids.

Client teaching for self-care

- Reinforce importance of following the prescribed diet
- Give information about preparing foods with rice and corn products
- Teach to read all food labels
- Schedule regular visits with a dietician
- Instruct to take vitamins, minerals, folic acid, and iron as prescribed
- Refer to resources for assistance as: American Celiac Society, Gluten Intolerance Group

INFLAMMATORY BOWEL DISEASE

Inflammatory bowel disease (IBD) has two major forms: Crohn's disease and ulcerative colitis. The pathology of both the forms is different but they are similar in other aspects; both are chronic and recurrent.

Etiology: Genetic factors: IBD associated with permissive genes on chromosomes 5 and 6 and CARD 15 gene mutations are associated with some forms of Crohn's disease. Positive family history is the most important risk factor but these are permissive; actual triggering factors not known. Smoking is one environmental factor

S&S:

- Ulcerative colitis—Continuous inflammation with edema and shallow ulcers primarily affecting the distal colorectal area (left-sided disease); ultimately the colon wall becomes inelastic and thick like a pipe and can no longer absorb. Pseudopolyps that can become malignant may result. Classic symptoms are bloody diarrhea (3–4 times per day up to hourly, mushy, urgent) and abdominal pain (left-sided, colicky, relieved by defecation); incontinence can occur because the urge to defecate can be lost as bowel thickens
- Crohn's disease—Cobblestone (affected areas separated by normal tissue) inflammation primarily affecting the proximal colon and ileum (right-sided disease); bowel wall thickens, ulcerates, and lumen narrows; fistulas to bladder, vagina, or other areas of bowel may form; scar tissue may obstruct the bowel, absorptive capacity may be lost. Diarrhea and abdominal pain are classic but pattern varies with location and severity of disease. Ileal disease: 3–5 large semisolid stools containing mucus and pus but no blood. Colorectal disease: urgent, small volume diarrhea and tenesmus. Severe, colicky pain after eating may be diffuse or localized in right lower quadrant (RLQ).
- Systemic symptoms of IBD: Anorexia, nausea, weakness, malaise, weight loss, anemia, fever, and leukocytosis. Almost any organ can be affected by a related systemic disorder that are believed to result from some underlying immune phenomenon, for example, arthritis and renal stones

Clinical Alert

Primary complications of IBD are hemorrhage, obstruction, perforation, toxic megacolon, and malignancy developing in area of cellular dysplasia.

Dx: Stool culture and other laboratory work to rule out infectious origin; serologic antibody assay to help distinguish type of IBD; barium enema which can show “string

lesions” of ulcerative colitis and cobblestones of Crohn's disease; endoscopy for direct visualization of characteristic changes; ultrasound to identify abscesses and fistulas

Rx:

- Stepped protocol in which drug regimen progressed until a response occurs
 - Step 1(a): Aminosalicylates
 - 5-ASA preparations such as sulfasalazine, mesalamine, and olsalazine are not absorbed and have an anti-inflammatory effect on the colon inducing and sustaining remission in clients with mild to moderate IBD. Aminosalicylates can be used topically via enema or suppository
 - Step 1(b): Antibiotics (metronidazole and ciprofloxacin)
 - Step 2: Corticosteroids (prednisone and budesonide)
 - IV, PO, PR used to treat acute flares; never for maintenance therapy because of severe side effects (fluid and electrolyte abnormalities, osteoporosis, aseptic necrosis, peptic ulcers, cataracts, neurologic and endocrine problems, infection, and psychiatric problems)

Clinical Alert

When corticosteroids are given, dose is tapered as soon as clinical response occurs, usually in 1–2 days.

- Step 3: Immunomodulators (azathioprine, mercaptopurine) or in Crohn's, the monoclonal antibody infliximab
 - Slow onset of action; may take 4 months to have effect

Nursing Intervention Alert

Clients on immune modifiers need CBC with differentials and platelets monthly for at least a year to check for neutropenia or pancytopenia, less frequently thereafter, if stable. LFTs also need monitoring.

- Step 4: Agents known to work on selected clients only
- Supportive care for severe episodes: bed rest, NPO, IV rehydration, parenteral nutrition for malnutrition
- Surgery: For ulcerative colitis, total colectomy with ileostomy is curative; in Crohn's disease, surgery avoided when possible because disease tends to recur in remaining bowel

Nursing Process Elements

- Assess S&S with particular attention to pain, bowel elimination pattern, and nutritional status
- Check usual meal pattern and intake, recent weight changes, food intolerances, bowel sounds, condition of perianal skin, skin turgor, condition of mucous membrane, fluid and electrolyte values, and current medication regimen
- Assess impact of illness on daily activities, family, and social relationships
- Encourage client to keep a record of pain and its relationship to eating, drinking, and passing stool or flatus; also of the frequency, severity, and urgency of defecation and whether blood or pus was present
- Monitor daily weight, I&O, signs of dehydration
- Administer anticholinergic or antispasmodic drugs as prescribed to reduce cramping
- Recommend attendance at support group

Client teaching for self-care

Instruct client to

- eat a high-calorie, well-balanced diet of whatever appeals when feeling well; limit raw fruits and vegetables and spicy or fatty foods or other aggravating foods when experiencing pain or diarrhea
- drink 2500–3000 ml of fluid per day to make up for losses with diarrhea
- use salt and drink Gatorade if tolerated during flares to replace electrolytes
- limit activity when diarrhea is severe and to lie down for 20 minutes after meals to limit peristalsis
- keep anal area clean and dry; use sitz baths, medicated wipes, and/ or a protective ointment
- monitor weight during flares
- use bulk-forming hydrophilic laxatives as directed if constipation is a problem
- apply warm heating pad to abdomen for comfort but not during acute exacerbations
- maintain a balanced schedule of rest and activity with regular sleep pattern
- use stress-reduction strategies
- report signs of problems requiring intervention: change in pattern of pain or diarrhea, change in stool characteristics, unusual rectal discharge, fever
- keep appointments for regular follow-up care

PEDS

INTUSSUSCEPTION

- Intussusception refers to an intestinal obstruction that occurs when one portion of the bowel slips into an adjacent section.

- It is also called invagination or telescoping.

Etiology: Usually has an unknown cause; the passage of stool is obstructed beyond the defect; most common site is the ileocecal valve; onset can be abrupt, a previously healthy client suddenly develops abdominal pain and vomiting.

Precipitating factors: Present more often in males; most common at about 6 months, majority of cases are under the age of 2 years; associated with cystic fibrosis, celiac disease, Merkel's diverticulum, and Down's syndrome.

S&S:

- History of a piercing cry, severe abdominal pain, and pulling legs up to the trunk
- Currant jelly like stools with mucous and blood
- Failure to grow and weight loss
- Vomiting that is bile stained with a foul odor
- Increasing absence of stools
- A palpable sausage-like mass in the upper right quadrant of the stomach
- Between episodes the child is comfortable

Dx: Based on infant's or child's history; barium enema shows obstruction to the flow of barium; ultrasound of abdomen to identify the location

Rx: To reduce the intussusception, a nonsurgical hydrostatic reduction of the bowel is attempted with a barium enema or use of a water-soluble contrast and air pressure. Surgery is used if treatments are not successful. First, a manual reduction of the telescoping bowel is tried. If this is not effective and if the bowel is gangrenous or strangulated, a resection of the affected bowel is performed

Clinical Alert

Hydrostatic reduction is not recommended when the infant or child shows signs of perforation or shock.

Without treatment, necrosis with hemorrhage, strangulation of the intestine, perforation, gangrene, and peritonitis occur. This is considered a pediatric emergency; these complications may be fatal.

Nursing Process Elements

- Check vital signs frequently, increased pulse and decreased blood pressure may indicate peritonitis

- Monitor I&O
- Check for bleeding
- Evaluate for fluid and electrolyte imbalances
- Offer reassurance and information about treatment to the parents
- Observe for passage of barium or contrast material
- Encourage parents to participate in child's care to help reduce stress
- Postoperative care
 - manage pain
 - assess vital signs
 - maintain NG tube functioning
 - evaluate bowel sounds

Client teaching for self-care

- Encourage parents to monitor stools and note any changes
- Instruct parents to notify physician if symptoms reoccur, appetite is poor, and a fever develops
- Teach parents that reoccurrence can occur after nonsurgical treatment
- Provide pre- and postoperative teaching about abdominal surgery

Assessment Alert

Report passage of a normal stool, this indicates that the intussusception has been reduced.

BOWEL OBSTRUCTION

- Bowel obstruction may be mechanical if a result of narrowing of the bowel lumen.
- It may be nonmechanical if a result of impaired peristalsis.
- Either type may be partial or complete.

Etiology:

- Mechanical—adhesions, hernias, volvulus (twisting of intestine on self), tumors, intussusception (leading segment of bowel invaginates into an adjacent segment), strictures from IBD, fecal impaction.
- Nonmechanical—paralytic or adynamic ileus (impaired or absent peristalsis for 72 hours, common after abdominal surgery), failure of nervous innervation as seen in Parkinson's disease, MS, Hirschsprung's disease, metabolic factors as seen with endocrine disorders such as diabetes mellitus, effects of drugs.

When an obstruction causes ischemia of the bowel, the bowel becomes increasingly permeable to bacteria and the risk of peritonitis increases. Paralytic ileus rarely causes ischemia.

S&S:

- Abdominal pain: crampy, poorly localized
- N&V: profuse with small bowel obstruction, may have fecal odor if distal small bowel, occurs late in process if large bowel obstructed
- Frequent high-pitched bowel sounds early; decreased or absent, late in obstruction
- Abdominal distention
- Obstipation
- Signs of dehydration and fluid shifts: dry mucous membrane, decreased skin turgor, decreased urinary output, hemoconcentration, hypokalemia, and hyponatremia

Dx: Based on S&S, abdominal X-ray shows air and fluid trapped in obstructed area; once hypovolemia is severe, Hct and Hgb increase and serum K⁺ decreases

Rx:

- Correct fluid and electrolyte imbalance
- Decompress the GI tract by means of an NG tube and suction to relieve distention, pain, and vomiting
- Prevent infection by use of antibiotics to combat bacterial overgrowth in the bowel
- Promotility drugs may be used for nonmechanical obstruction
- Usually bowel resection with end-to-end anastomosis though an ostomy is sometimes necessary, for acute, complete obstruction
- Endoscopic balloon dilation or laser removal of tumor segments may be done for mechanical obstruction

Clinical Alert

Opioids are not given because of their negative effects on peristalsis. Other analgesics are used sparingly because they can conceal the pattern and severity of pain needed for diagnosis.

Nursing Process Elements

- Assess vital signs, urinary output, NG tube output, pain, fluid and electrolyte values, especially serum K⁺
- Check for edema and measure abdominal girth every 2–4 hours because of third spacing of fluids
- Be alert for signs of shock

Assessment Alert

Immediately report pain that changes from crampy to constant and/or increases significantly. This can mean perforation or strangulation of the bowel.

- Administer IV fluids and potassium supplement as ordered to make up for losses due to vomiting and fluid shifts
- Elevate the head of the bed to relieve pressure on abdomen; side lying often comfortable
- Assist OOB and ambulate to promote peristalsis as ordered
- Keep NPO with small amounts of ice chips for thirst
- Provide frequent oral and nasal care

PERITONITIS

- Peritonitis refers to a local or generalized inflammation of the peritoneum.
- In response to this acute inflammation, large amounts of fluid shift into the abdominal cavity, blood is shunted to the involved area, and peristalsis slows or stops. Bowel becomes distended with gas and fluid.

Etiology: Most often due to bacteria entering the peritoneal cavity

- through an opening in the intestinal wall due to trauma, surgical injury, ruptured appendix, perforation associated with peptic ulcer, diverticulitis, ulcerative colitis, Crohn's disease, or malignancy.
- by extension of infection through the wall of a hollow organ such as the gall bladder, uterus, or urinary bladder.
- secondary to continuous ambulatory peritoneal dialysis.

Also may occur due to chemical irritation from GI secretions secondary to a leak in a GI suture line or hemorrhagic pancreatitis.

S&S:

- Local or diffuse abdominal pain, rebound tenderness, guarding, and rigidity
- Distention and absence of bowel sounds as inflammation progresses
- Generalized: fever (100–101 F), elevated WBC, N&V
- S&S of early shock (tachycardia, tachypnea, oliguria, restlessness, weakness, pallor, diaphoresis)

GERI

- S&S initially significantly less severe in older clients

Assessment Alert

Pain may be absent in elderly clients as well as those with severe diabetic neuropathy, those on high doses of corticosteroids or analgesics, or those under the influence of alcohol.

Dx: Based on history, physical findings, abdominal X-ray showing abnormal gas and air patterns

Clinical Alert

WBC counts elevated to 20,000/mm³ or higher with a shift to the left are the most common indicators of peritonitis in immunocompromised clients.

Rx: Fluid and electrolyte replacement; antibiotics based on culture of blood and peritoneal fluid; NG tube to relieve gastric distention; surgery to correct underlying problem and remove infected material. Parenteral nutrition if sepsis is severe and prolonged recovery is expected

Nursing Process Elements

- Assess S&S, vital signs, and I&O including NG tube drainage. Be particularly alert for signs of shock and for impaired ventilation secondary to pain and abdominal distention
- Monitor electrolyte values for deviations from normal range
- Maintain bed rest in semi-Fowler's position to promote ventilation and comfort
- Encourage deep breathing because of the risk of hypoventilation
- Institute measures to reduce client and family anxiety, which tends to be significant because of the rapid onset of the disease

APPENDICITIS

Etiology: Perhaps obstruction.

S&S:

- Pain is the primary symptom; classical presentation—vague periumbilical or epigastric discomfort, which intensifies, becomes colicky, and localizes in LRQ in about 4 hours.

Variations—diffuse, lower abdominal pain, which may radiate to R thigh or testicle or even localize in LLQ. Sudden relief of pain if rupture occurs, subsequently pain from peritonitis develops. Pain worse on coughing; relieved with flexion of right knee on abdomen

- Tenderness over McBurney's point (midway between umbilicus and right anterior iliac spine)
- Anorexia, nausea with or without vomiting
- Rigidity of rectus muscle and rebound tenderness
- Low grade fever (100.4–101.4°F); higher if appendix ruptured
- Leukocytosis (12,000/mm³ or more) with increased neutrophils

Dx: Often difficult especially in young children and elderly clients

Rx: NPO, no analgesics which can mask symptoms; no laxatives or enemas which can stimulate peristalsis and cause perforation; IV antibiotics, appendectomy ASAP

Nursing Process Elements

See appendectomy in the section on surgery

DIVERTICULAR DISEASE

- Diverticulum: a small, finger-like, outpouching of the mucosa through the muscle bands of the colon.
- Diverticulosis refers to the presence of diverticula.
- Number of diverticula increases with age. **GERI**
- Most diverticula are asymptomatic.
- Diverticulitis—acute inflammation of a diverticulum secondary to obstruction with mucus or fecal matter.

Etiology: Increased intraluminal pressure and decreased muscle strength in the colon.

Risk factors: Low-fiber diet and aging.

S&S:

- Crampy LLQ abdominal pain with low-grade fever is classic presentation of diverticulitis
- N&V and bloating also common
- Occasionally abrupt, copious, self-limited rectal bleeding and urinary symptoms occur

Complications: Abscess, (symptoms of local peritonitis), perforation with peritonitis

Dx: CT scan shows diverticula and abscesses; episode of diverticulitis diagnosed based on Hx and physical examination

Rx: NPO or clear fluid diet to rest the bowel, IV fluids, antibiotics, analgesics, anticholinergics to decrease bowel spasms

- Relief in 48–72 hours
- Surgical bowel resection with or without a temporary colostomy may be necessary to treat abscesses or perforation

Nursing Process Elements

- Assess for S&S with special attention to
 - pain and fluid and electrolyte balance
 - response to therapy
 - development of complications such as bleeding, perforation, and peritonitis

Assessment Alert

Usual symptoms are less pronounced or underreported in older clients. **GERI**

Client teaching for self-care

- For prevention of episodes of diverticulitis, instruct client to
 - consume diet to prevent constipation—2500–3000 ml fluids per day, high-fiber, soft foods such as fruits, vegetables, and whole grains with small amounts of bran added to foods or use of bulk forming agents as needed
 - avoid activities that increase intra-abdominal pressure
 - lose weight if needed to lower resting intra-abdominal pressure
- Teach client to avoid high-fiber foods during episodes of diverticulitis because of irritating effect

ABDOMINAL HERNIAS

Hernia refers to the protrusion of an organ through an abnormal opening. Abdominal hernias are most common and involve protrusion of intestine out of the abdominal cavity.

Abdominal hernia is classified based on location:

- Inguinal—Occurs in the groin where the spermatic cord in men and the round ligament in women emerge through the abdominal wall.
- Femoral—Occurs at the femoral ring, usually in women.
- Incisional—Occurs at the site of a surgical incision.

Hernias are further classified as the following:

- Reducible—can be manually placed back into abdominal cavity.
- Irreducible or incarcerated—cannot be pushed back into abdominal cavity.

- Strangulated—irreducible with obstruction of both blood flow to the involved intestine and flow of contents through the intestine.

S&S: Visible or palpable protrusion, more obvious on coughing or bearing down, discomfort at site, S&S of intestinal obstruction if strangulated

Assessment Alert

Crampy abdominal pain and abdominal distention are symptoms of bowel obstruction due to a strangulated hernia.

Dx: Physical examination

Rx: Manual reduction, use of a truss (pad placed over hernia and held in place with a belt). Herniorrhaphy (hernia repair) with or without hernioplasty (reinforcement of weakened area) if strangulated or as prophylaxis against strangulation

Nursing Process Elements

- Assess for skin irritation in clients who wear a truss
- Teach client about the symptoms of strangulation and the importance of immediate report to a health care provider
- For pre- and postoperative care, see section on herniorrhaphy

COLORECTAL CANCER

- Most colorectal cancers develop from epithelium; they may project into lumen or the encircle bowel and cause stenosis, ulceration, or perforation.
- They spread through the bowel wall into the small intestine or uterus or via lymph and portal vein to liver (most common), lungs, kidneys, or bones.

Etiology: Interaction of genetic and environmental factors.

Risk factors:

- Family history or previous self-history of colorectal cancer; familial polyposis, colorectal polyps, or chronic IBD.
- Diet has not been shown to increase risk; heavy alcohol intake and smoking appear to slightly increase the risk. Long-term use (5 years) of ASA or NSAIDs appears to decrease risk.

S&S: Often asymptomatic early in disease; then vary with tumor location.

- Left colon: constipation or diarrhea along with gradual development of flat, ribbon-like or pencil-shaped stool, crampy gas pains, bright red blood in stool, and abdominal distention
- Right colon: vague, dull abdominal pain worsened with walking, and dark red or mahogany blood in stool
- Rectal cancer: straining at stool, mucous discharge, sense of incomplete rectal emptying, bright red bleeding, and pain in late disease
- Systemic S&S of late disease: weakness, anorexia, weight loss, and anemia

Dx: Biopsy, which can be done via colonoscopy, provides the definitive diagnosis. Tumors low in the rectum are often found on digital rectal examination, higher tumors on colonoscopy or suggested by a positive stool for occult blood. Other studies include CT of the abdomen and pelvis to size and localize the tumor and check for local invasion and metastases to the liver or other area. CEA levels are useful in judging response to therapy

Rx:

- Surgery is preferred therapy because it offers potential for cure. Procedure depends on location of tumor:
 - Left hemicolectomy
 - Right hemicolectomy
 - Abdominal—perineal resection
 - Laparoscopic colectomy
- Radiation may be used preoperatively or to shrink tumors and relieve symptoms in advanced disease
- Chemotherapy is used when lymph nodes are positive or metastases are found. Common drugs used are: 5-FU, methotrexate, levamisole, and irinotecan

Nursing Process Elements

See sections on intestinal resection, abdominal–perineal resection, radiation therapy, and chemotherapy. Also see sections on screening and health promotion

HEMORRHOIDS

Hemorrhoids refer to dilated, swollen rectal veins and are of the following types:

- Internal—protrude within the rectal canal.
- External—protrude at the anal opening.

Etiology: Stasis in anal veins.

Risk factors: Straining at stool, prolonged sitting on the toilet, heavy lifting, prolonged standing, pregnancy, infiltrating cancer, portal hypertension secondary to liver disease.

S&S:

- Internal—pain and bleeding on defecation; bleeding is red, often appears as red streaks on stool or toilet tissue

- External—rectal itching, lumps of pink to red tissue at anus (tender, tense, and blue if thrombosed)

Dx:

- External—visual inspection
- Internal—Visualization with an anoscope

Rx:

- Symptomatic treatment:
 - Sitz baths and topical preparations such as dibucaine ointment to shrink mucous membrane and relieve pain
 - High-fiber diet, 2000 ml or more fluid per day, stool softeners or mild laxatives to keep stool soft and formed and prevent straining
- Alternative treatment of internal hemorrhoids:
 - Rubber band ligation
 - Rubber bands placed at bottom of hemorrhoids that bleed or are prolapsed
 - Result is ischemia with necrosis and sloughing in about a week
 - Outpatient procedure not requiring anesthesia
 - Slight postoperative discomfort easily managed with OTC analgesic
 - Sclerosing Rx: An agent such as 5% phenol in oil is injected subcutaneously between and around hemorrhoids; results in sclerosis and shrinking of tissue; one to four injections 5–7 days apart
- Neither Rx used for external hemorrhoids—too painful due to sensory innervation of area.
- Hemorrhoidectomy—removal of hemorrhoids—done in cases of multiple prolapsed or thrombosed hemorrhoids with severe symptoms (see hemorrhoidectomy under surgery)

**Nursing Process Elements**

- Assess for S&S with particular attention to frequency and severity of each
- Assess for lifestyle factors such as prolonged standing at work, heavy lifting, bowel and toilet habits that can predispose to hemorrhoids

**Client teaching for self-care**

Instruct client to

- avoid activities that can contribute to development or worsening of hemorrhoids when possible
- prevent constipation and straining at stool by eating a high-fiber diet with 2000 ml of fluid per day, taking stool softeners or mild laxatives as directed, and exercising regularly

- use sitz baths and topical preparations such as cold witch hazel compresses or dibucaine ointment for relief of symptoms
- report excessive pain, bleeding, or prolapse of hemorrhoids

PEDS**HIRSCHSPRUNG'S DISEASE**

- Hirschsprung's disease refers to an obstructive disorder of the colon caused by the absence of autonomic parasympathetic ganglion cells resulting in inadequate motility.
- It is also called congenital aganglionic megacolon.

Etiology: The precise etiology is unclear; absence of ganglion cells in the GI tract results in a lack of enervation needed for peristalsis or propulsive movements. This results in accumulation of intestinal contents proximal to the problem; usually includes the rectum and proximal portion of the large intestine; develops during embryonic development.

Precipitating factors: Occurs more often in males in the ratio 4:1; the greatest percentage of cases are detected by the first year while some remain undetected by 3 years of age; may develop along with Down's syndrome, congenital heart defects, and Waardenburg syndrome; disease is related to a genetic component.

S&S: Vary with age

- Newborn and infant:
 - newborn's failure to pass meconium within approximately 24–48 hours
 - reluctance to take feedings, failure to suck
 - abdominal distention
 - bile stained and fecal vomiting
 - constipation
 - dehydration
 - failure to thrive
- Older child:
 - without symptoms at birth
 - progressive abdominal distention
 - stools are watery, ribbon or pellet-like
 - vomiting
 - constipation
 - failure to gain weight and delayed growth

Dx: Assessment for signs of bowel obstruction; newborn's failure to pass meconium; barium enema reveals structural changes: client may fail to evacuate the barium; rectal biopsy to check for presence or absence of ganglion cells; anorectal manometry demonstrates failure of the intestinal sphincter to relax in response to distention and palpation reveals a small rectum

Rx: For a mild defect treatment, it is based on relieving constipation; dietary modification; administering stool softeners and using isotonic irrigations to prevent impaction. Surgery

is required for most infants and children, removal of the ganglion portion of the intestine relieves obstruction and provides for normal bowel function or a temporary colostomy is formed and repaired when the child is about 20 lbs or 9 kg

Nursing Process Elements

- Obtain a complete history of nutritional intake, weight gain, and bowel habits
- Evaluate bowel sounds and abdominal distention; measure abdominal circumference at the umbilicus
- Maintain fluid and electrolyte balance
- Provide adequate nutrition to promote healing and to prepare for surgery if needed
- Administer daily irrigation with normal saline solution to promote adequate elimination
- Assess family concerns and how they will deal with the problem; support parent and promote infant bonding
- To relieve anxiety for an older child, evaluate his/her feelings about constipation and treatments
- Refer parents to a home care agency for supportive continuing care

Nursing Intervention Alert

If Hirschsprung's disease does occur in an older child, he or she can be taught to take total care of the colostomy.

Client teaching for self-care

- Instruct parents to notify the physician if no stool is passed
- Teach parents about the infant's or child's health needs such as irrigation, low-residue diet
- Offer pre- and postoperative teaching: place diapers below site to avoid infection
- Instruct parents to participate in colostomy care and child care also. Inform parents that the colostomy is temporary

PEDS

IMPERFORATE ANUS

- Imperforate anus refers to the absence of a normal rectal opening.
- It is also called anal atresia.

Etiology: Malformation occurring during fetal development; rectum can end and not connect to the anus or may

connect to wrong location as the vagina, urethra, or bladder; anal agenesis in which rectal pouch ends blindly above the perineum, can be an anal fistula formation or anal stenosis; defect is classified as high or low according to the relationship to the levator ani muscles; no prevention is known.

Predisposing factors: Due to an abnormal congenital defect formed during fetal development; associated with other congenital defects as Down's syndrome, cardiac defects, esophageal atresia, or renal anomalies.

S&S:

- Without an anal opening, or misplaced anal opening
- No passage of stool 24–48 hours after birth
- Passage of meconium from vagina or urinary meatus
- Abdominal distention

Assessment Alert

Evaluate for complications such as bowel incontinence, intestinal obstruction, constipation, or infection.

Dx: Made by examination of the perineum, abdominal X-ray, ultrasound of rectal and vaginal areas to evaluate for malformations

Rx: Prophylactic antibiotics; excision of membrane; daily anal dilation by nurse and at home by parents; surgical reconstruction, called an anoplasty, to repair malformations; postoperative pain medications; temporary colostomy may be performed if classified as high

Clinical Alert

Successful treatment depends upon location of the abnormality and age and sex of client.

Nursing Process Elements

- Assess newborn for malformations
- Instruct parents about the problems caused by imperforate anus
- Assess for other congenital problems
- Perform manual dilation, as ordered

- Preoperative care
 - Administer broad-spectrum antibiotics as ordered
 - Maintain NG tube, used for decompression
- Postoperative care
 - Keep perineum very clean
 - Position client on side for easy access to perineum and to prevent pressure on site
- Monitor vital signs and general condition
- Begin formula when normal peristalsis is present

Client teaching for self-care

- Offer reassurance to parents, especially for a child with a colostomy; inform that colostomy will later be reanastomosed
- Teach parents correct technique for manual dilation of anus
- Instruct parents to perform scrupulous care of perineal area
- Review care of colostomy, if needed
- Inform parents not to take a rectal temperature

WORKSHEET

SHORT ANSWER QUESTIONS

1. Why is it important to decrease crying in an infant who has had cleft-palate repair?
2. Which piece of equipment should be available at the bedside of a patient with a fractured jaw that has been wired in place?
3. Why does cancer of the tongue metastasize rapidly?
4. What surgical procedure treats GERD by reinforcing the LES?
5. Which is the most common symptom of esophageal cancer?
6. What are the two major causes of hemorrhagic gastritis?
7. Gnawing epigastric pain occurring 1–3 hours after meals and at night is characteristic of which GI problem?
8. In what position would an infant be placed after surgery for an imperforate anus?
9. When are antibiotics used to treat gastroenteritis?
10. Vomiting a half to one hour after feeding and visible peristalsis in an infant are symptoms of which problem?
11. At what age does colic usually disappear?
12. Results of which laboratory tests must be monitored in patients taking immune modulators?
13. What observation indicates that intussusception has been reduced?
14. Which type of analgesic is contraindicated for pain associated with bowel obstruction?
15. Proton pump inhibitors may be used to treat which type of bowel obstruction?

(continued)

16. What is the most common sign of peritonitis in immunocompromised clients?
17. How should a client with peritonitis be positioned while on bed rest?
18. Which two categories of drugs are contraindicated in a client with possible appendicitis?
19. What type of diet should a client ingest during an episode of diverticulitis?
20. What are the two major symptoms that occur when a strangulated hernia causes a bowel obstruction?
21. Stool containing mahogany-colored blood is indicative of cancer in which part of the colon?
22. What is the goal of radiation therapy when it is used in advanced cases of colorectal cancer?
23. What makes a hemorrhoid tender, tense, and blue?
24. Failure of a neonate to pass meconium within 24–48 hours after birth is indicative of which genetically related disease?
25. What type of diet supports the symptomatic relief of hemorrhoids?
26. Why is alcohol contraindicated for clients experiencing symptoms of GERD?
27. What lifestyle habit puts a client at risk for peptic ulcer disease?
28. Why are infants at particular risk for gastroenteritis?
29. Which anomaly has as a major symptom projectile vomiting of stale milk 30–60 minutes after a feeding?
30. Which substance found in some foods cannot be digested by clients with celiac disease?

APPLICATION QUESTIONS

1. When evaluating the ability of a mother to care for her newborn, who has a cleft palate, which maternal behavior would indicate to the nurse that the mother needs teaching?
 - a. Supports infant in a low Fowler's position to feed
 - b. Burps the infant frequently during feeding
 - c. States that weight gain will have to be carefully monitored
 - d. Feeds small amounts slowly
2. What symptom reported in the health history of a 55-year-old woman should be interpreted by the nurse as requiring immediate follow-up evaluation for cancer of the right colon?
 - a. Black, tarry stools
 - b. Loose, frothy stool
 - c. Flat, ribbon-shaped stool
 - d. Mahogany-colored, formed stool
3. When planning teaching for a client with chronic gastritis, which information should be included?
 - a. "Decrease acid secretion by drinking a glass of milk an hour before bedtime."
 - b. "Remain in an upright position for at least 30 minutes after meals."
 - c. "Avoid foods that are high in simple carbohydrates and fiber or roughage."
 - d. "Report development of a sore tongue or sore gums to the health care provider."

4. When teaching at a health fair about the prevention and treatment of hemorrhoids, which information should the nurse include?
 - a. "Avoid use of laxatives."
 - b. "Avoid strenuous sports."
 - c. "Avoid dietary roughage."
 - d. "Avoid extended sitting on the toilet."
5. Which symptoms in a man with a left inguinal hernia are indicative of development of hernia strangulation?
 - a. Crampy abdominal pain and abdominal distention
 - b. Fever and abdominal rigidity
 - c. Absence of bowel sounds and LLQ tenderness
 - d. RUQ rebound tenderness and flatulence
6. Which is a priority nursing goal, specific to a neonate who has had a cleft-lip repair?
 - a. Decrease crying
 - b. Keep nares patent
 - c. Protect from exposure to cold
 - d. Prevent dehydration
7. Allowing parents to practise feeding their infant is a critical aspect of care when the child has which problem?
 - a. Failure to thrive
 - b. Hirschsprung's disease
 - c. Cleft palate
 - d. Pyloric stenosis
8. What should a client with a wired jaw following a traumatic fracture be instructed to do if difficulty in breathing occurs?
 - a. Cut the wires
 - b. Take prescribed decongestant
 - c. Use a humidifier
 - d. Call the physician
9. When teaching a local club group about oral cancer, which comment by a participant indicates that the nurse needs to clarify the information presented?
 - a. "Most oral cancers occur on the tongue."
 - b. "The most rapidly spreading oral cancer is on the floor of the mouth."
 - c. "Early oral cancers are generally asymptomatic."
 - d. "Smoking is a risk factor for cancer of the lip."
10. A client under treatment for GERD asks why she needs to avoid caffeine. What fact should form the basis of the nurse's response?
 - a. Caffeine delays gastric emptying
 - b. Caffeine lowers LES pressure
 - c. Caffeine increases secretion of gastric acid
 - d. Caffeine thins the mucus coating of the esophagus
11. The need to avoid factors that increase intra-abdominal pressure is an important part of client teaching about the management of which problem?
 - a. Acute gastritis
 - b. Paralytic ileus
 - c. Diverticulosis
 - d. Irritable bowel disease
12. When a patient's medical history indicates Barrett's epithelium, questions should be asked which would elicit information about symptoms of which disease?
 - a. Esophageal cancer
 - b. Peptic ulcer disease
 - c. Crohn's disease
 - d. Ulcerative colitis
13. Which findings would the nurse expect when assessing a client with celiac disease? (Select all that apply.)
 - a. Steatorrhea
 - b. Respiratory alkalosis
 - c. Anemia
 - d. Leukocytosis
 - e. Melena
 - f. Anorexia
14. Which is the primary goal of care for a child with a mild case of Hirschsprung's disease?
 - a. Promote parent-child bonding
 - b. Teach colostomy care
 - c. Avoid exposure to gluten products
 - d. Relieve constipation
15. Which interventions are appropriate when caring for an infant with colic? (Select all that apply.)
 - a. Provide rhythmic movement
 - b. Swaddle
 - c. Give a cool bath
 - d. Massage abdomen
 - e. Increase environmental stimuli
16. When corticosteroids are prescribed for a client with Crohn's disease, which dosage protocol should the nurse expect?
 - a. Dose will be calculated daily based on serum levels of drug
 - b. Loading doses will be given for the first 5 days of therapy
 - c. Daily maintenance doses will be initiated after 2-3 days of therapy
 - d. Dose will be tapered as soon as symptoms decrease

(continued)

17. Which is a priority teaching point for the client with inflammatory bowel disease (IBD) who is placed on immunomodulator therapy?
- “Take with at least 200 ml of Gatorade.”
 - “Expect initial worsening of symptoms.”
 - “Renal function must be regularly monitored.”
 - “No effect may be seen for up to 4 months.”
18. Which is an appropriate nursing goal for the client experiencing a flare of ulcerative colitis?
- Encourage rest for half an hour before meals to decrease peristalsis
 - Maintain NPO status
 - Decrease dietary sodium
 - Promote relaxation by application of heat to the abdomen
19. When caring for a child who has had a nonsurgical hydrostatic reduction of an intussusception, which finding indicates that the procedure was successful in reducing the intussusception?
- Presence of bowel sounds
 - Absence of abdominal distention
 - Passage of normal stool
 - Cessation of abdominal pain
20. When a bowel obstruction causes ischemia of the bowel, the patient is at significantly increased risk for which complication?
- Hemorrhage
 - Peritonitis
 - Embolus
 - Hyponatremia
21. Which client would most likely *not* experience abdominal pain associated with peritonitis?
- Client with diabetes
 - Client with HIV infection
 - Client on high dose of corticosteroids
 - Client taking an anticholinergic drug
22. Which dietary instruction should be given to a client when the nurse is teaching him or her about the prevention of episodes of diverticulitis?
- “Eat low-fiber foods and avoid seeds.”
 - “Avoid spicy, high-fat foods.”
 - “Eat soft, high-fiber foods with 2500–3000 ml of fluid daily.”
 - “Avoid raw fruits, vegetables, and bran products.”
23. Which factors found in a client’s health history indicate increased risk for colorectal cancer? (Select all that apply.)
- Family history of colon polyps
 - Chronic inflammatory bowel disease
 - Long-term use of NSAIDs
 - Diet high in fat and carbohydrate
 - Chronic constipation
24. Which assessment finding is suggestive of an imperforate anus in a newborn?
- Hyperactive bowel sounds
 - Passage of meconium from the vagina
 - Fecal vomiting
 - Sausage-like mass in lower, left quadrant
25. Which assessment finding suggests that the appendix of a client with appendicitis has ruptured?
- WBC of 15,000/mm³
 - Temperature of 101 F
 - Sudden relief of abdominal pain
 - Onset of rebound tenderness

ANSWERS & RATIONALES

SHORT ANSWER QUESTIONS

1. Why is it important to decrease crying in an infant who has had cleft-palate repair?

Answer

Crying increases stress on the suture line.

2. Which piece of equipment should be available at the bedside of a patient with a fractured jaw that has been wired in place?

Answer

Wire cutter.

3. Why does cancer of the tongue metastasize rapidly?

Answer

The tongue has a rich blood and lymph supply.

4. What surgical procedure treats GERD by reinforcing the LES?

Answer

Fundoplication.

5. Which is the most common symptom of esophageal cancer?

Answer

Progressive dysphagia.

6. What are the two major causes of hemorrhagic gastritis?

Answer

NSAID use and stress.

7. Gnawing epigastric pain occurring 1–3 hours after meals and at night is characteristic of which GI problem?

Answer

Duodenal ulcer.

8. In what position would an infant be placed after surgery for an imperforate anus?

Answer

Side lying.

9. When are antibiotics used to treat gastroenteritis?

Answer

If the gastroenteritis is severe and caused by bacteria.

10. Vomiting a half to one hour after feeding and visible peristalsis in an infant are symptoms of which problem?

Answer

Pyloric stenosis.

11. At what age does colic usually disappear?

Answer

At the age of 3 months.

12. Results of which laboratory tests must be monitored in patients taking immune modulators?

Answer

CBC with differential and platelets and LFTs.

13. What observation indicates that intussusception has been reduced?

Answer

Passage of stool.

14. Which type of analgesic is contraindicated for pain associated with bowel obstruction?

Answer

Opioid.

(continued)

15. Promotility drugs may be used to treat which type of bowel obstruction?

Answer

Nonmechanical obstruction.

16. What is the most common sign of peritonitis in immunocompromised clients?

Answer

White blood cell count of 20,000/mm³ or higher with a shift to the left.

17. How should a client with peritonitis be positioned while on bed rest?

Answer

In semi-Fowler's position.

18. Which two categories of drugs are contraindicated in a client with possible appendicitis?

Answer

Analgesics and laxatives.

19. What type of diet should a client ingest during an episode of diverticulitis?

Answer

Low-fiber diet.

20. What are the two major symptoms that occur when a strangulated hernia causes a bowel obstruction?

Answer

Crampy abdominal pain and abdominal distention.

21. Stool containing mahogany-colored blood is indicative of cancer in which part of the colon?

Answer

Right colon.

22. What is the goal of radiation therapy when it is used in advanced cases of colorectal cancer?

Answer

Relief of symptoms.

23. What makes a hemorrhoid tender, tense, and blue?

Answer

Thrombosis.

24. Failure of a neonate to pass meconium within 24–48 hours after birth is indicative of which genetically related disease?

Answer

Hirschsprung's disease.

25. What type of diet supports the symptomatic relief of hemorrhoids?

Answer

High-fiber diet with at least 2000 ml of fluid per day.

26. Why is alcohol contraindicated for clients experiencing symptoms of GERD?

Answer

Alcohol lowers LES pressure and therefore worsens the problem.

27. What lifestyle habit puts a client at risk for peptic ulcer disease?

Answer

Smoking.

28. Why are infants at particular risk for gastroenteritis?

Answer

Infants are at risk for gastroenteritis because their immune systems are immature.

29. Which anomaly has as a major symptom projectile vomiting of stale milk 30–60 minutes after a feeding?

Answer

Pyloric stenosis.

30. Which substance found in some foods cannot be digested by clients with celiac disease?

Answer

Clients with celiac disease cannot digest gluten.

APPLICATION ANSWERS

1. When evaluating the ability of a mother to care for her newborn, who has a cleft palate, which maternal behavior would indicate to the nurse that the mother needs teaching?
 - a. Supports infant in a low Fowler's position to feed
 - b. Burps the infant frequently during feeding
 - c. States that weight gain will have to be carefully monitored
 - d. Feeds small amounts slowly

Rationale

Correct answer: a.

The infant's head should be held upright for feeding therefore option "a" is an incorrect behavior which indicates the mother needs more teaching. Options "b," "c," and "d" are all correct. The infant with a cleft palate should be fed small amounts slowly and for a short time; burped frequently to help prevent regurgitation and aspiration; and weight needs to be monitored to determine if the infant is getting sufficient nourishment.

Think Smart/Test Smart

Note: This question asks what behavior indicates the mother needs more teaching. More teaching is required when something is not known or something is wrong. Therefore, you are looking for a behavior that is incorrect.

2. What symptom reported in the health history of a 55-year-old woman should be interpreted by the nurse as requiring immediate follow-up evaluation for cancer of the right colon?
 - a. Black, tarry stools
 - b. Loose, frothy stool
 - c. Flat, ribbon-shaped stool
 - d. Mahogany-colored, formed stool

Rationale

Correct answer: d.

A symptom of right-sided cancer of the colon is mahogany-colored stool due to the presence of blood from the tumor being mixed with the stool and exposed to digestive tract secretions as it progresses through the remaining colon. Black, tarry stools are indicative of blood from the upper GI tract which has been in the GI tract long enough to be completely digested. Loose, frothy stool is indicative of high fat content and is associated with malabsorptive disorders. Flat, ribbon-shaped stool is consistent with a tumor which alters the shape of the left colon and prevents formation and passage of normally formed stool.

3. When planning teaching for a client with chronic gastritis, which information should be included?
 - a. "Decrease acid secretion by drinking a glass of milk an hour before bedtime."
 - b. "Remain in an upright position for at least 30 minutes after meals."
 - c. "Avoid foods that are high in simple carbohydrates and fiber or roughage."
 - d. "Report development of a sore tongue or mouth to the health care provider."

Rationale

Correct answer: d.

Clients with chronic gastritis are at risk for developing pernicious anemia because of a deficiency of intrinsic factor produced in the stomach, which is necessary for the

(continued)

absorption of vitamin B 12 in the ileum. Glossitis, sore tongue, and stomatitis (sore oral mucous membranes) are two presenting symptoms of pernicious anemia.

4. When teaching at a health fair about the prevention and treatment of hemorrhoids, which information should the nurse include?
 - a. "Avoid use of laxatives."
 - b. "Avoid strenuous sports."
 - c. "Avoid dietary roughage."
 - d. "Avoid extended sitting on the toilet."

Rationale

Correct answer: d.

Extended sitting on the toilet increases stasis of blood and pressure in the anal veins and predisposes to hemorrhoid formation so it should be avoided.

Routine use of laxatives is not a good health practice but laxatives do not directly contribute to hemorrhoid development. Roughage in the diet is essential for good bowel function. Prolonged standing and heavy lifting are contraindicated but strenuous sports as a group are not.

5. Which symptoms in a man with a left inguinal hernia are indicative of development of hernia strangulation?
 - a. Crampy abdominal pain and abdominal distention
 - b. Fever and abdominal rigidity
 - c. Absence of bowel sounds and LLQ tenderness
 - d. RUQ rebound tenderness and flatulence

Rationale

Correct answer: a.

Crampy abdominal pain and distention are symptoms of bowel obstruction due to strangulation (irreducible hernia with obstruction of both blood flow and bowel contents). Fever and abdominal rigidity are signs of peritonitis. Absence of bowel sounds occur late in obstruction not when it first develops. Pain is poorly localized and crampy. Flatulence is not associated with hernia strangulation.

6. Which is a priority nursing goal, specific to a neonate who has had a cleft-lip repair?
 - a. Decrease crying
 - b. Keep nares patent
 - c. Protect from exposure to cold
 - d. Prevent dehydration

Rationale

Correct answer: a.

Crying increases tension on the suture line and can disrupt it. Keeping nares patent is not specific to an infant with a cleft-palate repair because all neonates are nose breathers so keeping nares patent is important for all. Similarly all neonates need to be protected from cold and from dehydration, not just those with a cleft-lip repair.

7. Allowing parents to practice feeding their infant is a critical aspect of care when the child has which problem?
 - a. Failure to thrive
 - b. Hirschsprung's disease
 - c. Cleft palate
 - d. Pyloric stenosis

Rationale

Correct answer: c.

Cleft palate results in feeding difficulties with risk of regurgitation, aspiration, and inadequate nutrition and in addition, requires use of various techniques and adaptive devices depending on the extent of the abnormality. As a result, it is critical that parents have the opportunity to practice feeding the infant.

8. What should a client with a wired jaw following a traumatic fracture be instructed to do if difficulty in breathing occurs?
 - a. Cut the wires
 - b. Take prescribed decongestant
 - c. Use a humidifier
 - d. Call the physician.

Rationale

Correct answer: d.

Call the physician for direction appropriate to the problem. Wires would be cut if the patient started to choke or vomit and needed to expel material from the mouth to avoid blocking the respiratory tree.

9. When teaching a local club group about oral cancer, which comment by a participant indicates that the nurse needs to clarify the information presented?
 - a. "Most oral cancers occur on the tongue."
 - b. "The most rapidly spread oral cancer is on the floor of the mouth."
 - c. "Early oral cancers are generally asymptomatic."
 - d. "Smoking is a risk factor for cancer of the lip."

Rationale

Correct answer: b.

The most rapidly spread oral cancer is not cancer of the floor of the mouth but the cancer of the tongue because of its rich blood and lymph supply.

Think Smart/Test Smart

The question asks which information must be clarified. That means you must identify which information is wrong or misunderstood. Option "b" contains incorrect information because the most rapidly spread oral cancer is the cancer of the tongue.

10. A client under treatment for GERD asks why she needs to avoid caffeine. What fact should form the basis of the nurse's response?
- Caffeine delays gastric emptying
 - Caffeine lowers LES pressure
 - Caffeine increases secretion of gastric acid
 - Caffeine thins the mucus coating of the esophagus

Rationale

Correct answer: b.

Caffeine lowers lower esophageal sphincter pressure and thus increases the likelihood of reflux of gastric contents into the esophagus. Delayed gastric emptying may contribute to GERD but it is not caused by caffeine. Increased gastric acid is unrelated to the development of GERD. The stomach mucosa has a thick mucus coating to aid in protecting against gastric enzymes; the esophagus does not.

11. The need to avoid factors that increase intra-abdominal pressure is an important part of client teaching about the management of which problem?
- Acute gastritis
 - Paralytic ileus
 - Diverticulosis
 - Irritable bowel disease

Rationale

Correct answer: c.

Diverticuli are outpouchings of intestinal mucosa through the muscle bands of the colon associated with increased intraluminal pressure and muscle weakness. Increasing intra-abdominal pressure can increase or worsen diverticula. It is unrelated to acute gastritis, paralytic ileus, or irritable bowel disease.

12. When a patient's medical history indicates Barrett's epithelium, questions should be asked which would elicit information about symptoms of which disease?
- Esophageal cancer
 - Peptic ulcer disease
 - Crohn's disease
 - Ulcerative colitis

Rationale

Correct answer: a.

Barrett's epithelium, which is abnormal epithelium in the lower esophagus, is a risk factor for adenocarcinoma of the esophagus after 10–20 years. Barrett's epithelium is not a risk factor for PUD, Crohn's disease, or ulcerative colitis.

13. Which findings would the nurse expect when assessing a client with celiac disease? (Select all that apply.)
- Steatorrhea
 - Respiratory alkalosis
 - Anemia
 - Leukocytosis
 - Melena
 - Anorexia

Rationale

Correct answers: a, c, and f.

Celiac disease is a malabsorption syndrome related to the inability to breakdown gluten, a protein found in wheat, rye, oats, and barley. Steatorrhea results from the inability to absorb fats and anemia from iron and protein deficiency. Anorexia also occurs. Respiratory alkalosis, leukocytosis, and melena are not signs or symptoms of celiac disease.

14. Which is the primary goal of care for a child with a mild case of Hirschsprung's disease?
- Promote parent–child bonding
 - Teach colostomy care
 - Avoid exposure to gluten products
 - Relieve constipation

Rationale

Correct answer: d.

Mild defects only require measures to prevent constipation. More severe defects, which are the majority, require surgical removal of the affected area of intestine. Occasionally, a temporary colostomy is created. Parent–child bonding is important for all children and the child with mild Hirschsprung's disease does not present a significant risk for impaired bonding. Avoidance of gluten products is essential for the child with celiac disease, not Hirschsprung's disease.

15. Which interventions are appropriate when caring for an infant with colic? (Select all that apply.)
- Provide rhythmic movement
 - Swaddle
 - Give a cool bath
 - Massage abdomen
 - Increase environmental stimuli

Rationale

Correct answers: a, b, and d.

There is no medical treatment for colic however rhythmic movement, swaddling, and abdominal massage are often effective in soothing the infant. Decreasing environmental stimuli, not increasing stimuli, and warm, not cold, baths may also be helpful.

16. When corticosteroids are prescribed for a client with Crohn's disease, which dosage protocol should the nurse expect?
- Dose will be calculated daily based on serum levels of drug
 - Loading doses will be given for the first 5 days of therapy

(continued)

- c. Daily maintenance doses will be initiated after 2–3 days of therapy
- d. Dose will be tapered as soon as symptoms decrease

Rationale

Correct answer: d.

Doses are tapered as soon as a clinical response is obtained. Doses are not calculated on serum levels of blood and loading doses and maintenance doses do not apply.

17. Which is a priority teaching point for the client with inflammatory bowel disease (IBD) who is placed on immunomodulator therapy?
- a. “Take with at least 200 ml of Gatorade.”
 - b. “Expect initial worsening of symptoms.”
 - c. “Renal function must be regularly monitored.”
 - d. “No effect may be seen for up to 4 months.”

Rationale

Correct answer: d.

The effect of immunomodulator therapy such as mercaptopurine for ulcerative colitis or infliximab for Crohn’s Disease may not be seen for 4 months. Symptoms do not worsen with initiation of these drugs and they do not have to be taken with Gatorade. CBCs with platelets and liver function need to be monitored but not renal function

18. Which is an appropriate nursing goal for the client experiencing a flare of ulcerative colitis?
- a. Encourage rest for half an hour before meals to decrease peristalsis
 - b. Maintain NPO status
 - c. Decrease dietary sodium
 - d. Promote relaxation by application of heat to the abdomen

Rationale

Correct answer: b.

For severe episodes, clients are NPO, on bed rest, and receive IV rehydration and parenteral nutrition, if needed, for malnutrition. Rest after meals decreases peristalsis and is helpful in decreasing diarrhea. Dietary salt is needed during flares to make up for loss. A warm heating pad to the abdomen can provide comfort but should not be used during acute flare-ups of the disease.

19. When caring for a child who has had a nonsurgical hydrostatic reduction of an intussusception, which finding indicates that the procedure was successful in reducing the intussusception?
- a. Presence of bowel sounds
 - b. Absence of abdominal distention
 - c. Passage of normal stool
 - d. Cessation of abdominal pain

Rationale

Correct answer: c.

Passage of normal stool beyond the point of intussusception is impossible. Once the intussusception is reduced the bowel is no longer obstructed so normal stool can pass. Bowel sounds, absence of distention, and cessation of abdominal pain are not specific indicators of reduction.

20. When a bowel obstruction causes ischemia of the bowel, the patient is at significantly increased risk for which complication?
- a. Hemorrhage
 - b. Peritonitis
 - c. Embolus
 - d. Hyponatremia

Rationale

Correct answer: b.

When an obstruction causes ischemia of the bowel, the bowel becomes increasingly permeable to bacteria and the risk of peritonitis also increases. Ischemia is not associated with increased risk for hemorrhage, embolism, or hyponatremia.

21. Which client would be most likely *not* experience abdominal pain associated with peritonitis?
- a. Client with diabetes
 - b. Client with bone marrow disease
 - c. Client on high dose of corticosteroids
 - d. Client taking an anticholinergic drug

Rationale

Correct answer: c.

High doses of corticosteroids inhibit the inflammatory reaction of which pain is a classic sign. Diabetic clients if they have severe neuropathy, and clients taking high doses of analgesics or under the influence of alcohol may also not experience pain. Bone marrow diseases as a group and anticholinergic drugs are unrelated to the occurrence of pain with peritonitis.

22. Which dietary instruction should be given to a client when the nurse is teaching him or her about the prevention of episodes of diverticulitis?
- a. “Eat low-fiber foods and avoid seeds.”
 - b. “Avoid spicy, high-fat foods.”
 - c. “Eat soft, high-fiber foods with 2500–3000 ml of fluid daily.”
 - d. “Avoid raw fruits, vegetables, and bran products.”

Rationale

Correct answer: c.

To prevent episodes of diverticulitis, constipation must be prevented. Thus, a diet of soft foods that are high in fiber such as fruits, vegetables and whole grains with small amounts of bran and 2500–3000 ml of fluid daily is recommended. NPO or clear fluid diet is used in treatment of acute episodes to rest the bowel.

Think Smart/Test Smart

Note the question asks about preventing episodes of diverticulitis, not treating them.

23. Which factors found in a client's health history indicate increased risk for colorectal cancer? (Select all that apply.)
- Family history of colon polyps
 - Chronic inflammatory bowel disease
 - Long-term use of NSAIDs
 - Diet high in fat and carbohydrate
 - chronic constipation

Rationale

Correct answers: a and b.

Chronic inflammatory bowel disease and self or family history of colon polyps or colorectal cancer are major risk factors. Heavy alcohol use and smoking increase risk slightly. Long-term use of NSAIDs appears to decrease risk. Diet and constipation have not been shown to be risk factors.

24. Which assessment finding is suggestive of an imperforate anus in a newborn?
- Hyperactive bowel sounds
 - Passage of meconium from the vagina
 - Fecal vomiting
 - Sausage-like mass in lower, left quadrant

Rationale

Correct answer: b.

Passage of meconium from vagina or urethral meatus suggests an imperforate anus. Hyperactive bowel sounds are characteristic of a variety of intestinal disorders including gastroenteritis and early bowel obstruction. Fecal vomiting can occur with distal small bowel obstruction. A sausage-like mass in the Upper Right Quadrant (URQ), not the LLQ, is symptomatic of intussusception.

25. Which assessment finding suggests that the appendix of a client with appendicitis has ruptured?
- WBC of 15,000/mm³
 - Temperature of 101 F
 - Sudden relief of abdominal pain
 - Onset of rebound tenderness

Rationale

Correct answer: c.

Pain is the primary symptom of appendicitis; sudden relief of the pain is associated with rupture and release of pressure. Subsequently, pain from the resulting peritonitis develops. WBC of 12,000/mm³ or higher, low-grade fever (100.4–101.4 F), and presence of rebound tenderness are all characteristic of appendicitis prior to rupture.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems

Illness Management

Section 8: Hepatic and Biliary Tract Problems

| | | | |
|-------------------|-----|---------------------|-----|
| ▶ Biliary Atresia | 859 | ▶ Hepatitis | 857 |
| ▶ Cholecystitis | 862 | ▶ Liver Cancer | 861 |
| ▶ Cholelithiasis | 861 | ▶ Pancreatic Cancer | 863 |
| ▶ Cirrhosis | 859 | ▶ Pancreatitis | 862 |

HEPATITIS

- Hepatitis is widespread inflammation and necrosis of the liver, which alters structure and function causing impaired metabolism of carbohydrates, fats, proteins, and drugs, impaired detoxification of alcohol and toxins, impaired immune function, and impaired blood clotting.
- It can be acute or chronic with mild to severe symptoms.
- Forms: hepatitis A, HAV; hepatitis B, HBV; hepatitis C, HCV; hepatitis D, HDV; hepatitis E, HEV; and hepatitis G, HGV.
- Hepatitis D occurs only in those infected with hepatitis B.
- Hepatitis E, rare in United States, generally affects young adults.
- Hepatitis B is a main cause of cirrhosis and liver cancer.

Etiology: Viral infection or non-viral inflammation is caused by exposure to drugs, toxins, and chemicals.

Risk factors, mode of transmission, and mean incubation period:

- Hepatitis A: fecal–oral transmission: poor sanitation and overcrowding, ingestion of foods and liquids infected by human waste (shellfish can be a particular risk as can travel to underdeveloped areas), poor hygiene, infected food handlers, and presence of HIV infection. Incubation: 28–30 days
- Hepatitis B: spread by infected blood or body fluids: contact with blood or body fluids including needlesticks, and sexual activity with multiple partners. Incubation: 6–9 weeks
- Hepatitis C: primarily transmitted by contaminated blood and blood products: also suspected from tattooing, body piercing, manicures, and air gun vaccinations
- Hepatitis D: same as hepatitis B

- Hepatitis E: fecal–oral route: fecal contamination of water supplies in developing areas is a high risk. Incubation: 26–42 days

Think Smart/Test Smart

When a risk factor for a disease is contact with blood or body fluids, then groups that are at particular risk include health care workers (MDs, RNs, EMTs, paramedics, phlebotomists, laboratory technicians), recipients of blood transfusions, dialysis clients, transplant recipients, those with multiple sexual partners, IV drug users, etc.

S&S:

- N&V and anorexia
- Dark urine and clay-colored stool
- General aching
- Jaundice
- Pruritus
- Fatigue
- Low-grade fever
- Muscle and joint pain

Assessment Alert

Usual course of hepatitis has three stages:

- Preicteric: headache, fatigue, and poor appetite
- Icteric: jaundice, weight loss, and liver tenderness
- Posticteric: energy improved, appetite better, and jaundice decreased.

Dx: Presence of S&S, elevated liver enzymes, serum bilirubin level, ESR, and PT; specific serology tests to identify hepatitis A, B, and C; liver biopsy evaluates chronic hepatitis.

Assessment Alert

In most acute cases, pharmacological treatment is not recommended since most drugs are metabolized in the liver.

Rx: Low-fat, high-carbohydrate diet with increased calories and protein, (not high-protein diet during the acute phase), frequent fluids, small meals as tolerated; IV fluids PRN. Interferon alpha for chronic hepatitis B and C and for acute hepa-

titis C, this interferes with viral replication, alternative drug for hepatitis B—lamivudine (Epivin HBV), treatment of choice for chronic hepatitis C—interferon alpha plus (Rebetol) ribavirin. Antiemetics for nausea, vitamin K if PT prolonged.

Vaccines:

- Hepatitis A: initial dose then booster in 6–12 months, used if visiting an area with poor sanitation or if IV drug user. For those not vaccinated, immunoglobulin administered IM during incubation period.
- Hepatitis B: three doses, initial dose then second in 1–2 months and a third dose 4–6 months after the first. Third dose results in prolonged immunity. If a dose is not received on schedule, there is no need to start over simply get it as soon as possible. Hepatitis B immunoglobulin provides passive immunity, used for exposure to HBV when not vaccinated.

Nursing Process Elements

- Obtain history of IV drug use, multiple partners, ingestion of contaminated foods or water, and previous history of liver disease
- Monitor VS and I&O
- Assess color of sclera and skin; color of stool and urine; and abdominal contour and tenderness
- Administer IV fluids if unable to tolerate fluids
- Provide periods of rest
- Maintain a quiet, calm environment
- Offer emotional support and diversional activities when recovery is prolonged
- Evaluate PT and administer vitamin K as ordered
- Evaluate for complications such as hypokalemia, dehydration, and fulminant hepatitis

Client teaching for self-care

- Teach client about disease and treatment
- Explain to client and family about prevention of transmission: proper hygiene such as hand washing, food preparation, not sharing eating utensils, use of condoms
- Instruct about prophylactic treatment for those in close contact with infected clients, not necessary if exposed person is vaccinated or known to be immune
- Teach to avoid agents toxic to the liver such as alcohol
- Encourage to drink fluids frequently as tolerated
- Instruct about gradual participation in activities and exercise during convalescence
- Recommend hepatitis A and B vaccine for those in high-risk groups
- Inform adolescents about risks of piercing and tattooing related to transmission of hepatitis C

PEDS

BILIARY ATRESIA

- Biliary atresia is the congenital absence of the biliary duct system or acquired fibrosis of the bile duct.
- Accumulation of bile in the liver (cholestasis) takes place.
- Bile fails to reach duodenum
- Untreated biliary atresia leads to cirrhosis of the liver and liver failure in the toddler/preschool period.

Etiology: Unknown. May be the result of an infection or other injury resulting in fibrosis of the bile duct.

Risk factor: More common in girls than boys. Seen more frequently in African-American children than in Caucasians.

S&S:

- Normal appearance at birth
- Symptoms begin to appear at 2–3 months of life
- Accumulation of direct bilirubin leads to jaundice, liver enlargement, and abdominal distention
- Absence of bile in the duodenum leads to clay-colored stools
- Bile salts are excreted in the urine causing tea-colored urine
- Damage to the liver leads to diminished clotting factors with bruising and easy bleeding

Dx: Elevated bilirubin levels; liver tests indicate dysfunction—elevated liver enzymes and prolonged clotting times. Liver biopsy confirms the diagnosis.

Rx: Palliative treatment includes the Kasai surgical procedure (also called a hepatic portoenterostomy), where a portion of the intestine is anastomosed to the hepatic portal extravascular structures to establish bile drainage and reduce liver damage. In a small percentage of children, this may permanently resolve the problem. The majority of children will eventually require a liver transplant. The child will require

vitamin K to support clotting, vitamin D to prevent rickets. Antihistamines and cholestyramine may reduce itching from bile excretion through the skin.

**Nursing Process Elements**

- Emotional support for family during diagnosis and treatment
- Lack of bile salts interferes with absorption of fat-soluble vitamins. Nutritional guidance is given to promote nutrition
- Itching is a major concern that can affect skin integrity and sleep. Tepid baths may promote comfort in addition to medication. Nails should be kept short to prevent skin damage
- Postoperative care is the same as for other abdominal surgeries
- Care after a transplant includes monitoring the child for infection, and liver rejection

**Client teaching for self-care**

- Teach parents about disease and treatment
- Teach nutritional needs of the child
- Explain to the parents that the child may have bleeding tendencies and teach means of protection for the child as well as bleeding control methods
- Teach the parents measures to reduce itching
- Teach the parents about the surgical procedures
- Explain proper drug administration including the reasons for the medication and side effects of the medications
- Teach the parents of a child with a liver transplant the signs of liver rejection (vomiting, jaundice, and fever)

CIRRHOSIS

- Cirrhosis is a destructive, progressive liver disease resulting in damage to hepatic cells.
- It eventually leads to liver failure.

Etiology:

Two most common causes:

- Alcohol abuse of 10 years or more—can be as little as — two to three drinks per day in women and three to four in men; appears to injure liver by blocking normal metabolism of proteins, fats, and carbohydrates

- Chronic hepatitis C. Infection with this virus causes inflammation of and low-grade damage to the liver that over several decades can lead to cirrhosis

Other causes: Chronic hepatitis B and D, Autoimmune hepatitis, inherited diseases such as alpha-1 antitrypsin deficiency, hemochromatosis, Wilson's disease, galactosemia, and glycogen storage diseases; nonalcoholic steatohepatitis (NASH) that appears to be associated with diabetes, protein malnutrition, obesity, coronary artery disease, and treatment with corticosteroid medications; reactions to drugs, exposure

to environmental toxins, infections such as schistosomiasis, and repeated episodes of heart failure (HF). Blocked bile ducts (primary biliary or obstructive cirrhosis): liver damage due to back up of bile. Biliary atresia (bile ducts are absent or injured) is most common cause in infants; in adults, the most common cause is inflammation, blockage, and scarring of the ducts.

Risk factors:

- Alcohol, poor nutrition, bile obstruction, viral hepatitis, drugs, toxins, and chemicals.

S&S:

- Early: anorexia, nausea, vomiting, weight loss, weakness, tender enlarged liver, dull liver pain
- Late: ascites in peritoneal cavity, distended abdomen, peripheral edema, jaundice, and pruritus due to impaired bile excretion and metabolism, brownish urine due to presence of urobilinogen, clay-colored stool due to absence of bilirubin, easy bruising and bleeding due to decreased absorption of vitamin K and low production of prothrombin, splenomegaly, and spider angiomas, gynecomastia, amenorrhea, impotence, infertility due to altered hormone metabolism, hepatic encephalopathy—personality change, mild mental confusion, restlessness, personality change, and possible progression to irreversible coma, changes in handwriting, slurred, slow speech, and unkept appearance
- Complications:
 - Esophageal Varices—enlarged esophageal veins that rupture and bleed, which develop as a result of elevated pressure in the portal vein (portal hypertension)
 - Insulin resistance and ultimately type 2 diabetes
 - Liver cancer
 - Immune system dysfunction
 - Kidney dysfunction and failure
 - Osteoporosis

Assessment Alert

Asterixis or liver flap is a symptom defined as jerky movements of the hands and wrists in advanced cirrhosis.

Dx: Elevated alanine aminotransferase, ALT; aspartate aminotransferase, AST; gamma globulin transferase, GTT. Coagulation studies, PT and PTT are prolonged. CT scan shows enlarged liver nodules and vascular changes. Liver scan indicates abnormal thickening of the liver mass. Liver biopsy confirms the diagnosis.

Rx: Directed toward slowing the disease process and treating complications.

- Treat underlying cause, e.g., avoid alcohol, relieve bile obstruction
- Dietary support with vitamins and minerals, reduced protein
- Rest and moderate exercise
- Medications
 - Antiemetics for nausea
 - Diuretics to decrease edema
 - Antihistamines to relieve pruritus
 - Neomycin and lactulose to reduce ammonia-producing bacteria in the GI tract are given for hepatic encephalopathy, which is due in part to the accumulation of ammonia in the blood due to the liver's inability to remove it.
 - Beta-blockers for portal hypertension; for bleeding varices.
- Injection with a clotting agent or a rubber-band ligation.
- Liver transplant for liver failure or uncontrollable complications

Assessment Alert

Medications cannot reverse the disease process. Hepatotoxic drugs such as opioids, sedatives, INH, acetaminophen, and aspirin are avoided.

Nursing Process Elements

- Assess for fluid retention, check weight, edema, and I&O
- Observe for behavior changes
- Assess skin (prone to breakdown associated with pruritus, decreased mobility, compromised nutrition and edema)
- Maintain bleeding precautions, avoid IM and SC injections.
- Evaluate nutrition
- Promote comfort
- Monitor fluid and electrolyte balance, especially for hypokalemia and sodium retention.
- Long-term, low-protein diet, preferably high in dairy products and vegetables that contain less ammonia than meat.

Client teaching for self-care

- Avoid alcohol
- Follow prescribed diet
- Avoid spicy, hot foods that may irritate esophageal varices
- Avoid exposure to infectious diseases

- Monitor for bleeding tendencies, check for blood in urine or stool, check gums for bleeding
- Use an electric razor and soft tooth brush
- Conserve energy
- Make an appointment for follow-up care with a health professional

LIVER CANCER

- Liver cancer may be primary (hepatocellular cancer) or a result of metastasis from another site.
- Primary liver cancer grows rapidly and metastasizes early most often to the lung, lymph nodes, adrenal glands, the stomach, ovary, and kidney.
- More than half of advanced liver cancers are a result of spread from another source.
- Liver cancer is usually detected at a late stage and the prognosis is poor.

Etiology: Primary liver cancer can be caused by damage to hepatocellular DNA from hepatitis B and C viruses leading to DNA mutations. Metastatic tumors reach the liver through lymphatic channels, the portal system, and by extension of an abdominal tumor to the liver.

Risk factors: Primary cancer: history of HBV, HCV and cirrhosis; smoking; alcohol use; exposure to chemicals and toxins; male sex; and hereditary influences.

S&S:

- Pain, dull or aching
- A palpable mass in the right upper lobe of the liver
- Abdominal distention with ascites
- Fatigue, anorexia, and malaise
- Jaundice if larger bile ducts are occluded
- Symptoms of liver failure which are portal hypertension, splenomegaly, and hepatomegaly.

Dx: Based on history and physical and S&S. AFP, AST, ALD and alkaline phosphatase are elevated, ultrasound, CT scan and MRI to locate tumor and identify site for biopsy which is done to confirm diagnosis and identify tumor type and origin.

Rx: Lobectomy or liver transplant; chemotherapy to slow growth but not cure; radiation for pain relief; percutaneous biliary drainage for comfort and to decrease pruritus and jaundice.

Nursing Process Elements

- Provide emotional support for the client and family
- Offer pre- and postoperative teaching PRN, answer questions about the procedure (see Chapter 19)
- Discuss pain management and response to pain control measures
- Consult with other health team members to manage client problems
- Initiate a referral to Home Care, if the client can live at home. The Home Care RN can treat and evaluate needs such as comfort, nutrition and use of alternative measures of pain relief such as massage or guided imagery.

Client teaching for self-care

- Encourage independence and activity as tolerated
- Assist with referral to support groups, Hospice
- Encourage client and family to discuss and participate in care
- Teach about the complications of chemotherapy, radiation or surgery and the need to report to the nurse or physician if a problem occurs
- Discuss end-of-life issues
- Encourage small meals and supplementary feedings

CHOLELITHIASIS

Cholelithiasis is a disease characterized by stones in the gall bladder, cystic duct, or common bile duct.

Etiology: Unknown.

Risk factors: Five Fs: fair, fat, female, forty, and flatulent. Also, use of oral contraceptives, history of pregnancy, and family history of disease.

Precipitating factors: Bile stasis, imbalances of cholesterol metabolism, and infection

S&S: Asymptomatic and not treated unless cause cholecystitis (see below)

CHOLECYSTITIS

Cholecystitis is inflammation of the gall bladder.

Etiology: Most often associated with cholelithiasis.

S&S:

- Early disease: intolerance of fatty foods, nausea with or without vomiting, flatulence, fever, right upper quadrant discomfort after a heavy meal or at night
- Acute episode: RUQ pain, may radiate to right scapula and shoulder
- Elevated WBC count, alkaline phosphatase, amylase, and lipase
- If bile flow is obstructed, jaundice, clay-colored stool, dark amber-colored urine, and elevated serum bilirubin

PEDS

Assessment Alert

Gallstones are rare in children with the exception of children with sickle cell.

Dx: Visualization of gallstones usually with ultrasound imaging or oral cholecystogram.

Rx:

- Acute episode: supportive treatment
 - IV antibiotics for infection
 - Narcotic analgesics (Demerol not morphine) and anticholinergics (atropine) for pain
 - NPO, NG tube to suction, antiemetics for N&V

—F&E replacement

—Diet as tolerated clear or minimum-fat full liquids progressing to a fat restricted soft diet

- Removal of gallstones:

—Surgical: open or laparoscopic cholecystectomy is the most common procedure. Choledochostomy—opening of common bile duct with stone removal and T-tube insertion

—Gallstone dissolution therapy—substances that dissolve stones administered orally or via percutaneous catheter

—Mechanical litholysis of common bile duct stones—crushing and removal of stones via an endoscope

—Extracorporeal shock wave lithotripsy—use of high pressure, high-energy sound waves to crush stones

Nursing Process Elements

See cholecystectomy in Chapter 18 for perioperative care.

Client teaching for self-care

To manage symptoms of chronic indigestion related to cholecystitis and lower the risk of gallstone formation:

- Reduce weight to normal range
- Eat a high-fiber, high-calcium diet
- Reduce intake of saturated fatty acids
- Eat at regular intervals
- Exercise regularly

PANCREATITIS

- Pancreatitis is inflammation of pancreas.
 - It may be acute or chronic.
 - It is mild and self-limiting to life-threatening with severe hemorrhagic necrosis.
 - It is most common in middle-aged men.

Etiology: Apparently due to autodigestion secondary to pancreatic cell injury or activation of pancreatic enzymes in pancreas rather than small intestine.

Risk factors: Alcoholism, biliary tract disease, trauma, viral infection, drugs such as steroids, thiazides, oral contraceptives, NSAIDs, sulfonamides, metabolic disorders such as hyperparathyroidism, hyperlipidemia, and renal failure.

S&S: Acute:

- LUQ pain radiating subternally or to the back or flank, worsened by eating and unrelieved by vomiting, abdominal tenderness with guarding; N&V; jaundice; decreased or absent bowel sounds; tachycardia and hypotension; presence of Grey-Turner spots (flank ecchymoses); positive Cullen's sign (periumbilical ecchymoses)

Chronic:

- malabsorption, weight loss, mild jaundice, dark urine, and diabetes mellitus

Dx: Elevated serum amylase, urinary amylase, renal amylase-creatinine clearance, blood glucose, lipids; decreased

serum calcium; pancreatic enlargement on CT scan. Secretin stimulation test showing reduced volume of pancreatic secretions is most diagnostic of chronic disease.

Rx:

- Analgesics and smooth muscle relaxants such as papaverine and nitroglycerine for pain.

Clinical Alert

Morphine is not given because of its ability to cause spasm in the muscles of the ducts.

- Anticholinergics (atropine, Pro-Banthine) and antacids, NPO, NG suction to prevent acidic gastric contents from entering small intestine; small amounts of bland, high - CHO, high PRO, low-fat foods when oral intake resumed to decrease pancreatic stimulation.
- Fluid and electrolyte replacement
- Pancreatic enzyme replacement for chronic pancreatitis

Complications: Pseudocyst, abscess, pleural effusion, atelectasis, pneumonia, hypocalcemic tetany, fluid and electrolyte imbalance, and hemorrhagic shock

Nursing Process Elements

- Assess S&S, effect of medications; fluid and electrolyte status because risk of imbalance due to vomiting and NG suction. Monitor I&O and for signs of hypocalcemic tetany.

Assessment Alert

First sign of hypocalcemia: numbness and tingling in fingers and around lips.

- Eliminate environmental sources of pancreatic stimulation: sight, smell, and talk of food
- Implement nonpharmacologic measures to manage pain; positioning (fetal); relaxation techniques; calm, quiet environment
- Turn, cough and deep breathe to prevent respiratory infection which is a risk due to pain and elevation of diaphragm secondary to effects of inflammation
- Monitor blood glucose to check for damage to insulin-producing cells

Assessment Alert

Monitor closely for infection because inflamed, necrotic pancreatic tissue is at high risk for bacterial invasion.

Client teaching for self-care

- Avoid alcohol, caffeine, smoking, and stress all of which stimulate the pancreas
- Eat a high-carbohydrate, high-protein, low-fat diet
- Eat small frequent meals
- Maintain a relaxed atmosphere for meals
- Report signs of complications: continued N&V; increasing abdominal distention; continued weight loss; severe epigastric or back pain; frothy, foul-smelling stool; elevated temperature of 48-hours duration; irritability; and confusion

PANCREATIC CANCER

Prognosis is poor, usually well advanced, and metastasized at diagnosis.

Etiology: Unknown but some association with diabetes mellitus and chronic pancreatitis.

Risk factors: Smoking, high-fat diet, diabetes, exposure to chemicals such as benzidine.

S&S:

- Dull, aching upper abdominal pain, which may radiate to the back and occurs after eating or at night
- Anorexia, nausea, rapid weight loss, and jaundice
- Tumors in body or tail of pancreas often asymptomatic until well advanced.

Dx: Difficult; ERCP demonstrates obstructions in ducts. Cytology of pancreatic juice may show malignant cells. CEA is elevated in advanced disease but is nonspecific; CA1-9 is a more specific tumor marker. CT scan shows tumor mass and lymph node spread.

Rx: Surgery: Whipple procedure. Palliative procedures for bile duct obstruction such as a cholecystojejunostomy bypass or placement of a biliary stent. Radiation for pain relief; chemotherapy has a limited effect.

Nursing Process Elements

- Combines care of the client with pancreatitis, general care of the client with cancer, and care of the client at end-of-life
- Assess and manage pain
- Assess for bleeding secondary to impaired vitamin K synthesis
- Control N&V
- Stimulate appetite

WORKSHEET

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|-------|-------|
| 1. A risk factor for hepatitis A is poor hygienic practices. | _____ | _____ |
| | T | F |
| 2. Liver tenderness is a sign associated with the preicteric phase of hepatitis. | _____ | _____ |
| | T | F |
| 3. Hepatitis A vaccine is given as an initial dose and then a booster in 6–12 months. | _____ | _____ |
| | T | F |
| 4. Flapping hand tremors (asterixis) are characteristic of hepatic encephalopathy. | _____ | _____ |
| | T | F |
| 5. Clients with cirrhosis must be assessed for thrombus formation due to altered clotting factors. | _____ | _____ |
| | T | F |
| 6. Hepatitis B and C viruses can damage DNA of liver cells and result in the development of primary liver cancer. | _____ | _____ |
| | T | F |
| 7. Intramuscular and subcutaneous injections should be avoided in the client with cirrhosis. | _____ | _____ |
| | T | F |
| 8. Morphine is the analgesic of choice for clients with pancreatitis. Morphine is not given to clients with pancreatitis because it can cause spasm in the muscles of the pancreatic ducts. | _____ | _____ |
| | T | F |
| 9. To avoid stimulating the pancreas, high-fat foods should be avoided when oral intake is resumed in clients with pancreatitis. | _____ | _____ |
| | T | F |
| 10. The surgical procedure of choice for cancer of the pancreas is a Whipple procedure. | _____ | _____ |
| | T | F |
| 11. An elevated AFT confirms the diagnosis of primary liver cancer. | _____ | _____ |
| | T | F |
| 12. CA1-9 is more reliable than CEA as a marker for pancreatic cancer. | _____ | _____ |
| | T | F |

- | | | |
|---|------------------|------------------|
| 13. Part of the nursing care plan for the client with pancreatitis should be avoidance of the sight, smell, or talk of food. | <u> </u> T | <u> </u> F |
| 14. Pancreatitis places the client at risk for concurrent renal infection. | <u> </u> T | <u> </u> F |
| 15. Signs of severe hemorrhagic pancreatitis include a positive Cullen's sign and presence of Grey-Turner spots. | <u> </u> T | <u> </u> F |
| 16. Hepatic damage associated with alcoholic cirrhosis can be reversed by abstaining from alcohol and eating a nutritionally complete diet. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Match the following.

- | | |
|---|---|
| 1. ____ Risk factor for cholelithiasis | a. Test for chronic pancreatitis |
| 2. ____ Clay-colored stool | b. Treatment of chronic pancreatitis |
| 3. ____ Sign associated with cirrhosis | c. Palliative treatment for bile duct obstruction |
| 4. ____ Drug to be avoided in cirrhosis | d. Acetaminophen |
| 5. ____ Hypocalcemic tetany | e. Necessary for diagnosis of liver cancer |
| 6. ____ Secretin stimulation | f. Gynecomastia |
| 7. ____ Pancreatic enzyme replacement | g. Oral contraceptives |
| 8. ____ CT scan | h. Treatment for esophageal varices |
| 9. ____ Biliary stent | i. Complication of cirrhosis |
| 10. ____ Portal hypertension | j. Treatment for chronic hepatitis B |
| 11. ____ Vasopressin | k. Treatment of pain of acute cholecystitis |
| 12. ____ Interferon alpha | l. Treatment of hepatic encephalopathy |
| 13. ____ Anticholinergics | m. Demonstrates vascular changes in the liver associated with cirrhosis |
| 14. ____ Biopsy | n. Complication of pancreatitis |
| 15. ____ Neomycin | o. Sign of hepatitis or cholecystitis |

APPLICATION QUESTIONS

1. Which forms of hepatitis can be transmitted by contaminated blood and blood products? Mark all that apply.
 - a. ___ Hepatitis A
 - b. ___ Hepatitis B
 - c. ___ Hepatitis C
 - d. ___ Hepatitis D
 - e. ___ Hepatitis E
2. Which lab values are consistent with a diagnosis of hepatitis? Mark all that apply.
 - a. ___ Increased AST
 - b. ___ Increased ESR
 - c. ___ Increased serum bilirubin
 - d. ___ Increased ALT
3. How should the nurse interpret the development of frothy, foul-smelling stool in a client with pancreatitis?
 - a. Expected sign of the disease
 - b. Reportable sign of a complication
 - c. Sign that bilirubin drainage is reestablished
 - d. Indication that liver damage has occurred
4. Which assessment data would the nurse gather to monitor for damage to the cells in the Islet of Langerhans in the client with pancreatitis?
 - a. Serum bilirubin levels
 - b. Urobilinogen levels
 - c. Creatinine levels
 - d. Blood glucose levels
5. When caring for the client with pancreatitis, which question should be asked to check for the onset of hypocalcemia?
 - a. Do you have numbness or tingling in your fingers or around your lips?
 - b. Do you have any muscle cramps in your feet or legs?
 - c. Do you have any difficulty swallowing?
 - d. Do you feel weak or dizzy when you stand up?
6. Vaccines are available against which forms of hepatitis? Mark all that apply.
 - a. ___ Hepatitis A
 - b. ___ Hepatitis B
 - c. ___ Hepatitis C
 - d. ___ Hepatitis D
 - e. ___ Hepatitis E
7. In what stage(s) of hepatitis would the nurse expect the client to have liver tenderness and weight loss?
 - a. preicteric
 - b. icteric
 - c. posticteric
 - d. both icteric and posticteric
8. The mother of an 11-year-old girl with hepatitis asks why her daughter is not receiving any medication for the disease. Which fact should serve as the basis for the nurse's answer?
 - a. Most drugs are metabolized in the liver.
 - b. There are no drugs for hepatitis, which are safe for children.
 - c. Drug therapy is only used when jaundice has resolved.
 - d. The risk of kidney damage from drugs when the liver is impaired is high.
9. Which statement about the hepatitis A vaccine made by a client at an immunization clinic indicates understanding about the vaccine?
 - a. I have to come back in 6 months to a year for the booster dose.
 - b. I won't have lasting protection until after the third dose of the vaccine.
 - c. I'll be able to get a tattoo without worry once I get all these injections.
 - d. I need to avoid shellfish now that I have had this first injection.
10. Which unvaccinated client would be a candidate for hepatitis A immunoglobulin?
 - a. Client planning to visit a developing country in 10-months time
 - b. Client who had a tattoo 2 weeks ago
 - c. Client with a history of drug abuse
 - d. Client with a spouse diagnosed with hepatitis A
11. Which are risk factors for cholelithiasis? Mark all that apply.
 - a. ___ Use of oral contraceptives
 - b. ___ Female gender
 - c. ___ Elevated serum bilirubin
 - d. ___ Fair skin
 - e. ___ Obesity
 - f. ___ Elevated serum calcium
 - g. ___ Diet high in legumes

12. Which classes of drugs would the nurse expect to be ordered for the treatment of an acute episode of cholecystitis? Mark all that apply.
- ___ Narcotic analgesics
 - ___ Antiemetics
 - ___ Anticholinergics
 - ___ Parasympathomimetics
 - ___ Antilipemics
 - ___ Antibiotics
13. A client asks what is the difference between gallstone dissolution therapy and lithotripsy. On which fact should the nurse's response be based?
- Lithotripsy involves crushing gallstones through an endoscope; dissolution therapy involves using a chemical.
 - Dissolution therapy involves inserting a T-tube; lithotripsy involves use of radiation.
 - Lithotripsy uses sound waves to break up stones; dissolution therapy uses p.o. or IV substances to dissolve them.
 - Dissolution therapy uses a combination of drugs and radio waves; lithotripsy uses a laser to destroy stones.
14. A client suspected of having cirrhosis asks what test will confirm the diagnosis. What is the nurse's most appropriate reply?
- Measures of liver enzymes: ALT and AST
 - CT scan
 - Liver biopsy
 - Prothrombine Time (PT)
15. Impaired bile metabolism and excretion are directly related to which symptom of cirrhosis?
- Prolonged PTT
 - Pruritus
 - Ascites
 - Esophageal varices
16. Which direction would not be given to a client with cirrhosis?
- Take not more than 1300 mg of acetaminophen per day for pain
 - Avoid IM or SC injections
 - Use an electric razor
 - Avoid exposure to people with colds or other infections
17. When caring for a client with cholecystitis, the nurse would question an order calling for administration of which drug?
- Morphine
 - Demerol
 - Atropine
 - Compazine
18. Which are risk factors for primary cancer of the liver?
- Hepatitis A and cirrhosis
 - History of gastric cancer and alcohol abuse
 - Portal hypertension and exposure to environmental toxins
 - Smoking and hepatitis C
19. A client says his physician told him he has a liver tumor and before it is treated it has to be determined if it started in the liver or if it came from somewhere else. The client asks what test is used to figure this out. Which test would the nurse say is used to identify the origin of a liver tumor?
- CT scan of the liver
 - MRI of the liver
 - Liver biopsy
 - Test for alpha-fetoprotein
20. The nurse would expect a history of left upper quadrant pain worse after eating and not relieved by vomiting when assessing a client with which problem?
- Cholecystitis
 - Splenomegaly
 - Acute pancreatitis
 - Liver cancer
21. Which is a major indicator of chronic pancreatitis?
- Positive Cullen's sign
 - Postprandial elevated serum amylase
 - Decreased pancreatic secretion with secretin stimulation
 - Midepigastic pain worsened by fasting
22. The spouse of a client with pancreatitis asks what is the reason for the NG tube? Which fact should form the basis of the nurse's reply?
- To prevent vomiting
 - To remove gastric contents so they don't enter the intestine
 - To allow for monitoring of gastric pH
 - To protect the gastric lining from pancreatic enzymes
23. For which complication of pancreatitis is the nurse monitoring when the client is asked about the presence of numbness and tingling around the lips?
- Hyperkalemia
 - Hypocalcemic tetany
 - Hemorrhagic shock
 - Hyponatremia

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- A risk factor for Hepatitis A is poor hygienic practices. *True*
- Liver tenderness is a sign associated with the preicteric phase of hepatitis. *False*
Liver tenderness occurs in the icteric phase; the preicteric phase is characterized by headache, fatigue, and anorexia.
- Hepatitis A vaccine is given as an initial dose and then a booster in in 6–12 months. *True*
- Flapping hand tremors (asterixis) are characteristic of hepatic encephalopathy. *True*
- Clients with cirrhosis must be assessed for thrombus formation due to altered clotting factors. *False*
With cirrhosis the ability of the liver to produce clotting factors is often decreased therefore the client must be assessed for signs of abnormal bleeding.
- Hepatitis B and C viruses can damage DNA of liver cells and result in the development of primary liver cancer. *True*
- Intramuscular and subcutaneous injections should be avoided in the client with cirrhosis. *True*
- Morphine is the analgesic of choice for clients with pancreatitis. *False*
Morphine is not given to clients with pancreatitis because it can cause spasm in the muscles of the pancreatic ducts.
- To avoid stimulating the pancreas, high-fat foods should be avoided when oral intake is resumed in clients with pancreatitis. *True*
- The surgical procedure of choice for cancer of the pancreas is a Whipple procedure. *True*
- An elevated AFT confirms the diagnosis of primary liver cancer. *False*
Diagnosis of any liver cancer, primary or metastatic, can only be confirmed by liver biopsy.
- CA1-9 is more reliable than CEA as a marker for pancreatic cancer. *True*
- Part of the nursing care plan for the client with pancreatitis should be avoidance of the sight, smell, or talk of food. *True*

14. Pancreatitis places the client at risk for concurrent renal infection. *False*
Pancreatitis puts the client at risk for respiratory infection because pain and elevation of the diaphragm predispose to shallow breathing and stasis of secretions.
15. Signs of severe hemorrhagic pancreatitis include a positive Cullen's sign and presence of Grey-Turner spots. *True*
16. Hepatic damage associated with alcoholic cirrhosis can be reversed by abstaining from alcohol and eating a nutritionally complete diet. *False*
Cirrhosis damage is irreversible; good nutrition and abstinence from alcohol can prevent further damage.

MATCHING ANSWERS

Match the following:

- | | |
|---|---|
| 1. <u>g</u> Risk factor for cholelithiasis | a. Test for chronic pancreatitis |
| 2. <u>o</u> Clay-colored stool | b. Treatment of chronic pancreatitis |
| 3. <u>f</u> Sign associated with cirrhosis | c. Palliative treatment for bile duct obstruction |
| 4. <u>d</u> Drug to be avoided in cirrhosis | d. Acetaminophen |
| 5. <u>n</u> Hypocalcemic tetany | e. Necessary for diagnosis of liver cancer |
| 6. <u>a</u> Secretin stimulation | f. Gynecomastia |
| 7. <u>b</u> Pancreatic enzyme replacement | g. Oral contraceptives |
| 8. <u>m</u> CT scan | h. Treatment for esophageal varices |
| 9. <u>c</u> Biliary stent | i. Complication of cirrhosis |
| 10. <u>i</u> Portal hypertension | j. Treatment for chronic hepatitis B |
| 11. <u>h</u> Vasopressin | k. Treatment of pain of acute cholecystitis |

| 15. <u>l</u> Neomycin | o. Sign of hepatitis or cholecystitis |

APPLICATION ANSWERS

1. Which forms of hepatitis can be transmitted by contaminated blood and blood products? Mark all that apply.
- ___ Hepatitis A
 - ___ Hepatitis B
 - ___ Hepatitis C
 - ___ Hepatitis D
 - ___ Hepatitis E

Rationale

Correct answers: b, c, and d.

Incorrect answers: a and e both of which are transmitted by the fecal–oral route.

2. Which lab values are consistent with a diagnosis of hepatitis? Mark all that apply.
- ___ Increased AST
 - ___ Increased ESR
 - ___ Increased serum bilirubin
 - ___ Increased ALT

Rationale

Correct answers: a, b, c, and d.

AST and ALT are liver enzymes, which become elevated with liver damage. ESR is elevated due to the inflammation in the liver. Serum bilirubin is increased as a result of impaired bilirubin metabolism and obstruction of the hepatobiliary duct.

3. How should the nurse interpret the development of frothy, foul-smelling stool in a client with pancreatitis?
- Expected sign of early disease
 - Reportable sign of progressive disease
 - Sign that bilirubin drainage is reestablished
 - Indication that liver damage has occurred

Rationale

Correct answer: b.

Frothy, foul-smelling stool is characteristic of steatorrhea, which is indicative of malabsorption. Malabsorption that leads to nutritional deficiencies occurs when the pancreas no longer produces sufficient amounts of enzymes needed for digestion. Bilirubin does not drain; it is the pigment, which gives bile its color. It is a product of RBC breakdown by the spleen and circulates in the blood stream to the liver where it is used in the production of bile. When bile is released into the intestine, bilirubin is metabolized and gives stool its color.

4. Which assessment data would the nurse gather to monitor for damage to the cells in the Islet of Langerhans in the client with pancreatitis?
- Serum bilirubin levels
 - Urobilinogen levels

- Creatinine levels
- Blood glucose levels

Rationale

Correct answer: d.

Monitoring for elevations in blood glucose checks for damage to insulin producing cells because if insulin production is impaired, blood glucose will rise. Bilirubin is the pigment, which gives bile its characteristic green color; urobilinogen is a breakdown product of bilirubin metabolism in the small intestine that gives stool its color. These are unrelated to the function of the Islet of Langerhans, which produce insulin. Creatinine is a metabolic end product of a substance in skeletal muscle. It is formed and excreted through the glomerulus of the kidney in constant amounts and therefore is used to approximate glomerular filtration rate.

5. When caring for the client with pancreatitis, which question should be asked to check for the onset of hypocalcemia?
- Do you have numbness or tingling in your fingers or around your lips?
 - Do you have any muscle cramps in your feet or legs?
 - Do you have any difficulty swallowing?
 - Do you feel weak or dizzy when you stand up?

Rationale

Correct answer: a.

The first sign of onset of hypocalcemic tetany is numbness and tingling in the hands and around the mouth. This progresses to paresthesias in the legs and feet, carpedal spasm and ultimately to laryngeal, glottic and bronchial spasms and respiratory arrest as the calcium level falls below 7 mg/dL.

6. Vaccines are available against which forms of hepatitis? Mark all that apply.
- ___ Hepatitis A
 - ___ Hepatitis B
 - ___ Hepatitis C
 - ___ Hepatitis D
 - ___ Hepatitis E

Rationale

Correct answers: a and b.

Hepatitis A vaccine requires an initial dose and a booster in 6–12 months. Hepatitis B vaccine requires three injections with dose two at least 1 month after dose one and the third dose at least 2 months after the second and 4 months after the first.

7. In what stage(s) of hepatitis would the nurse expect the client to have liver tenderness and weight loss?
- Preicteric
 - Icteric

- c. Posticteric
- d. Both icteric and posticteric

Rationale

Correct answer: b.

Weight loss, jaundice, and liver tenderness are characteristics of the icteric stage of hepatitis. Headache, fatigue, and anorexia are characteristics of the preicteric stage. Decreased jaundice and improved appetite are characteristics of the posticteric stage.

8. The mother of an 11-year-old girl with hepatitis asks why her daughter is not receiving any medication for the disease. Which fact should serve as the basis for the nurse's answer?
- a. Most drugs are metabolized in the liver.
 - b. There are no drugs for hepatitis, which are safe for children.
 - c. Drug therapy is only used in acute cases when jaundice is prominent.
 - d. The risk of kidney damage from drugs when the liver is impaired is high.

Rationale

Correct answer: a.

Most drugs are metabolized in the liver so pharmacological treatment is not recommended for acute cases of hepatitis to avoid further stress and damage to the liver and to avoid other problems related to impaired drug metabolism. The other options are not valid.

9. Which statement about the hepatitis A vaccine made by a client at an immunization clinic indicates understanding about the vaccine?
- a. I have to come back in 6 months to a year for the booster dose.
 - b. I won't have lasting protection until after the third dose of the vaccine.
 - c. I'll be able to get a tattoo without worry once I get all these injections.
 - d. I need to avoid shellfish now that I have had this first injection.

Rationale

Correct answer: a.

Hepatitis A vaccine requires a booster dose in 6–12 months after the initial dose is given. It does not require a third dose; that is hepatitis B vaccine. Hepatitis A is transmitted by the fecal–oral route—the danger with tattoos is from bloodborne hepatitis viruses so hepatitis A offers no protection. Shellfish contaminated with fecal matter can be a source of hepatitis A virus and hence disease; contaminated shellfish should always be avoided. Receiving a dose of hepatitis A vaccine has no relationship to avoiding shellfish.

10. Which unvaccinated client would be a candidate for Hepatitis A immunoglobulin?

- a. Client planning to visit a developing country in 10-months time
- b. Client who had a tattoo 2 weeks ago
- c. Client with a history of heroin abuse
- d. Client with a spouse diagnosed with hepatitis A

Rationale

Correct answer: d.

Persons exposed to hepatitis A who have not been vaccinated can receive passive immunity through administration of immunoglobulin. A person planning to visit a developing country in 10 months has time to receive the vaccine and develop active immunity which is preferable. Tattoos have a potential risk of hepatitis B not A as does heroin abuse.

11. Which are risk factors for cholelithiasis? Mark all that apply.
- a. Use of oral contraceptives
 - b. Female gender
 - c. Elevated serum bilirubin
 - d. Fair skin
 - e. Obesity
 - f. Elevated serum calcium
 - g. Diet high in legumes

Rationale

Correct answers: a, b, d, and e.

Risk factors for cholecystitis are the five Fs (fair, fat, forty, female, and flatulent) as well as use of oral contraceptives, history of pregnancy, and family history of the disease. Elevated serum bilirubin or serum calcium or a diet high in legumes have no relationship to risk for gall bladder disease.

12. Which classes of drugs would the nurse expect to be ordered for the treatment of an acute episode of cholecystitis? Mark all that apply.
- a. Narcotic analgesics
 - b. Antiemetics
 - c. Anticholinergics
 - d. Parasympathomimetics
 - e. Antilipemics
 - f. Antibiotics

Rationale

Correct answers: a, b, c, and f.

Narcotic analgesics, but not morphine because of its ability to cause spasm of the ducts, are given for pain. Antiemetics are given for N&V. Anticholinergics are given to ease pain by reducing tone and contraction of smooth muscle. Antibiotics are given for infection. Antilipemics and parasympathomimetics have no role in the treatment of acute cholecystitis.

(continued)

13. A client asks what the difference is between gallstone dissolution therapy and lithotripsy. On which fact should the nurse's response be based?
- Lithotripsy involves crushing gallstones through an endoscope; dissolution therapy involves using a chemical.
 - Dissolution therapy involves inserting a T-tube; lithotripsy involves use of radiation.
 - Lithotripsy uses sound waves to break up stones; dissolution therapy uses p.o. or IV substances to dissolve them.
 - Dissolution therapy uses a combination of drugs and radio waves; lithotripsy uses a laser to destroy stones.

Rationale

Correct answer: c.

Lithotripsy uses the pressure of high-energy sound waves to crush stones so they can be passed into the intestine and out of the body. Dissolution therapy involves the administration, either oral or through percutaneous catheter, of substances which dissolve gallstones. Mechanical litholysis (grasping and crushing a stone with an instrument designed for the purpose) is performed through an endoscope; a T-tube is inserted when a choledochostomy (opening of the common bile duct) is done to remove stones. Radiation or lasers are not used for gallstone removal.

14. A client suspected of having cirrhosis asks what test will confirm the diagnosis. What is the nurse's most appropriate reply?
- Measures of liver enzymes: ALT and AST
 - CT scan
 - Liver biopsy
 - Prothrombin Time (PT)

Rationale

Correct answer: c.

Liver biopsy allows for microscopic examination of liver tissue in which changes diagnostic of cirrhosis can be identified. Liver enzymes are elevated by many different liver problems; CT scans show structural changes but are also nonspecific. PT is a measure specific to blood clotting and may be lengthened with cirrhosis but it can also be affected by many other disorders.

15. Impaired bile metabolism and excretion are directly related to which symptom of cirrhosis?
- Prolonged PTT
 - Pruritus
 - Ascites
 - Esophageal varices

Rationale

Correct answer: b.

Pruritus results from deposition of bile salts in the skin. Prolonged PTT, ascites, and esophageal varices all accom-

pany cirrhosis but are not direct results of impaired bile metabolism and excretion.

16. Which direction would not be given to a client with cirrhosis?
- Take not more than 1300 mg of acetaminophen per day for pain
 - Avoid IM or SC injections
 - Use an electric razor
 - Avoid exposure to people with cold or other infections

Rationale

Correct answer: a.

Acetaminophen is hepatotoxic and contraindicated in cirrhosis. Avoiding injections and using an electric razor are appropriate because of the risk of bleeding due to impaired clotting. Avoiding exposure to infection is appropriate because of decreased immune function.

17. When caring for a client with cholecystitis, the nurse would question an order calling for administration of which drug?
- Morphine
 - Pro-Banthine
 - Atropine
 - Compazine

Rationale

Correct answer: a.

Morphine is not given because it can cause spasms in the muscles of the ducts. The anticholinergics atropine and Pro-Banthine are used for pain and antiemetics such as Compazine is used for N&V.

18. Which are risk factors for primary cancer of the liver?
- Hepatitis A and cirrhosis
 - History of gastric cancer and alcohol abuse
 - Portal hypertension and exposure to environmental toxins
 - Smoking and hepatitis C

Rationale

Correct answer: d.

Smoking and hepatitis C are identified as risk factors for liver cancer. Other risk factors are HBV, cirrhosis, alcohol use, exposure to chemicals and toxins, male sex, and heredity factors.

19. A client says his physician told him he has a liver tumor and before it is treated it has to be determined if it started in the liver or if it came from somewhere else. The client asks what test is used to figure this out. Which test would the nurse say is used to identify the origin of a liver tumor?
- CT scan of the liver
 - MRI of the liver

- c. Liver biopsy
- d. Test for alpha-fetoprotein

Rationale

Correct answer: c.

A liver biopsy confirms the presence of cancer and shows the tumor type and origin. CT scans and MRIs show liver enlargement and nodules as well as vascular changes and indicate if tumor removal is possible. Alpha-fetoprotein is elevated in liver cancer but it is nonspecific and has no relationship to the origin of a liver cancer.

20. The nurse would expect a history of left upper quadrant pain worse after eating and not relieved by vomiting when assessing a client with which problem?
- a. Cholecystitis
 - b. Splenomegaly
 - c. Acute pancreatitis
 - d. Liver cancer

Rationale

Correct answer: c.

Acute pancreatitis is characterized by left upper quadrant pain, which is worse after eating but unrelieved by vomiting. Cholecystitis causes right upper quadrant pain referred to the back under the shoulder blade. Enlarged spleen can press on the diaphragm and stimulate the phrenic nerve resulting in referred shoulder pain. Liver cancer causes dull, aching pain in the right abdomen.

21. Which is a major indicator of chronic pancreatitis?
- a. Positive Cullen's sign
 - b. Postprandial elevated serum amylase
 - c. Decreased pancreatic secretion with secretin stimulation
 - d. Midepigastric pain worsened by fasting

Rationale

Correct answer: c.

Reduced volume of pancreatic secretions on a secretin stimulation test is the most diagnostic measure of chronic disease. Positive Cullen's sign is symptomatic of acute disease. Elevated serum amylase is found with both acute and chronic disease. LUQ pain radiating to the back, not midepigastric pain, is characteristic of acute disease; pain is not prominent with chronic disease.

22. The spouse of a client with pancreatitis asks what is the reason is for the NG tube? Which fact should form the basis of the nurse's reply?
- a. To prevent backup of secretions to the liver
 - b. To remove gastric contents so they don't enter the intestine
 - c. To allow for monitoring of gastric pH
 - d. To protect the gastric lining from pancreatic enzymes

Rationale

Correct answer: b.

The NG tube serves to remove acidic gastric contents so they don't enter and damage the intestine since alkaline pancreatic secretions are not available to neutralize them. Gastric secretions do not back up to the liver; gastric pH is not measured; and pancreatic enzymes back flowing to the stomach is not a problem.

23. For which complication of pancreatitis is the nurse monitoring when the client is asked about the presence of numbness and tingling around the lips?
- a. Hyperkalemia
 - b. Hypocalcemic tetany
 - c. Hemorrhagic shock
 - d. Hyponatremia

Rationale

Correct answer: b.

The first sign of onset of hypocalcemic tetany is numbness and tingling in the hands and around the mouth. If untreated, carpopedal spasm and tetany ensue. Numbness and tingling are not associated with hyperkalemia, hemorrhagic shock, or hyponatremia.

24. Which assessment finding would indicate that papaverine administered to a client with pancreatitis is exerting the desired effect?
- a. Pancreatic secretions have increased.
 - b. Pain has decreased.
 - c. Oral fluids are tolerated
 - d. Electrolyte values are within normal range.

Rationale

Correct answer: b.

Papaverine is a muscle relaxant used along with analgesics for the control of pain in clients with pancreatitis. It is not used for any effect on pancreatic secretions, ability to tolerate oral intake, or electrolyte values.

25. Teaching about the need for a long-term, low-protein diet would be part of the plan of care for a client with which problem?
- a. Chronic pancreatitis
 - b. Liver cancer
 - c. Pancreatic cancer
 - d. Hepatic encephalopathy

Rationale

Correct answer: d.

Buildup of ammonia in the blood due to the inability of the liver to clear it, is a major factor in hepatic encephalopathy. Ammonia is produced in the body by intestinal bacteria as an end product of protein metabolism. Therefore, decreasing protein in the diet decreases ammonia available to accumulate to toxic levels.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 9: Endocrine Problems

| | | | |
|--|-----|--|-----|
| ▸ Adrenal Gland Hypofunction (Addison's Disease) | 883 | ▸ Hypoparathyroidism | 882 |
| ▸ Diabetes Insipidus (DI) | 876 | ▸ Hypothyroidism (Myxedema) | 879 |
| ▸ Diabetes Mellitus (DM) | 887 | ▸ Myxedema Coma | 879 |
| ▸ Excess Adrenal Cortical Hormones | 885 | ▸ Pheochromocytoma | 886 |
| ▸ Growth Hormone (GH) Hypersecretion | 875 | ▸ Syndrome Of Inappropriate Antidiuretic Hormone (SIADH) | 878 |
| ▸ Hyperparathyroidism | 883 | ▸ Thyroid Cancer | 882 |
| ▸ Hyperthyroidism | 880 | ▸ Thyroid Storm | 880 |

Think Smart/Test Smart

As you study the endocrine diseases, remember that there are S&S related to the hypersecretion and hyposecretion of each. Overtreatment of hypersecretion results in the symptoms of hyposecretion. Overtreatment of hyposecretion results in the symptoms of hypersecretion. With undertreatment of either, symptoms may be reduced but will not be different.

GROWTH HORMONE (GH) HYPERSECRETION

- **PEDS** Called gigantism when it occurs in children before epiphyses close
 - Causes excessive growth of both bones and connective tissue; height of 8 ft may be reached with proportional growth in head and other body parts.
 - Bony changes are permanent but connective tissue changes may regress somewhat when excess GH is removed.

- Called acromegaly when it occurs after epiphyses close; growth is horizontal rather than vertical.
 - Causes excessive growth of connective tissues in every part/organ of the body.
 - Signs of acromegaly evolve slowly over a period of years.

Etiology: Hypersecretion of GH (somatotropin) usually as a result of a pituitary tumor; ectopic GH-secreting tumor in the pancreas; GH-releasing, hormone-producing tumors.

S&S:

- **PEDS** Children: increased weight, height, muscle mass, and size of viscera; with pituitary tumor, headache and other signs of increasing intracranial pressure may be present.
- Adults: thickened facial features, enlarged hands and feet, deep voice from thickened vocal cords, enlarged heart with resultant increased BP and signs of congestive heart failure, pressure on nerves and related symptoms, arthritis, backache, and kyphosis from bony overgrowth, snoring, altered glucose tolerance leading to diabetes mellitus (DM), and lipidemia from changes in fat metabolism. If etiology is a pituitary tumor, headaches and vision changes may occur. Premature death from the cardiovascular effects is typical.

Dx: Clinical presentation and measurement of GH secretion.

Rx: Goal: prevent worsening of disorder.

- Removal of the GH-producing tumor
- Adjunctive pharmacological treatment: Octreotide acetate (Sandostatin LAR) injection given monthly; effectiveness is assessed by serial IGF-1 and GH levels.

Nursing Process Elements

Assessment Alert

Clients with acromegaly are at risk for carbohydrate intolerance or outright DM.

- Promote self-esteem
 - **PEDS** Reinforce to tall preadolescent girls that boys will grow taller and many will match or exceed their height
- Support confidence by capitalizing on idol worship in adolescents by noting famous couples in which the woman is taller than the man
- Encourage participation in a support group
- Promote coping

PEDS Growth Hormone (GH) Deficiency

- GH deficiency is defined as the deficient secretion of somatotropin.

- It is idiopathic in more than half the cases with site of dysfunction believed to be the hypothalamus.

Etiology: Known causes include tumors, trauma, vascular abnormalities, and hereditary disorders.

S&S: Short stature: normal at birth but progressively drops behind growth charts.

Assessment Alert

Most children presenting with short stature have a constitutional delay not hypopituitarism.

Dx: Radioimmunoassay of plasma GH levels stimulated pharmacologically in two tests below 10 ng/ml.

Rx: Treat underlying cause and/or administration of GH. Before GH is given, an extensive workup is done including family history, imaging to check for brain abnormalities, and evaluation of growth through radiographic study of ossification centers in the hands and wrist.

Nursing Process Elements

- Encourage parents to treat the child in an age-appropriate manner: it is easy to treat the child as younger than he or she is because they look younger
- Encourage parents to work with family members and teachers to treat child in an age-appropriate manner

Client teaching for self-care

- Take injections at bedtime to approximate normal circadian rhythm
- Reinforce realistic expectations of therapy: response to GH varies with young, obese, and severely GH-deficient children responding best; even with good response, adult height is reached more slowly than normal

DIABETES INSIPIDUS (DI)

- DI occurs when there is deficiency in the secretion of antidiuretic hormone (ADH) by the posterior lobe of the pituitary gland or an inability of the kidneys to respond to ADH.
- It causes reduced ability of the renal tubules to reabsorb water and concentrate urine.
- Because the distal tubules remain impermeable to water, large amounts of fluid and electrolytes are excreted in dilute urine.

Etiology:

- Primary DI: tumor of the hypothalamus or posterior pituitary gland
- Secondary DI: head injury or surgical irradiation of the gland

- Transient DI: sequela to transsphenoidal surgery for pituitary adenoma

S&S:

- Polyuria: 4–20 l of dilute urine voided per 24 hours
- Polydipsia (excessive thirst) from dehydration related to excessive water loss in urine
- Decreased urine specific gravity (1.005 or less), hypo-osmolar urine (200 or less), and only slightly increased serum osmolality as long as fluid intake is maintained
- With inadequate water replacement,
 - hypotension, tachycardia, and weight loss develop, without treatment vascular collapse ensues, and the client may develop shock from the fluid loss.
 - hypernatremia coexists as a result of this rapid fluid loss and the concurrent neurological complications of this electrolyte imbalance including irritability, decreased cognition, lethargy, and coma develop.
- Sleep problems due to frequent voiding
- **PEDS** In children, the first sign may be enuresis
- **PEDS** In infants, irritability that is relieved by feeding water but not milk is the initial symptom

Dx:

- Water deprivation test to determine ability of renal tubule to concentrate urine
 - Positive for DI if after fluid is restricted, there is no change in urine formation; urine osmolality and specific gravity do not rise

**Assessment Alert**

Children need close supervision during fluid restriction because they may drink fluid from any available source including toilet bowls and puddles.

- Vasopressin stimulation test to determine if ADH is being secreted from the posterior pituitary gland
 - Positive for DI if after subcutaneous administration of five units of aqueous vasopressin, increased specific gravity and decreased urine output occur
- Serum findings:
 - Decreased levels of ADH
 - Increased osmolality
 - Increased sodium
- Urinary findings:
 - Specific gravity less than 1.005
 - Decreased osmolality (50–200 mOsm/kg)

Rx:

- Long-term ADH replacement therapy

—Desmopressin (DDAVP)

- 0.1–0.4 ml in single or divided doses
- Nasal spray
- An upright position promotes better absorption
- Parenteral administration used for transient DI when use of a nasal spray is impossible due to nasal packing

—Aqueous vasopressin (Pitressin)

- 5–20 units in divided doses
- Subcutaneous, IM, or nasal spray
- Monitor client weight and I&O

**Assessment Alert**

Overdosage of ADH replacement therapy is indicated by S&S of water intoxication and SIADH.

—Chlorpropamide (Diabinese)

- Thought to stimulate the production of ADH
- Used for its antidiuretic effects
- Monitor for signs of hypoglycemia
- Oral and hypotonic IV therapy hydration and replacement:
 - Given if clinical signs of hypernatremia are present
 - Calculated by adding insensible water loss and urinary output to estimated water deficit
 - Administered slowly over 48 hours to avoid cerebral edema and/or seizures
- For nephrogenic DI (caused by lack of responsiveness of the kidney to ADH), low-protein, low-sodium diet and thiazide diuretics.

**Nursing Process Elements**

- Assess for early signs of dehydration and maintain adequate hydration
 - Ensure IV access site and monitor hourly infusion
- Assess neurologic status
- Measure fluid I&O
 - Urge client to drink fluids in an amount equal to output
- Check urine specific gravity
- Record daily client weight
- Monitor client for education need and ability to participate in health care
- **PEDS** Counsel parents to speak with school personnel regarding the problems so that the child has unrestricted access to the lavatory

**Client teaching for self-care**

- Weigh self daily using the same scale at the same time of day

- Notify health care provider if weight loss occurs; notify health care provider if polydipsia and polyuria occur because this signals the need for additional medication doses
- Wear a Medic-Alert bracelet
- Older children and adults should carry the vasopressin nasal spray with them for temporary symptom relief when needed

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE (SIADH)

- Syndrome of inappropriate antidiuretic hormone (SIADH) occurs when vasopressin (ADH) is secreted even when plasma osmolality is low or normal.
- The feedback mechanism that regulates ADH does not function properly and ADH continues to be released.
- A nonendocrine source of ADH develops such as when malignant cells synthesize and release ADH.

Etiology:

- Disorders of the CNS, such as head injury, stroke, brain surgery or tumor and infection, which are thought to produce direction stimulation of the pituitary gland
- Medication induced SIADH: vincristine, phenothiazines, tricyclic antidepressants, thiazide diuretics, general anesthetics, opioids, and nicotine have been implicated
- Pulmonary disorders such as tuberculosis, ventilator clients receiving positive pressure, lung abscess
- Malignancies such as small cell lung adenoma, pancreatic and prostate cancer, Hodgkin's and non-Hodgkin's disease, lymphoma, sarcoma, and leukemia that tend to synthesize and release ADH

S&S:

- Early manifestations are related to water retention, the inability to excrete diluted urine, and the resultant hyponatremia: oliguria, anorexia, N&V, muscle weakness, irritability, disorientation, malaise, anxiety, anger, and uncooperativeness
- Because free water (no salt) is retained, weight gain but not edema also occurs
- Neurologic manifestations can progress to lethargy, headache, decreased responsiveness, seizures, and coma with a decrease in deep tendon reflexes
- Decreased plasma sodium and osmolality

Dx:

- Radioimmunoassay of ADH can diagnose SIADH when ADH levels are inappropriately elevated if the plasma osmolality is normal or decreased
- Serum tests
 - Plasma osmolality rises
 - Serum sodium levels are decreased, often as low as 110/mEq/l

- Urine tests
 - Urine volume decreases
 - Urine osmolality increases
 - Urine sodium levels rise
 - Urine specific gravity rises, as a result of the increased urine concentration

Rx:

- Treat cause
- Restricted fluids to 500–600 ml/24hr
- High-sodium diet if client is able to take foods orally
- Use saline to dilute tube feedings, irrigate GI tubes, and mix drugs
- Diuretic therapy, particularly if heart failure is present from fluid overload, but manage concurrent sodium loss
- IV hypertonic saline (3% NaCl), given cautiously to avoid adding to existing fluid overload and a loop diuretic for serum sodium less than 12 mEq/l and CNS symptoms, which requires more rapid replacement. Goal is to raise serum sodium, not to normal but to 125–130 mEq/l or to relieve symptoms or to raise serum sodium by 25 mEq/l
- Demeclocycline (Declomycin) blocks action of ADH on renal tubules

Nursing Process Elements

- Identify clients at risk
- **PEDS** Institute seizure precautions for children
- Obtain daily serum and urinary sodium and osmolality levels
- Measure I&O
 - a 1-kg weight increase is equal to a 1000-ml fluid retention
- Record daily client weight
 - Teach client to use the same scale at the same time
 - Notify health care provider if weight gain occurs
- Monitor client for education need and ability to participate in health care
- Observe changes in client neurologic status
 - Assess for muscle twitching
 - Check orientation to time, place, and person
 - Reduce environmental noise to prevent overstimulation

Assessment Alert

Report immediately, if serum sodium is less than 125 mEq/l or any decline in neurological status occurs.

- Give ice chips to combat thirst when fluids are restricted; they must be counted as part of the fluid intake but relieve thirst with less fluid intake than if drinking water.
- Provide mouth care often

HYPOTHYROIDISM (MYXEDEMA)

- Hypothyroidism is the inadequate secretion of thyroid hormones triiodothyronine (T3) and thyroxine (T4), which affects all body functions and can range from mild, subclinical forms to myxedema, an advanced form.
- Sometimes thyroid cells are functional but the person does not ingest enough of the substances needed to make thyroid hormones function properly, especially iodide and tyrosine.
- Failure of the anterior pituitary gland, hypothalamus, or both will cause central hypothyroidism with decreases in TRH and TSH.
- It can occur anytime throughout the life span, more common in older women.

Etiology:

- Most common cause in adults is autoimmune thyroiditis (Hashimoto's disease), in which the immune system attacks the thyroid gland
- Occurs in clients who are being treated for hyperthyroidism with radioiodine, antithyroid medication, or surgical removal of the gland

S&S:

Adults

- Weight gain and constipation
- Thickened skin
- Cold intolerance
- Dull mental processes
- Subnormal temperature and pulse rate
- Development of iodine-deficient goiter
- Other manifestations of decreased metabolism
 - Extreme fatigue
 - Hair loss, brittle nails, and dry skin
 - Menstrual disturbances, and loss of libido
 - Possible atherosclerosis as a result of decreased myocardial metabolism

Children (Juvenile hypothyroidism)

- Decelerated growth
- Dry skin
- Puffiness around the eyes
- Sparse hair
- Sleepiness
- Constipation
- Mental decline

MYXEDEMA COMA

- Myxedema coma is the most extreme stage of hypothyroidism manifestations; precipitated by factors such as cold, surgery, infection, or trauma in any client with severe, prolonged hypothyroidism.

- Hypothermia and bradycardia
- Increasing lethargy, stupor, and coma
- Abnormal sensitivity to opioids, sedatives, and anesthetic agents
- Depressed respiratory drive, cardiovascular collapse, and shock develop

Dx:

- Decreased levels of serum T3, T4, FT4, and T3 resin uptake
- Delayed TSH response to TRH stimulation test
 - Increased TRH and TSH serum levels if primary hypothyroidism and hypothalamus and pituitary are intact
- Elevated levels of cholesterol due to hypometabolic state
- Decreased results to radioactive iodine uptake test
- Determine whether client has taken medications (contrast agents) or foods (shellfish or cough syrups) containing iodine as these may alter test results

Clinical Alert

Prompt treatment is needed for the infant in order to avoid mental retardation or other neurologic effects because the brain's growth occurs primarily in the first 2–3 years of life.

Rx:

- Primary objective is to restore a normal metabolic state by replacing the missing hormone.
 - Synthetic levothyroxine (Synthroid or Levothroid)
 - Dosage is based upon the client's TSH serum concentration
- Prevention of cardiac dysfunction
 - Cardiac monitoring
- Prevention of medication interactions
 - Increases in metabolism may affect insulin needs
 - Increases in blood glucose levels, Dilantin levels, digitalis glycoside levels, and anticoagulant levels affected by replacement drugs

Nursing Process Elements

- Alert physician to medications taken that can alter results of diagnostic tests, especially estrogen, salicylates, amphetamines, antibiotics, corticosteroids, and mercurial diuretics
- Modify client activity to accommodate fatigue
 - Promote independence in self-care activities
- Provide extra layers of clothing or extra blanket
 - Monitor body temperature and report decreases from baseline
- Provide foods high in fiber

- Monitor respiratory rate, depth, pattern, pulse oximetry, and arterial blood gas
- Orient client to time, place, and events
- Monitor for increasing severity of S&S of hypothyroidism
 - Decreased LOC, VS changes, and increasing difficulty in arousal

PEDS

- Position a newborn with a goiter with the neck hyperextended to aid breathing; provide supplemental oxygen; and have a tracheostomy set immediately available in case tracheal compression by the goiter requires emergency ventilation.

Client teaching for self-care

- Take levothyroxine on an empty stomach
- Side effects relate to under or over replacement and therefore are signs of hypo or hyperthyroidism
- Explain rationale for thyroid hormone replacement
 - Describe desired effects of medication
 - Explain the necessity for long-term follow-up to client and family

HYPERTHYROIDISM

- Hyperthyroidism is the second most prevalent endocrine disorder, after DM.
- Results from an excessive secretion of thyroid hormones, T3 and T4, which may be temporary or permanent depending upon the cause.
- The normal feedback control over thyroid hormone secretion fails producing a state of hypermetabolism.
- Oversecretion of the releasing and stimulating hormones from the hypothalamus and anterior pituitary gland play a role in the excess of the thyroid hormones.
- Thyrotoxicosis occurs due to toxic effects of excess thyroid hormone.

Etiology:

- The most common cause is a toxic diffuse goiter, autoimmune in nature, which increases the size of the gland and production of its hormones (Graves' disease).
- Thyroid adenoma, a benign thyroid tumor, secretes hormone without stimulus of TSH.

S&S:

- The hallmark of hyperthyroidism is heat intolerance.
 - Diaphoresis even when the environmental temperatures are comfortable for others
- Visual changes
 - Blurred or double vision

- Palpitations or chest pain
 - Changes in breathing patterns due to dyspnea
- Weight loss and diarrhea are often reported.
- Fatigue and weakness are common due to the hypermetabolic demands of the disorder.
- Ophthalmopathy
 - Exophthalmus
 - Bulging eyes, “startled” look
 - Proptosis
 - Eyelid retraction and eyeball lag
- Thyroid gland enlargement
- Increased systolic BP and tachycardia
- Increased restlessness and irritability

THYROID STORM

- Thyroid storm is a life-threatening event, which consists of rapid onset of exaggerated symptoms of hyperthyroidism.
 - Abnormally elevated temperature (may be as high as 105–106°F), tachycardia, dysrhythmia, and systolic hypertension
 - Abdominal pain, N&V, and excessive diarrhea
 - As the crisis progresses, increased restlessness, confusion, disorientation, psychosis, and seizures ensue

Precipitating factors: Discontinuing needed medications for hyperthyroidism; overreplacement of thyroid hormone; recent treatment with radioactive iodine; surgery, trauma, severe infection, myocardial infarct, or other severe illness in a client with hyperthyroidism.

Dx: Based on clinical presentation and presence of elevated serum levels of T3 and T4.

- Mortality rate is 25% even with treatment

Dx:

- Increased levels of serum T3, T4, FT4, T3 resin uptake
- Thyroid suppression test fails to suppress RAIU or T4 levels
- Elevated titer of antithyroglobulin antibodies
- Elevated thyrotropin receptor antibodies
- Decreased levels of TRH and TSH if primary hyperthyroidism and hypothalamus and pituitary are intact

Rx:

- Nonsurgical management
 - The most commonly used antithyroid drugs are the thioamides, including propylthiouracil (PTU) and methimazole (Tapazole), which block synthesis of thyroid hormone in the gland.
 - Spreading out dosage helps maintain hormone suppression.

- It takes several weeks before the effect of these drugs is seen because already synthesized hormone must be used up.
- Dose of antithyroid drug is gradually tapered as the client regains euthyroid status.
- A side effect of these drugs is agranulocytosis so baseline and periodic WBC count is needed and client must be monitored for signs of infection or jaundice.
- **PEDS** In children, sore throat and fever can be the first indicators of drug-induced leukopenia so occurrence of these symptoms requires a checkup by the health care provider.

—Iodine preparations that decrease blood flow to the gland thereby reducing the release of the hormones.

- Saturated solution of potassium iodide (SSKI), Lugol's solution, taken after meals to enhance absorption
- Beta-adrenergic blocking agents such as propranolol (Inderal), relieve diaphoresis, anxiety, tachycardia, and palpitations
- Radioactive iodine therapy (I 131) that destroys some of the thyroid cells, which produce the hormone; effects seen in 6 weeks to 6 months; most clients will become hypothyroid after treatment because of the difficulty in titrating the dose of I 131 and will need thyroid hormone replacement
- Surgical management (Also see thyroidectomy in Chapter 18)
 - May be needed for clients who have a large goiter causing tracheal or esophageal compression or who do not respond to antithyroid drugs.
 - Lifelong thyroid replacement therapy is required after a total thyroidectomy.
 - Accidental removal of the parathyroid glands may result in hypocalcemia and tetany, damage to the laryngeal nerves, and thyroid storm.
- Emergency measures include providing a patent airway and adequate ventilation
- Pharmacotherapy

Clinical Alert

Doses of drugs used to treat the client in thyroid storm are higher than for other clients because of the accelerated metabolism of the client in thyroid storm.

- PTU: oral loading dose then 200–300 mg every 6 hours
- Iodide preparations
- Dexamethasone 2 mg IV every 6 hours; helps inhibit release of thyroid hormone
- Beta-adrenergic blockers IV for dysrhythmias as needed
- Nonsalicylate antipyretics

Clinical Alert

Salicylates are contraindicated for clients with thyroid storm because they increase free thyroid hormone levels by interfering with the hormone binding to protein carriers.

- Apply cool blanket or ice packs
- Monitor for cardiac arrhythmias
- Monitor VS
- Identify the cause and stabilize hemodynamic status

Nursing Process Elements

- Monitor VS especially heart rate and rhythm
- Monitor serum albumin, hemoglobin, and lymphocyte levels
- Encourage a diet high in calories, proteins, and carbohydrates to replace energy stores lost due to the hypermetabolic states
- Encourage six meals per day to ensure nutritional needs are consistently and adequately met
- Weigh at least weekly
- Assess for visual changes: photophobia, decreased acuity, or ability to close eyes
- If exophthalmos is present, protect eyes with glasses, wet with artificial tears, elevate head of bed at night; avoid sleeping in a prone position and wear a patch at night if eyelids do not fully close
- Assess level of mentation for impending storm

PEDS Assessment Alert

Exophthalmos may be the initial sign. Later “weight loss” despite an excellent appetite, short attention span, and inability to sit still interfering with school performance, unexplained tiredness, and inability to sleep, and impaired fine motor skills may develop.

- **PEDS** Limit activity of children with symptomatic hyperthyroidism; restrict vigorous exercise until thyroid levels approach normal
- Instruct client how to support neck when coughing or moving after surgery
 - Place in semi-Fowler's position that decreases suture line tension to avoid hematoma

- Provide humidified oxygen and ice collar to avoid swelling at the surgical site
- Have tracheostomy available set at bedside in the event of an airway emergency
 - Assess for postoperative hemorrhage, especially at the posterior neck dressing
 - Monitor calcium levels
 - Have client report circumoral tingling or numbness of toes and fingers
- Muscle twitching is a sign of calcium deficiency
 - Have calcium gluconate available at the bedside in the event of hypocalcemic emergency

Client teaching for self-care

- I 131 treatment
- May cause nausea so limit oral intake 2 hours before and after treatment
- Take acetaminophen for sore throat, which may occur a few days after the treatment
- I 131 is eliminated in urine over 4–5 days so drink a lot of fluid, void frequently and flush twice, and thoroughly clean up any spilled urine
- Wash laundry separately if the treated person has sweated heavily, such as after exercise
- Keep an arm's length from anyone who will be in contact with you for more than 2 hours in every 4-hour period; especially if in contact with children and pregnant women. Sleeping together, watching television, going to movies, long car, or plane trips should be avoided for approximately 11 days after treatment
- Small amount found in saliva so avoid kissing and any sharing of food, fluids, or utensils
- After I 131 treatment, women should not get pregnant or breast-feed for 6 months
- Report palpitations, chest pain, or dizziness
- **PEDS** Counsel parents to establish a regular routine for the child with frequent rest periods

THYROID CANCER

Etiology: Papillary cancer, the most common type of thyroid cancer, is related to prior radiation exposure to the head and neck.

Dx: Fine needle biopsy of the thyroid nodule, which may have been discovered by the client or on physical examination or during diagnostic imaging for other problems.

TSH assay: Suppressed TSH suggests a benign nodule.

RAI uptake: Hot nodules (those that pick up the radioactive iodine are always benign); cold nodules may be benign or malignant.

Rx: Most curative therapy is total thyroidectomy with I 131 ablation of any remaining thyroid tissue followed by levothyroxine replacement beginning the day after surgery.

Neck dissection is also done if metastases in cervical lymph nodes are palpable.

T4 and TSH levels are monitored 6–12 weeks after surgery. Serum thyroglobulin is monitored as a marker for remaining functioning thyroid tissue.

Nursing Process Elements

- Support the client during the diagnostic process
- Provide perioperative care as described under thyroidectomy
- Following I 131 ablation therapy,
 - place client in private room
 - collect all urine and feces in a radiation sewage disposal system
 - ensure disposable dishes and utensils are used for the client
 - allow no visitors
- When I 131 falls to less than 30 mCi as measured by a Geiger counter (usually about 3 days if kidney function is normal), follow radiation safety guidelines as for client having I 131 treatment of hyperthyroidism
- Restrict contact with health care personnel

HYPOPARATHYROIDISM

- Hypoparathyroidism is the disorder of calcium metabolism due to inadequate production of parathyroid hormone.
- Decreased parathormone (PTH) causes decreased resorption of calcium from bone, decreased intestinal absorption, and decreased reabsorption of calcium in the renal tubules with increased retention of phosphate.
- Resultant hypocalcemia increases neuromuscular excitability.

Etiology:

- Most often iatrogenic: result of removal of parathyroid glands or injury from radiation to the neck
- Idiopathic disease may have an autoimmune basis
- Chronic hypomagnesemia inhibits release of parathyroid hormone from normal glands.
- **PEDS** May occur transiently in infants fed—a milk formula with a high phosphate to calcium ratio.

S&S:

- Early: irritability, apprehension, muscle cramps in abdomen and extremities, photophobia; numbness and tingling around the mouth, nose, ear lobes, hands and feet; and positive Chvostek and Trousseau's signs
- Late: hypocalcemic tetany, respiratory stridor, crowing on inspiration due to laryngospasm, cardiac dysrhythmias, seizures, and respiratory arrest

Assessment Alert

Stridor, hoarseness, and a sense of tightness in the throat are signs of laryngospasm.

- **PEDS** Retarded skeletal growth; dental and enamel hypoplasia; possible mental retardation; thin, brittle nails with transverse grooves; brittle hair; dry, scaly skin with eruptions

Dx: Radioimmunoassay to measure serum level of PTH and concurrent measures of serum calcium and phosphorus. With hypoparathyroidism, serum hormone and calcium is low; phosphorus is high.

Rx: Tetany is an emergency and is treated with IV calcium gluconate or calcium chloride until serum calcium is above 7 mg/dl. When serum calcium above 7 mg/dl, oral vitamin D and calcium is prescribed.

Nursing Process Elements

- Monitor serum calcium
- If client complains of paresthesias suggestive of hypocalcemia check for Chvostek and Trousseau's signs
- Report signs of impending tetany immediately
- Make certain a tracheostomy set and IV calcium gluconate or calcium chloride is immediately available

Client teaching for self-care

- Ingest diet high in calcium, low in phosphorus
- Foods to be limited are high-protein foods (meat, fish, poultry, eggs, legumes, nuts) because they are also high in phosphorus
- Take calcium and vitamin D supplements together preferably with meals
- Regular follow-up is needed to prevent hypercalcemia from the increased calcium and vitamin D
- Report signs of vitamin D toxicity: dry mouth, N&V, metallic taste, or constipation
- Report signs of hypercalcemia: urinary frequency, thirst, slow mentation, fatigue, and muscle weakness
- Report signs of hypocalcemia

HYPERPARATHYROIDISM

- Hyperparathyroidism is a disorder of calcium metabolism due to overproduction of parathyroid hormone.
- It is found most often in clients over age 50.

- It is characterized by increased resorption of calcium from bone and in renal tubules; increased absorption from the intestine; increased urinary excretion of phosphorus.
- Resultant hypercalcemia decreases neuromuscular excitability and calcium is deposited in tissues throughout the body.

Etiology:

- Primary disease: enlargement and increased secretion of one or more glands due to adenoma or other cause
- Secondary disease: compensatory response of normal glands to mild long-term hypocalcemia from problems such as vitamin D or calcium deficiency, elevated serum phosphate, malabsorption, chronic renal failure, or pregnancy

S&S: Fatigue, malaise, lethargy, muscle weakness, memory lapses, poor concentration, depression from slowed nerve impulse transmission; abdominal pain, N&V, constipation from decreased peristalsis; renal calculi from precipitation of calcium; metabolic acidosis, bradycardia, hypertension, osteoporosis, and renal calculi.

Assessment Alert

The client in acute hypercalcemic crisis can progress from the symptoms above to severe dehydration, coma, cardiac dysrhythmia, and cardiac arrest.

Dx: Elevated serum PTH and serum calcium; decreased serum phosphorus.

Rx: Subtotal parathyroidectomy.

Nursing Process Elements

- See parathyroidectomy in Chapter 18
- Hypercalcemic crisis:
 - Monitor VS, CVP, and output hourly while administering high-volume IV normal saline (NS)
 - Administer medications to lower serum calcium
 - Assess for early signs of hypocalcemia, which are indicative of overtreatment

ADRENAL GLAND HYPOFUNCTION (ADDISON'S DISEASE)

- Production of adrenocortical steroids may decrease as a result of inadequate secretion of adrenocorticotropic hormone (ACTH).
- This decrease may also result from a dysfunction of the hypothalamic–pituitary control mechanism.

- Insufficient secretion of ACTH causes decreases in aldosterone and cortisol secretion from the adrenal gland.
- Manifestations may develop gradually or quickly with stress and life-threatening manifestations may appear without warning.

Etiology:

- Adrenal cortex function is inadequate to meet the physiological need for cortical hormones.
- Can be the result of malfunction anywhere along the hypothalamic–pituitary adrenal axis.
- Called primary when problem is with the adrenal glands themselves.
- Autoimmune or idiopathic atrophy of the adrenal glands is responsible for 80% of the cases.
- Infection or surgical removal of the glands.
 - Tuberculosis and histoplasmosis are the most common infections
- Hemorrhage into the gland from trauma or a prolonged, difficult delivery.
- Therapeutic use of corticosteroids or abrupt cessation of exogenous adrenocortical hormone therapy results in temporary or permanent adrenal insufficiency.

S&S:

- Muscle weakness, fatigue, and dark skin pigmentation, especially of the knuckles, knees, and elbows
- Hypoglycemia, hyponatremia, and hyperkalemia
 - Sweating, tachycardia, and tremors
 - Postural hypotension, and dysrhythmias
- Depression and apathy from glucocorticoid deficiency are frequent
- In severe cases, the disturbance of sodium and potassium metabolism may be marked by depletion of water and severe dehydration: decreased weight, increased BUN, increased Hct, decreased skin turgor, and hypovolemic shock

Assessment Alert

With primary disease, ACTH level is high in an effort to compensate for the insufficient amount of hormones in the body and this results in a concomitant increase of melanin-stimulating hormone and the marked bronzy discoloration of the skin. Clients with primary disease are mineralcorticoid deficient; those with secondary disease are not. Deficiency of aldosterone, the major mineralcorticoid, causes major loss of sodium and water and retention of potassium. Deficiency of glucocorticoids causes a milder effect.

Addisonian Crisis

- Addisonian crisis is the most severe form of the disorder as the disease progresses, commonly as a result of a stressful event (surgery, trauma, or severe infection).
 - Cyanosis and the classic signs of circulatory shock
 - Pallor, apprehension, rapid and weak pulse, rapid respirations, low BP, confusion, and restlessness
- If left untreated, may eventually lead to death
- **PEDS** In the neonate: hyperpyrexia, tachypnea, cyanosis, seizures and if due to hemorrhage into the gland, palpable retroperitoneal mass

Dx:

- Low levels of serum cortisol
- Low- fasting serum glucose and serum sodium
- Elevated serum potassium and ACTH
- ACTH stimulation test is the most definitive test for primary disease: plasma cortisol levels do not rise after administration of ACTH
- Head CT and MRI may help to determine if a pituitary problem is responsible for the adrenal insufficiency, or if atrophy of the adrenal gland is present

Rx:

- Immediate treatment is directed toward combating circulatory shock.
 - Restoring blood circulation, administering fluids and corticosteroids, and monitoring VS
 - Hydrocortisone (Solu-Cortef) IV followed with 5% dextrose in NS
 - Vasopressor amines if hypotension persists
 - Antibiotics if infection is the precipitator
- Lifelong replacement of corticosteroids (Hycort); for primary disease, replacement of mineralocorticoids (Florinef) is also needed to prevent reoccurrence
- Different schedules of daily dosing are used and there is no agreement on which is best; often two-thirds of the dose is given in the morning and one-third at night; alternatively three doses per day may be given to more closely mimic the normal diurnal rhythm
- Additional supplementary therapy with glucocorticoids during stressful events: for minor stress, the glucocorticoid dose is generally doubled; for major stress 200 mg/d is given in divided doses and then tapered as recovery occurs

Nursing Process Elements

Assessment Alert

With adrenal crisis, assessing for changes in mental status due to hyponatremia and respiratory depression is critical. EKG monitoring with hyperkalemia.

- Interventions to promote fluid balance and monitor for fluid deficit
 - Weigh daily, record I&O
- Assess VS every 1–4 hours
 - Depending upon client status and presence of dysrhythmias or postural hypotension
 - Kayexalate may be needed if severe hyperkalemia is present
- Monitor blood glucose levels every 4 hours for hypoglycemia.
- Monitor effects of replacement medication effects
 - Generally divided doses are given, with two-thirds in the morning and one-third in the late afternoon
- Manage activity intolerance with gradual increases in self-care activities
- Alert client to strategies to minimize anxiety and stress

Client teaching for self-care

- Wear Medic-Alert with the name of disease, medications, doses, and physician
- Always carry medication with you when traveling and be sure to bring extra doses in case of unexpected need
- Never skip a dose of medication; take parenteral form of medication if unable to take oral
- Increase dose of glucocorticoid as directed when minor stresses occur such as personal or family issues, accidents, dental work, or infection
- Report signs of inadequate dosing immediately: anorexia, N&V, weakness, depression, dizziness, polyuria, or weight loss. Report signs of overmedication immediately: rapid weight gain, round face, edema, or hypertension
- Maintain a regular schedule of eating, sleeping, and exercising
- Maintain a fluid intake of at least 2 l/d unless contraindicated
- Eat a diet with normal amounts of sodium; increase sodium, if diaphoresis is expected

EXCESS ADRENAL CORTICAL HORMONES

- Cushing's syndrome results from excess circulating glucocorticoids.
- Hyperaldosteronism results from excess circulating mineralcorticoids.

Cushing's Syndrome

Etiology:

- Use of corticosteroid medications is a common cause.

Nursing Intervention Alert

When symptoms are due to steroid therapy, administering the drug early in the day or on alternate days can decrease symptoms.

- Excessive corticosteroid production by the adrenal cortex (less frequently cause)
- A tumor of the pituitary gland that produces ACTH and stimulates the adrenal cortex.
- Regardless of the cause, the normal feedback mechanisms that control the function of the adrenal cortex become ineffective and the pattern of cortisol control is lost.
- Manifestations are usually a result of oversecretion of glucocorticoids and androgens (sex hormones), although mineralcorticoid secretion also may be affected.
- Women 20–40 years are five times more likely to develop Cushing's syndrome.

S&S:

- Changes in physical appearance are the classic signs —"Moon face," central obesity, "buffalo hump" in the neck, heavy trunk, and thin extremities
- Thin, fragile skin with development of ecchymoses, petechiae, red cheeks, and striae
- Excessive protein catabolism produces muscle wasting and osteoporosis, which leads to vertebral compression fractures, kyphosis, backache, and retarded linear growth in children
- Retention of sodium and water occurs producing hypertension and heart failure
- Increased susceptibility to infection, hyperglycemia, and poor wound healing
- Decreased inflammatory response
- Renal calculi
- Peptic ulcer
- If Cushing's syndrome is from a pituitary tumor, visual disturbances may occur because of pressure on the optic chiasm
- Virilization: hirsutism, acne, deepening of the voice, clitoral enlargement, and tendency to a male body shape in females
- Amenorrhea
- Impotence
- Psychological effects: irritability, insomnia, euphoria, depression, and psychosis

Dx:

- Indicators of Cushing's syndrome include an increase in serum sodium and blood glucose levels and a decrease in serum concentration of potassium, eosinophils, and lymphoid tissue.

- Elevated serum cortisol levels are present in clients with hypercortisolism.
- An overnight dexamethasone suppression test is the most widely used screening test.
 - Dexamethasone: 1 mg is administered orally at 11 p.m. and a plasma cortisol level is obtained at 8 a.m. the next morning
 - Suppression of cortisol to less than 5 mg/dl indicates that the hypothalamic–pituitary axis is functioning properly.
- 24-hour urinary free cortisol level is elevated.
- CT, MRI, and angiography may identify lesions of the adrenal or pituitary glands.

Rx:

- Goals of treatment are the reduction of plasma cortisol levels, removal of tumors, prevention of complications, and restoration of normal or acceptable body appearance.
 - Nonsurgical management
 - Radiation therapy if hypercortisolism is caused by a pituitary adenoma
 - Drugs that interfere with adrenocorticotropic hormone production: mitotane (Lysodren), Aminoglutethimide (Cytradren)
 - Surgical management
 - Hypophysectomy (removal of the pituitary gland) if caused due to pituitary adenoma
 - Transsphenoidal approach is usually used
 - Adrenalectomy (removal of the adrenal gland) if cause is an adrenal tumor

**Nursing Process Elements****Assessment Alert**

Clients with Cushing's syndrome are at risk for carbohydrate intolerance or frank DM.

- Monitor for electrolyte imbalances, hyperglycemia, and opportunistic infections
 - Common signs of infection may be masked by the anti-inflammatory effects of corticosteroid production.
- Provide a diet low in sodium, high in potassium, limited in calories and with increased amounts of calcium and vitamin D
- Provide measures to prevent skin breakdown
 - Use lift sheet to avoid skin tears and shearing
- Assist the client in avoiding pathologic fractures
 - Use of assistive devices if needed
- Monitor and manage potential for Addisonian crisis, which can result from withdrawal of exogenous

corticosteroids, adrenalectomy, or by removing a pituitary tumor

**Client teaching for self-care**

- Advise the client to avoid caffeine and alcohol, which increase risk of GI ulcers and bone density loss
- Lifelong ACTH replacements are needed if adrenal or pituitary gland is removed
- Need to consult with health care provider to adjust doses of replacement hormones when periods of marked physical or emotional stress occur
- Importance of wearing a Medic-Alert

PHEOCHROMOCYTOMA

- Catecholamine-producing tumor of the adrenal medulla and sympathetic ganglia
- Main catecholamine produced is norepinephrine.
- Most are within the adrenal gland but can be extra-adrenal as well.
- Most are benign but if untreated can be fatal.

S&S: Labile hypertension, which may be resistant to control with unusual treatment; palpitations; pallor; profuse generalized perspiration; paroxysmal pulsing headaches, chest and abdomen pain, orthostatic hypotension, hypoglycemia, and hypercalcemia. Episodes of symptomatology may be spontaneous or associated with activities that increase intra-abdominal pressure or by diagnostic tests or anesthesia. Arrhythmias and stroke are risks.

Dx: Screening test: 24-hour urine total metanephrines.

**Nursing Intervention Alert**

Urine collection for 24 hour; urine total metanephrines should start at the beginning of a hypertensive episode.

MRI or CT imaging of adrenals and abdomen

Rx: Laparoscopic surgical removal of the tumor. Catecholamine blockade with the alpha-adrenergic blocker phenoxybenzamine started 2 weeks prior to surgery followed by beta-blockers. Metyrosine (Demser) also may be given to decrease catecholamine content of the tumor and thereby decrease blood loss and the amount of vasoactive medication needed to control BP during surgery.

Catecholamine levels return to normal in 6 weeks in most clients and normal life activities are resumed.

Nursing Process Elements

Assessment Alert

Abdominal palpation can precipitate a hypertensive episode.

- During hypertensive crisis, client should be in ICU to allow for needed cardiac, BP, and neurological monitoring
- Manage postoperative pain because untreated it can cause hypertension
- Avoid activities that increase intra-abdominal pressure

Client teaching for self-care

- Self BP measurement
- Avoidance of precipitating factors: straining at stool, bending, lifting, etc.
- Importance of a Medic-Alert bracelet

DIABETES MELLITUS (DM)

- DM is a metabolic disorder characterized by elevated levels of glucose in the blood as a result of a defect in insulin secretion, insulin action, or both.
- Type 1 diabetes
 - Formerly referred to as insulin-dependent diabetes or juvenile diabetes.
 - Insulin-producing pancreatic beta cells are destroyed by an autoimmune process.
 - The beta cells produce little or no insulin. People with type 1 diabetes, therefore, require an exogenous form of insulin (injections or inhaled form) in addition to diet and exercise to control blood glucose levels.
- Type 2 diabetes
 - Formerly referred to as non-insulindependent DM or maturity onset diabetes.
 - Results from decreased sensitivity to insulin (called insulin resistance) and impaired beta cell functioning results in decreased insulin production.
 - Standard, cornerstone treatment is diet and exercise.
 - May be supplemented with an oral hypoglycemic agent.
 - Insulin injections may be required during periods of acute stress (physiological or psychological), which can markedly increase blood sugar levels and compromise control of the diabetes.
 - Insulin is usually used to control type 2 diabetes during periods of hospitalization for either uncontrolled diabetes or concomitant illness.

Incidence/Prevalence

- Affects 20 million people, 5.9 million (approximately 1/3) of whom are undiagnosed.
- Type 2 diabetes is especially prevalent in the elderly, with up to 50% of people older than 65 years of age suffering some form of glucose intolerance.
 - Type 2 diabetes occurs more frequently among people who are older than 40 years of age and obese.
 - Recently, there has been an increased incidence of type 2 diabetes in children and adolescents, as a result of the high incidence of obesity in this population.
- Minority groups share a disproportionate burden of diabetes compared to nonminority groups.
- Non-Hispanic black women have the highest incidence of diabetes.
- Hispanic people also have very high incidence.
- Native American population has very high incidence as well.

Etiology:

Genetic predisposition for both type 1 and type 2

- Type 1 diabetes is thought to be the result of an autoimmune response following viral infection.
- Type 2 diabetes occurs as a result of a variety of risk factors including obesity, sedentary life style, increasing age, past history of gestational diabetes, past history of glucose intolerance, and ethnicity.

Pathophysiology

- Type 1
 - Genetic, immunologic, and possibly environmental factors contribute to beta cell destruction in the pancreas.
 - Results in decreased insulin production, unchecked glucose production by the liver, which in turn results in a fasting hyperglycemia.
 - Glucose derived from food cannot be utilized for energy and metabolic processes without insulin, causing it to remain in the bloodstream and contribute to postprandial (after meals) hyperglycemia.
 - Increased levels of sugar in the blood cause fluids to be pulled from the intracellular and interstitial spaces into the bloodstream or vascular space (osmosis). Once this extra fluid circulating in the bloodstream reaches the kidneys, diuresis occurs as the kidneys try to maintain normal fluid volume; hence the term “osmotic diuresis.” The urine takes with it some of the excess sugar (glucosuria) as well as electrolytes. This can result in profound dehydration and electrolyte imbalance.
 - Insulin normally inhibits glycogenolysis (breakdown of stored glucose) and gluconeogenesis (production of new glucose from amino acids). With defective insulin

production or action, both occur in an unrestrained fashion and further contribute to hyperglycemia

—Since the body is unable to utilize carbohydrates or sugar for energy, it resorts to breaking down fats, proteins, and body fat for energy; the by-product of which is ketones. This accounts for the ketoacidosis associated most commonly with type 1 diabetes.

- TYPE 2

—The main problems associated with type 2 diabetes are insulin resistance and impaired insulin secretion.

—The body attempts to counteract the effects of insulin resistance by secreting increased amounts of insulin in an effort to keep blood sugar levels near normal.

- When the beta cells can not keep up with this increased demand for insulin, clinical symptoms of type 2 diabetes occur.

—There is usually enough insulin present to prevent the breakdown of fats and proteins. As a result unless the client is experiencing some type of physiological or severe psychosocial stress that demands increased amounts of energy, ketoacidosis does not occur.

—Ketoacidosis may occur when infection, dental problems, or other medical conditions that require increased energy production are present. If quantity or effectiveness of insulin is insufficient to meet these energy demands through metabolism of carbohydrates, proteins and fats are used for energy.

S&S:

- Onset of S&S

—Abrupt in type 1 diabetes since there is very little insulin present

—Insidious in type 2, a contributing factor to the high number of undiagnosed people living with type 2 diabetes

- Development of the 3 Ps

—Polyuria (increased urination): This is the result of osmotic diuresis.

—Polydipsia (increased thirst): This is the result of the dehydration that occurs as a result of diuresis.

—Polyphagia (increased appetite): Result of decreased satiety (inability to metabolize carbohydrates for energy).

- Other symptoms: fatigue, weakness, vision changes, tingling in hands or feet, dry skin, and wounds that are slow to heal

Dx:

- Symptoms of diabetes

OR

- Fasting plasma glucose levels of 126 mg/dl or more and random plasma glucose levels exceeding 200 mg/dl

OR

- 2-hour postload glucose equal to or greater than 200 mg/dl on a Glucose Tolerance Test (GTT) using 75 g of anhydrous glucose dissolved in water

—2-hour GTT is not routinely performed if a fasting plasma glucose of 126 mg/dl or more or random sugar of greater than 200 mg/dl is established because these are diagnostic.

Rx:

Treatment goals:

- Normalize insulin activity and blood glucose levels to reduce the development of vascular and neuropathic complications

—Achieve normal glucose levels without hypoglycemia and without disrupting the client's normal lifestyle

—Research indicates that maintaining glycemic control can reduce the incidence of complications as much as 50%

- Minimize likelihood of complications that include

—Retinopathy: vascular changes in the retina which if untreated may lead to blindness

—Neuropathy

- Peripheral neuropathy that results in loss of sensation, pain, burning in extremities beginning with toes/fingers, and working its way up

- Autonomic neuropathy that results in loss of nervous innervation to vital organs such as the cardiovascular system and gastrointestinal tract

—Renal failure from changes in microvasculature of kidneys, which results in need for dialysis or transplant

—Amputation can be required as a result of vascular changes and decreased blood flow to the lower extremities, or sores and infections that do not respond to therapies

—Cardiovascular disease: higher incidence of stroke and heart disease in people with diabetes

- Client education in diabetes self-management: Diabetes is a condition that requires that the clients take an active role in managing their disease. Clients make day-to-day choices regarding behaviors that influence their blood sugars or glycemic control. As such, clients must be knowledgeable about their condition, the factors that influence changes in blood sugar, and be able to make informed decisions regarding their illness. The role of the nurse is to facilitate education and promote autonomy in clients with diabetes. The American Diabetes Association standards for education include teaching the client about:

—Diet/nutrition

—Exercise

—Complications: acute and long-term

- Acute-hypo/hyperglycemia

- Long-term heart disease, stroke, renal failure, or blindness

—Blood glucose monitoring

—Stress management/social support

—Pharmacological therapies

- Care during periods of illness
- Traveling with diabetes
- Follow-up resources
- Nutrition
 - Primary goal of nutrition therapy is to control blood sugar.
 - Secondary goal may include weight loss and maintenance (particularly in type 2).
 - Higher distribution of calories in carbohydrates than fats and proteins (consistent with food pyramid).
 - 50–60% carbohydrates
 - 20–30% fats
 - 10–20% proteins
 - Exchange lists provide information on serving size and categories of foods so that patients may enjoy a variety of foods by “exchanging” those within each food group.
 - For example, one slice of bread is equal to one serving or 15 gm of carbohydrates or one serving of carbohydrates; three squares of graham crackers are also equal to 15 gm or one serving of carbohydrate, so that patients may “exchange” i.e. choose either a slice of bread; or three squares of graham crackers as one of their carbohydrate servings based on personal preference.
 - The same holds true for proteins, fats, fruits, milk, and vegetables.
 - The number of servings of each group that a patient is allowed is based on the recommendations set forth by the US government food pyramid as well as the total number of calories the patient is prescribed daily.
 - So, while a patient on a 2500-calorie diet is permitted 11 servings of starch and 8 servings of meat daily, a patient on a 1200-calorie diet would be allowed only 5 servings of starch and 4 servings of meat.
 - The primary goal in diet therapy is to attain glycemic control, secondary goals may be related to body weight.
 - Carbohydrate counting; measuring the total grams of carbohydrate contained in a food; 15 grams of carbohydrate is equal to 1 starch (carb) exchange. This provides increased freedom of choices. Also, clients using insulin therapy may be taught to calculate insulin dose based on the number of carbohydrates to be consumed. Commonly, 1 unit of regular or short-acting insulin will cover 1 carbohydrate (15 grams). This is modified based on individual client response.
 - Clients are encouraged to choose foods with lower glycemic index (foods that take longer to break down to sugar in the body), e.g., select whole grains over products containing white flour.
- Exercise
 - Lowers the blood glucose level by increasing the uptake of glucose by body muscles and improving insulin utilization.
 - Clients should not begin exercising if glucose is above 250mg/dl and ketones are present in the urine.
 - Clients are encouraged to exercise daily at the same time, using the same type of activity if exercise is used to control blood sugar.
 - Exercise also may be used as a method to control weight.
 - Because there is a strong relationship between diabetes and heart disease, clients must be cautioned to consult their primary care providers before beginning an exercise program.
 - Clients should be encouraged to monitor blood sugar before, during, and after exercise particularly if there is a potential for hypoglycemia (particularly so for clients using insulin therapy and sulfonylurea treatment).
 - Clients should be encouraged to exercise with a “buddy” who knows about their diabetes and is aware of methods to treat hypoglycemia.
- Monitoring glucose levels
 - Self-monitoring of blood glucose
 - Two to four times daily if insulin is required.
 - Three times daily if insulin is required before all meals.
 - Two to three times per week if insulin is not required, including one test that is done after meals (2 hours is suggested time).
 - Whenever hypoglycemia or hyperglycemia is suspected.
 - Increase frequency of testing with changes in medications, activity, or diet and with stress or illness.

Clinical Alert

Ketone bodies in the urine indicate that control of type 1 diabetes is deteriorating and the risk of diabetic ketoacidosis (DKA) is high.

- Glycosylated hemoglobin (HgbA1c)
 - HgbA1c contains glucose molecules, which attach to red blood cells; RBCs live in body for 2–3 months; therefore, the HgbA1c reflects the average blood glucose level over 2–3 months.
 - Normal ranges are usually 4–6% and indicate an almost normal blood glucose control.
 - Levels over seven would indicate less than optimal control, putting the client at risk for complications.
- Research indicates that every decline of one in HgbA1c produces up to a 40% risk reduction; for example decrease in level from 8 to 7.
- Clients are encouraged to know their values and plan care with the goal of achieving an HgbA1c as close to normal as possible.

- Pharmacological therapy
 - Rapid-acting insulin: for rapid reduction of glucose before a meal; in some cases taken after meals, e.g., clients with a history of N&V may wait to see if meal is retained
 - Humalog/Novolog
 - Onset; 10–15 minutes
 - Peak; 1 hour
 - Duration; 3 hours
 - Short-acting insulin: taken 20–30 minutes before a meal
 - Humalog R/Novolog R
 - Onset; 1 hour
 - Peak; 2–3 hours
 - Duration; 4–6 hours
 - Intermediate-acting insulin: taken after food
 - NPH/Humulin N/Lente/Novolin L
 - Onset; 2–4 hours
 - Peak; 6–12 hours
 - Duration; 16–20 hours
 - Long-acting insulin: controls fasting glucose level
 - Ultralente
 - Onset; 6–8 hours
 - Peak; 12–16 hours
 - Duration; 20–30 hours
 - Very long-acting insulin: used for basal dose
 - Lantus
 - Onset; 1 hour
 - Peak; continuous, very little peak
 - Duration; 24 hours
 - Note: Lantus may not be mixed in same syringe with any other insulin
 - Inhaled insulin: short-acting form, does not come in long-acting form
 - Exubera
 - Used only in absence of lung disease.
 - No history of smoking for at least 6 months prior to beginning therapy.
 - Pulmonary function tests must be monitored.
 - Insulin therapy complications
 - Systemic allergic reactions
 - Insulin lipodystrophy; loss of subcutaneous adipose tissue or development of fibrotic tissue in areas of injection—seen less frequently in younger patients since use of human insulin minimizes development, also minimized by site rotation
 - Insulin resistance
 - Morning hyperglycemia
 - Insulin waning
 - Increase evening dose of intermediate or long-acting insulin
- Dawn phenomenon—result of normal nighttime release of hormones, which are counterregulatory to insulin and cause an increase in blood sugar level
 - Change time of injection of evening intermediate-acting insulin from dinnertime to bedtime
- Somogyi effect—result of medications acting at the wrong time, blood sugar drops during night, liver attempts to correct hypoglycemia and client arises with high blood sugar levels
 - Decrease evening dose of intermediate-acting insulin
 - Snack before bedtime
- Oral antidiabetic agents, used in addition to other treatment modalities in type 2 diabetes.
 - Sulfonylureas
 - Glucotrol
 - Diabeta
 - Amaryl
 - Increase insulin secretion
 - As a result, side effects include weight gain and hypoglycemia
 - Biguanides
 - Glucophage; Metformin
 - Insulin sensitizer does not cause hypoglycemia
 - Some clients lose weight
 - GI side effects are usually self-limiting to 2 weeks
 - Lactic acidosis rare but requires client teaching
 - Alpha glucosidase inhibitors
 - Acarbose and glycot
 - Inhibit glucose absorption
 - Major deterrent severe flatulence
 - Thiazolidinediones
 - Avandia: recent research indicates high incidence of MI in clients using this drug
 - Actos
 - Insulin sensitizers
 - Liver enzymes must be monitored
 - Delayed onset of action: 2 weeks
 - Meglitinides
 - Prandin
 - Starlix
 - Insulin secretagogues
 - Used to control postprandial rises in blood sugar
 - Taken with first bite of food at each meal
 - Alternate insulin delivery methods
 - Insulin pens, injectors, and pumps
 - Insulin pumps can
 - deliver a premeal dose of insulin before each meal;
 - deliver a varying hourly basal rate of insulin;

- deliver a dose of insulin based on a pre-programmed insulin to carbohydrate ratio; and
- monitor blood sugar levels at preset intervals
- Implantable and inhalant insulin delivery

Nursing Process Elements

- Education is the ongoing focus of care to aid clients in mastering the concepts and skills necessary for long-term management of diabetes and its potential complications.
- Recognize that NPO status requires adjustments in usual insulin regimens:
 - Eliminating insulin for type 1 diabetes may lead to DKA; eliminating insulin for type 2 is safer
 - Question regarding continuing administration of oral hypoglycemic agents even when NPO
- Monitor for and manage episodes of hypoglycemia:
 - Symptoms are shakiness, sweating, hunger, and weakness, which are caused by too much insulin, exercise, or not enough food.
 - Treat with 15 g concentrated carbohydrate such as two to three glucose tablets, half cup juice, 8-oz skim milk
 - Follow with snack such as cheese or milk and crackers.
 - Clients at risk for hypoglycemia should be instructed to always carry some form of simple carbohydrate with them such as glucose tabs, lifesavers or other candies, crackers, or juice.
 - Significant others of those clients receiving insulin therapy must be instructed on the administration of glucagon in the event of severe hypoglycemia where the patient is unable to ingest oral forms of glucose.
- Monitor for and manage DKA, which is a consequence of severe insulin deficiency in the adipose tissue, liver, and skeletal muscle.
 - Symptoms are hyperglycemia (300–800 mg/dl), signs of dehydration, electrolyte loss, and ultimately acidosis: N&V, abdominal pain, acetone breath (fruity odor), hyperventilation (Kussmaul respirations), and mental status changes caused by absence or markedly inadequate amount of insulin.
 - Treat with IV regular insulin, rehydration with NS at 500 ml/hr for 1 hour and then 250 ml/hr, electrolyte restoration (IV K⁺ if serum level is less than 3.5 mEq/l once renal output is established) and acidosis reversal to arterial pH of 7.0 or greater.
- Monitor for and manage hyperglycemic hyperosmolar nonketotic coma which is an acute complication of type 2 DM
- Symptoms are similar to those of DKA except dehydration is profound; serum glucose ranges from 600 to 2000 mg/dl; serum osmolarity is 350 mOsm/l or higher; ketosis

is absent because some insulin is available; thirst perception is usually impaired by some problem; and another illness generally exists; polyuria disappears early; and lethargy and somnolence may be present.

- Treat with hypotonic (0.45% NS) IV and correct precipitating disease; insulin usually not required.

Client teaching for self-care

- Reinforce information and instructions related to daily schedule, diet, exercise, blood glucose monitoring, stress management, and lifestyle changes
- Self-administration of insulin
 - Use correct type and amount of insulin
 - Rotate sites
 - Roll bottle to mix before drawing up
 - Use opened bottles within 30 days
 - Keep refrigerated or at room temperature
 - Rapid- or short-acting forms of insulin can be given simultaneously with longer-acting insulins; mix together in the same syringe, drawing the regular insulin first
- Foot and leg care
 - Thoroughly dry and lubricate feet, no water or lotion between toes
 - Never go barefoot
 - Wear closed-toe shoes, with extra cushioning for bony prominences
 - Trim toenails straight across
 - Avoid walking barefooted, using heating pads on feet or shaving-toe calluses
 - Inspect feet daily for open areas and sores
 - Ask physician or nurse practitioner to examine feet at each office visit
 - Yearly examination by podiatrist
 - Goal: early detection of neuropathy and lesions
- Prevention/early detection of renal disease
 - Screen urine for microalbuminuria, which is an early sign of kidney disease that occurs when small particles of protein are leaking into urine.
 - Clients should be instructed to question provider if microalbuminuria is present.
 - Importance of taking angiotensin-converting enzyme (ACE) inhibitors as prescribed because of their protective effect on the kidneys, which can reverse and/or slow progression of kidney disease.
- Prevention/early detection of eye disease
 - Obtain a dilated eye exam at least annually to detect early signs of retinopathy; eye exam also allows detection of cataracts and macular degeneration for which diabetic clients are at high risk.

- Dental care
 - See dentist at least twice annually because diabetes increases risk of dental problems and conditions such as an abscess can cause blood sugar to rise.

Client teaching for self-care

- Diagnostic criteria:
 - Fasting Blood Sugar (FBS): 100–126 mg/dl or
 - Oral Glucose Tolerance Test (OGTT): 140–200 mg/dl
- Early detection and treatment may prevent or delay onset of type 2 diabetes in more than 50% of clients
- Treatment consists of lifestyle changes including incorporation of diet and exercise
- Diabetic emergencies
 - DKA
 - Life-threatening condition that occurs as a result of severe insulin deficiency
 - Occurs primarily in type 1 diabetes
 - Clinical manifestations
 - Elevation in blood glucose levels typically between 300–800 mg/dl
 - Decreased pH of blood
 - Ketonuria
 - Electrolyte imbalance
 - Dehydration
- Treatment
 - Rehydration: Restore circulating fluid volume initiated with NS until blood sugar levels reach 250–300 mg/dl at which point the client is typically switched to a solution containing dextrose such D5W or D5NS.
 - Insulin: Regular insulin is administered IV to treat hyperglycemia
 - IV insulin administration will continue until the client is stabilized and subcutaneous administration can be resumed
 - Blood sugar levels are monitored closely sometimes at least hourly until stabilized
 - Potassium levels may be compromised due to dehydration so should be monitored frequently to assess for the need for replacement.
- Hyperglycemic hyperosmolar nonketotic syndrome (HHNS)
 - Extreme hyperglycemia occurring without ketosis
 - Occurs most frequently in clients with type 2 diabetes
 - May occur rapidly or slowly over period of days
 - May occur in individuals with subclinical type 2 diabetes, undiagnosed who are further compromised by the onset of a concurrent illness or condition
 - Clinical manifestations
 - Hyperglycemia manifested in blood glucose levels of 600–1200 mg/dl.
 - Dehydration: often profound resulting in hypotension and compensatory tachycardia
 - Change in mental status
 - Neurological manifestations, coma, and death if not corrected
- Treatment
 - Fluid replacement with NS; and then dextrose solution levels once reach 250–300 mg/dl
 - IV insulin to treat hyperglycemia
 - Monitor electrolyte status/replacement as indicated
 - Monitor mental/neurologic status
 - Monitor VS
 - Rehydration is key in both ketoacidosis and HHNS

WORKSHEET

MATCHING QUESTIONS

Match the following:

Column A

1. ____ Addison's disease
2. ____ Myxedema coma
3. ____ Thyroid cancer

Column B

- a. Insulin resistance
- b. Graves' disease
- c. Extreme stage of hypothyroidism

- | | |
|------------------------------|---|
| 4. ____ GH deficiency | d. Characterized by elevated serum calcium and decreased serum phosphorus |
| 5. ____ Pheochromocytoma | e. May be precipitated by hypomagnesemia |
| 6. ____ Hyperthyroidism | f. Classic presenting sign is labile hypertension |
| 7. ____ Type 1 DM | g. Only occurs prior to closure of epiphyses |
| 8. ____ Acromegaly | h. Growth deceleration is characteristic of the juvenile form |
| 9. ____ DI | i. Characterized by horizontal growth |
| 10. ____ Hypoparathyroidism | j. May be iatrogenic secondary to use of Prednisone |
| 11. ____ Hypoglycemia | k. Lack of insulin due to beta cell destruction |
| 12. ____ DKA | l. Manifests in the neonate with hyperpyrexia, tachypnea, and seizures |
| 13. ____ SIADH | m. Signs include acetone breath and Kussmaul's respirations |
| 14. ____ Cushing's syndrome | n. Cold nodule |
| 15. ____ Hypothyroidism | o. Short stature is the usual presenting complaint |
| 16. ____ Gigantism | p. Signs predominantly the result of excessive glucocorticoids and androgens |
| 17. ____ Thyroid storm | q. Can be a transient event after transsphenoidal pituitary surgery |
| 18. ____ Type 2 DM | r. Associated with malignancies such as opioids and small cell cancer of the lung |
| 19. ____ Hyperparathyroidism | s. Temperature may reach 105–106°F |
| 20. ____ Addisonian crisis | t. Precipitated by inadequate food intake |

MATCHING QUESTIONS

Match the following:

Column A: Drugs

Column B: Diseases

- | | |
|--------------------|----------------------------|
| 1. ____ Tapazole | a. Acromegaly |
| 2. ____ Exubera | b. DI |
| 3. ____ Avandia | c. DM |
| 4. ____ SSKI | d. Somatotropin deficiency |
| 5. ____ Glucophage | e. Nephrogenic DI |

| 9. ____ Levothyroxine | i. Hypoparathyroidism |
| 10. ____ Metyrosine | j. Addison's disease |
| 11. ____ Humalin | k. Cushing's disease |
| 12. ____ DDAVP | l. Pheochromocytoma |
| 13. ____ Vitamin D | m. SIADH |
| 14. ____ Sulfonylureas | |
| 15. ____ Thiazide diuretics | |
| 16. ____ Solu-Cortef | |
| 17. ____ Octreotide acetate | |
| 18. ____ Calcium gluconate | |
| 19. ____ GH | |
| 20. ____ Mitotane | |
| 21. ____ Aminoglutethimide | |
| 22. ____ Propylthiouracil | |
| 23. ____ Metformin | |
| 24. ____ Prandin | |
| 25. ____ Actos | |

FILL IN THE BLANK

Fill in the blank space with the correct word or phrase to complete each statement

1. The client is performing a return demonstration on preparing insulin. The morning dose of insulin is 10 units of regular and 22 units of NPH. The nurse determines that the client has prepared the correct dose when the syringe reads ____ units.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------|-------|
| 1. The alpha-adrenergic blocker phenoxybenzamine is started 2 weeks prior to surgery for a pheochromocytoma. | _____ | _____ |
| | T | F |
| 2. Abdominal palpation should be avoided in clients with a pheochromocytoma because it can precipitate a hypotensive episode. | _____ | _____ |
| | T | F |
| 3. Peripheral neuropathy is a potential complication of diabetes that places the client at risk for injury such as burns and falls. | _____ | _____ |
| | T | F |
| 4. Dental problems in the diabetic client have the potential to trigger ketoacidosis. | _____ | _____ |
| | T | F |
| 5. Tube feedings for a client with SIADH should be diluted with saline rather than water. | _____ | _____ |
| | T | F |

APPLICATION QUESTIONS

- When assessing a client with a PTH deficiency, the nurse would expect abnormal serum levels of which substances?
 - Sodium and chloride
 - Potassium and glucose
 - Urea and uric acid
 - Calcium and phosphorus
- When answering a client's question about the use of a RAIU test, on which fact should the nurse's answer be based?
 - RAIU increases in hyperthyroidism and decreases in hypothyroidism.
 - RAIU decreases in hyperthyroidism and increases in hypothyroidism.
 - RAIU increases in both secretion disorders of the thyroid gland.
 - RAIU decreases in both secretion disorders of the thyroid gland.
- When assessing a client diagnosed with Graves' disease, which finding would the nurse consider to be a hallmark of the disease?
 - Low specific gravity of urine
 - Heat intolerance
 - Hirsutism
 - Dulled mentation
- A client with a history of mitral valve replacement using long-term warfarin (Coumadin), is diagnosed with myxedema. When levothyroxine is prescribed, which other type of order should the nurse expect the physician to write?
 - Decrease in warfarin dosage
 - Protamine sulfate PRN
 - 2-weeks follow-up with radioactive iodine
 - Weekly APTT measures
- A client with thyroid cancer undergoes a thyroidectomy. After surgery, the client develops peripheral numbness, tingling, and muscle twitching. Which type of medication should the nurse be prepared to administer?
 - Thyroid supplement
 - Antispasmodic
 - Barbiturate
 - Calcium replacement
- A client with asthma develops Cushing's syndrome and tells the nurse she doesn't understand what could have caused the problem. The nurse's response would be based in part on the understanding that

(continued)

- Cushing's syndrome can develop as a complication from the chronic use of which medication?
- Theophylline
 - Prednisone
 - Alupent
 - Intal
7. Which action helps to combat the Dawn phenomenon in a client with DM?
- Eat a snack at bedtime
 - Inject evening intermediate-acting insulin at bedtime rather than dinnertime
 - Decrease evening dose of intermediate-acting insulin
 - Increase evening dose of long-acting insulin
8. A client recently diagnosed with type 1 diabetes is learning foot care. Which of the following responses by the client would indicate additional teaching is needed?
(Select all that apply.)
- "I will never go barefoot outside; only in my house is it permissible."
 - "My toenails need to be trimmed straight across."
 - "I will always wear socks and closed-toe shoes."
 - "I will inspect my feet every week for any sores or open areas."
9. When assessing a client during an acute episode of DI, on which problem would the nurse focus?
- Imbalanced nutrition
 - Deficient fluid volume
 - Ineffective coping
 - Risk for impaired skin integrity
10. When teaching a diabetic client about his insulin protocol, the nurse explains that intermediate-acting insulin should reach its "peak" in how many hours?
- 16–20 hours
 - 3–4 hours
 - 6–12 hours
 - 1–2 hours
11. When answering a client's question about insulin pumps and how they work, which information could appropriately be included in the nurse's response? Mark all that apply.
Insulin pumps can
- deliver a pre-meal dose of insulin before each meal.
 - deliver a varying hourly basal rate of insulin.
 - deliver a dose of insulin based on a preprogrammed insulin to carbohydrate ratio.
 - monitor blood sugar levels at preset intervals.
12. A diabetic client taking an oral antidiabetic agent asks if he will also need parenteral insulin therapy at times. The nurse's response would be based on the knowledge that parenteral insulin therapy will be temporarily substituted for oral antidiabetic agents if the diabetic
- develops an infection with fever.
 - suffers trauma.
 - undergoes major surgery.
 - all of the above.
13. In evaluating laboratory results, the nurse interprets which findings as indicative of DKA? Mark all that apply.
- ___ Increased blood pH
 - ___ Decreased total body potassium
 - ___ Elevated blood glucose
 - ___ Decreased serum bicarbonate level
14. A client with DM receives a prescription for an ACE inhibitor and asks what this drug will do for him. The nurse responds that the drug reduces changes in the blood vessels and may help delay the onset of which problem?
- Chronic obstructive pulmonary disease
 - Pancreatic cancer
 - Renal failure
 - Cerebral vascular accident
15. When teaching a diabetic client, which symptom should the nurse identify as most commonly indicative of hypoglycemia?
- Nervousness
 - Anorexia
 - Kussmaul's respirations
 - Bradycardia
16. A female client with type 1 DM is experiencing a minor flu-like illness with nausea, muscle aches, and low-grade fever. Which instruction should the nurse give her?
- Increase the frequency of glucose self-monitoring
 - Try to reduce food intake to diminish nausea
 - Do not take any insulin if she cannot eat
 - Take half of the normal dose of insulin
17. Which of the following is a priority nursing diagnosis for the diabetic client who is taking insulin and has N&V from a viral illness or influenza?
- Imbalanced nutrition; less than body requirements
 - Impaired health maintenance related to ineffective coping skills
 - Risk for acute pain
 - Activity intolerance

18. During a home visit, a diabetic client begins to cry and say, "I just cannot stand the thought of having to give myself a shot every day." Which would be the best response by the nurse?
- "If you do not give yourself your insulin shots, you will die."
 - "We can teach your daughter to give the shots so you will not have to do it."
 - "I can arrange to have a home care nurse give you the shots every day."
 - "What is it about giving yourself the insulin shots that bothers you?"
19. A client presents in the emergency room with DKA. Which nursing diagnosis would be the priority problem?
- Disturbed sleep pattern
 - Impaired health maintenance
 - Imbalanced nutrition; less than body requirements
 - Deficient fluid volume
20. Which of the following would the nurse include when developing a teaching plan for a newly diagnosed client with type 2 DM. (Select all that apply.)
- A major risk factor for complications is cigarette smoking.
 - Insulin is mandatory for controlling the disease.
 - Exercise increases insulin resistance.
 - The primary nutritional source requiring monitoring in the diet is carbohydrates.
 - Annual eye and foot examinations are recommended by the American Diabetes Association.
21. Which of the following would the nurse report for a client with unstable type 2 DM? (Select all that apply.)
- Systolic BP of 145 mmHg
 - Diastolic BP of 87 mmHg
 - HDL of 30 mg/dl
 - HgbA1c of 10.2%
 - Triglycerides of 425 mg/dl
 - Urinary ketones negative
22. When should the diabetic client who is taking insulin (Humalog) injections be advised to eat?
- Within 20 minutes after the injection
 - 1 hour after the injection
 - At any time, because timing of meals with Humalog is unnecessary
 - 2 hours before the injection
23. Teaching for a client beginning therapy with methimazole (Tapazole) would appropriately include which information? Mark all that apply.
- The effect of the treatment will be noticeable in 7–10 days.
 - Periodic RBC counts will be needed during therapy.
 - Any signs of infection need to be reported to the health care provider.
 - Dose of Tapazole will be tapered as normal thyroid status is attained.
24. A client is being treated for hypercalcemic crisis. Which assessment findings would the nurse interpret as indicating overtreatment of the problem? Mark all that apply.
- Decreased bowel sounds
 - Photophobia
 - Leg cramps
 - Positive Chvostek sign
 - Vomiting
 - Perioral numbness and tingling
 - Bradycardia

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following:

Column A

Column B

- | | |
|-------------------------------|-----------------------|
| 1. <u>j</u> Addison's disease | a. Insulin resistance |
| 2. <u>c</u> Myxedema coma | b. Graves' disease |

(continued)

- | | |
|----------------------------------|---|
| 3. <u>n</u> Thyroid cancer | c. Extreme stage of hypothyroidism |
| 4. <u>o</u> GH deficiency | d. Characterized by elevated serum calcium and decreased serum phosphorus |
| 5. <u>f</u> Pheochromocytoma | e. May be precipitated by hypomagnesemia |
| 6. <u>b</u> Hyperthyroidism | f. Classic presenting sign is labile hypertension |
| 7. <u>k</u> Type 1 DM | g. Only occurs prior to closure of epiphyses |
| 8. <u>i</u> Acromegaly | h. Growth deceleration is characteristic of the juvenile form |
| 9. <u>q</u> DI | i. Characterized by horizontal growth |
| 10. <u>e</u> Hypoparathyroidism | j. May be iatrogenic secondary to use of Prednisone |
| 11. <u>t</u> Hypoglycemia | l. Manifests in the neonate with hyperpyrexia, tachypnea, and seizures |
| 12. <u>m</u> DKA | k. Lack of insulin due to beta cell destruction |
| 13. <u>r</u> SIADH | m. Signs include acetone breath and Kussmaul's respirations |
| 14. <u>p</u> Cushing's syndrome | n. Cold nodule |
| 15. <u>h</u> Hypothyroidism | o. Short stature is the usual presenting complaint |
| 16. <u>g</u> Gigantism | p. Signs predominantly the result of excessive glucocorticoids and androgens |
| 17. <u>s</u> Thyroid storm | q. Can be a transient event after transsphenoidal pituitary surgery |
| 18. <u>a</u> Type 2 DM | r. Associated with malignancies such as opioids and small cell cancer of the lung |
| 19. <u>d</u> Hyperparathyroidism | s. Temperature may reach 105–106 degrees F |
| 20. <u>l</u> Addisonian crisis | t. Precipitated by inadequate food intake |

MATCHING ANSWERS

Match the following:

Column A: Drugs

Column B: Diseases

- | | |
|------------------------|----------------------------|
| 1. <u>f</u> Tapazole | a. Acromegaly |
| 2. <u>c</u> Exubera | b. DI |
| 3. <u>c</u> Avandia | c. DM |
| 4. <u>f</u> SSKI | d. Somatotropin deficiency |
| 5. <u>c</u> Glucophage | e. Nephrogenic DI |

- | | |
|---------------------------------|------------------------|
| 6. <u>m</u> Declomycin | f. Hyperthyroidism |
| 7. <u>c</u> Novolog | g. Hypothyroidism |
| 8. <u>c</u> Acarbose | h. Hyperparathyroidism |
| 9. <u>g</u> Levothyroxine | i. Hypoparathyroidism |
| 10. <u>l</u> Metyrosine | j. Addison's disease |
| 11. <u>c</u> Humalin | k. Cushing's disease |
| 12. <u>b</u> DDAVP | l. Pheochromocytoma |
| 13. <u>i</u> Vitamin D | m. SIADH |
| 14. <u>c</u> Sulfonylureas | |
| 15. <u>e</u> Thiazide diuretics | |
| 16. <u>j</u> Solu-Cortef | |
| 17. <u>a</u> Octreotide acetate | |
| 18. <u>i</u> Calcium gluconate | |
| 19. <u>d</u> GH | |
| 20. <u>k</u> Mitotane | |
| 21. <u>k</u> Aminoglutethimide | |
| 22. <u>f</u> Propylthiouracil | |
| 23. <u>c</u> Metformin | |
| 24. <u>c</u> Prandin | |
| 25. <u>c</u> Actos | |

ANSWER FOR FILL IN THE BLANK

Fill in the blank space with the correct word or phrase to complete the statement.

1. The client is performing a return demonstration on preparing insulin. The morning dose of insulin is 10 units of regular and 22 units of NPH. The nurse determines that the client has prepared the correct dose when the syringe reads 32 units.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. The alpha-adrenergic blocker phenoxybenzamine is started 2 weeks prior to surgery for a pheochromocytoma. *True*
2. Abdominal palpation should be avoided in clients with a pheochromocytoma because it can precipitate a hypotensive episode. *False*
Abdominal palpation should be avoided in clients with a pheochromocytoma because it can precipitate a hypertensive episode.
3. Peripheral neuropathy is a potential complication of diabetes, which places the client at risk for injury such as burns and falls. *True*
4. Dental problems in the diabetic client have the potential to trigger ketoacidosis. *True*
5. Tube feedings for a client with SIADH should be diluted with saline rather than water. *True*

APPLICATION ANSWERS

1. When assessing a client with a PTH deficiency, the nurse would expect abnormal serum levels of which substances?
 - a. Sodium and chloride
 - b. Potassium and glucose
 - c. Urea and uric acid.
 - d. Calcium and phosphorus

Rationale

Correct answer: d.

Decreased PTH reduces resorption of calcium from bone, reduces intestinal absorption of calcium, and reduces reabsorption of calcium in the renal tubules. At the same time, it increases retention of phosphate in the renal tubules. The net effect of these actions is that serum calcium is low and serum phosphate is high. Changes in serum sodium, chloride, potassium, glucose, urea, or uric acid are not direct effects of PTH deficiency.

2. When answering a client's question about the use of a RAIU test, on which fact should the nurse's answer be based?
 - a. RAIU increases in hyperthyroidism and decreases in hypothyroidism.
 - b. RAIU decreases in hyperthyroidism and increases in hypothyroidism.
 - c. RAIU increases in both secretion disorders of the thyroid gland.

- d. RAIU decreases in both secretion disorders of the thyroid gland.

Rationale

Correct answer: a.

The more active the thyroid gland is, the more iodide it concentrates. Thus in hyperthyroidism with its increase in thyroid activity, radioactive iodine is concentrated in the thyroid in above normal amounts. In hypothyroidism, with its decrease in thyroid activity, lower than normal amounts of radioactive iodine are picked up by the thyroid gland.

3. When assessing a client diagnosed with Graves' disease, which finding would the nurse consider to be a hallmark of the disease?
 - a. Low specific gravity of urine
 - b. Heat intolerance
 - c. Hirsutism
 - d. Dulled mentation

Rationale

Correct answer: b.

Heat intolerance with diaphoresis when environmental temperature is comfortable to others is a classic sign of hyperthyroidism or Graves' disease. Low specific gravity of urine is a classic sign of DI. Hirsutism accompanies hypersecretion of glucocorticoids from the adrenal glands. Dulled mentation is a sign of hypothyroidism.

4. A client with a history of mitral valve replacement using long-term warfarin (Coumadin), is diagnosed with myxedema. When levothyroxine is prescribed which other type of order should the nurse expect the physician to write?
- Decrease in warfarin dosage
 - Protamine sulfate PRN
 - 2-week follow-up with radioactive iodine
 - Weekly APTT measures

Rationale

Correct answer: a.

Levothyroxine interacts with anticoagulants including warfarin increasing available levels of active anticoagulant. As a result, dosage needs to be decreased to avoid bleeding problems. Protamine sulfate is an antidote for heparin. Follow-up with radioactive iodine is not done. APTT guides the dosage of heparin; INR guides the dosage of warfarin.

5. A client with thyroid cancer undergoes a thyroidectomy. After surgery, the client develops peripheral numbness, tingling, and muscle twitching. Which type of medication should the nurse be prepared to administer?
- Thyroid supplement
 - Antispasmodic
 - Barbiturate
 - Calcium replacement

Rationale

Correct answer: d.

The parathyroid glands can be unintentionally removed along with the thyroid gland. If this occurs, hypocalcemic tetany is a risk, the first signs of which include numbness and tingling in the extremities and muscle twitching. The treatment of hypocalcemic tetany is IV calcium gluconate or calcium carbonate, which should be readily available at the bedside.

6. A client with asthma develops Cushing's syndrome and tells the nurse she doesn't understand what could have caused the problem. The nurse's response would be based in part on the understanding that Cushing's syndrome can develop as a complication from the chronic use of which medication?
- Theophylline
 - Prednisone
 - Alupent
 - Intal

Rationale

Correct answer: b.

Prednisone is a corticosteroid and long-term use of corticosteroids is a common cause of Cushing's syndrome.

7. Which action helps to combat the Dawn phenomenon in a client with DM?
- Eat a snack at bedtime
 - Inject evening intermediate-acting insulin at bedtime rather than dinner time
 - Decrease evening dose of intermediate-acting insulin
 - Increase evening dose of long-acting insulin

Rationale

Correct answer: b.

Inject evening intermediate-acting insulin at bedtime rather than dinnertime. Eating a snack at bedtime and decreasing the evening dose of intermediate-acting insulin combat the Somogyi effect. Increasing the evening dose of long-acting insulin helps combat insulin waning.

8. A client recently diagnosed with type 1 diabetes is learning foot care. Which of the following responses by the client would indicate additional teaching is needed? (Select all that apply.)
- "I will never go barefoot outside; only in my house is it permissible."
 - "My toenails need to be trimmed straight across."
 - "I will always wear socks and closed-toe shoes."
 - "I will inspect my feet every week for any sores or open areas."

Think Smart/Test Smart

This is a negative question. It asks which statements indicate a need for more teaching. More teaching is needed if the client has not learned needed information correctly. Therefore, you are looking for what the client says that is wrong.

Rationale

Correct answers: a and d.

Option a is an incorrect statement because the diabetic client should never go barefoot. Option d also is incorrect because feet need to be inspected daily not weekly. Therefore, both of these statements indicate a need for further teaching. Options b and c are true statements: toenails need to be trimmed straight across and socks and closed-toed shoes should always be worn.

(continued)

9. When assessing a client during an acute episode of DI, on which problem would the nurse focus?
- Imbalanced nutrition
 - Deficient fluid volume
 - Ineffective coping
 - Risk for impaired skin integrity

Rationale

Correct answer: b.

During an acute episode of DI between 4 and 20 l of dilute urine is voided per 24 hours. With inadequate fluid replacement, hypotension, tachycardia, and weight loss develop and ultimately shock from fluid loss can occur. Thus, deficient fluid volume should be the focus of assessment. Imbalanced nutrition, ineffective coping, and risk for impaired skin integrity may be problems but they are not the priority.

10. When teaching a diabetic client about his insulin protocol, the nurse explains that intermediate-acting insulin should reach its “peak” in how many hours?
- 16–20 hours
 - 3–4 hours
 - 6–12 hours
 - 1–2 hours

Rationale

Correct answer: c.

Intermediate-acting insulin (NPH/Humulin N/Lente/Novolin L) has its onset in 2–4 hours, peaks at 6–12 hours, and has a duration of 1–20 hours.

11. When answering a client’s question about insulin pumps and how they work, which information could appropriately be included in the nurse’s response? (Mark all that apply.) Insulin pumps can
- deliver a premeal dose of insulin before each meal.
 - deliver a varying hourly basal rate of insulin.
 - deliver a dose of insulin based on a preprogrammed insulin to carbohydrate ratio.
 - monitor blood sugar levels at preset intervals.

Rationale

Correct answers: a, b, and c.

Insulin pumps can deliver a bolus of insulin before a meal or a continuous basal rate, which can be programmed to vary hourly to best match normal diurnal rhythm. Smart pumps also can be preprogrammed with an insulin to carbohydrate ratio so at mealtime or snack time, the client programs in the number of grams of carbohydrate that he or she plans to eat and the pump calculates the insulin dose accordingly. The pump does not test blood sugar levels but an algorithm allows additional insulin to be administered based on a blood sugar value entered by the client following a fingerstick.

12. A diabetic client taking an oral antidiabetic agent asks if he will also need parenteral insulin therapy at times. The nurse’s response would be based on the knowledge that parenteral insulin therapy will be temporarily substituted for oral antidiabetic agents if the diabetic
- develops an infection with fever.
 - suffers trauma.
 - undergoes major surgery.
 - all of the above.

Rationale

Correct answer: d.

Any major physical stress such as infection, trauma, or surgery requires the temporary use of insulin rather than an oral antidiabetic agent.

13. In evaluating laboratory results, the nurse interprets which findings as indicative of DKA? (Mark all that apply.)
- ___ Increased blood pH
 - ___ Decreased total body potassium
 - ___ Elevated blood glucose
 - ___ Decreased serum bicarbonate level

Rationale

Correct answers: b, c, and d.

In DKA, blood glucose is elevated as a result of glycogen breakdown into glucose and accelerated gluconeogenesis. As the liver produces ketone bodies in excess of the number that can be cleared by the kidney, ketones in the plasma rise. Serum bicarbonate decreases as the acidic ketones are buffered by the bicarbonate. Total body potassium is decreased even though serum potassium is increased, because acidosis is associated with a shift of potassium out of the cells into the serum from which it is lost through the kidney. Blood pH decreases, not increases, as acidosis occurs.

14. A client with DM receives a prescription for an ACE inhibitor and asks what this drug will do for him. The nurse responds that the drug reduces changes in the blood vessels and may help delay the onset of which problem?
- Chronic obstructive pulmonary disease
 - Pancreatic cancer
 - Renal failure
 - Cerebral vascular accident

Rationale

Correct answer: c.

ACE inhibitors are renal protective and may reverse or delay the onset of renal disease.

15. When teaching a diabetic client, which symptom should the nurse identify as most commonly indicative of hypoglycemia?
- Nervousness
 - Anorexia
 - Kussmaul's respirations
 - Bradycardia

Rationale

Correct answer: a.

Nervousness along with shakiness, weakness, trembling, pallor, diaphoresis, tachycardia, irritability, and palpitations are all adrenergic symptoms associated with hypoglycemia. Headache, mental confusion, circumoral paresthesia, fatigue double vision, incoherent speech, seizures, and coma are neuroglycopenic symptoms. Kussmaul's respirations are a symptom of hyperglycemia.

16. A female client with type 1 DM is experiencing a minor flu-like illness with nausea, muscle aches and low grade fever. Which instruction should the nurse give her?
- Increase the frequency of glucose self-monitoring
 - Try to reduce food intake to diminish nausea
 - Do not take any insulin if she cannot eat
 - Take half of the normal dose of insulin

Rationale

Correct answer: a.

The client should be instructed to increase the frequency of glucose self-monitoring in order to determine if insulin dosage needs to be adjusted.

17. Which of the following is a priority nursing diagnosis for the diabetic client who is taking insulin and has N&V from a viral illness or influenza?
- Imbalanced nutrition; less than body requirements
 - Impaired health maintenance related to ineffective coping skills
 - Risk for acute pain
 - Activity intolerance

Rationale

Correct answer: a.

Imbalanced nutrition: less than body requirements. Insulin and dietary intake must be in balance for hypoglycemia or hyperglycemia to be avoided. With decreased intake from N&V, the need for insulin will be decreased placing the client at risk for hypoglycemia. Ineffective coping skills and activity intolerance may be problems but are not life-threatening at the moment so are not the priority. Acute pain is not an expected symptom.

18. During a home visit, a diabetic client begins to cry and say, "I just cannot stand the thought of having to give myself a shot every day." Which would be the best response by the nurse?

- "If you do not give yourself your insulin shots, you will die."
- "We can teach your daughter to give the shots so you will not have to do it."
- "I can arrange to have a home care nurse give you the shots every day."
- "What is it about giving yourself the insulin shots that bothers you?"

Rationale

Correct answer: d.

Asking "What is it about giving yourself the insulin shots that bothers you?" acknowledges the existence of a problem and gives it validity. It also facilitates identifying the exact nature of the problem so it can be addressed. Threatening the client as in option a does not address the problem or give confidence in one's ability to manage self-care. Having another person—family member or nurse, is not the best approach because not only doesn't it determine what the problem is but puts potentially unnecessary constraints on the client.

19. A client presents in the emergency room with DKA. Which nursing diagnosis would be the priority problem?
- Disturbed sleep pattern
 - Impaired health maintenance
 - Imbalanced nutrition; less than body requirements
 - Deficient fluid volume

Rationale

Correct answer: d.

Deficient fluid volume occurs because insulin deficiency results in hyperglycemia as a result of the breakdown of glycogen into glucose and accelerated gluconeogenesis. The progressive hyperglycemia results in glycosuria, which acts as an osmotic diuretic and causes dehydration. Initially, thirst increases fluid intake and dehydration is minimized but with progressive ketosis, N&V ensue and dehydration becomes severe. Thus, deficient fluid volume that can lead to circulatory collapse and shock is the priority diagnosis because it is immediately life-threatening; the other diagnoses are not.

20. Which of the following would the nurse include when developing a teaching plan for a newly diagnosed client with type 2 DM. (Select all that apply.)
- A major risk factor for complications is cigarette smoking.
 - Insulin is mandatory for controlling the disease.
 - Exercise increases insulin resistance.
 - The primary nutritional source requiring monitoring in the diet is carbohydrates.
 - Annual eye and foot examinations are recommended by the American Diabetes Association.

(continued)

Rationale

Correct answers: a and e.

Cigarette smoking is a major risk factor for every known complication of DM. Annual eye and foot examinations are recommended by the American Diabetes Association. Insulin is not always necessary for the control of DM. Type 2 DM is characterized by insufficient insulin or impaired action of insulin, not absence of insulin. Thus diet, exercise, and/or oral antidiabetic medications may control the problem. Exercise lowers blood sugar by increasing uptake of glucose by muscles and improving insulin utilization. Intake of carbohydrates, fats, and proteins must be monitored and should be consistent with the food pyramid with most calories derived from carbohydrates.

21. Which of the following would the nurse report for a client with unstable type 2 DM? (Select all that apply.)
- Systolic BP of 145 mmHg
 - Diastolic BP of 87 mmHg
 - HDL of 30 mg/dl
 - HgbA1c of 10.2%
 - Triglycerides of 425 mg/dl
 - Urinary ketones negative

Rationale

Correct answers: a, b, c, d, and e.

Hypertension in the diabetic exacerbates retinopathy, renal changes, and cardiovascular disease. Therefore, it must be aggressively monitored and treated. For the diabetic person, a BP of 130/85 or higher either systolically or diastolically requires intervention and therefore should be reported. HDL of 30 mg/dl is consistent with dyslipidemia as is the elevated triglyceride level. HgbA1c reflects the average blood glucose of over 2–3 months. Normal range is 4–6%. Over 7% indicates less than optimal control of blood sugar and risk for complications.

22. When should the diabetic client who is taking insulin (Humalog) injections be advised to eat?
- Within 20 minutes after the injection
 - 1 hour after the injection
 - At any time, because timing of meals with Humalog is unnecessary
 - 2 hours before the injection

Rationale

Correct answer: a.

The onset of Humalog is in 10–15 minutes with a peak in 1 hour and a duration of 3 hours. It is typically taken before meals to ensure a rapid reduction in glucose. In a few cases, it is taken after a meal as when a client with N&V waits to make certain that the ingested food is going to stay down.

23. Teaching for a client beginning therapy with methimazole (Tapazole) would appropriately include which information? (Mark all that apply.)
- The effect of the treatment will be noticeable in 7–10 days.
 - Periodic RBC counts will be needed during therapy.
 - Any signs of infection need to be reported to the health care provider.
 - Dose of Tapazole will be tapered as normal thyroid status is attained.

Rationale

Correct answers: c and d.

Infection may be the first sign of agranulocytosis, which is a side effect of the thiomides which include Tapazole and PTU. The dose of antithyroid drug is gradually tapered as the client regains a euthyroid state. The effect of treatment is not seen for several weeks because hormone which is already synthesized must be used up. Periodic WBC counts are required during therapy.

24. A client is being treated for hypercalcemic crisis. Which assessment findings would the nurse interpret as indicating overtreatment of the problem? (Mark all that apply.)
- Decreased bowel sounds
 - Photophobia
 - Leg cramps
 - Positive Chvostek sign
 - Vomiting
 - Perioral numbness and tingling
 - Bradycardia

Rationale

Correct answers: b, c, d, and f.

Overtreatment of hypercalcemia results in hypocalcemia. Signs of hypocalcemia include photophobia, cramps in the extremities, positive Chvostek and Trousseau's signs, and numbness and tingling around the mouth and in the hands and feet. Decreased bowel sounds that occur with decreased peristalsis, vomiting and bradycardia are signs of hypercalcemia so they would be associated with undertreatment not overtreatment.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 10: Urinary Problems

| | | | |
|----------------------------------|-----|-------------------------------------|-----|
| ▶ Acute Renal Failure | 908 | ▶ Urinary Calculi (Nephrolithiasis) | 910 |
| ▶ Chronic Renal Failure | 909 | ▶ Urinary Tract Infection (UTI) | 905 |
| ▶ Nephrosis (Nephrotic Syndrome) | 908 | | |

URINARY TRACT INFECTION (UTI)

- UTI is acute or chronic bacterial infection of the normally sterile lower urinary tract including the urethra (urethritis) and bladder (cystitis).
- Sepsis may result, particularly in the elderly and the immunocompromised.

Etiology: Bacteria (most commonly *E. coli*) enters the urinary tract through the urethra and begins to multiply and produce symptoms of infection.

Risk factors: Incomplete emptying of the bladder; urethral stricture; inadequate fluid intake; bowel incontinence; decreased mobility; improper cleaning of perineal area; urinary catheterization; clothing or personal care products that encourage irritation and inflammation of the perineal area; females and the elderly are at highest risk.

Assessment Alert OB

UTIs are frequently seen in late pregnancy due to the pressure of the uterus on the urinary structures. UTIs are also frequent in the postpartal period secondary to bladder trauma during the birth process.

S&S:

- Dysuria
- Urinary frequency and urgency
- Suprapubic pain
- Nocturia
- Cloudy, foul-smelling urine

- Hematuria
- N&V
- Fever and chills
- Fatigue

Assessment Alert GERI

Atypical presentations of infection are common in the elderly. Mental changes or confusion may be the only signs of possible UTI.

Dx: Urinalysis indicates leukocyturia, hematuria, albuminuria; urine C&S identifies causative organism; abdominal ultrasound or X-ray (KUB) may be needed to evaluate the status of the renal system.

Rx: Antibiotic therapy, commonly co-trimoxazole (Bactrim, Septra), nitrofurantoin (Macrochantin), or amoxicillin (Amoxil) to reduce pathogen count; prophylactic antibiotic therapy commonly ordered for recurrent UTIs; phenazopyridine (Pyridium) for its analgesic effects to relieve dysuria; increased fluid intake encourages passage of bacteria out of the body; drinking two to three glasses of cranberry juice a day increases acidity of the urine, which discourages bacteria from attaching to the wall of the bladder.

Clinical Alert

Chronic or recurrent episodes must be treated thoroughly to reduce the risk of progression to pyelonephritis and possible permanent kidney damage.

Nursing Process Elements

- Assess for S&S
- Recognize high-risk populations
- Support efforts to prevent recurrence
- Maintain asepsis with urinary catheter insertion and follow standards for routine catheter care

Client teaching for self-care

- Take all medications as prescribed, even if symptoms of infection subside
- Anticipate that urine will be red–orange with Pyridium use
- Void at regular and frequent intervals; void after intercourse
- Increase fluid intake to at least 8 oz/d

- Wear cotton underwear; avoid tight-fitting pants, and nylon pantyhose
- Shower, rather than tub bathe
- Avoid douching, bubble bath, powder, sprays, or harsh soaps
- Keep the genital area clean and wipe from front to back
- Notify physician if symptoms persist or recur

Nursing Intervention Alert OB

Pregnant women with UTIs are at risk for preterm labor. The pregnant client should be monitored closely for S&S of the onset of labor. A preterm infant faces many additional challenges, which can lead to physical and/or mental deficits.

Pyelonephritis

- Pyelonephritis is acute or chronic bacterial infection of the upper urinary tract including the kidneys and ureters.
- It can result in renal failure secondary to damage and atrophy of the nephrons.
- Sepsis may result particularly in the elderly and immunosuppressed.

Etiology: Bacterial pathogens cause inflammation of the renal parenchyma and collecting system; the inflammatory process may result in formation of scar tissue over time; most often occurs as a result of UTI, particularly in the presence of backflow of urine from the bladder into the ureters or kidney pelvis (vesicoureteric reflux).

Risk factors: History of chronic or recurrent UTI, renal papillary necrosis, kidney stones, vesicoureteric reflux, and obstructive uropathy.

S&S:

- UTI symptoms (dysuria, frequency & urgency, pyuria, hematuria, nocturia)
- Fever
- Chills
- Malaise
- Fatigue
- Flank pain
- Costovertebral angle tenderness
- N&V

Assessment Alert GERI

Atypical presentations of infection are common in the elderly. Mental changes or confusion may be the only indication of an acute infection.

Dx: Urinalysis indicates leukocyturia, hematuria, albuminuria; urine C&S identifies causative organism; intravenous pyelogram (IVP) or CT scan of the abdomen may reveal enlarged kidneys with poor flow of dye through the kidneys; blood culture is positive in the presence of sepsis.

Rx: Antibiotic therapy (intravenous or oral depending on severity), commonly cephalosporins, levofloxacin, ciprofloxacin, amoxicillin. Prophylactic antibiotics may be prescribed for chronic pyelonephritis; increased fluid intake (up to 3 l/d) encouraged; analgesics to relieve pelvic or flank pain; hospitalization may be required.

Clinical Alert

GERI

Prompt treatment is critical for the elderly due to the high mortality rate and risk of permanent damage.

Nursing Process Elements

- Assess for S&S
- Recognize high-risk populations
- Administer medications and IV fluids as ordered
- Monitor for complications, including sepsis and acute renal failure, and report immediately if any develop
- Support prompt and complete treatment of UTIs
- Educate the client about ways to prevent UTIs (See client teaching under UTI.)

Glomerulonephritis

- Glomerulonephritis is acute or chronic inflammation of the glomeruli.
- It is among the leading causes of chronic renal failure and end-stage renal disease (ESRD).

Etiology: Infection, injury, or autoantibodies stimulate an immune response within the body and the glomeruli become inflamed, scar tissue forms, and tubular atrophy and loss of renal function ultimately occurs.

Precipitating factors: Acute glomerulonephritis can occur 2–3 weeks following streptococcal infection.

Risk factors: Vasculitis, polyarteritis, abscess of any internal organ, collagen vascular diseases, history of malignant tumors, or blood or lymphatic system disorders.

S&S:

- Dark, smoke-colored, or foamy urine
- Edema
- Oliguria or anuria
- Hematuria
- Nocturia

- Resistant hypertension
- Shortness of breath
- Cough
- Fever
- Malaise
- Arthralgia
- Myalgia
- Abdominal pain
- Anorexia and unintentional weight loss
- N&V
- Decreased alertness
- Seizure
- Polyneuropathy

Dx: Urinalysis indicates hematuria, leukocyturia, proteinuria; BUN, creatinine, and potassium levels are elevated; creatinine clearance is decreased; ultrasound, CT, or IVP may reveal altered kidney size; chest X-ray may reveal pulmonary congestion; kidney biopsy indicates inflammation and may identify crescent-shaped abnormalities.

Rx: Hospitalization; bed rest; restriction of fluids, sodium, potassium, and dietary protein; corticosteroids (Prednisone) to suppress inflammatory response; antibiotics to treat infection; ACE inhibitors to reduce proteinuria and control hypertension; diuretics for moderate edema; dialysis or kidney transplant if progresses to ESRD.

Clinical Alert

PEDS

Outcome varies with disease process responsible for the glomerulonephritis. Children tend to recover more quickly and completely.

Nursing Process Elements

- Emphasize importance of early detection and treatment of streptococcal infections
- Monitor for complications, including renal failure, pulmonary edema, and heart failure and notify physician immediately if any S&S develop
- Administer medications as prescribed
- Educate client about the importance of strict compliance with medication and diet regime

Client teaching for self-care

- Take medication as prescribed, even if symptoms subside
- Follow dietary restrictions on salt, fluid, and protein

- Seek treatment for possible streptococcal infections, vascular diseases, hypertension, or fluid retention
- Report development of new symptoms particularly shortness of breath, decreased urine output, or changes in level of alertness

NEPHROSIS (NEPHROTIC SYNDROME)

- A group of symptoms including protein in the urine (exceeding 3.5 g/d), low serum protein, high serum cholesterol, and generalized edema associated with functional damage to glomeruli.
- Outcome varies; may be acute and short-term or chronic and unresponsive to treatment, leading to ESRD.

Etiology: Infection, drug exposure, malignancy, immune disorders, or disease damage the basement membrane of the glomeruli, disrupting the filtering and excretion of protein, lipids, and blood. As vital protein is lost from the intravascular space, extravascular fluid accumulates.

Risk factors: Can affect all age groups; occurs slightly more often in males than females; can accompany kidney disease including glomerulonephritis.

S&S:

- Edema
- Ascites
- Foamy urine
- Unintentional weight gain (edema-related)
- Anorexia
- Hypertension
- Atherosclerosis

Dx: Urinalysis reveals large amounts of protein; urine may also contain fat, which is visible under the microscope; serum protein and cholesterol levels elevated.

Rx: Moderate protein, sodium-restricted diet; corticosteroids (Prednisone) to diminish inflammatory response; ACE inhibitors to reduce proteinuria and control hypertension; cholesterol-reducing medications; antithrombotics may be ordered to prevent clot formation. Immunosuppressant drugs such as Cytoxan may be added to reduce the risk of relapse. Note: the edema of nephritic syndrome does not usually respond to diuretic agents.

Nursing Process Elements

- Encourage compliance with diet and medication therapy
- Educate client to recognize serious symptoms and seek medical attention
- Monitor blood pressure and cholesterol levels routinely and encourage vigorous treatment

- Monitor for development of complications including atherosclerotic disease, renal vein thrombosis, pulmonary edema, congestive heart failure, and renal failure

Client teaching for self-care

- Take medications as prescribed even if symptoms subside
- Follow dietary restrictions
- Monitor blood pressure, cholesterol levels, and weight changes
- Report if symptoms persist or new symptoms develop, particularly severe headache, fever, sores on the skin, cough, discomfort with urination, or decreased urine output

ACUTE RENAL FAILURE

- Acute renal failure is a sudden loss of the kidney's ability to excrete wastes, concentrate urine, and conserve electrolytes.
- Outcomes are affected by the underlying cause, severity of condition, and timing of treatment initiation.
- It may progress to uremic syndrome, ESRD, or death.

Etiology: Both kidneys rapidly become unable to excrete the daily accumulation of metabolic wastes; toxins build up and damage tissues and impair organ functioning. Acute renal failure is classified as prerenal, intrarenal, or postrenal based on the location of its cause.

Prerenal failure is characterized by diminished renal perfusion resulting from a decrease in blood supplying the kidneys.

Intrarenal failure (also called intrinsic) results from an abrupt decrease in glomerular filtration rate (GFR) due to tubular cell damage because of renal ischemia or nephrotoxic injury.

Postrenal failure is associated with conditions causing an obstruction of urinary flow.

Risk factors: Cardiovascular disorders, hemolytic disorders, autoimmune disorders, sepsis, shock, hypovolemia, exposure to nephrotoxic agents (contrast dyes, aminoglycosides, etc.), surgery, trauma, neurogenic bladder, renal calculi, renal tubular necrosis, and obstruction of the bladder, ureters, or urethra. The elderly and immunosuppressed are at highest risk.

S&S:

- Oliguria (usually the earliest sign)
- Anorexia
- Fatigue
- N&V
- Diarrhea or constipation
- Pruritus
- Edema
- Dyspnea

- Mental status changes
- Dry mucous membranes
- Bleeding and bruising
- Tinnitus
- Uremic breath and metallic taste
- Hypertension and tachycardia
- Hypotension (if renal hypoperfusion)
- Pleuritic chest pain
- Seizures

Dx: Blood tests reveal elevated BUN, creatinine, and potassium levels and decreased pH, bicarbonate levels, and hematocrit/hemoglobin. Urine specimens indicate decreased specific gravity, proteinuria, and urine osmolality close to serum osmolality. Urine sodium is usually <20 mEq/l when the failure is related to hypoperfusion and >40 mEq/l when the cause is intrinsic. Creatinine clearance (measures GFR) is used to estimate the number of remaining functioning nephrons. Kidney ultrasound, CT scan, retrograde pyelography, MRI, and KUB may be needed to evaluate the status of the renal system.

Rx: Goal is to identify and treat any reversible causes and reestablish renal functioning. Hospitalization is usually required. Supportive measures include a high-calorie, vitamin-supplemented diet with restricted fluid, sodium, protein, and potassium. Offending drugs are discontinued; life-threatening hyperkalemia is treated with hypertonic glucose and insulin infusions, oral or rectal Kayexalate, or dialysis; antibiotics are given to treat or prevent infection; ACE inhibitors to control blood pressure; digoxin to improve cardiac function; diuretics to eliminate excess fluid retention; renal replacement therapy (peritoneal dialysis or hemodialysis) to remove the accumulation of nitrogenous waste products.

Clinical Alert

Monitor and report elevated serum creatinine levels. Renal dosing should be considered when prescribing medications that are excreted by the kidneys to a client with a serum creatinine level >2.0 .

Nursing Process Elements

- Accurately record I&O, vital signs, and daily weight
- Administer medications as ordered
- Support nutrition and hydration status
- Monitor for complications including metabolic acidosis, fluid volume overload, hyperkalemia, and seizures. Report immediately if any develop

Client teaching for self-care

- Take all medications as prescribed
- Follow high-calorie, low-protein, low-sodium, low-potassium diet with vitamin supplements
- Follow fluid restrictions
- Report decreased urine output, weight gain, edema, changes in respiratory and neurological status, or irregular heartbeats

CHRONIC RENAL FAILURE

- Chronic renal failure is a gradual, progressive, irreversible syndrome of impaired renal function resulting from a decreased number of functioning nephrons.
- It occurs in three stages reflecting progressive loss of nephron systems.
 - Stage I (Diminished renal reserve)—50% functional loss, serum creatinine in high normal range (2 mg/dl), and asymptomatic
 - Stage II (Renal insufficiency)—75–80% functional loss, serum creatinine around 4 mg/dL, BUN/creatinine elevated, and anemia present
 - Stage III (ESRD)—90% functional loss, serum creatinine ~ 8 mg/dl, GFR critically low (≤ 10), homeostasis cannot be maintained and all body systems are affected

Etiology: Chronic inflammation, renal ischemia, or obstruction leads to progressive nephron and glomerular damage. Remaining healthy nephrons are able to compensate by enlarging and increasing clearance until 75% or more of the nephrons become nonfunctioning. At that point, the kidney's ability to excrete wastes, concentrate urine, and conserve electrolytes is lost and uremic toxins accumulate and produce life-threatening changes in all major organ systems.

Risk factors: Chronic infections, glomerulonephritis, vascular disease, hypertension, diabetes, long-term use of nephrotoxic agents, renal calculi, obstructive uropathy, and acute renal failure that fails to respond to treatment.

S&S (early):

- Fatigue
- Malaise
- Anorexia
- N&V
- Unintentional weight loss
- Nocturia

S&S (late):

- Edema
- Dyspnea

- Severe anemia
- Oliguria or anuria
- Pruritus
- Easy bruising/bleeding
- Mental status changes
- Peripheral neuropathy
- Muscle and bone pain
- Hypertension
- Cardiac arrhythmias
- Uremic breath
- Sexual dysfunction
- Skeletal demineralization

Dx: Progressively increasing BUN and creatinine levels; decreased 24-hour urine creatinine clearance; elevated potassium level; ABGs and blood chemistry may indicate metabolic acidosis; CT, MRI, X-ray, or ultrasound may reveal decreased kidney size.

Rx:

- Diphenhydramine to relieve itching
- Calcium carbonate to lower serum phosphate levels
- Vitamin B & D supplementation to treat deficiencies
- Loop diuretic (Lasix) to reduce fluid retention
- Digoxin to improve cardiac functioning
- ACE inhibitors to control blood pressure
- Antiemetics to relieve nausea
- Famotidine to decrease gastric irritation
- Docusate sodium to prevent constipation
- Epoetin alfa to increase RBC production
- Blood transfusions to treat severe anemia
- Kayexalate to treat hyperkalemia

Think Smart/Test Smart

Remember that diuretics move fluid out of the body by means of the kidney. In order for a diuretic to work, there must be functioning kidney cells. Diuretics do not cure sick kidneys. Therefore, once ESRD sets in, diuretics are of almost no value and in fact can cause harmful effects.

- Supportive treatment includes a diet restricted in fluid, protein, sodium, potassium, and phosphate and promotion of rest and conservation of energy. Renal replacement therapy (peritoneal dialysis, hemodialysis, or kidney transplant) is necessary when the GFR falls to between 5 and 10

Clinical Alert

Frequent transfusions to treat anemia increase the risk of hepatitis for clients with chronic renal failure.

Nursing Process Elements

- Monitor lab values including BUN/Creatinine, H&H, and potassium levels
- Monitor vital sign changes, daily weight, and strict I&O
- Observe for signs of bleeding
- Educate about dietary restrictions, compliance with medication and treatment plan, importance of maintaining normal glucose levels and blood pressure
- Educate about dialysis treatment and monitor response to therapy (see Chapter 16)
- Provide opportunity for client to vent feelings about imposed diet and activity limitations
- Refer client and family for appropriate counseling and support
- Monitor for complications including infection at dialysis access site, hyperkalemia, and impaired organ functioning

Client teaching for self-care

- Regularly monitor blood glucose levels and blood pressure; report abnormal results
- Avoid foods high in sodium, potassium, and phosphate
- Comply with protein and fluid restrictions
- Take medications as prescribed
- Report decreased urine output, persistent nausea, unexplained weight loss, presence of swelling, shortness of breath, changes in mental status, elevated blood pressure.

URINARY CALCULI (NEPHROLITHIASIS)

- Urinary calculi are stones of varying size which result from the accumulation and precipitation of deposits of mineral crystals.
- Calculi may remain in the renal pelvis or enter the ureters.
- Obstruction of urine flow, infection, and bleeding may result.

Etiology: Inadequate water or excessive mineral levels lead to an accumulation, then precipitation, of substances normally dissolved in the urine. The most common types are calcium oxalate calculi, uric acid calculi, cystine calculi, and struvite calculi.

Risk factors: Dehydration; infection; urinary obstruction; urinary stasis; excessive intake of calcium, vitamin C & D, and protein; immobility; gout; arthritis; hyperparathyroidism; genetically defective metabolism of cystine; consistent urine acidity or alkalinity.

S&S:

- Pain (flank, back, testicle, or groin)
- N&V
- Fever and chills
- Hematuria
- Pyuria
- Anuria (rare)
- Abdominal distention

Dx: Stones or obstruction may be seen on ultrasound, X-rays, IVP, MRI, or CT; urine culture may indicate UTI; urinalysis may be normal or may indicate elevated specific gravity, altered pH, hematuria, and pyuria; 24-hour urine collection may be elevated for calcium oxalate, phosphorus, and uric acid excretion levels; serum uric acid levels may indicate gout as the cause.

Rx: Vigorous hydration and ambulation to encourage natural passage; analgesics (opioid and adjuvant) for pain; antibiotic therapy if infection present; low-purine, low-protein, low-calcium diet; allopurinol to reduce uric acid levels; bicarbonate or potassium citrate to alkalinize urine; ascorbic acid to acidify urine; thiazide diuretics to decrease calcium excretion; parathyroidectomy to treat hyperparathyroidism; ureteroscopy, lithotripsy, or percutaneous nephrolithotomy to surgically remove large stones (>7 mm). Ninety percent of stones are smaller than 5 mm in diameter.

Clinical Alert

Approximately 90% of renal calculi are smaller than 5 mm in diameter; stones larger than 7 mm usually require some form of surgical intervention.

Nursing Process Elements

- Assess and treat pain
- Force fluids

- Encourage ambulation
- Strain urine; save solid material for analysis
- If surgery necessary, explain preoperative and postoperative care
- Monitor for complications including urine flow obstruction, hydronephrosis, infection, or bleeding

Client teaching for self-care

- Take all medications as prescribed
- Increase fluid intake (up to 3–4 l/d)
- Report symptoms of infection, pain, bleeding, and inability to void
- Save urine for straining

Vesicoureteral Reflux

- Vesicoureteral reflux is characterized by the reflux of urine from the bladder back into the ureter and kidney.
- It may lead to pyelonephritis, scarring, nephrotic syndrome, and ESRD.

Etiology: One-way ureteral valve fails, allowing urine to back flow.

Risk factors: Previous or family history; renal calculi; bladder outlet obstruction; congenital abnormalities of the urinary tract; neurogenic bladder; ureteral edema or trauma.

S&S:

- Flank, back, or abdominal pain
- Fever and chills
- Dysuria
- Nocturia
- Hematuria
- Recurrent UTIs
- Hydronephrosis
- Hypertension
- May be asymptomatic if only one kidney involved

Dx: BUN, creatinine, and urine protein levels may be elevated; urine culture may be positive; cystogram, IVP, or abdominal CT may reveal reflux, hydronephrosis, scarring, or small kidney; voiding cystourethrogram (VCUG) confirms diagnosis.

Rx: Antibiotics if infection present; annual ultrasounds to monitor development; ureteral reconstruction or reimplantation if condition is severe.

Clinical Alert

Close monitoring is warranted. It may resolve without intervention; however, damage to kidney is irreversible.

Nursing Process Elements

- Educate client about the S&S of reflux; emphasize importance of follow-up
- Monitor for complications including hypertension, pyelonephritis, nephrotic syndrome, and renal failure

Client teaching for self-care

- Keep appointments for monitoring progression
- Report new or persistent symptoms, including pain, fever, bleeding, diminished output, generalized swelling, or high blood pressure

Hydronephrosis

- Hydronephrosis is unilateral or bilateral dilation of renal calyces and pelvis proximal to an obstruction of urine flow.
- Symptoms, treatment, and outcomes are related to the cause of the obstruction.
- The unaffected kidney, in unilateral cases, hypertrophies and may function up to 80% as effectively as both kidneys did before the obstruction.
- Bilateral obstruction leads to renal failure.

Etiology: Obstruction of any part of the urinary system generating backflow of urine, increased pressure, and distention. The urine backup eventually reaches the kidney pelvis and results in increased tubular pressure and damage.

Risk factors: Vesicoureteral reflux, renal calculi, prostate enlargement, advanced pregnancy, uterine cancer, bladder outlet obstruction, neurogenic bladder, acute or chronic obstructive uropathy.

S&S:

- Flank pain
- Abdominal mass
- N&V
- Fever
- Dysuria
- Urinary frequency, urgency, and retention
- Recurrent UTIs
- Sometimes unilateral hydronephrosis does not have symptoms

Dx: Diagnostic studies vary depending on whether the obstruction is in the upper or lower urinary tract; generally an IVP, ultrasound, CT scan, or MRI confirms disorder; urinalysis may suggest etiology; serum BUN, creatinine levels may help to determine degree of renal impairment.

Rx: Surgical management includes balloon dilation, nephrostomy tube placement, or stenting; IV fluids and electrolyte

replacements as indicated for postobstructive diuresis; opioid analgesics and antispasmodics for pain management; antibiotics if infection present; prophylactic antibiotics if condition is chronic.

Nursing Process Elements

- Assess and treat pain
- Report fluid and electrolyte imbalances
- If surgery necessary, explain preoperative and postoperative care
- Educate client about S&S of infection and recurrent obstruction
- Monitor for complications including renal failure

Client teaching for self-care

- Reduce occurrence/recurrence of conditions that increase risk (renal calculi, frequent UTIs, vesicoureteral reflux, etc.)
- If postsurgical, follow instructions for incision and drain care
- Take medications as prescribed
- Keep appointments for follow-up
- Report S&S of infection and recurrent obstruction, including pain, fever, diminished urine output, and swelling

Bladder Cancer

- Most common is transitional cell (cells lining the bladder); other types include squamous cell and adenocarcinoma.
- Graded and staged (TNM staging system) based on aggressiveness and degree of mutation; treatment and prognosis varies according to staging category.

Etiology: Unknown, though several factors may contribute to development.

Risk factors: Cigarette smoking; exposure to certain industrial chemicals, chemotherapeutic agents, or pelvic irradiation; chronic infections; three times more common in men.

S&S:

- Painless hematuria
- Urinary urgency
- Dysuria
- Bladder outlet or ureter obstruction
- Cystitis
- Pelvic or abdominal pain and distention
- Anemia
- Weight loss
- Fatigue and lethargy

Dx: Physical exam may reveal rectal or pelvic mass; urinalysis may be positive for blood; urine cytology may identify

malignant cells; cystoscopy allows visualization and biopsy; IVP enables evaluation of upper urinary tract for tumors or blockage; chest X-ray, bone scan, CT, and MRI studies rule out metastases

Rx: Intravesical chemotherapy; radiotherapy; surgical options include transurethral resection of tumor; partial cystectomy, or radical cystectomy with urinary diversion (see Chapter 18)

Nursing Process Elements

- Assess presence and severity of unpleasant symptoms; take measures to alleviate
- Explain chemotherapy and radiotherapy procedures
- Teach about preoperative and postoperative care and long-term management
- Assess and treat postoperative pain
- Provide opportunity for venting feelings about diagnosis and change in body appearance; make referrals as appropriate.
- Monitor for complications including anemia, stomal problems, and infection
- Support efforts to reduce occupational exposure to carcinogens and smoking cessation

Client teaching for self-care

- Take medications as directed
- Keep appointments for treatment and follow-up
- Participate in education for urinary diversion care prior to performing independently
- Report complications of disease or treatment including obstructed urine flow, bleeding, fever, pain, malaise, and peristomal skin problems

Renal Cancer

- May be unilateral or bilateral cancer of the kidney.
- Most common is renal cell carcinoma involving the cells of tubule lining.
- Graded and staged based on aggressiveness and degree of mutation; prognosis is based on progression at the time of diagnosis.
- About one-third of clients have metastasis at the time of diagnosis; most common sites of metastasis are the lungs, lymph nodes, liver, and bone.

Etiology: Unknown, though several factors may contribute to development.

Risk factors: Cigarette smoking; positive family history; obesity; occupational exposure to certain industrial chemicals; occurs twice as often in men; usually occurs between the ages of 40–70.

S&S:

- Painless hematuria
- Flank, back, or abdominal pain
- Unexplained weight loss
- Testicular or abdominal distention
- Fever
- Hypertension
- Polycythemia
- Constipation
- Elevated alkaline phosphatase and serum calcium levels

Dx: Kidney X-ray or abdominal CT confirms diagnosis; chest X-ray, bone scan, and MRI may reveal metastasis.

Rx: Chemotherapy, radiotherapy, surgical removal of all or part of the kidney (nephrectomy), or a combination of these treatments.

Clinical Alert

Early detection and aggressive treatment improves clinical outcomes.

Five-year survival rate for early stages without metastasis is 60–75%

Five-year survival after lymph node metastasis is 5–15%

Five-year survival after other organ metastasis is less than 5%

Nursing Process Elements

- Educate about preoperative and postoperative care and long-term management
- Explain chemotherapy and radiotherapy procedures
- Assess and treat pain
- Provide opportunity for venting feelings and make referrals as appropriate
- Monitor for complications including hypertension and metastasis
- Support efforts to reduce occupational exposure to carcinogens and smoking cessation

Client teaching for self-care

- Immediately report presence of blood in urine
- Stop smoking
- Take medications as directed
- Keep appointments for treatment and follow-up

PEDS **Wilm's Tumor**

- Wilm's tumor is the most common renal cancer in children.
- Rapidly developing kidney tumor may become quite large, but usually remains encapsulated.
- Complications include hypertension, impaired renal functioning, possible metastasis to lungs, liver, bone, or brain, or death
- Early detection and aggressive treatment improves clinical outcomes

Etiology: Unknown.

Risk factors: Early childhood (3–8 years); positive history in twin or sibling; presence of certain birth defects including urinary tract abnormalities, absence of an iris, or hemihypertrophy (enlargement of one side of the body).

S&S:

- Abdominal pain and swelling
- Hematuria
- Anorexia
- N&V
- Generalized malaise
- Hypertension
- Constipation

Dx: CBC may reveal anemia; BUN and creatinine elevated; abdominal U/S, X-ray, or CT scan confirm a mass; CXR, bone scan, and MRI studies rule out metastasis.

Clinical Alert

Children with a known risk for Wilm's tumor should be routinely screened with kidney ultrasounds.

Rx: Surgery, radiotherapy, chemotherapy, or a combination of these.

Nursing Process Elements

- Report hypertension in children
- Explain chemotherapy and radiotherapy procedures
- Teach about preoperative and postoperative care
- Assess and treat postoperative pain
- Support child and family; make referrals as appropriate
- Monitor for complications including renal failure and metastasis

Client teaching for self-care

- If postsurgical, follow instructions for incision and drain care
- Take medications as prescribed
- Keep appointments for follow-up
- Report development of new or worsening symptoms including pain, fever, bleeding, cough, chest pains, or weight loss.

Nursing Intervention Alert

Care should be taken to avoid palpating the abdomen prior to surgical removal of the tumor to reduce the risk of seeding the tumor.

PEDS

Extrophy of the Bladder

- Extrophy of the Bladder is an infrequent congenital defect in which the abdominal wall and anterior bladder wall fail to fuse in utero resulting in the posterior wall of the bladder protruding through the abdominal wall
- Accompanied by congenital pelvic bone separation and epispadias (abnormal location of urethral opening)
- Complications include chronic UTIs, incontinence, or erectile/sexual dysfunction

Etiology: Unknown.

Risk factors: Occurs more often in males.

S&S:

- Red, angry-looking mass on abdominal surface, continuous leakage of urine onto surface
- Widened pubic bones
- Outwardly rotated legs and feet
- Short, small penis with urethral opening along top of penis in the male.
- Narrow vaginal opening, wide labia, and short urethra in the female.

Dx: Usually diagnosed by fetal ultrasound before birth and physical examination after birth.

Rx: Surgical repair to internalize the bladder and attach the pelvic bones within the first 48 hours after birth. Epispadias repair may be completed at the same time or repair may be delayed.

Nursing Process Elements

- Sterile, nonadherent dressing covers bladder in preoperative period

- Educate about preoperative and postoperative care and long-term management
- Explain that the child may be in a lower body cast or sling postoperatively
- Assess and treat postoperative pain
- Assess family's coping style and support systems; make referrals as appropriate
- Monitor for complications including skin impairment from urinary incontinence, infection, or sexual dysfunction

Client teaching for self-care

- If postsurgical, follow instructions for incision and drain care
- Take medications as prescribed
- Keep appointments for follow-up
- Anticipate stages of surgical correction
- Report development of new or worsening symptoms including pain, fever, cloudy, foul-smelling urine, or skin impairment

PEDS

Cryptorchidism

- Cryptorchidism is a developmental defect in which one or both testicles fail to descend into the scrotum prior to birth.
- About 65% will typically descend without intervention by 9 months of age.
- Infertility, testicular torsion, and an increased risk for testicular cancer may develop if the testicle fails to descend by age 1.

Etiology: Unknown.

Risk factors: Premature birth.

S&S:

- Visual and palpable variance in scrotal assessment

Dx: Examination confirms that one or both testicles are not present in the scrotum.

Clinical Alert

The risk for testicular cancer is 40% greater in men with a history of cryptorchidism.

Rx: Testicle most often descends without intervention within the first year of life; hormonal injections (B-HCG or

testosterone) may be given to stimulate testicular movement; surgical correction (orchiopexy) is definitive therapy (in rare cases, no testicle may be found upon surgical exploration).

Nursing Process Elements

- Perform scrotal assessments on all male infants; assess for natural testicular descent within first year of life
- Administer medication as ordered and monitor response
- If surgery necessary, educate about preoperative and postoperative care
- Educate about increased risk for infertility and testicular cancer
- Teach males over the age of 15 to perform testicular self-examinations to screen for testicular cancer (see Chapter 8)

Client teaching for self-care

- If postsurgical, follow instructions for incision and drain care
- Take medications as prescribed
- Keep appointments for follow-up
- Perform monthly testicular self-examinations after age 15 because the risk of testicular cancer is 40% greater in men with a history of cryptorchidism

PEDS

Hypospadias

- Hypospadias is a congenital condition in which the male urethral opening is located on the ventral surface of the penis and the foreskin is incompletely formed.
- It is associated with chordee (a downward curvature of the penis).
- If left untreated, it may lead to difficulty with toilet training, sexual dysfunction, urethral strictures, and fistulas

Etiology: Unknown.

S&S:

- Urethra is displaced to the underside, midshaft, or base of the penis
- Downward curvature of penis

Dx: Physical examination reveals disorder; radiologic studies rule out other congenital anomalies.

Rx: Surgical revision of the urethral tract and meatus; may require temporary urinary diversions; repair may need to be performed in stages, requiring multiple surgeries. Results typically good, both cosmetically and functionally, approximately 10–20% require revision for fistulas and chordee recurrence.

**Clinical Alert**

Infants with hypospadias should not be circumcised. The foreskin should be preserved for use in later surgical repair.

**Client teaching for self-care**

- Anticipate stages of surgical correction
- Do not have child circumcised if hypospadias is suspected
- If postsurgical, follow instructions for incision and drain care
- Keep appointments for follow-up
- Report new or recurring symptoms including urinary straining or an abnormal location of urine passage

**Nursing Process Elements**

- Assess presence of disorder
- Educate about preoperative and postoperative care
- Monitor for complications including strictures or fistulas

WORKSHEET**TRUE & FALSE QUESTIONS**

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|------------------|------------------|
| 1. Confusion may be the only clinical sign of a UTI in the older adult. | <u> </u> T | <u> </u> F |
| 2. Recurrent episodes of UTIs could progress to permanent kidney damage. | <u> </u> T | <u> </u> F |
| 3. Placement of an indwelling catheter to treat urinary incontinence decreases the risk for a UTI. | <u> </u> T | <u> </u> F |
| 4. A client with nocturia should be instructed to schedule the majority of fluid intake prior to 4 p.m. | <u> </u> T | <u> </u> F |

| 10. Flank pain is a prominent symptom of hydronephrosis. | <u> </u> T | <u> </u> F |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. What lifestyle habit puts a client at risk for prostatitis? _____
2. What is the term for the amount a client should weigh after urinating if renal functioning is not impaired? _____
3. What type of screening is needed by a child with a known risk of Wilm's tumor? _____
4. What volume per hour of urine is considered significantly low and warrants notifying the physician? _____
5. What percentage of cardiac output circulates each minute through the kidneys? _____
6. Polyuria is described as a daily urine output exceeding _____

MATCHING QUESTIONS

Match the following:

Column A

1. _____ Hematuria
2. _____ Glomerulonephritis
3. _____ Nephrotic syndrome
4. _____ Dysuria
5. _____ Renal insufficiency
6. _____ Costovertebral angle tenderness
7. _____ Pyridium
8. _____ ESRD
9. _____ Oliguria
10. _____ Kayexalate
11. _____ Calcium carbonate
12. _____ Anuria

Column B

- a. Inability to filter and excrete proteins
- b. Glomerulonephritis is among the leading cause
- c. Symptom of pyelonephritis
- d. Urine output between 100–400 cc in 24 hours
- e. Urinary analgesic that discolors urine
- f. Can follow untreated streptococcal infections
- g. May obstruct urine flow
- h. Connects artery and vein
- i. Urethra on ventral surface of penis
- j. Surgical removal of the kidney
- k. Surgical removal of the bladder
- l. Lowers serum potassium levels

(continued)

- | | |
|-------------------------------|--|
| 13. ____ Renal calculi | m. Lowers serum phosphate levels |
| 14. ____ AVF | n. 75–80% loss of nephron functioning |
| 15. ____ Hydronephrosis | o. Urine output <100 cc in 24 hours |
| 16. ____ Hypospadias | p. Helps keep urine acidic |
| 17. ____ Nephrectomy | q. Bladder must be full at onset of procedure |
| 18. ____ Cystectomy | r. Applying pressure over symphysis pubis to expel urine |
| 19. ____ Ureterosigmoidostomy | s. Percutaneously introduced urinary catheter |
| 20. ____ Vitamin C | t. Measures bladder pressure and volume during filling and storage |
| 21. ____ Cystoscopy | u. Urinary diversion that mixes urine and stool |
| 22. ____ Urinary flow rate | v. Endoscopic visualization of the bladder and urethra |
| 23. ____ Cystometrogram | w. Bloody urine |
| 24. ____ Suprapubic catheter | x. Painful urination |
| 25. ____ Credé maneuver | y. Stretching of the renal pelvis as a result of obstruction |

APPLICATION QUESTIONS

1. A client develops renal failure from a massive hemorrhage following a motor vehicle accident. This client's renal failure would be classified as
 - a. Prerenal
 - b. Intrarenal
 - c. Postrenal
 - d. Chronic
2. The nurse has completed client education on a renal diet. The nurse will recognize that the client understands the teaching when the client states that he will restrict (Mark all that apply)
 - a. calories
 - b. proteins
 - c. fluids
 - d. potassium
3. The client is diagnosed as being in acute renal failure. The nurse would expect the lab results to show
 - a. metabolic acidosis
 - b. metabolic alkalosis
 - c. respiratory acidosis
 - d. respiratory alkalosis
4. The nurse is teaching a group of women about UTIs. The nurse would identify risk factors for developing UTIs as including (Mark all that apply)
 - a. decreased mobility
 - b. wearing cotton underwear
 - c. bowel incontinence
 - d. consumption of cranberry juice
5. A client is being treated for renal failure. Which assessment data would indicate a progression of the disease?
 - a. Lowering GFR
 - b. Rising hematocrit and hemoglobin
 - c. Decreased blood glucose levels
 - d. Elevated urine bicarbonate

6. The client has a history of painless hematuria. The client asks the nurse what to do if it occurs again. The nurse would respond by
 - a. reassuring the client that bleeding is only significant if it is accompanied by pain.
 - b. instructing the client to seek treatment if it persists past 3 days.
 - c. encouraging prompt reporting of any visible bleeding.
 - d. informing the client that painless hematuria is diagnostic of bladder cancer.
7. When asked about organisms causing UTIs, which bacteria would the nurse identify as the most common cause?
 - a. Streptococcus
 - b. *E. coli*
 - c. Staphylococcus
 - d. Bacillus anthracis
8. A client has a surgical procedure on the urinary system. Which are potential postoperative problems for which the nurse must monitor? (Mark all that apply)
 - a. surgery on any part of the urinary tract may result in bleeding.
 - b. surgical blood loss could decrease renal perfusion.
 - c. anesthetics may decrease the perception of the need to void.
 - d. urethra may swell following cystoscopy or catheterization.
9. A pregnant woman seeks help for a UTI. The physician places the client on antibiotics. Which of the following nursing actions is appropriate for this client?
 - a. Stop medication as soon as symptoms subside
 - b. Stop medications if symptoms do not improve the 3rd day of administration
 - c. Obtain specimen for culture and sensitivity immediately after initiating
 - d. Administer around the clock at timed intervals
10. The nurse working on a urology hospital unit monitors clients for urosepsis. The nurse would recognize that the population most at risk for the development of urosepsis is
 - a. females
 - b. males
 - c. elderly
 - d. athletes
11. The nurse is evaluating a client for a UTI. To correctly assess for costovertebral angle tenderness, the nurse would
 - a. use fist percussion performed bilaterally on the posterior chest below the rib cage.
 - b. have the client contract pelvic floor muscles for 10 seconds, then relax them for 10 seconds.
 - c. apply pressure over symphysis pubis.
 - d. have the client contract abdominal muscles and hold his or her breath while straining.
12. A woman is 28-weeks pregnant and develops a UTI. The maternity nurse will monitor the client for
 - a. uterine contractions
 - b. hypertension
 - c. a white, cheesy vaginal discharge
 - d. varicose veins
13. A nurse inserts a urinary catheter into the bladder immediately after the child has voided. The child's mother asks why the nurse does this since the child has voided. The nurse explains that this procedure checks for retained urine referred to as
 - a. Insensible
 - b. Residual
 - c. Incidental
 - d. Tubular
14. A client has returned from surgery for a radical prostatectomy. The nurse would adjust the flow of sterile normal saline in a three-way bladder irrigation to keep the urine
 - a. bright red
 - b. pale yellow
 - c. pink-tinged
 - d. dark amber
15. The urology clinic nurse conducts a class on urinary health for a group of clients. After teaching, the nurse asks the clients "What volume of daily fluid intake is recommended for a healthy adult?" The client that best understands the concept is the client who answers
 - a. 750 ml/d
 - b. 1000 ml/d
 - c. 2000 ml/d
 - d. 3000 ml/d

(continued)

16. A client is being admitted for urinary retention and bladder distention. On completing the admission history, the nurse would expect the client to describe which urinary symptom as preceding the development of urinary retention and bladder distention?
 - a. Nocturnal enuresis
 - b. Hesitancy
 - c. Dysuria
 - d. Hematuria
17. The mother of a child diagnosed with glomerulonephritis asks about the normal function of the kidney. Which functions would be correct for the nurse to identify?
 - a. Excretion of waste products
 - b. Control of blood pressure
 - c. Manufacture of electrolytes
 - d. Regulation of red blood cell production
18. The nurse hears a group of mothers discussing their children, all of whom have nocturnal enuresis. The mothers ask the nurse if it is normal that their children are bed-wetting. The nurse would explain that nocturnal enuresis is considered abnormal after
 - a. age 2
 - b. age 4
 - c. age 6
 - d. the onset of puberty
19. The client has a history of nephrolithiasis. The nurse has completed the appropriate client teaching. Which statement by the client demonstrates an understanding of the teaching?
 - a. "I will decrease fluid intake to 1000 ml/d."
 - b. "I will strain urine and save solid material for analysis."
 - c. "I will avoid calcium-rich foods or calcium supplements."
 - d. "I will maintain bed rest with bathroom privileges."
20. A nurse assesses four pediatric clients and finds each client has one of the following symptoms. The nurse would suspect a Wilm's tumor in the child with
 - a. hypertension
 - b. nocturnal enuresis
 - c. oliguria
 - d. painful hematuria
21. The nurse reviews the medical orders for a client with acute prostatitis. The nurse would question the order for which intervention?
 - a. NSAIDS
 - b. Broad-spectrum antibiotics
 - c. Massage prostate
 - d. Sitz baths
22. After being diagnosed with pyelonephritis, the client asks the nurse what causes this disorder. The nurse's response would be based on the knowledge that the most common cause of pyelonephritis is/are
 - a. urethritis and cystitis
 - b. potassium imbalances
 - c. sodium imbalances
 - d. uremic syndrome
23. A client is being treated for nephrolithiasis. The nurse should monitor the client for the common complication of
 - a. hydronephrosis
 - b. gout
 - c. immobility
 - d. defective cystine metabolism
24. The nurse observes that the client's urine is dark yellow and appears very concentrated. The lab test that would correlate with this data would be
 - a. high urine specific gravity.
 - b. low hemoglobin and hematocrit.
 - c. elevated WBC count.
 - d. proteinuria.
25. A child has been diagnosed with nephritic syndrome. The nurse tells the mother that the child needs to be protected from infection. The mother asks why. The nurse explains the child is susceptible to infection because (Select all that apply)
 - a. edema fluid is a good medium for bacterial growth.
 - b. decreased blood proteins reduce the production of gamma globulin.
 - c. the child is on a low-sodium diet.
 - d. the child is lethargic.

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Confusion may be the only clinical sign of a UTI in the older adult. *True*
2. Recurrent episodes of UTIs could progress to permanent kidney damage. *True*
3. Placement of an indwelling catheter to treat urinary incontinence decreases the risk for a UTI. *False*
Regardless of the reason for placement, indwelling catheters increase the risk for infection by providing a portal of entry for bacteria.
4. A client with nocturia should be instructed to schedule the majority of fluid intake prior to 4 p.m. *True*
5. Symptoms of renal failure occur when 40% of nephrons become nonfunctioning. *False*
Healthy nephrons enlarge and compensate until 75% or more of the nephrons become nonfunctioning.
6. Renal calculi larger than 7 mm usually require some form of surgical intervention. *True*
7. Surgical correction of cryptorchidism is usually performed prior to the age of 6 months. *False*
Testicles often descend without intervention in the first year of life.
8. Infants with hypospadias should not be circumcised. *True*
9. Dehydration is a risk factor for urinary calculi. *True*
10. Flank pain is a prominent symptom of hydronephrosis. *True*

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. What lifestyle habit puts a client at risk for prostatitis? Multiple sexual partners.
2. What is the amount a client should weigh after urinating if renal functioning was not impaired? Dry weight.
3. What type of screening is needed by a child with a known risk of Wilm's tumor? Kidney ultrasound.
4. What volume per hour of urine is considered significantly low and warrants notifying the physician? 30 ml.
5. What percentage of cardiac output circulates each minute through the kidneys? approximately 25%.
6. Polyuria is described as a daily urine output exceeding 2500 ml.

MATCHING ANSWERS

Match the following:

- | | |
|---|--|
| 1. <u>w</u> Hematuria | a. Inability to filter and excrete proteins |
| 2. <u>f</u> Glomerulonephritis | b. Glomerulonephritis is among the leading cause |
| 3. <u>a</u> Nephrotic syndrome | c. Symptom of pyelonephritis |
| 4. <u>x</u> Dysuria | d. Urine output between 100–400 cc in 24 hours |
| 5. <u>n</u> Renal insufficiency | e. Urinary analgesic that discolors urine |

| 21. <u>v</u> Cystoscopy | u. Urinary diversion that mixes urine and stool |
| 22. <u>q</u> Urinary flow rate | v. Endoscopic visualization of the bladder and urethra |
| 23. <u>t</u> Cystometrogram | w. Bloody urine |
| 24. <u>s</u> Suprapubic catheter | x. Painful urination |
| 25. <u>r</u> Credé maneuver | y. Stretching of the renal pelvis as a result of obstruction |

APPLICATION ANSWERS

1. A client develops renal failure from a massive hemorrhage following a motor vehicle accident. This client's renal failure would be classified as
- Prerenal
 - Intrarenal
 - Postrenal
 - Chronic

Rationale

Correct answer: a.

Prerenal failure results from a decrease in blood supplying the kidneys.

Incorrect answers: b, c, and d.

Intrarenal failure results from renal tubular cell damage; postrenal failure results from obstructed urinary flow; chronic renal failure is a progressive, irreversible loss of renal function not based on the location of its cause.

2. The nurse has completed client education on a renal diet. The nurse will recognize that the client understands the teaching when the client states that he will restrict (Mark all that apply.)
- calories
 - proteins
 - fluids
 - potassium

Rationale

Correct answers: b, c, and d.

Incorrect answer: a.

Renal diets are high in calories.

3. The client is diagnosed as being in acute renal failure. The nurse would expect the lab results to show
- metabolic acidosis
 - metabolic alkalosis
 - respiratory acidosis
 - respiratory alkalosis

Correct answer: a.

Clients with acute oliguria cannot eliminate the daily metabolic load of acid-type substances produced by metabolic processes and normal buffering mechanisms fail.

Incorrect answers: b, c, and d.

Metabolic alkalosis occurs with losses of H⁺ and chloride acid, most commonly with vomiting, gastric suctioning, or hyperkalemia. Respiratory acidosis and alkalosis are rooted in ventilation problems.

4. The nurse is teaching a group of women about UTIs. The nurse would identify risk factors for developing UTIs as including (Mark all that apply.)

- decreased mobility
- wearing cotton underwear
- bowel incontinence
- consumption of cranberry juice

Rationale

Correct answers: a and c.

Incorrect answers: b and d.

Wearing cotton underwear discourages irritation and inflammation and cranberry juice discourages bacterial growth by increasing urine acidity, so both decrease the risk for UTI.

5. A client is being treated for renal failure. Which assessment data would indicate a progression of the disease?
- Lowering GFR
 - Rising hematocrit and hemoglobin
 - Decreased blood glucose levels
 - Elevated urine bicarbonate

Rationale

Correct answer: a.

As renal functioning declines, the GFR decreases.

Incorrect answers: b, c, and d.

H&H would decrease as the body retains fluid and production of RBCs is impaired; low blood glucose is not linked with renal impairment; kidneys would not increase bicarbonate excretion in response to the metabolic acidosis associated with renal failure because it would worsen the acidosis.

6. The client has a history of painless hematuria. The client asks the nurse what to do if it occurs again. The nurse would respond by
- reassuring the client that bleeding is only significant if it is accompanied by pain.
 - instructing the client to seek treatment if it persists past 3 days.
 - encouraging prompt reporting of any visible bleeding.
 - informing the client that painless hematuria is diagnostic of bladder cancer.

Rationale

Correct answer: c.

Incorrect answers: a, b, and d.

Significant bleeding is often painless and should be investigated promptly; may be associated with genitourinary problems, cancer, or a bleeding disorder.

(continued)

7. When asked about organisms causing UTIs, which bacteria would the nurse identify as the most common cause?
- Streptococcus
 - Escherichia coli (*E.coli*)
 - Staphylococcus
 - Bacillus anthracis

Rationale

Correct answer: b.

E. coli is responsible for 80% of UTIs.

Incorrect answers: a, c, and d.

8. A client has a surgical procedure on the urinary system. Which are potential postoperative problems for which the nurse must monitor? (Mark all that apply.)
- surgery on any part of the urinary tract may result in bleeding.
 - surgical blood loss could decrease renal perfusion.
 - anesthetics may decrease the perception of the need to void.
 - urethra may swell following cystoscopy or catheterization.

Rationale

Correct answers: a, b, c, and d.

Bleeding, decreased renal perfusion, decreased perception of need to void, and edema are all risks associated with urological surgery.

9. A pregnant woman seeks help for a UTI. The physician places the client on antibiotics. Which of the following nursing actions is appropriate for this client?
- Stop medication as soon as symptoms subside
 - Stop medications if symptoms do not improve the third day of administration
 - Obtain specimen for culture and sensitivity immediately after initiating
 - Administer around the clock at timed intervals

Rationale

Correct answer: d.

Incorrect answers: a, b, and c.

Client should take the complete course of medication, even if symptoms of infection subside. Specimens for C&S are collected prior to the administration of antibiotics.

10. The nurse working on a urology hospital unit monitors clients for urosepsis. The nurse would recognize that the population most at risk for the development of urosepsis is
- females
 - males

- elderly
- athletes

Rationale

Correct answer: c.

The elderly and immunosuppressed are at higher risk and should be closely monitored for S&S of sepsis.

Incorrect answers: a, b, and d.

Gender and athletic activity do not play a role in increasing risks.

11. The nurse is evaluating a client for a UTI. To correctly assess for costovertebral angle tenderness, the nurse would
- use fist percussion performed bilaterally on the posterior chest below rib cage.
 - have the client contract pelvic floor muscles for 10 seconds, then relax them for 10 seconds.
 - apply pressure over symphysis pubis.
 - have the client contract abdominal muscles and hold his or her breath while straining.

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

Pelvic floor muscle contractions are Kegel exercises; pressure over symphysis pubis is Credé maneuver; abdominal muscle contraction while bearing down is Valsalva maneuver.

12. A woman is 28-weeks pregnant and develops a UTI. The maternity nurse will monitor the client for
- uterine contractions
 - hypertension
 - a white, cheesy vaginal discharge
 - varicose veins

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

UTIs during pregnancy are associated with preterm labor. The nurse should monitor for uterine contractions. The other complications occur in pregnancy but not in relation to a UTI.

13. A nurse inserts a urinary catheter into the bladder immediately after the child has voided. The child's mother asks why the nurse does this since the child has voided. The nurse explains that this procedure checks for retained urine referred to as
- Insensible
 - Residual
 - Incidental
 - Tubular

Rationale

Correct answer: b.

Incorrect answers: a, c, and d.

Residual urine.

14. A client has returned from surgery for a radical prostatectomy. The nurse would adjust the flow of sterile normal saline in a three-way bladder irrigation to keep the urine
- bright red
 - pale yellow
 - pink-tinged
 - dark amber

Rationale

Correct answer: c.

Incorrect answers: a, b, and d.

15. The urology clinic nurse conducts a class on urinary health for a group of clients. After teaching, the nurse asks the clients “What volume of daily fluid intake is recommended for a healthy adult?” The client that best understands the concept is the client who answers
- 750 ml/d
 - 1000 ml/d
 - 2000 ml/d
 - 3000 ml/d

Rationale

Correct answer: c.

A healthy adult consumes up to 2000 ml of fluid per day and normally all but 400–500 ml of this is excreted as urine. The remainder is lost from the skin, lungs, and GI tract.

Incorrect answers: a, b, and d.

16. A client is being admitted for urinary retention and bladder distention. In completing the admission history, the nurse would expect the client to describe which urinary symptom as preceding the development of urinary retention and bladder distention?
- Nocturnal enuresis
 - Hesitancy
 - Dysuria
 - Hematuria

Rationale

Correct answer: b.

Hesitancy may impair complete emptying

Incorrect answers: a, c, and d.

Nocturnal enuresis is incontinence while sleeping, dysuria is painful urination, and hematuria is bleeding into the urine.

17. The mother of a child diagnosed with glomerulonephritis asks about the normal function of the kidney. Which functions would be correct for the nurse to identify?

- Excretion of waste products
- Control of blood pressure
- Manufacture of electrolytes
- Regulation of red blood cell production

Rationale

Correct answers: a, b, and d.

Incorrect answer: c.

The kidney plays an important role in regulating electrolytes through excretion or retention, but does not actually manufacture them.

18. The nurse hears a group of mothers discussing their children, all of whom have nocturnal enuresis. The mothers ask the nurse if it is normal that their children are bed-wetting. The nurse would explain that nocturnal enuresis is considered abnormal after
- age 2
 - age 4
 - age 6
 - the onset of puberty

Rationale

Correct answer: c.

There is a developmental aspect to nocturnal enuresis and it is not considered a problem until age 6.

Incorrect answers: a, b, and d.

19. The client has a history of nephrolithiasis. The nurse has completed the appropriate client teaching. Which statement by the client demonstrates an understanding of the teaching?
- “I will decrease fluid intake to 1000 ml/d”
 - “I will strain urine and save solid material for analysis.”
 - “I will avoid calcium-rich foods or calcium supplements”
 - “I will maintain bed rest with bathroom privileges.”

Rationale

Correct answer: b.

All urine should be strained through gauze

Incorrect answers: a, c, and d.

Fluid intake should be increased to 3000–4000 ml/d; low-calcium intake is generally not recommended and can lead to osteoporosis; ambulation would encourage natural passage.

20. A nurse assesses four pediatric clients and finds each client has one of the following symptoms. The nurse would suspect a Wilm’s tumor in the child with
- hypertension
 - nocturnal enuresis
 - oliguria
 - painful hematuria

(continued)

Rationale

Correct answer: a.

Wilm's tumor is the most common renal cancer in children and complications include hypertension.

Incorrect answers: b, c, and d.

None are associated with Wilm's tumor.

21. The nurse reviews the medical orders for a client with acute prostatitis. The nurse would question the order for which intervention?

- a. NSAIDS
- b. Broad-spectrum antibiotics
- c. Massage prostate
- d. Sitz baths

Rationale

Correct answer: c.

Massaging an obviously swollen and tender prostate may potentially spread infection and increase the risk for sepsis.

Incorrect answers: a, b, and d.

All are therapeutic for acute prostatitis—NSAIDS relieve inflammation, broad-spectrum antibiotics treat infection, and Sitz baths provide comfort.

22. After being diagnosed with pyelonephritis, the client asks the nurse what causes this disorder. The nurse's response would be based on the knowledge that the most common cause of pyelonephritis is/are

- a. urethritis and cystitis
- b. potassium imbalances
- c. sodium imbalances
- d. uremic syndrome

Rationale

Correct answer: a.

Pyelonephritis most often occurs as the result of chronic or recurring UTIs.

Incorrect answers: b, c, and d.

Electrolyte imbalances and metabolic waste accumulation are the result of renal failure.

23. A client is being treated for nephrolithiasis. The nurse should monitor the client for the common complication of

- a. hydronephrosis
- b. gout
- c. immobility
- d. defective cystine metabolism

Rationale

Correct answer: a.

Dilation of the renal calyces is a potential complication of kidney stones.

Incorrect answers: b, c, and d.

All of these are risk factors for the development of nephrolithiasis.

24. The nurse observes that the client's urine is dark yellow and appears very concentrated. The lab test that would correlate with this data would be:

- a. high urine specific gravity
- b. low hemoglobin and hematocrit
- c. elevated WBC count
- d. proteinuria

Rationale

Correct answer: a.

Concentrated urine is measured by specific gravity of the urine.

Incorrect answers: b, c, and d.

These findings are not specific to concentrated urine.

25. A child has been diagnosed with nephritic syndrome. The nurse tells the mother that the child needs to be protected from infection. The mother asks why. The nurse explains the child is susceptible to infection because (Select all that apply.)

- a. edema fluid is a good medium for bacterial growth.
- b. decreased blood proteins reduce the production of gamma globulin.
- c. the child is on a low-sodium diet.
- d. the child is lethargic.

Rationale

Correct answers: a and b.

Incorrect answers: c and d.

These responses are related to nephritic syndrome but do not relate to fighting infection.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 1

Topics: Alterations in Body Systems
Illness Management
Section 11: Skin Problems

| | | | |
|----------------------------|-----|-------------------|-----|
| ▸ Acne Rosacea | 928 | ▸ Impetigo | 930 |
| ▸ Acne Vulgaris | 927 | ▸ Pressure Ulcers | 932 |
| ▸ Candidiasis | 930 | ▸ Psoriasis | 929 |
| ▸ Eczema | 928 | ▸ Scabies | 931 |
| ▸ Herpes Zoster (Shingles) | 929 | ▸ Skin Cancer | 931 |

SKIN PROBLEMS

Think Smart/Test Smart

As you review problems of the skin, remember that the skin plays a critical role in how the world views the client and in turn, how the client views himself or herself. As a result, there is significant psychological overlay to almost every skin problem. Further, many skin problems are difficult to treat and treatment regimes must be followed carefully for an extended length of time before any improvement is seen. Many problems are often recurrent. Thus being supportive and sensitive to the client's feelings and aware of the potential impact of the disease on the client's self concept and social interactions are essential components of care.

ACNE VULGARIS

Etiology: Multifactorial: free fatty acids, hormones, stress, heredity, infection all seem to play a role. Diet not a causative factor.

S&S: Hair follicles plugged with sebum and other cellular debris to form open (at the skin surface) or closed (under the surface) comedos (blackheads, color due to melanin not dirt, or whiteheads), inflammation occurs when sebum escapes into dermis; occurs mostly on face and neck, upper chest, and back. Healing occurs in 5–10 days without scarring; large, deep lesions last for weeks and typically cause ice-pick-type scars.

Dx: Clinical presentation

Rx:

- Topical—benzoyl peroxides, retinoids, retinoid-like drugs, for example, tretinoin, and antibiotics, for example, sulfa, erythromycin, etc.
- Systemic—antibiotics, for example, tetracyclines and erythromycin for inflammatory lesions, low-progestin oral contraceptives help some; isotretinoin (accutane) also an option

Clinical Alert

Isotretinoin causes birth defects and cannot be used if pregnant or likely to become pregnant so the client must be on birth control.

- Intralesional—corticosteroids for severe lesions
- Surgical—dermabrasion and laser resurfacing for scars
- Chemical peels may be used in addition to topical or systemic drug therapy

Nursing Process Elements

Client teaching for self-care

Teach client to

- keep hands and hair away from face
- avoid use of oily products
- shampoo daily
- use a gentle, nongreasy cleanser on skin; do not overwash
- use only water-based cosmetics and never leave on overnight
- avoid vigorous rubbing
- exercise care if using medication
 - avoid sun exposure if using tretinoin, tetracycline, or sulfa
 - recognize that it takes up to 8 weeks for improvement with therapy

ACNE ROSACEA

Acne rosacea is a follicular eruption of the skin with acne and a vascular component. It affects 30–50-year olds; more women are affected than men.

Etiology: Unknown.

Risk factors: Fair complexion, genetic predisposition, and easy flushing and blushing.

S&S: Erythema, papules, pustules, and enlarged superficial blood vessels of central face, cheeks and nose; ultimately,

skin of nose can become thickened, and reddish purple in color (rhinophyma)

Dx: Clinical presentation

Rx: Topical antibiotics such as Metrogel; responds slowly with frequent relapses

Nursing Process Elements

Client teaching for self-care

Teach client to

- avoid triggers, i.e., anything that induces flushing such as heat, cold, sunlight, alcohol, and spicy foods
- use sun protection daily
- use mild cleansers and avoid alcohol-based products

ECZEMA

- Eczema refers to the superficial inflammation of the skin; it is also called dermatitis.
- It occurs in many different forms each of which is triggered by specific flare factors such as dryness, change in environment or temperature, stress, etc.
- The lesions that develop are similar regardless of type. It results in erythema and local edema followed by vesicle formation with oozing and then crusting and scaling.
- The commonly identified forms include
 - contact dermatitis. Which may be allergic or irritant, lesions appear on exposed areas; patch testing may be done to determine responsible agent; Domeboro soaks are used for weeping vesicular lesions; crusts and scales are allowed to drop off naturally; topical steroids may be used along with oral antihistamines, topical antipruritics or colloidal oatmeal baths for itch.
 - atopic dermatitis. Which is a genetically based disorder occurring most commonly in children; it appears first as rough, dry skin at an age as early as 1 month; major symptom is intense pruritus; skin thickening and pigment change can occur due to scratching; hydrating the skin is the most important therapy; topical corticosteroids and immunomodulators as well as oral antihistamines are also used.
 - seborrheic dermatitis. Which occurs on the hairy areas of the body; it often worsens in winter; the cause is unknown but overgrowth of yeast is suspected; scalp sites are treated with tar, selenium, zinc, or ketoconazole preparations; facial sites are treated with topical low-potency steroids or antifungal agents.

Nursing Process Elements

Client teaching for self-care

- For contact dermatitis: teach client about the recognition and prevention of causative agent(s)
- For atopic dermatitis: teach client
 - about the proper application of topical medications (apply a thin layer, rub in well)
 - about the methods of hydrating the skin such as a 15–20 minute a warm bath with immediate application of moisturizer after patting away excess water or use of wet wraps
 - to avoid overheating, which can cause sweating and itching; to wear loose, cool clothing; to use air conditioning
 - to avoid excessive cold, which is drying
 - to avoid sunburn and other irritants such as wool, fur, rough fabrics; to wash new garments before wearing to avoid exposure to potentially irritating chemicals

PSORIASIS

Etiology: T-cell–mediated disease; specific precipitating factors typically unknown though stress, climate change, drugs, trauma, or infection seem to play a role in causing psoriasis in some people.

S&S:

- Scaling, pruritus, and erythema are classic
- Papules and plaques are raised, red, sharply circumscribed, and with a silvery scale; most common on scalp, elbows, knees, and sacrolumbar area
- Removal of scale yields pinpoint bleeding called Auspitz sign
- Characterized by remissions and exacerbations

Assessment Alert

Plaques may appear purple in dark-skinned individuals.

Dx: Clinical presentation

Rx:

- Localized disease: topical corticosteroids for a defined time; coal tar remedies for pruritus and epidermal cell turnover

- Diffuse disease: phototherapy (PUVA) therapy in which psoralens are taken 1–2 hours before exposure to UV light
- Advanced disease: methotrexate, acitretin, and the immunosuppressive, cyclosporine

Assessment Alert

Methotrexate, acitretin, and cyclosporine require monitoring of CBC, lipid, and liver function tests (LFTs).

Nursing Process Elements

Assess for effect on self-concept

Client teaching for self-care

Teach client to

- avoid possible precipitating factors: skin trauma including sunburn, extremes of temperature and stress, etc.
- shampoo frequently; use a tar, zinc, or selenium shampoo. If scalp has scales presoften plaques with mineral overnight PRN and use a fine-toothed comb to remove scales.
- apply topical medications in a thin layer as directed
- avoid self-medication

HERPES ZOSTER (SHINGLES)

Etiology: Herpes zoster (chicken pox) virus.

S&S: Clusters of vesicles in a line along the course of peripheral sensory nerves—lesions never cross the midline and typically occur unilaterally. Itching and/or intermittent or constant light burning to deep pain; persists 2–3 weeks or longer.

Complication: Postherpetic neuralgia pain syndrome that may last a year or more.

Dx: Clinical presentation

Rx: Antiviral therapy for high-risk individuals or when diagnosis is made in first 48–72 hours to decrease pain and incidence of postherpetic neuralgia; analgesics for pain; topical antipruritic agents

Clinical Alert

NSAIDs are not usually effective for pain.

**Client teaching for self-care**

Instruct client to

- wear loose clothing
- avoid contact with those who have not had chickenpox or who are immunosuppressed

CANDIDIASIS

- Candidiasis refers to an inflammation caused by an overgrowth of the fungus *Candida albicans* on the skin or the mucous membrane.
- It is normally found in mouth and GI tract and in the vagina.
- Overgrowth on mucous membrane of mouth or GI tract is called thrush or oral candidiasis or oral moniliasis.

Etiology: Overgrowth of *Candida albicans*; can be transmitted to the neonate from the mother's vagina during delivery, or by contaminated hands, bottles, or nipples. Person-to-person transmission is also possible.

Risk factors: Pregnancy, oral contraceptives, inhaled corticosteroids, poor nutrition, antibiotic therapy, diabetes mellitus, and other endocrine problems, and immunocompromise.

S&S:

- Skin infection: Moist, macerated, itchy/burning patches with vesicles and pustules most often found in warm, moist skin fold areas such as under the breasts, groin, and intergluteal region. Satellite lesions at the periphery of the inflamed area is a classic sign
- Vaginal infection: Thick, white “cottage cheese” like vaginal discharge, itching and burning
- Thrush: White, milk curd-like plaques on buccal mucosa; may extend into esophagus; causes painful burning and dysphagia

PEDS**Assessment Alert**

Plaques of oral thrush look like coagulated milk. To tell the difference, attempt to remove with a tongue blade—thrush plaques do not come off.

Dx: History, clinical presentation, microscopic examination

Rx:

- Antifungal agents such as nystatin (Mycostatin), clotrimazole (Lotrimin), ketoconazole (Nizoral), fluconazole (Diflucan)

—Topical nystatin (1 ml over oral mucous membrane every 6 hours) effectively treats thrush in most infants

- Long-term antifungal therapy may be prescribed for immunocompromised individuals
- Elimination of predisposing factors

**Clinical Alert**

Good hand washing is essential in preventing the transmission of candidiasis.

**Nursing Process Elements****Client teaching for self-care**

Teach client

- to eliminate warm, moist environments that support growth of the fungus by
 - thoroughly drying skin after bathing
 - wearing loose, absorbent clothing
- to use powder to keep skin folds from rubbing against each other
- about the early detection and treatment
- about the antifungal medications, their correct use, side effects, and importance of compliance

IMPETIGO

Etiology: Contagious, superficial skin infection caused by beta hemolytic *Streptococcus* or *Staphylococcus aureus*.

Risk factors: Childhood, *Streptococcus* in nares, spring or fall, tropical climate, poor nutrition or health, and poor hygiene.

S&S: Vesicles that rupture and leave weeping denuded area. With *Streptococcus*, honey-colored crusts form lesions on the face, arms, and legs

Dx: Clinical appearance and culture

Rx:

- Crusts removed and area washed gently bid or tid.
- Topical antibiotics bid × 10 days
- Antimicrobial soaps/washes to decrease bacteria on skin

**Nursing Process Elements**

Client teaching for self-care

- Teach client about the contagious nature of the disease
- Instruct about good hand washing of client and family members
- Instruct about keeping linens and clothing separate and washing after contact with an infected area

SCABIES

Etiology: Infestation by scabies mite; incubation period: 4–6 weeks.

Risk factors: Crowded living environments, close skin-to-skin contact.

S&S:

- Intense itching, especially at night
- Thread-like linear or serpentine gray-brown burrows visible under skin followed by papules and nodules especially in webs of fingers, on wrists, in axillae, breasts, waist, thighs, lower buttocks, and genitalia

Complication: Infection with excoriation and pustules from scratching.

Dx: Mite removed from burrow and identified under microscope

Rx:

- Permethrin applied topically from head to toe and under nails at bedtime, shower in 8 hours; repeat in 2 weeks if symptoms persist
- Gamma benzene hexachloride applied at bedtime from neck down, washed off in 8–12 hours; repeated in a week if live mites found. Low-dose topical corticosteroids bid for 1–2 weeks for posttreatment itching

Nursing Process Elements

Client Teaching for Selfcare

Instruct client to

- washing underwear, bed linens and towels in hot water and drying in dryer or iron on day of treatment
- putting nonwashable items in a tightly closed, plastic bags for several weeks

Clinical Alert

Close contacts of client must be treated even if asymptomatic because the mite is so easily transmitted.

SKIN CANCER

- The major types of skin cancer are malignant melanoma (tumor of the melanocytes), squamous cell carcinoma, and basal cell carcinoma.
- Incidence and deaths from melanoma, which metastasizes readily to regional lymph nodes and then to lungs, liver, brain and other areas, and has the worst prognosis of the three types, are increasing.
- Squamous cell carcinoma, arising on hair-bearing skin, rarely metastasizes; lesions on lip or ear may metastasize to regional nodes.
- Basal cell carcinoma rarely metastasizes but can cause extensive local tissue destruction.

Melanoma

Etiology: Often develops from a mole but may arise from healthy skin.

Risk factors:

- Genetic predisposition
- Light complexion especially with light hair and eyes
- History of blistering sunburns as a child
- Presence of multiple atypical nevi (moles)

S&S: Most lesions occur on head, neck, and the lower extremities and vary greatly. Lesions that are suspect are those that are new, have undergone change, or have grown; have deep, variegated (yellow, blue, black, gray), or no pigmentation, irregular borders, surrounding erythema or halo. Late changes are bleeding and ulceration

Dx: Excisional biopsy with sufficient margins to allow depth of invasion to be determined. Other types of biopsy contraindicated

Rx: Wide surgical excision to decrease chance of local recurrence. If invasion is more than 1-mm deep, sentinel lymph node dissection may be done followed by a complete lymphadenectomy, if the sentinel node is positive. Latter is also done when there are enlarged regional nodes found at time of diagnosis. Metastatic melanoma is resistant to chemotherapy

Squamous Cell Carcinoma

Etiology: Unknown.

Risk factors: Long-term sun damage, possibly genetic predisposition, fair skin, light hair, blue-, gray-, or green-eyed individuals, immunocompromised, previous skin cancer.

S&S: If develops from a preexisting lesion, appears indurated and surrounded by an inflammatory base. If new lesion, appears as a firm keratotic nodule with indurated base. Occurs most often on areas of the body exposed to sun with rim of the ear and the lower lip especially vulnerable.

Also can occur in areas of skin damage such as scars, burns, chronic inflammation, and areas exposed to radiation or chemicals

Dx: Biopsy

Rx: Removal by surgical excision, Mohs micrographic surgery, curettage with electrodesiccation, irradiation, or chemosurgery. Area may be treated with methotrexate following excision to destroy any remaining tumor cells and prevent local recurrence

Basal Cell Carcinoma

Etiology: Chronic overexposure to the sun.

Risk factors: Outdoor work, fair skin that sunburns easily, living in an area with long hours of sun.

S&S: Flesh color to pale pink lesion with a translucent pearly appearance with a few telangiectic blood vessels across its surface. Can cause severe tissue destruction, infection, and hemorrhage. Occurs most often on face, ears, scalp, neck, back, and shoulders

Dx: Biopsy

Rx: Same as for squamous cell

Nursing Process Elements

Client teaching for self-care

Teach client about

- how to take care of the wound if surgically treated
- the need for follow-up care to check for recurrence, metastasis, or new lesions
- the methods of reducing skin cancer risk See Chapter •••)
- periodic skin self-examination, which is best done monthly
- the importance of seeking care if any suspicious changes are noted
- washing underwear, bed linens and towels in hot water and drying in dryer or iron on day of treatment
- putting nonwashable items in a tightly closed, plastic bags for several weeks

PRESSURE ULCERS

A pressure ulcer refers to any lesion caused by unrelieved pressure.

Etiology:

- Decreased bloodflow to an area of tissue as a result of compression and damage to blood vessels. This decreases the

amount of oxygen and nutrients delivered to the cells and allows waste products to accumulate; ultimately, cells die.

- Friction—can remove superficial skin layers.
- Shearing force—combination of friction and pressure which damages blood vessels and tissues in area where deep and superficial tissues meet—occurs when deeper tissues move and surface tissues stay in place for example, when clients are pulled up in bed and the skin of the lower back and buttocks is in contact with the sheets and drags behind the deeper tissues as the client is moved.

Risk factors: Immobility, inactivity, inadequate nutrition, fecal and urinary incontinence, decreased mental status, diminished sensation, excessive body heat, advanced age, chronic medical conditions such as diabetes and cardiovascular disease that impair delivery of oxygenated blood to the tissues, and care-related factors such as poor positioning, incorrect use of pressure-relieving devices, and inappropriate lifting techniques.

S&S: Decreased blood flow causes pallor; when pressure is relieved reactive hyperemia (bright red flush due to vasodilation) occurs to compensate for the period of ischemia

Assessment Alert

The period of reactive hyperemia lasts for a period half to three-fourths as long as the period of ischemia if no permanent tissue damage has occurred. If the red flush lasts longer than this amount of time, tissue has been damaged.

S&S during the four stages of pressure ulcers:

Stage I—Nonblanchable erythema

Stage II—Partial-thickness skin loss as seen with an abrasion or blister, may involve epidermis only or epidermis and some dermis

Stage III—Full-thickness skin loss with damage to subcutaneous tissue that may go as deep as the fascia but not through it—ulcer looks like a deep crater. Undermining of adjacent tissue may or may not be present

Stage IV—Full-thickness skin loss with tissue necrosis or damage to muscle, bone, or supporting structures. Tissue undermining and sinus tracts may also be present

Dx: Clinical appearance

Rx:

- Prevention is the best treatment
- Clean and dress according to the stage of ulcer and agency protocol

- Stage I: Keep ulcer moist by use of a transparent barrier or occlusive hydrocolloid dressing
- Stage II: Keep ulcer moist by use of an occlusive hydrocolloid dressing or a hydrogel dressing
- Stage III: Use dry gauze or wet to dry gauze to wick drainage away from ulcer surface or use hydrocolloid or hydrogel to keep ulcer moist or alginate to both keep moist and absorb exudate
- Stage IV: Use dry or wet to dry gauze, hydrogel, or alginate
- Surgical treatment: Myocutaneous flaps and skin grafts in selected cases
- Diet: Increased protein (1.5–2 g/kg body weight/day) and increased calories

Clinical Alert

Ulcer will not heal unless pressure is relieved.

Complications: Most complications result from infection

- Septicemia
- Osteomyelitis

Nursing Process Elements

- Use risk assessment tools, for example, Braden scale or the Norton scale to identify clients at high risk; use on admission and then at regular intervals
- Assess essential areas such as immobility, incontinence, nutrition, and level of consciousness as part of risk
- Assess common pressure sites (bony prominences) such as sacrum, heels, elbows, shoulder blades, back of head, hip, knee, medial and lateral malleoli, shoulder, side of head, ear, vertebrae for pale or reddened areas; abrasions which occur due to friction, and excoriations which can result from exposure to body secretions/excretions particularly in skin folds
- Palpate skin over pressure areas for increased warmth and for a spongy feel characteristic of edema, both of which can be the result of inflammation
- Assess and document pertinent information about pressure ulcer: Location, size (length, width, and depth measured by inserting a sterile gloved finger or sterile applicator into the deepest part of the wound and then

measuring it against a measuring guide) in centimeters, presence of tissue undermining or sinus tracts, stage of the ulcer, color of the ulcer bed and location of necrotic tissue or eschar, appearance of the wound margins and the surrounding skin, presence or absence of signs of infection (redness, warmth, edema, pain, odor, color, and amount of exudates)

- Nursing diagnosis:
 - risk for impaired skin integrity
 - impaired skin integrity (stage I or II pressure ulcers)
 - impaired tissue integrity (stage III or IV pressure ulcers)
- Prevention:
 - Keep skin dry and free of irritating substances such as soap, alcohol, sweat, urine, and feces. Use liquid, spray or moist wipe skin barrier/prep to keep irritants off skin
 - Avoid rubbing and excessive friction during bathing and other activities
 - Use small amounts of mild, nonirritating, nondrying cleansers; avoid harsh soaps; rinse thoroughly
 - Use tepid not hot water
 - Apply moisturizer to dry skin while still moist after bathing.
- Avoid trauma to the skin:
 - Keep the surface smooth and wrinkle free
 - Use layer of cornstarch on sheet or protective film on client to protect from friction
 - Elevate the head of the bed to no more than 30 degrees to protect against shearing
 - Use a trapeze or lift to move client without dragging skin against bed surface
- Use pressure-reducing devices such as foam or gel cushions, sheepskins, wedges, or pillows to keep heels off the bed, heel protectors, egg crate, foam or alternating pressure pads or mattresses, air fluidized (AF), or static low air loss (LAL) bed
- Avoid use of doughnut-type devices, which actually decrease blood flow to central area and can damage tissue in contact with the device

Nursing Process Elements

Client teaching for self-care

- Shift position, even if slightly, every 15–30 minutes
- Report areas of persistent erythema

WORKSHEET

MATCHING QUESTIONS

Match the following:

- | | |
|--|--|
| 1. ____ Metrogel | a. Requires monitoring of LFTs |
| 2. ____ Squamous cell carcinoma | b. Infection characterized by honey-colored crusts |
| 3. ____ T-cell-mediated disease | c. Nonblanchable erythema |
| 4. ____ Thrush | d. Absorbs exudates |
| 5. ____ PUVA | e. Itch |
| 6. ____ Isotretinoin | f. Used in treatment of candidiasis |
| 7. ____ Methotrexate | g. Used in treatment of melanoma |
| 8. ____ Stage-I pressure ulcer | h. Used for acne rosacea |
| 9. ____ Melanoma | i. Form of light therapy |
| 10. ____ Intralesional corticosteroids | j. Most likely to metastasize skin cancer |
| 11. ____ Permethrin | k. Protection against effects of ischemia |
| 12. ____ Mohs surgery | l. Oral moniliasis |
| 13. ____ Rhinophyma | m. Long-term effect of acne rosacea |
| 14. ____ Alginate dressing | n. Acne treatment |
| 15. ____ Diflucan | o. Characterized by an indurated base |
| 16. ____ Basal cell carcinoma | p. Lesion with a translucent, pearly appearance |
| 17. ____ Impetigo | q. Occlusive dressing |
| 18. ____ Pruritus | r. Psoriasis |
| 19. ____ Reactive hyperemia | s. Acne therapy causing birth defects |
| 20. ____ Hydrocolloid dressing | t. Kills the scabies mite |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Persons using tretinoin, tetracycline, or sulfa for the treatment of acne need to avoid _____.
2. Oral contraceptives are required for women who could become pregnant, if _____ is prescribed for acne.
3. Raised, thread-like lesions located in the webs of the fingers are characteristic of _____.
4. Fair skin and easy flushing are risk factors for _____.
5. The rim of the ear and the lower lip are sites where _____ is particularly likely to occur.
6. Candidiasis of the skin most often occurs in the _____ areas of the body.
7. A long-term complication of herpes zoster infection is _____.
8. Pruritus is the major symptom of _____ dermatitis.
9. The type of dermatitis found primarily in young children is _____.
10. The two types of skin change found as a result of repeated scratching in clients with dermatitis are _____ and _____.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------|-------|
| 1. Need to avoid triggers such as hot, spicy foods and alcohol is an important part of the teaching for clients with psoriasis. | _____ | _____ |
| | T | F |
| 2. Domeboro soaks are used for the weeping vesicular lesions of contact dermatitis. | _____ | _____ |
| | T | F |
| 3. Removal of the scale of psoriasis yields pinpoint bleeding called the Auspitz sign. | _____ | _____ |
| | T | F |
| 4. Lesions of herpes zoster never cross the midline. | _____ | _____ |
| | T | F |
| 5. NSAIDs are not usually effective for the pain of shingles. | _____ | _____ |
| | T | F |
| 6. Inhaled corticosteroids place the client at risk for oral candidiasis. | _____ | _____ |
| | T | F |
| 7. Full-thickness skin loss with damage to subcutaneous tissue that may go as deep as the fascia is a stage-IV pressure ulcer. | _____ | _____ |
| | T | F |
| 8. Metastatic melanoma is resistant to chemotherapy. | _____ | _____ |
| | T | F |
| 9. Intense itching especially in the morning is characteristic of scabies. | _____ | _____ |
| | T | F |
| 10. White, milk curd-like plaques on buccal mucosa are characteristic of <i>Candida albicans</i> overgrowth. | _____ | _____ |
| | T | F |

APPLICATION QUESTIONS

1. Which direction must be given to an adolescent being treated with tetracycline for acne?
 - a. Eliminate fatty foods from the daily diet
 - b. Wash affected areas thoroughly at least every 4 hours during the day
 - c. Keep out of direct sunlight
 - d. Use only oil-based skin care products
2. Which information should the nurse include in the teaching plan for a woman being treated for acne rosacea?
 - a. Alcohol-based products help reduce erythema
 - b. Rhinophyma only occurs in men
 - c. Metrogel rapidly eliminates large pustules and papules
 - d. Sun block needs to be used daily
3. When assessing a dark-skinned client with psoriasis, which finding would be consistent with the S&S of the disorder?
 - a. Raised, sharply-demarcated plaques that appear purple in color
 - b. Silvery scales on an indurated, erythematous base
 - c. Translucent, pearly appearing pink to red papules
 - d. Honey-colored crusts on shallow ulcers
4. Which information would the nurse include when developing a teaching plan for a client receiving methotrexate for psoriasis?
 - a. Creatinine clearance and other tests of renal function are required weekly for the first month of therapy
 - b. Periodic EKGs will be done from the start of therapy until 6 months after its completion
 - c. Pulmonary function tests and arterial blood gases need to be checked before the start of therapy
 - d. Liver function tests, lipid levels, and blood counts need to be monitored during therapy
5. Which order would the nurse expect to be included in the plan of care for a client with herpes zoster?
 - a. Administer ibuprofen 800 mg q 4 hours for pain
 - b. Prevent contact with persons who have never had chickenpox
 - c. Keep affected area tightly covered with a moisture-preserving dressing
 - d. Monitor for change in respiratory status every 4 hours
6. The mother of an infant diagnosed with “diaper” candidiasis (candidiasis affecting the area of the body covered by a diaper) asks what caused this problem. Which information should serve as the basis of the nurse’s response?
 - a. It is caused by a type of bacteria that is normal on the skin of older children and adults
 - b. It is an inflammatory response due to irritation from urine and fecal matter
 - c. It is caused by a fungus which normally is found in areas of the body such as the mouth and vagina
 - d. Its cause is unknown but likely involves an allergy to some substance that the infant has encountered
7. Escape of sebum into the dermis is the cause of inflammation in which disorder?
 - a. Moniliasis
 - b. Impetigo
 - c. Acne vulgaris
 - d. Psoriasis
8. Which direction would be appropriate to give to the mother of an 8-year-old child diagnosed with impetigo?
 - a. Allow crusts to drop off the affected area naturally
 - b. Keep the child’s linens and clothing separate from others
 - c. Cover the affected area at night with a dry, sterile dressing
 - d. Keep the child away from anyone who has not had chicken pox
9. Which characteristics of a skin lesion make it a suspect for being melanoma? (Select all that apply.)
 - a. Congenital
 - b. Variegated in color
 - c. Irregular border
 - d. Ulcerated
 - e. Bleeding
 - f. Sharply demarcated
10. When gamma benzene hexachloride is prescribed for the management of scabies, which directions should the nurse give the client regarding its use?
 - a. Apply from head to toe; wait 4 hours; wash off; repeat in 2 weeks
 - b. Apply to intertriginous areas; rub in well; repeat daily until itch disappears

- c. Apply from neck down at bedtime; wash off in 8–12 hours; repeat in 1 week if live mites seen
 d. Apply to hairy areas of the body; do not rub in; wait 8 hours and rinse off thoroughly
11. When an adolescent who is beginning acne treatment asks if his skin will be clear in time for the junior prom, on which fact should the nurse's reply be based?
 a. The response to therapy is completely unpredictable
 b. Lesions should begin to clear in about 2 weeks
 c. It can take up to 8 weeks for a response to therapy to be noticeable
 d. It will depend on how well the client complies with the prescribed diet
12. Which client would the nurse expect to have an order for antiviral therapy?
 a. 3-month-old boy with diaper candidiasis
 b. 10-year-old girl with eczema affecting the face and neck
 c. 45-year-old woman with impetigo of 10 days duration
 d. 75-year-old man who broke out with herpes zoster 12 hours ago
13. What is the major symptom of atrophic dermatitis in children?
 a. Marked erythema
 b. Intense itching
 c. Pinpoint ecchymoses
 d. Peeling epidermis
14. For which type of skin lesion would Domeboro's solution most likely be used?
 a. Weeping vesicular
 b. Pustular
 c. Dry, scaly
 d. Seborrheic papule
15. A coal tar based topical preparation is prescribed for a client with psoriasis. The client asks what this preparation is expected to do. The nurse's response should be based on which fact?
 a. Coal tar preparations protect against excessive loss of skin oils
 b. Coal tar preparations have an anti-infective effect
 c. Coal tar preparations decrease epidermal cell turnover and pruritus
 d. Coal tar preparations counteract the allergic component of the disease
16. A client with psoriasis who is to begin PUVA therapy calls to verify when the ordered psoralen is to be taken. Which is the appropriate answer to be given?
 a. At bedtime, the night before treatment
 b. With breakfast, on the day of treatment
 c. One and a half to two hours before treatment
 d. Immediately following treatment
17. Which assessment finding best supports the conclusion that the care given to a client with a stage-II pressure ulcer has been effective?
 a. The client changes position every hour
 b. The dressing over the ulcer is intact
 c. Diameter of the ulcer has decreased by 50%
 d. The ulcerated area is free of drainage
18. Which is an appropriate expected outcome for a client with postherpetic neuralgia?
 a. Client states pain is 2 or less on a scale from 1 to 10
 b. Skin lesions have disappeared
 c. Antibody titers are positive for varicella
 d. Affected area is limited to one dermatome.
19. An elderly client at risk for impaired skin integrity is to have moisturizer applied to her skin. When delegating this task to a nursing assistant, which direction should be given?
 a. Dry skin thoroughly and then apply generous amounts of moisturizer
 b. Do not rub in moisturizer that is applied to skin fold areas
 c. Apply moisturizer only to areas of the skin that appear chapped or flaky
 d. Apply moisturizer while skin is still moist from bathing
20. Which measure is effective in preventing shearing forces from causing tissue damage over the lumbosacral area?
 a. Adjusting sheets so they are wrinkle free
 b. Changing client's position every 2 hours
 c. Maintaining head of bed at an elevation of 0–30 degrees
 d. Keeping client's skin clean and dry
21. Assessment of a newly admitted client shows a full-thickness skin loss with an ulcer that looks like a deep crater and clear undermining of adjacent tissue. This finding would be documented as which stage of pressure ulcer?
 a. I
 b. II
 c. III
 d. IV

(continued)

22. An alginate dressing is ordered for a client with a stage-IV pressure ulcer. The client's daughter asks what this type of dressing does. On which fact should the nurse's answer be based?
- Alginate dressings are impregnated antibiotics
 - Alginate dressings keep the wound moist and absorb exudates
 - Alginate dressings keep the wound dry and encourage granulation
 - Alginate dressings have an antibacterial effect
23. When planning care of the client with a stage-III pressure ulcer, the nurse must be cognizant of the fact that most complications of pressure ulcers relate to which type of event?
- Infection
 - Immune reaction
 - Fluid imbalance
 - Malabsorption
24. Which measure might the nurse use to assess a client's risk for developing a pressure ulcer?
- Barthel Index
 - Glasgow Coma Scale
 - Katz Index
 - Braden Scale
25. When assessing the daily diet of a client with a pressure ulcer, how much protein should the nurse consider to be an adequate intake?
- 0.5–1 g/kg body weight/day
 - 1–2 g/kg body weight/day
 - 1.5–2 g/kg body weight/day
 - 2–2.5 g/kg body weight/day

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following:

- | | |
|--|--|
| 1. <u>h</u> Metrogel | a. Requires monitoring of LFTs |
| 2. <u>o</u> Squamous cell carcinoma | b. Infection characterized by honey-colored crusts |
| 3. <u>r</u> T-cell-mediated disease | c. Nonblanchable erythema |
| 4. <u>l</u> Thrush | d. Absorbs exudates |
| 5. <u>i</u> PUVA | e. Itch |
| 6. <u>s</u> Isotretinoin | f. Used in treatment of candidiasis |
| 7. <u>a</u> Methotrexate | g. Used in treatment of melanoma |
| 8. <u>c</u> Stage I pressure ulcer | h. Used for acne rosacea |
| 9. <u>j</u> Melanoma | i. Form of light therapy |
| 10. <u>n</u> Intralesional corticosteroids | j. Most likely to metastasize skin cancer |
| 11. <u>t</u> Permethrin | k. Protection against effects of ischemia |

- | | |
|------------------------------------|---|
| 12. <u>g</u> Mohs surgery | l. Oral moniliasis |
| 13. <u>m</u> Rhinophyma | m. Long-term effect of acne rosacea |
| 14. <u>d</u> Alginate dressing | n. Acne treatment |
| 15. <u>f</u> Diflucan | o. Characterized by an indurated base |
| 16. <u>p</u> Basal cell carcinoma | p. Lesion with a translucent, pearly appearance |
| 17. <u>b</u> Impetigo | q. Occlusive dressing |
| 18. <u>e</u> Pruritus | r. Psoriasis |
| 19. <u>k</u> Reactive hyperemia | s. Acne therapy causing birth defects |
| 20. <u>q</u> Hydrocolloid dressing | t. Kills the scabies mite |

ANSWERS FOR FILL IN THE BLANKS

- Persons using tretinoin, tetracycline, or sulfa for the treatment of acne need to avoid sun exposure.
- Oral contraceptives are required for women who could become pregnant, if isotretinoin is prescribed for acne.
- Raised, thread-like lesions located in the webs of the fingers are characteristic of scabies.
- Fair skin and easy flushing are risk factors for acne rosacea.
- The rim of the ear and the lower lip are sites where squamous cell carcinoma is particularly likely to occur.
- Candidiasis of the skin most often occurs in the skin fold or intertriginous areas of the body.
- A long-term complication of herpes zoster infection is postherpetic neuralgia.
- Pruritus is the major symptom of atopic dermatitis.
- The type of dermatitis found primarily in young children is atopic.
- The two types of skin change found as a result of repeated scratching in clients with dermatitis are thickening and pigment change.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Need to avoid triggers such as hot, spicy foods and alcohol is an important part of the teaching for clients with psoriasis. *False*
It is important for clients with acne rosacea, not psoriasis.
2. Domeboro soaks are used for the weeping vesicular lesions of contact dermatitis. *True*
3. Removal of the scale of psoriasis yields pinpoint bleeding called the Auspitz sign. *True*
4. Lesions of herpes zoster never cross the midline. *True*
5. NSAIDs are not usually effective for the pain of shingles. *True*
6. Inhaled corticosteroids place the client at risk for oral candidiasis. *True*
7. Full-thickness skin loss with damage to subcutaneous tissue that may go as deep as the fascia is a stage-IV pressure ulcer. *False*
It is a stage-III ulcer; stage-IV ulcer goes through the fascia into the underlying structures.
8. Metastatic melanoma is resistant to chemotherapy. *True*
9. Intense itching especially in the morning is characteristic of scabies. *False*
Intense itch occurs at night.
10. White, milk curd-like plaques on buccal mucosa are characteristic of *Candida albicans* overgrowth. *True*

APPLICATION ANSWERS

1. Which direction must be given to an adolescent being treated with tetracycline for acne?
 - a. Eliminate fatty foods from the daily diet
 - b. Wash affected areas thoroughly at least every 4 hours during the day
 - c. Keep out of direct sunlight
 - d. Use only oil-based skin care products
2. Which information should the nurse include in the teaching plan for a woman being treated for acne rosacea?
 - a. Alcohol-based products help reduce erythema
 - b. Rhinophyma only occurs in men
 - c. Metrogel rapidly eliminates large pustules and papules
 - d. Sun block needs to be used daily

Rationale

Correct answer: c.

Clients on tetracycline, sulfa, or tretinoin need to avoid exposure to sunlight so this is correct advice. The other options are incorrect because there is no documented relationship between diet and acne; overwashing should be avoided; and only water-based cosmetic and skin products should be used.

Rationale

Correct answer: d.

Daily sun protectant is needed. Alcohol-based products should be avoided; rhinophyma occurs in both males and females; and acne rosacea responds slowly, not rapidly, to Metrogel.

3. When assessing a dark-skinned client with psoriasis, which finding would be consistent with the S&S of the disorder?
- Raised, sharply-demarcated plaques that appear purple in color
 - Silvery scales on an indurated, erythematous base
 - Translucent, pearly appearing pink to red papules
 - Honey-colored crusts on shallow ulcers

Rationale

Correct answer: a.

In dark-skinned persons, the raised, sharply demarcated plaques of psoriasis may appear purple. Silvery scales do occur with psoriasis but the lesions do not have an indurated, erythematous base. Translucent pink to red papules that have a pearly appearance are characteristic of basal cell carcinoma while honey-colored crusts are characteristic of impetigo.

4. Which information would the nurse include when developing a teaching plan for a client receiving methotrexate for psoriasis?
- Creatinine clearance and other tests of renal function are required weekly for the first month of therapy
 - Periodic EKGs will be done from the start of therapy until 6 months after its completion
 - Pulmonary function tests and arterial blood gases need to be checked before the start of therapy
 - Liver function tests, lipid levels, and blood counts need to be monitored during therapy

Rationale

Correct answer: d.

Liver function, lipid levels and blood counts need to be monitored during therapy with methotrexate because of its side effects. Routine monitoring of respiratory, cardiac, and renal function is not necessary.

5. Which order would the nurse expect to be included in the plan of care for a client with herpes zoster?
- Administer ibuprofen 800 mg q 4 hours for pain
 - Prevent contact with persons who have never had chickenpox
 - Keep affected area tightly covered with a moisture-preserving dressing
 - Monitor for change in respiratory status every 4 hours

Rationale

Correct answer: b.

Herpes zoster is caused by the varicella (chickenpox) virus. Therefore, clients with herpes zoster can pass the viruses to others and if they are not immune to chickenpox, they can develop the disease. Ibuprofen is an NSAID and NSAIDs are generally not effective in treating pain

associated with herpes zoster so this order would not be expected. Lesions are left open to the air so an order for a dressing would not be expected; nor would an order for monitoring respiratory status be expected, as this is not altered by herpes zoster infection.

6. The mother of an infant diagnosed with “diaper” candidiasis (candidiasis affecting the area of the body covered by a diaper) asks what caused this problem. Which information should serve as the basis of the nurse’s response?
- It is caused by a type of bacteria that is normal on the skin of older children and adults.
 - It is an inflammatory response due to irritation from urine and fecal matter
 - It is caused by a fungus which normally is found in areas of the body such as the mouth and vagina
 - Its cause is unknown but likely involves an allergy to some substance that the infant has encountered

Rationale

Correct answer: c.

Candidiasis is caused by a fungus not by bacteria. Irritation may be a risk factor. Allergy is not the cause.

7. Escape of sebum into the dermis is the cause of inflammation in which disorder?
- Moniliasis
 - Impetigo
 - Acne vulgaris
 - Psoriasis

Rationale

Correct answer: c.

The inflammation of acne vulgaris is caused by escape of sebum into the dermis. Moniliasis is caused by a fungus, which is the source of irritation, and impetigo is caused by infection with bacteria such as *Staphylococcus aureus* or beta hemolytic *Streptococcus*. Psoriasis is a T-cell-mediated disease.

8. Which direction would be appropriate to give to the mother of an 8-year-old child diagnosed with impetigo?
- Allow crusts to drop off the affected area naturally
 - Keep the child’s linens and clothing separate from others
 - Cover the affected area at night with a dry, sterile dressing
 - Keep the child away from anyone who has not had chicken pox

Rationale

Correct answer: b.

Impetigo is contagious and therefore keeping potentially contaminated clothing and linens away from those

(continued)

if others is essential. Careful hand washing and laundering of linens and clothing that have come in contact with the affected area is also critical. Crusts should be removed and the area washed two to three times per day; lesions are not routinely covered. Impetigo is typically caused by either beta hemolytic *Streptococcus* or *Staphylococcus aureus* so the varicella virus that causes chicken pox is unrelated. Clients with herpes zoster need to be kept away from persons who have not had chicken pox.

9. Which characteristics of a skin lesion make it suspect for being melanoma? (Select all that apply.)
- Congenital
 - Variegated in color
 - Irregular border
 - Ulcerated
 - Bleeding
 - Sharply demarcated

Rationale

Correct answers: b, c, d, and e.

Melanoma lesions are typically variegated in color. Lesions occur that are yellow, blue, black, gray, and even colorless. They also typically have an irregular border and may ulcerate and bleed. Melanomas usually occur as new lesions although some develop in preexisting lesions so the fact that a lesion is congenital does not increase the likelihood that it is a melanoma. Melanomas are not sharply demarcated from surrounding tissue.

10. When gamma benzene hexachloride is prescribed for the management of scabies, which directions should the nurse give the client regarding its use?
- Apply from head to toe; wait 4 hours; wash off; repeat in 2 weeks
 - Apply to intertriginous areas; rub in well; repeat daily until itch disappears
 - Apply from neck down at bedtime; wash off in 8–12 hours; repeat in 1 week if live mites seen
 - Apply to hairy areas of the body; do not rub in; wait 8 hours and rinse off thoroughly

Rationale

Correct answer: c.

Directions for the application of gamma benzene hexachloride are to apply it from the neck down at bedtime; wash it off in 8–12 hours; and repeat in a week if more live mites are seen.

11. When an adolescent who is beginning acne treatment asks if his skin will be clear in time for the junior prom, on which fact should the nurse's reply be based?

- The response to therapy is completely unpredictable
- Lesions should begin to clear in about 2 weeks
- It can take up to 8 weeks for a response to therapy to be noticeable
- It will depend on how well the client complies with the prescribed diet

Rationale

Correct answer: c.

It takes up to 8 weeks for improvement to be seen; this is one reason why compliance with the therapeutic regimen is often a problem—it takes so long for results to be noticeable. Diet restriction is not a part of the treatment plan for acne vulgaris.

12. Which client would the nurse expect to have an order for antiviral therapy?
- 3-month-old boy with diaper candidiasis
 - 10-year-old girl with eczema affecting the face and neck
 - 45-year-old woman with impetigo of 10 days duration
 - 75-year-old man who broke out with herpes zoster 12 hours ago

Rationale

Correct answer: d.

Herpes zoster is a viral infection and can be treated with an antiviral medication when it is diagnosed in the first 48–72 hours in an effort to shorten the course of the disease and to prevent complications. Candidiasis is a fungal infection and impetigo is a bacterial infection so antiviral therapy is not used. The cause of eczema is unknown but there appears to be an allergic component; no viral role has been identified.

13. What is the major symptom of atrophic dermatitis in children?
- Marked erythema
 - Intense itching
 - Pinpoint ecchymoses
 - Peeling epidermis

Rationale

Correct answer: b.

Intense pruritus is the major symptom of atrophic dermatitis in children.

14. For which type of skin lesion would Domeboro's solution most likely be used?
- Weeping vesicular
 - Pustular
 - Dry, scaly
 - Seborrheic papule

Rationale

Correct answer: a.

Domeboro's (Burow's) solution (aluminum acetate solution) exerts an astringent effect and is used on vesicular lesions. It also has antiseptic and antipruritic effects.

15. A coal tar based topical preparation is prescribed for a client with psoriasis. The client asks what this preparation is expected to do. The nurse's response should be based on which fact?
- Coal tar preparations protect against excessive loss of skin oils
 - Coal tar preparations have an anti-infective effect
 - Coal tar preparations decrease epidermal cell turnover and pruritus
 - Coal tar preparations counteract the allergic component of the disease

Rationale

Correct answer: c.

Coal tar is an antiproliferative agent that acts by suppressing DNA synthesis in the epidermis. It also has antipruritic, astringent, vasoconstrictive and is infectant effects. Anthralin is a synthetic coal tar used to treat psoriatic plaques.

16. A client with psoriasis who is to begin PUVA therapy calls to verify when the ordered psoralen is to be taken. Which is the appropriate answer to be given?
- At bedtime, the night before treatment
 - With breakfast, on the day of treatment
 - One and a half to two hours before treatment
 - Immediately following treatment

Rationale

Correct answer: b.

Psoralen is a photosensitizer and is used to potentiate the effects of ultraviolet radiation used in the treatment of psoriasis. It is taken one and a half to two hours before treatment so it is in the system when the therapy is given.

17. Which assessment finding best supports the conclusion that the care given to a client with a stage-II pressure ulcer has been effective?
- The client changes position every hour
 - The dressing over the ulcer is intact
 - Diameter of the ulcer has decreased by 50%
 - The ulcerated area is free of drainage

Rationale

Correct answer: c.

Decrease in size of the pressure ulcer is the only definite sign of healing and therefore it supports a conclusion that therapy is working. Changing position every hour can effectively support healing as can an intact dressing

but neither indicates healing is occurring. Absence of drainage is not necessarily a sign of healing of a pressure ulcer.

18. Which is an appropriate expected outcome for a client with postherpetic neuralgia?
- Client states pain is 2 or less on a scale from 1 to 10
 - Skin lesions have disappeared
 - Antibody titers are positive for varicella
 - Affected area is limited to one dermatome

Rationale

Correct answer: a.

Postherpetic neuralgia is a pain syndrome that can occur as a complication of herpes zoster infection. Therefore, control of pain is the goal of therapy and so relief of pain is an expected client outcome. Skin lesions disappear as part of the course of the disease itself; they are not a postherpetic phenomenon. Antibody titers are irrelevant and the affected area refers to the original outbreak of disease.

19. An elderly client at risk for impaired skin integrity is to have moisturizer applied to her skin. When delegating this task to a nursing assistant, which direction should be given?
- Dry skin thoroughly and then apply generous amounts of moisturizer
 - Do not rub in moisturizer that is applied to skin fold areas
 - Apply moisturizer only to areas of the skin that appear chapped or flaky
 - Apply moisturizer while skin is still moist from bathing

Rationale

Correct answer: d.

Applying moisturizer while skin is still moist from bathing better hydrates the skin. Skin should not be thoroughly dried before applying moisturizer as this decreases effectiveness. Moisturizer is not left on the skin surface in areas of skin folds; this would only increase the medium for growth of microorganisms. Particularly dry areas of skin may appear chapped and flaky but dry skin occurs with age so all areas of an elderly person at risk for skin breakdown need to be moisturized.

20. Which measure is effective in preventing shearing forces from causing tissue damage over the lumbosacral area?
- Adjusting sheets so they are wrinkle free
 - Changing client's position every 2 hours
 - Maintaining head of bed at an elevation of 0–30 degrees
 - Keeping client's skin clean and dry

(continued)

Rationale

Correct answer: c.

Shearing forces, a combination of friction and pressure which damages blood vessels and tissues in area where deep and superficial tissues meet, occur when deeper tissues move and surface tissues stay in place. When the head of the bed is elevated more than 30 degrees, clients tend to slip down in bed and a shearing force results. Keeping sheets wrinkle free prevents areas of increased pressure as would occur on skin that was on top of wrinkles. Changing position at least every 2 hours prevents prolonged pressure on a single area and permits each area that was subjected to increased pressure to regain normal circulation and tissue oxygenation.

21. Assessment of a newly admitted client shows a full-thickness skin loss with an ulcer that looks like a deep crater and clear undermining of adjacent tissue. This finding would be documented as which stage of pressure ulcer?
- I
 - II
 - III
 - IV

Rationale

Correct answer: c.

A stage-III pressure ulcer is characterized by a full-thickness skin loss with damage to subcutaneous tissue that may go as deep as the fascia but not through it and an ulcer that looks like a deep crater. Undermining of adjacent tissue may or may not be present. A stage-I ulcer is characterized by nonblanchable erythema; a stage-II ulcer by partial-thickness skin loss which may involve epidermis only or epidermis and some dermis; and a stage-IV ulcer is characterized by full thickness skin loss with tissue necrosis or damage to muscle, bone, or supporting structures. Tissue undermining and sinus tracts may also be present.

22. An alginate dressing is ordered for a client with a stage-IV pressure ulcer. The client's daughter asks what this type of dressing does. On which fact should the nurse's answer be based?
- Alginate dressings are impregnated antibiotics
 - Alginate dressings keep the wound moist and absorb exudates
 - Alginate dressings keep the wound dry and encourage granulation
 - Alginate dressings have an antibacterial effect

Rationale

Correct answer: b.

Alginate dressings both keep the wound moist and absorb exudates. They do not contain antibiotics or have an antibacterial effect.

23. When planning care of the client with a stage-III pressure ulcer, the nurse must be cognizant of the fact that most complications of pressure ulcers relate to which type of event?
- Infection
 - Immune reaction
 - Fluid imbalance
 - Malabsorption

Rationale

Correct answer: a.

Most complications of a pressure ulcer result from infection with septicemia and osteomyelitis being two major ones. Immune reactions generally do not play a role. Fluid imbalance and malabsorption can increase risk of pressure ulcers and impair healing but complications per se are not directly related to either.

24. Which measure might the nurse use to assess a client's risk for developing a pressure ulcer?
- Barthel Index
 - Glasgow Coma Scale
 - Katz Index
 - Braden Scale

Rationale

Correct answer: d.

The Braden scale is used to predict pressure ulcer risk. It consists of 6 subscales: sensory perception, moisture, activity, mobility, nutrition, and friction and shear. Highest possible score is 23; a score of 18 or lower equals risk with the lower the score, the greater the risk. The Barthel Index and the Katz Index are measures of functional assessment; the Glasgow Coma Scale is a measure of level of consciousness.

25. When assessing the daily diet of a client with a pressure ulcer, how much protein should the nurse consider to be an adequate intake?
- 0.5–1 g/kg body weight/day
 - 1–2 g/kg body weight/day
 - 1.5–2 g/kg body weight/day
 - 2–2.5 g/kg body weight/day

Rationale

Correct answer: c.

The client with a pressure ulcer to be healed needs increased protein, 1.5–2 g/kg body weight/day. This client also needs increased calories.

Test Plan Category:

REPRODUCTIVE SYSTEM PROBLEMS

FIBROCYSTIC BREAST DISEASE

- Fibrocystic breast disease is the most widely accepted term for benign changes in breast tissue.

- It refers to the most common benign breast disorder.
- It affects an estimated 10% of women of 21 years and younger, 25% of women of 25 years and older, and 50% of postmenopausal women.

- Fibrocystic breast changes include three types:
 - Cystic
 - It involves formation of fluid-filled sacs, which are the most common feature; these changes are easily treated.
 - Fibrous
 - Fibrous tissue increases progressively until menopause and then regresses.
 - Epithelial proliferation
 - It includes structurally diverse lesions, such as sclerosing adenosis and the lobular and ductal hyperplasias.

Etiology: Exact cause unknown; causal theories are

- estrogen excess and progesterone deficiency during the luteal phase of the menstrual cycle and
- environmental toxins that inhibit cyclic guanosine monophosphate enzymes: methylxanthines (caffeine, tea, and chocolate), tyramine (cheese, wine, and nuts), and tobacco.

Predisposing factors: Age, parity, genetic background, history of lactation, caffeine, and use of exogenous hormones.

S&S:

- Breast pain due to inflammation and nerve root stimulation (most common symptom), beginning 4–7 days into the luteal phase of the menstrual cycle and continuing until the onset of menstruation
- Pain in the upper outer quadrant of breasts (usually bilaterally)
- Palpable lumps that increase in size premenstrually and are freely movable
- Granular feeling of breasts on palpation
- Occasional nipple discharge (greenish-brown to black) that contains fat, proteins, ductal cells, and erythrocytes (ductal hyperplasia)

Assessment Alert

If breast pain is not relieved after menses begins, the client should see her primary health care provider.

Dx:

- Ultrasonography distinguishes cystic (fluid-filled) sacs from solid masses
- Tissue biopsy distinguishes benign from malignant changes
- Cytologic analysis of bloody aspirate rules out malignancy

Rx:

- Symptomatic to relieve pain: p.o. anti-inflammatory agent (ibuprofen), supportive bra, diet low in fat, salt, and caffeine

- Draining of painful cysts under local anesthesia
- Synthetic androgen (Danazol) for severe pain
- Oral contraceptives

Nursing Intervention Alert

If diuretic agents or oral contraceptives are prescribed, the client needs to know that symptoms usually recur after these medications are discontinued.

Nursing Process Elements

- Identify client's concerns, anxieties, and fears
- Provide psychosocial support
- Reassure client that breast pain is rarely indicative of cancer in its early stages
- Encourage use of oral anti-inflammatory agent as prescribed
- Prior to a breast biopsy procedure, instruct client to avoid use of agents that can interfere with blood clotting and increase the risk of bleeding; NPO after midnight
- Postbiopsy, monitor for effects of anesthesia
- Inspect dressing for bleeding and/or drainage
- Monitor vital signs
- Provide pain relief as prescribed
- Prior to discharge, the nurse must insure that client is tolerating fluids, can ambulate, and is able to void

Client teaching for self-care

- Teach client about taking care of the biopsy site, pain management, and activity restrictions
- Ensure that the client knows how and when biopsy report will be obtained
- Teach client about the need for follow-up with surgeon for discussion of the final pathology report and assessment of the healing of the biopsy site

BREAST CANCER

- Breast cancer arises from the ductal epithelium.
- It is the most common cancer in women with one in every eight women in the United States expected to develop breast cancer in her lifetime.
- It may develop any time after puberty, but is most common after the age of 50 years (80% with 20% in women under the age of 30 years).

- The 5-year survival rate for localized breast cancer has improved from 72% in the 1940s to 97% in 2006.

Etiology: No single, specific cause rather a combination of hormonal, genetic, and possibly environmental events

High risk factors:

- Family history of breast cancer, particularly in first-degree maternal relatives (mother, sister, and/or maternal aunt)
- Positive tests for genetic mutations (*BRCA 1* and *BRCA 2*)
- Long menstrual cycles
- Early menarche, late menopause
- Nulliparous or first pregnancy after age of 30 years
- History of unilateral breast cancer or ovarian cancer
- Exposure to radiation between puberty and age of 30 years

Low risk factors:

- Pregnancy before age of 20 years, history of multiple pregnancies
- Native American or Asian ancestry
- Obesity
- Alcohol intake of one or more drinks daily

S&S:

- Painless lump or mass in the breast
- Breast pain
- Change in symmetry or size of the breast
- Changes in the skin—thickening, scaling skin around the nipple, dimpling, edema, and ulceration
- Change in the skin temperature (warm, hot, or pink area)
- Drainage or discharge
- Changes in nipple—itching, burning, and retraction
- Edema of the arm
- Axillary node enlargement
- Dilated blood vessels visible through the skin of the breast
- Bone pain
- Pathologic bone fractures, hypercalcemia

Dx:

- Mammography reveals tumors that are too small to palpate
- Ultrasonography distinguishes between a fluid-filled cyst and a solid mass
- Alkaline phosphatase levels and liver function tests uncover distant metastases
- Hormonal receptor assay determines whether the tumor is estrogen- or progesterone-dependent
- Fine-needle aspiration and excisional biopsy provide cells for histologic examination to confirm the diagnosis
- Chest X-rays pinpoint metastases in the chest
- Scans of the bone, brain, liver, and other organs detect distant metastases

Rx:

- Surgical:
 - lumpectomy
 - often radiation therapy is combined with this surgery
 - lumpectomy and dissection of axillary lymph nodes
 - quadrant excision
 - simple mastectomy
 - removes breast but not lymph nodes or pectoral muscles
 - modified radical mastectomy
 - removes breast and axillary lymph nodes
 - radical mastectomy (now rarely done)
 - removes breast, axillary lymph nodes, and pectoralis major and minor muscle
- Other treatments:
 - reconstructive surgery if no advanced disease
 - chemotherapy, adjuvant or primary therapy
 - tamoxifen (estrogen antagonist)
 - adjuvant treatment of choice for postmenopausal clients with positive estrogen-receptor status; has also been found to reduce risk of breast cancer in women of high risk
 - peripheral stem cell therapy for advanced disease
 - primary radiation therapy before or after tumor removal
 - effective for small tumors in early stages
 - helps make inflammatory breast tumors more surgically manageable
 - used to prevent or treat local recurrence
 - estrogen, progesterone, androgen, or antiandrogen aminoglutethimide therapy

Nursing Process Elements

- Assess client's understanding of breast cancer and treatment options
- Reduce fear and anxiety and improve coping ability
- Promote decision-making ability
- Maintain skin integrity
- Promote positive body image
- Promote positive adjustment and coping
- Promote participation in care
- Promote sexual functioning
- Encourage participation of partner in care

Client teaching for self-care

Instruct client to

- exhibit knowledge about diagnosis and treatment options
- demonstrate ability to make decisions regarding treatment options in a timely fashion

- verbalize ability to deal with anxiety and fears related to the diagnosis and the effects of surgery on self-image and sexual functioning

VAGINITIS

- Vaginitis refers to the inflammation of the vagina and vulva; because of their proximity, inflammation of one may cause inflammation of the other.
- It may occur at any age.
- It is common in women who use estrogen-containing birth control pills and among pregnant women due to increased estrogen.

Etiology: Bacterial vaginitis occurs from a disturbance of the normal vaginal flora and an overgrowth of anaerobic bacteria *Trichomonas vaginalis* usually transmitted through sexual intercourse, *Gardnerella vaginalis*, *Candida albicans*, parasitic infection, trauma (skin breakdown may lead to secondary infection), poor personal hygiene, chemical irritants or allergic reactions to hygiene sprays, douches, detergents, clothing, or toilet paper, vulvar atrophy in menopausal women due to decreasing estrogen levels, and retention of a foreign body (tampon, diaphragm).

S&S:

- *Trichomonas vaginalis*: thin, bubbly, green-tinged, malodorous discharge, irritation, itching; urinary symptoms such as burning and/or frequency
- *Candida albicans*: thick, white, cottage cheese-like discharge, red, edematous membranes, intense itching
- Bacterial vaginitis: gray, foul, “fish-smelling” discharge

Dx:

- Wet prep saline examination
- Pap smear
- Urinalysis

Rx:

- Trichomonal vaginitis: oral metronidazole (Flagyl)
- *Candida albicans*: topical miconazole or clotrimazole; single dose of oral fluconazole
- *Gardnerella vaginalis*: oral or vaginal metronidazole
- Acute vulvitis: cold compresses or cool sitz baths for pruritus; warm compresses for severe inflammation; and topical corticosteroids to reduce inflammation
- Chronic vulvitis: topical hydrocortisone or antipruritics; good hygiene, especially in elderly or incontinent clients
- Atrophic vulvovaginitis: topical estrogen ointment

Nursing Process Elements

- Adopt the following goals of care:
 - relieve discomfort
 - reduce anxiety
 - prevent reinfection or spread of infection

Clinical Alert OB

Avoid using Flagyl during first trimester of pregnancy

Client teaching for self-care

Teach client about

- cause of symptoms to reduce anxiety related to fear of a more serious illness
- importance of treating partner, if indicated, to decrease likelihood of reinfection
- role of abstinence in preventing spread of infection
- the need to avoid tight clothing and to wear cotton underwear
- good hygienic practices including daily bathing
- proper hand washing before and after administration of medication
- need to avoid douching unless therapeutically prescribed
- need to avoid alcohol during treatment with Flagyl

PELVIC INFLAMMATORY DISEASE

- Pelvic inflammatory disease (PID) is an inflammatory condition of the pelvic cavity that may involve the uterus, fallopian tubes, ovaries, pelvic peritoneum, or pelvic vascular system.
- Untreated PID may cause infertility and may lead to potentially fatal septicemia and shock.
- Approximately one million women are treated for PID in the United States each year; most of them are younger than 25 years of age, and one-fourth of them have serious sequelae (chronic pelvic pain, ectopic pregnancy, and infertility).

Etiology: Usually caused by bacterial infection but may be viral, fungal, or parasitic; presumption is that organisms enter the body through the vagina, pass through the cervical canal, colonize the endocervix, and move upward into the uterus. Under various conditions, the organisms may proceed to one or both of the fallopian tubes and ovaries and into the pelvis. In infections that occur after childbirth or abortion, pathogens are disseminated directly through the tissues that support the uterus by way of the lymphatic vessels and blood vessels

Risk/Precipitating factors: Conization or cauterization of the cervix, insertion of an intrauterine device, abortion, pelvic surgery, infections during or after pregnancy, early age of first intercourse, multiple sexual partners, frequent intercourse, intercourse without condoms, sex with a partner with an STI, history of previous STI or previous pelvic

infection, use of a biopsy curette or an irrigation catheter, tubal insufflation.

S&S:

- Profuse, purulent vaginal discharge
- Low-grade fever
- Dyspareunia
- Malaise
- Anorexia
- Vomiting
- Lower-abdominal pain
- Headache
- Chills
- Vaginal bleeding
- Severe pain on movement of the cervix or palpation of adnexa

Dx:

- Culture and sensitivity and Gram stain testing of endocervix or cul-de-sac secretions show the causative agent
- Urethral and rectal secretions reveal the causative agent
- Blood test reveals elevated C-reactive protein level
- Transvaginal ultrasonography shows the presence of thickened, fluid-filled Fallopian tubes
- CT scan shows complex tubo-ovarian abscesses
- Culdocentesis obtains peritoneal fluid or pus for C&S testing
- Diagnostic laparoscopy identifies cul-de-sac fluid, tubal distension, and masses

Rx:

- Intensive therapy including bed rest
- Antibiotic therapy beginning immediately after culture specimens are obtained and reevaluated as soon as laboratory results are available
- Analgesics
- IV fluids
- Adequate drainage if pelvic abscess forms
- Ruptured abscess (life-threatening complication): total abdominal hysterectomy with bilateral salpingo-oophorectomy
- Abdominal distension or ileus: nasogastric intubation and suction
- Treat sexual partners to prevent reinfection

Nursing Process Elements

- Relieve anxiety related to treatment/diagnosis
- Maintain on bed rest in semi-Fowler's position to facilitate dependent drainage
- Maintain accurate vital sign recordings

- Maintain accurate recordings of characteristics and amounts of vaginal discharge
- Administer analgesics as prescribed for pain relief
- Apply heat safely to abdomen to promote pain relief and comfort

Client teaching for self-care

Teach client about

- the importance of immediate evaluation of any pelvic pain and/or abnormal discharge, especially after sexual exposure, childbirth, or pelvic surgery
- proper perineal care procedures (wiping from front to back after defecation or urination)
- the fact that douching reduces the natural flora that combat infecting organisms and may introduce bacteria upward
- the importance of consulting a health care professional if unusual vaginal discharge or odor is noted
- the importance of safe sexual practices (i.e., using condoms, avoiding multiple sexual partners, etc.)
- the importance of use of condoms consistently before intercourse or any penile–vaginal contact if there is any chance of transmitting the infection
- the need for gynecologic examination at least once a year

TOXIC SHOCK SYNDROME

Etiology: Toxins produced by *Staphylococcus aureus*.

Risk/Precipitating factors: Menstruation and tampon use, postoperative infection, use of a diaphragm, cervical cap, or vaginal contraceptive sponge, focal infection, and postpartum and nonmenstrual vaginal conditions.

S&S: Flu-like symptoms for 24 hours, rapid onset of high fever, headache, sore throat, vomiting, diarrhea, generalized rash that initially looks like sunburn and subsequently like a drug rash followed in 1–2 weeks by peeling of the skin particularly on the palms and soles, and hypotension. Respiratory, renal, liver, cardiovascular, and central nervous system impairments can also occur

Dx: Presence of symptoms which meet CDC criteria

Rx: Antibiotics, drugs for hypotension, IV fluid and electrolyte replacement, corticosteroids for rash

Nursing Process Elements

- Provide supportive care related to treatment of shock and fluid and electrolyte imbalance.

Client teaching for self care

For prevention of recurrence, instruct client to

- avoid use of tampons
- avoid use of a diaphragm during menses
- wash hands thoroughly before inserting a diaphragm or contraceptive sponge
- avoid the use of sponge if dirty; wet with clean water; and do not leave in place for more than 30 hours at a time
- remove diaphragm within 24 hours; wash thoroughly; dry and store in a clean place

UTERINE PROLAPSE

- Uterine prolapse refers to the descent of the cervix or the entire uterus into the vaginal canal.
- In severe cases, the uterus falls completely through the vagina and protrudes outside of the body.
- As the uterus descends, it may pull the vaginal walls and even the bladder and rectum with it.
- Uterine prolapse is more prevalent in whites than in blacks, and rare in Canadian Indians.

Etiology: Progressive relaxation of the support structures of the pelvis.

Predisposing factors: Trauma to perineum (childbirth, pelvic surgery), occupational activities that require heavy lifting, chronic medical conditions such as lung disease and chronic constipation and straining, neural abnormalities that interfere with the innervation of the levator ani muscles, obesity, and strong familial tendency.

S&S:

- Pelvic pressure
- Urinary problems (retention or incontinence)
- Pain
- Collapse through the vagina
- Pain during sexual intercourse

Dx:

- Physical examination
- Ultrasound, fluoroscope, or magnetic resonance
- Urinary, sexual, anorectal review of systems for pelvic floor disorders provides comprehensive historical data

Rx:

- First-degree uterine prolapse is not treated unless it causes discomfort
- In second- and third-degree prolapse, or in elderly women who may not be candidates for surgery, a pessary (removable mechanical device that holds the uterus in position) may be placed

- The pelvic fascia may be strengthened by Kegel exercises or by a course of estrogen therapy in postmenopausal women; hysterectomy may be done in this age group
- Surgical repair is the last treatment of choice; in this procedure, the uterus is sutured back into place and repaired to strengthen and tighten the muscle bands

Clinical Alert

Rubber pessaries need to be avoided in women with latex allergies.

Nursing Process Elements

- Relieve anxiety related to treatment

CYSTOCELE

- Cystocele refers to the descent of a portion of the posterior bladder wall into the vaginal canal.
- In severe cases, the bladder and anterior vaginal wall bulge outside the introitus.

Etiology: Usually trauma of childbirth.

Predisposing factors: Pregnancy, obesity, constipation, pelvic tumors, bronchitis, heavy manual labor; hormone deficiency may also play a role

S&S:

- Usually symptoms are insignificant
- Pelvic pressure
- Fatigue
- Pelvic and/or back pain
- Urinary problems such as frequency, incontinence, and urgency

Dx:

- Physical examination
- Detailed genitourinary history

Rx:

- Depends on the age of the woman and severity of the condition; may include isometric exercise (Kegel exercises) to strengthen the pubococcygeal muscle, estrogen to improve tone and vascularity of fascial support, and pessary placement (mechanical device used to hold bladder in place)
- Surgical correction for severe anatomic injury unresponsive to medical treatment

Nursing Process Elements

- Reassure client to help relieve anxiety

Client teaching for self-care

Teach the client about

- importance of eliminating or decreasing or preventing stressors such as obesity, constipation, and heavy manual labor
- method of performing Kegel exercises
- importance of follow-up appointment with health care provider

RECTOCELE

- Rectocele refers to the bulging of the rectum and posterior vaginal wall into the vaginal canal
- Usually the symptoms of rectocele do not occur until several years after menopause.

Etiology: Usually results from injury and strain during childbirth.

Predisposing factors: Childbirth, chronic constipation and straining, and familial and genetic predisposition.

S&S:

- Most rectoceles are asymptomatic
- Vaginal pressure and/or pain
- Rectal fullness
- Incomplete bowel evacuation
- Back pain
- Uncontrollable gas
- Incontinence
- Bleeding
- Ulcerations

Dx:

- Physical examination
- Urinary, sexual, anorectal review of systems for pelvic floor disorders provides comprehensive historical data

Rx:

- Prevention and treatment of constipation
- Pessary insertion
- Rectocele alone (without associated enterocele, uterine prolapse, and cystocele) seldom requires surgery

Nursing Process Elements

- Provide reassurance to the client to relieve anxiety

Client teaching for self-care

Teach client about

- proper technique of performing isometric pelvic exercises (Kegel exercises)

- the need to do Kegel exercises regularly
- measures to prevent constipation (i.e., increase fluids, fruit, fiber, vegetables, etc.)
- the importance of keeping follow-up appointments with health care provider

LEIOMYOMAS (FIBROIDS)

- Leiomyomas refer to the benign, slow-growing, solid tumors of the uterine wall.
- Estrogen appears to stimulate the growth of these tumors.
- These often enlarge with pregnancy and regress after menopause.

Etiology: Unknown, possibly stress on an area of myometrium.

S&S: Often asymptomatic

- Abnormal bleeding is predominant symptom:
 - Menorrhagia refers to increased menstrual bleeding
 - Metrorrhagia refers to bleeding between menstrual periods
- Pelvic pressure
- Constipation
- Urinary frequency or retention

Dx:

- Pelvic examination
- Ultrasound
- Pregnancy test to rule out pregnancy as cause of uterine enlargement
- Endometrial biopsy to rule out malignancy
- CBC to check for anemia secondary to bleeding

Rx: Observation if close to menopause since tumors may shrink; observation or myomectomy (removal of tumors with preservation of uterus) if child bearing is desired; otherwise hysterectomy

Nursing Process Elements

- Reassure the client that tumors are not malignant
- If menopausal, explain that tumors may continue to grow if estrogen replacement therapy is used.
- Perioperative care (see Chapter 18)

CERVICAL CANCER

- Carcinoma of the cervix is predominantly squamous cell cancer.
- It is the third most common cancer of the female reproductive system.
- It is classified as either microinvasive or invasive.
- Preinvasive disease ranges from mild cervical dysplasia in which the lower-third of epithelium contains abnormal

cells, to carcinoma in situ, in which full thickness of epithelium contains abnormally proliferating cells.

- In invasive carcinoma, cancer cells penetrate the basement membrane and can spread directly to contiguous pelvic structures or disseminate to distant sites by lymphatic routes.

Etiology: Major cause is now known to be HPV.

Predisposing factors: Multiple sex partners, early age at first coitus, short interval between menarche and first coitus, sexual contact with men whose partners have had cervical cancer, exposure to the human papilloma virus (HPV), chronic cervical infections, nutritional deficiencies, and smoking.

S&S:

- *Preinvasive disease*
 - often produces no symptoms
- *Early invasive cervical cancer:*
 - abnormal vaginal bleeding
 - persistent vaginal bleeding
 - postcoital pain and bleeding
- *Advanced disease:*
 - pelvic pain
 - vaginal leakage of urine and stool from a fistula
 - anorexia, weight loss, and anemia

Dx:

- Papanicolaou (Pap) test screens for abnormal cells
- Colposcopy shows the source of the abnormal cells seen on the Pap test
- Cone biopsy is performed if endocervical curettage is positive
- Vira-pap test permits examination of the specimen's DNA structure to detect HPV
- Lymphangiography and cystography detect metastasis
- Organ and bone scans show metastases

Rx:

- *Preinvasive lesions:*
 - Loop electrosurgical excision procedure
 - Cryosurgery
 - Laser destruction
 - Conization (with frequent Pap smear follow-up)
 - Hysterectomy
- *Invasive carcinoma:*
 - Radical hysterectomy
 - Radiation therapy (internal, external, or both)
 - Chemotherapy
 - Combination of the above procedures

Nursing Process Elements

- Relieve anxiety related to surgical procedures
- Relieve pain

- Improve skin integrity
- Monitor for and manage potential complications: infection, deep vein thrombosis, and hemorrhage
- Support positive sexuality and sexual function

Client teaching for self-care

Teach client about

- the need for regular pelvic examinations and Pap tests
- reproductive health and safer sex
- smoking cessation program and provide referral

ENDOMETRIAL CANCER

- Endometrial cancer is also known as uterine cancer or cancer of the lining of the uterus.
- It is the most common gynecological cancer.
- It can also lead to adenocarcinoma that metastasizes late, usually from the endometrium to the cervix, fallopian tubes, and other peritoneal structures.

Etiology: Unknown.

Predisposing factors: Anovulation, abnormal uterine bleeding, history of atypical endometrial hyperplasia, unopposed estrogen stimulation, nulliparity, polycystic ovarian syndrome, familial tendency, obesity, hypertension, and diabetes.

S&S:

- Uterine enlargement
- Persistent and unusual premenopausal bleeding
- Any postmenopausal bleeding
- Late signs and symptoms, such as pain and weight loss (do not appear until the cancer is well advanced)

Dx:

- Endometrial, cervical, or endocervical biopsy confirms the presence of cancer cells
- Fractional dilatation and curettage identifies cancer when biopsy is negative
- Cervical biopsies and endocervical curettage pinpoint cervical involvement

Rx:

- Surgery
- Radiation therapy
- Hormonal therapy
- Chemotherapy

Nursing Process Elements

- Relieve anxiety related to surgical procedures
- Relieve pain

- Improve skin integrity
- Monitor and manage for complications: infection, deep vein thrombosis, and hemorrhage
- Support positive sexuality and sexual function

Client teaching for self-care

Teach client

- about stress reducing activities
- to care for incision and surgical site as directed; to observe for healing of surgical site without excoriated skin or purulent discharge
- to properly clean the surgical site after voiding and defecating
- to maintain a low-residue diet to prevent straining on defecation and wound contamination
- to avoid crossing legs or sitting with pressure against knees; to exercise ankles and legs to decrease the risk of venous thrombosis
- to discuss with primary care physician concerns and anxieties about sexual functioning; to discuss options and alternative approaches to sexual intercourse

OVARIAN CANCER

- There are two major types of ovarian cancer: epithelial neoplasms and germ cell neoplasms.
- Ovarian cancer causes more deaths than any other cancer of the reproductive system.
- It spreads rapidly intraperitoneally by local extension or surface seeding, and occasionally, through the lymphatic vessels and the bloodstream.
- Generally, extraperitoneal spread travels through the diaphragm into the chest cavity, where the tumor may cause pleural effusions.
- About 75% of cases are detected at a late stage.

Etiology: Unknown; may be linked to mutations in the *BRCA 1* or *BRCA 2* gene.

Associated factors: Infertility, nulliparity, familial tendency, ovarian dysfunction, irregular menses, exposure to asbestos, talc, industrial pollutants, fertility drugs, diet high in saturated fat, hormone replacement therapy.

S&S:

- May grow to considerable size before overt symptoms begin to appear
- *Occasionally, in the early stages:*
 - vague abdominal discomfort, and distension
 - mild GI discomfort (nausea, vomiting, and bloating)
 - urinary frequency and pelvic discomfort
 - constipation

—vaginal bleeding

—weight loss

- *Later stages:*

—tumor rupture, torsion, or infection

- *Advanced ovarian cancer:*

—ascites

—postmenopausal bleeding and pain

—symptoms of metastatic tumors, commonly pleural effusion

Assessment Alert

Pain associated with ovarian cancer in young clients may mimic appendicitis.

Dx:

- Exploratory laparotomy, including lymph node evaluation and tumor resection, is required for accurate diagnosis and staging
- Laboratory tumor-marker studies (such as ovarian carcinoma antigen, carcinoembryonic antigen, and human chorionadotropin) show abnormalities that may indicate complications
- Abdominal ultrasonography, CT scan, or X-rays delineate tumor size
- Aspiration of ascitic fluid reveals atypical cell

Assessment Alert

A palpable ovary in a woman who has gone through menopause should be investigated because ovaries normally become smaller and less palpable after menopause.

Rx:

- Varying combinations of surgery, chemotherapy, and radiation
- *Conservative treatment for a unilateral, encapsulated tumor in a young girl or a young woman:*
 - Resection of the involved ovary
 - Careful follow-up, including periodic chest X-rays to rule out lung metastasis
- *More aggressive treatment:*
 - Total abdominal hysterectomy and bilateral salpingo-oophorectomy with tumor resection, omentectomy, possible appendectomy, lymphadenectomy, tissue biopsies, and peritoneal washings

- If tumor has matted around other organs or involves organs that cannot be resected:
 - Surgical debulking of tumor implants to less than 2 cm (or smaller) in greatest diameter
- **Chemotherapy:**
 - may be curative; extends survival time in most clients; largely palliative in advanced disease
 - standard is combination paclitaxel and platinum-based chemotherapy

Nursing Process Elements

- Provide measures related to the client's treatment plan, be it surgery, chemotherapy, or palliation
- Provide emotional support to client and her family
- Provide comfort measures
- Clients with advanced ovarian cancer may develop ascites and pleural effusion, thus
 - administer intravenous therapy to alleviate fluid and electrolyte imbalances
 - initiate parenteral nutrition to provide adequate nutrition
 - provide postoperative care after intestinal bypass to alleviate an obstruction
 - provide pain relief and manage drainage tubes
- Provide comfort measures for women with ascites by providing small frequent meals, decreasing fluid intake, administering diuretic agents, and providing rest

Client teaching for self-care

Teach client

- about the need for regular pelvic examinations including Pap test for all women
- about reproductive health
- to eat small, frequent meals
- to take medications as prescribed
- to take frequent rest periods

CANCER OF THE VULVA

- Vulvar neoplasms may develop from various cell origins.
- Because much of the vulva is made of skin, any type of skin cancer can develop on the vulva.
- The majority of vulvar cancers arise from squamous epithelial cells.

Etiology: Primary cause unknown.

Predisposing factors: Leukoplakia in approximately 25% of clients, chronic vulvar granulomatous disease, chronic pruritus of the vulva with friction, swelling, and dryness, pigmented moles that are constantly irritated by clothing or

perineal pads, irradiation of the skin such as infection with HPV, obesity, hypertension, and diabetes.

S&S:

- *In 50% of clients:*
 - vulvar pruritus, bleeding
 - small vulvar mass
 - may begin as a small ulcer on the surface, which usually becomes infected and painful
- *Less common:*
 - mass in the groin
 - abnormal urination and/or defecation

Dx:

- Colposcopy and toluidine-blue staining identify biopsy sites
- Histologic examination of biopsy samples confirm diagnosis and identify the type of cancer

Rx:

- *Small, confined lesions with no lymph node involvement:*
 - Simple vulvectomy or hemivulvectomy (without pelvic node dissection)
 - Requires careful postoperative follow-up because it leaves the client at risk for developing a new lesion

Assessment Alert

Personal considerations such as young age of client and active sexual life may mandate conservative management.

- *For widespread tumor:*
 - Radical vulvectomy
 - Radical wide local excision
 - can be as effective as more radical resection, but with much less morbidity
 - Depending on degree of metastasis, resection may include the urethra, vagina, and bowel, leaving an open perineal wound until healing, that is, for about 2–3 months
 - Plastic surgery, including mucocutaneous graph to reconstruct pelvic structures
 - Radiation therapy
- *Extensive metastasis, advanced age, or fragile health:*
 - Rules out surgery
 - Palliative treatment with irradiation of the primary lesion or chemotherapy

Nursing Process Elements

- Relieve anxiety—a major goal for the client may include acceptance of and preparation for surgical intervention

- Relieve pain related to the surgical incision and subsequent wound care
- Improve skin integrity
- Support positive sexuality and sexual function
- Monitor and manage potential complications post-surgery: infection, deep vein thrombosis, and hemorrhage

Client teaching for self-care

Teach client

- about stress-reducing activities
- to care for incision and/or surgical site as directed, observe for excoriated skin or purulent drainage
- to take pain medication as ordered
- to prevent deep vein thrombosis, to avoid crossing legs or sitting with pressure against knees, and to exercise ankles and legs
- about the need to discuss with health care provider concerns and anxieties about altered body image and sexual functioning; to discuss options and alternative approaches to sexual intercourse
- to maintain a low-residue diet to prevent straining on defecation

PROSTATITIS

- Prostatitis refers to the sudden (acute) or gradual (chronic) inflammation of the prostate gland.
- It is generally classified as bacterial or nonbacterial.
- The complications include possible infertility and increased risk of prostate cancer.

Etiology: Urethral trauma or bacteria (*E. coli* is the most often identified organism) from the bladder or urethra cause inflammation, congestion, and obstructed urinary flow. Scarring of the prostate and urethra may result in permanent narrowing of the urethra. In nonbacterial prostatitis, the cause is unknown.

Risk factors: Frequent urinary tract infections (UTIs), urethritis, epididymitis, STIs, excessive alcohol intake, perineal injury, multiple sex partners, and advancing age.

S&S:

- Pain (low back, perineal, and testicular) associated with urination, ejaculation, or having a Bowel Movement (BM)
- Fever and chills
- Decrease in force and volume of urinary stream
- Urinary retention
- Hematuria
- Pyuria
- Urethral discharge

Dx: Culture of prostatic fluid, divided urine specimen for segmented urine culture and urinalysis. Physical examination

reveals enlarged, tender prostate; groin lymph nodes may be palpable; Prostatic specific antigen (PSA) may be elevated; WBCs elevated and bacteria may be present on urine and semen analysis; blood culture positive if infection is systemic

Clinical Alert

Massaging an obviously swollen and tender prostate may potentially spread the infection and increase the risk for sepsis.

Rx: Broad spectrum antibiotics (ciprofloxacin, tetracycline, penicillin, or trimethoprim-sulfamethoxazole) for 10–14 days; hospitalization and IV antibiotic therapy required in severe cases; continuous low-dose antibiotic therapy PRN to suppress infection; NSAIDs to relieve inflammation; stool softeners to relieve discomfort associated with bowel movements; antispasmodics, bladder sedatives, and sitz baths for comfort. Regular ejaculation by sexual intercourse or masturbation to reduce the retention of prostatic fluid. Transurethral resection of the prostate (TURP) may be done if medical therapy is unsuccessful

Nursing Process Elements

- Promote early detection and aggressive treatment of UTIs
- Encourage healthy lifestyle changes
- Provide teaching on effects and side effects of prescribed medications
- Avoid massaging inflamed prostate

Client teaching for self-care

Teach client

- to take medication as prescribed
- to avoid sitting for long periods of time
- to restrict intake of alcohol
- to increase fluid intake (64–128 oz of water per day)
- to avoid foods such as alcohol, coffee, tea, chocolate, cola, and spices that have diuretic action or that increase prostatic secretions
- to avoid sexual arousal and intercourse during periods of acute inflammation
- to limit number of sexual partners and use condoms
- to keep appointments for follow-up
- to report new or recurring symptoms including pain, difficulty with urination, fever, and chills
- about the need for evaluation/treatment of sexual partners to decrease risk of cross-infection

EPIDIDYMITIS

- Epididymitis refers to an infection of the epididymis.

Etiology: Usually descends from an infected prostate or urinary tract; may be a complication of gonorrhea.

Predisposing factors: Chlamydial infection in men under 35 years of age.

S&S:

- Unilateral pain and soreness in the inguinal canal
- Swelling and pain in the scrotum
- Elevated temperature
- Urine may contain pus
- Chills

Dx:

- Swelling in the scrotum and groin
- Urine C&S
- Culture for STIs (chlamydial infection)

Rx:

- Within 24 hours of onset, spermatic cord can be infiltrated with a local anesthetic agent to relieve pain
- Antibiotics for client and partner if from chlamydial infection
- Epididymectomy for recurrent, incapacitating episodes or for chronic, painful disease

Nursing Process Elements

- Assess for signs and symptoms
- Assess for risk factors for STIs

Client teaching for self care

Teach client

- about the need for bed rest with scrotum elevated
- to take antibiotics as ordered
- to use intermittent cold compresses to scrotum to relieve pain
- to apply local heat or take warm sitz baths later to relieve inflammation
- to take analgesics as prescribed and needed
- to expect it to take up to 4 weeks or longer for condition to subside

BENIGN PROSTATIC HYPERPLASIA

- Benign prostatic hyperplasia (BPH) is the enlargement of the prostate gland with extension upward to the bladder resulting in obstruction of the flow of urine.
- It is the most common condition of older men and the second most common cause of surgical intervention in men older than 60 years of age.

Etiology: Uncertain; some evidence that hormones initiate hyperplasia of the supporting stromal tissue and the glandular elements in the prostate.

Risk Factors: Age over 50 years.

S&S:

- Frequency of urination
- Nocturia
- Hesitancy in starting urination
- Abdominal straining with urination
- A decrease in the volume and force of the urinary stream
- Dribbling
- A sensation that bladder has not been completely emptied
- Acute urinary retention
- Recurrent UTIs
- Fatigue
- Anorexia
- Nausea
- Vomiting
- Epigastric discomfort

Dx:

- Physical examination
- Urinalysis and urodynamic studies to assess urine flow
- Renal function tests including serum creatinine levels
- Complete blood studies
- Clients with BPH often have cardiac or respiratory complications because of age so cardiac and respiratory assessments are also done

Rx:

- Treatment depends on cause of BPH, severity of obstruction, and overall condition of the client
- “Watchful waiting” is an appropriate treatment for many because the likelihood of progression is unknown; clients are monitored periodically for severity of symptoms, physical findings, and changes in laboratory and diagnostic urologic tests
- Transurethral resection of the prostate (TURP)
- Balloon dilation
- Alpha-blockers (e.g., terazosin) to constrict prostate reducing pressure on urethral and facilitating urine flow
- 5-alpha-reductase inhibitors (e.g., finasteride) to shrink the prostate by lowering level of dihydrotestosterone, which causes prostatic growth; can take 6 months to have an effect
- Transurethral laser resection
- Transurethral needle ablation
- Microwave therapy

Nursing Process Elements

- Provide information regarding diagnostic tests and procedures
- Encourage client to keep appointments with health care provider to monitor physical findings, laboratory work, and diagnostic tests
- Provide perioperative care if surgery is done (see Chapter 18)

Client teaching for self-care

Teach client to

- prevent overdistention of the bladder:
 - avoid drinking large amounts at one time
 - avoid diuretics, caffeine, and alcohol
 - void when first feel the urge; do not wait
- avoid medications such as anticholinergics, antihistamines, and decongestants that can cause urinary retention

IMPOTENCE (ERECTILE DYSFUNCTION)

- Impotence or erectile dysfunction (ED) refers to a male's inability to attain or maintain penile erection sufficient to complete intercourse.
- Primary impotence—erection sufficient for intercourse has never been achieved.
- Secondary impotence—intercourse has been successful in the past.
- It affects men of all age groups but increases in frequency with age.
- Transient periods of impotence are not considered ED; they probably occur in half of adult males.
- The prognosis depends on the severity and duration of impotence and the underlying causes.

Etiology: Personal and sexual anxieties, disturbed sexual relationships, situational impotence, chronic diseases that cause neurologic and vascular impairment, cirrhosis, spinal cord trauma, complications of surgery, particularly prostatectomy, drug or alcohol-induced ED, genital anomalies, or central nervous system defects.

S&S:

- Anxiety
- Palpitations
- Inability to achieve or sustain a full erection
- Loss of interest in sexual activity
- Depression

Dx:

- Detailed sexual history helps differentiate between organic or psychogenic factors and primary and secondary impotence

- Meeting the diagnostic criteria, either
 - persistent or recurrent, partial or complete failure to attain or maintain erection until completion of sexual activity or
 - experience of marked distress or interpersonal difficulty as a result of ED

Rx:

- *Organic impotence:*
 - Reversing the cause if possible
 - Psychological counseling to help couple deal realistically with their situation and explore alternatives for sexual expression if reversing the cause is not possible
 - Sildenafil, tadalafil, or vardenafil to cause vasodilation within the penis
 - Adrenergic antagonist, yohimbine, to enhance parasympathetic neurotransmission
 - Testosterone supplementation for hypogonadal men (not for men with prostate cancer)
 - Prostaglandin E injected directly into the corpus cavernosum (may induce an erection for 30–60 minutes in some men)
 - Surgically inserted inflatable or noninflatable penile implants
- *Psychogenic impotence:*
 - Sex therapy including both partners
 - Improve verbal communication skills, eliminate unreasonable guilt, and/or reevaluate attitudes toward sex and sexual roles

Nursing Process Elements

- Provide support
- Provide information about ED support groups for men and their partners (Impotence Anonymous and I-Anon)

PREMATURE EJACULATION

- Premature ejaculation refers to the inability to voluntarily control the ejaculatory reflex; once aroused, reaches orgasm before or shortly after intromission.
- It is the most common dysfunction in men.

Etiology: Trauma, chronic illness, and physical disability.

S&S:

- Ejaculation, once aroused, without control

Rx:

- Depends on the nature and severity of the problem
- Behavioral therapies often involving the man and his sexual partner

**Nursing Process elements**

- Provide support
- Reinforce therapeutic plan

RETROGRADE EJACULATION

- Retrograde ejaculation is the involuntary inhibition of the ejaculatory reflex.

Etiology: Disability and medications are the most common causes.

S&S:

- Inability to ejaculate

Rx:

- Usually multidisciplinary in approach; addresses both physical and psychological factors
- Chemical, vibratory, and electrical stimulation have been used with some success
- Urine may be collected after ejaculation and sperm collected from the urine for use in artificial insemination
- In men with spinal cord injury, electroejaculation may be used to produce sperm for artificial insemination

**Nursing Process Elements**

- Provide support
- Reinforce therapeutic plan

PROSTATE CANCER

- Prostate cancer is the most common cancer in men.
- It is a slow growing cancer.
- It has a predictable pattern of spread: lymph nodes, bone marrow, bones of pelvis, sacrum, and lumbar spine.
- In the later stages, it spreads to lungs, liver, adrenals, and/or kidneys.

Etiology: Androgen-dependent carcinoma.

Predisposing factors: Increasing age, high-fat diet, African-American descent.

S&S:

- Rare in early stages
- Late symptoms include
 - urinary obstruction: frequency, difficulty in urinating, urinary retention, and decreased size and force of the urinary stream
 - backache and hip pain from metastases to bone
 - perineal and rectal discomfort
 - anorexia, weight loss, weakness, and nausea

- oliguria
- hematuria

Dx:

- Elevated PSA level: concentration of PSA in the blood is proportional to the total prostatic mass so PSA is elevated with other conditions such as BPH; also elevated in older men
- Digital rectal examination
- Diagnosis confirmed by histologic examination of tissue removed surgically by transurethral resection, open prostatectomy, or transurethral needle biopsy

Rx:

- Based on the stage of the disease, symptoms, and the client's age
- Radical prostatectomy is standard for early-stage, potentially curable disease when life expectancy is at least 10 years
- Curative radiation therapy—for early disease (teletherapy with a linear accelerator or interstitial “seeds” irradiation)
- Androgen deprivation hormonal therapy, controls rather than cures; used for extensive or metastatic disease
 - Bilateral orchiectomy
 - Gonadotropin-releasing hormone agonist analogs (GnRH), for example, leuprolide (Lupron), suppress pituitary release of LH and reduces serum testosterone levels
 - Oral androgen blocking agent, for example, flutamide (Eulexin) blocks uptake of testicular and adrenal androgens by tumor
 - Estrogens, for example, DES inhibit LH release
- Cryosurgery—to ablate the cancer in clients unable to physically tolerate surgery or with a recurrence

**Nursing Process Elements**

- Help client identify measures to relieve anxiety
- Provide information about institutional and community resources for coping with prostate cancer: social services, support groups, and community agencies
- Determine effect of disease on sexual functioning; facilitate with partner identification of alternative and satisfying modes of relationship with each other
- Administer analgesics as ordered for pain
- Provide postoperative care, where indicated

**Client teaching for self-care**

Teach client about

- the medication regimen
- methods of attaining/maintaining bladder control
- prevention of urinary retention

- maintenance of optimal nutritional status
- prevention of infection
- determination of what effect the client's medical condition is having on his sexual functioning; include partner in developing understanding and discovering alternative, satisfying close relations with each other
- the need to avoid activities that aggravate or worsen pain

TESTICULAR CANCER

- Testicular cancer is the most common type of cancer in men aged 15–35 years.
- Ninety-five percent of the cases arise from the germinal cells of the testes.
- The remaining 5% cases are nongermlinal tumors arising from epithelium (Leydig cell and Sertoli cell tumors)

Assessment Alert

Risk of testicular cancer is higher in males with undescended testes.

Etiology: Cause unknown but infections, cryptorchidism, genetic, and endocrine factors appear to be involved.

S&S:

- Mass or lump on the testicle
- Painless enlargement of the testis (significant diagnostic finding)
- “Heaviness” of the scrotum, inguinal area, or lower abdomen
- Backache
- Lower abdominal pain
- Loss of weight
- General weakness

Dx:

- Painless enlargement of the testis
- Mass or lump on the testicle
- Tumor marker levels in the blood (alphafetoprotein [AFP] and the beta subunit of human chorionic gonadotropin [HCG])
- Intravenous urography
- Lymphangiography
- CAT scan of the chest, abdomen, and pelvis

Rx:

- Based on the cell type and the anatomic extent of the disease
- Orchiectomy
- Retroperitoneal lymph node dissection (RPLND)
- Postoperative irradiation of lymph nodes from the diaphragm to the iliac region
- Chemotherapy

Nursing Process Elements

- Encourage verbalization and fears/concerns related to body image and sexuality
- Provide postoperative care (see Chapter 18)

Client teaching for self-care

Teach client

- about sexuality and fertility pretreatment: normal function; potential effects of cancer and therapy; reproductive options including sperm banking:
 - low sperm count may be found at time of diagnosis and eliminate option of sperm banking
- that radiation therapy will not necessarily prevent having children
- that unilateral excision of a tumor does not necessarily decrease virility

WORKSHEET

MATCHING QUESTIONS

Match the following:

- | | |
|---------------------------|--|
| 1. _____ Prostatitis | a. Result of injury and strain during childbirth |
| 2. _____ Uterine prolapse | b. Removable mechanical device that holds the uterus in position |

(continued)

- | | |
|----------------------------------|--|
| 3. _____ Rectocele | c. Isometric exercises that strengthen the pubococcygeal muscle |
| 4. _____ Fibrocystic disease | d. Inability to voluntarily control the ejaculatory reflex once aroused |
| 5. _____ Breast cancer | e. Blood test to detect prostate cancer and monitor effectiveness of therapy |
| 6. _____ Testicular cancer | f. Most widely accepted term for benign changes in breast tissue |
| 7. _____ Pessary | g. Descent of a portion of the posterior bladder wall into the vaginal canal |
| 8. _____ Kegel | h. Most common cancer affecting women |
| 9. _____ Cystocele | i. Descent of the cervix or entire uterus into the vaginal canal |
| 10. _____ Premature ejaculation | j. Involuntary inhibition of the ejaculatory reflex |
| 11. _____ Symptom of PID | k. Laboratory test elevated in a variety of liver and bone disorders |
| 12. _____ Retrograde ejaculation | l. Inability to attain or maintain an erection |
| 13. _____ PSA | m. Undescended testicles are a risk factor |
| 14. _____ Impotence | n. STIs and excessive alcohol intake are risk factors |
| 15. _____ Alkaline phosphatase | o. Pain on manipulation of the cervix |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

- The most common type of gynecological cancer found in women is _____ cancer.
- _____ cancer causes more deaths than any other cancer of the reproductive system.
- A predisposing factor for epididymitis in males under 35 years of age is _____ infection.
- Intermittent cold packs and then later heat application to the scrotum may help relieve the pain of _____.
- Nursing care of the client with testicular cancer includes encouraging client to verbalize fears/concerns related to body image and _____.
- Noncancerous enlargement of the prostate gland is called _____.
- The most common causative organism of prostatitis is _____.
- The most common type of cancer found in males 15–35-years old is _____.
- Tumor specific antigens found in testicular cancer are _____ and _____.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------------|-------------|
| 1. Acute bacterial prostatitis may produce sudden fever, chills, and perineal, rectal, or low back pain. | <u> </u> | <u> </u> |
| | T | F |
| 2. Prostate cancer is the most commonly found cancer in men. | <u> </u> | <u> </u> |
| | T | F |
| 3. In prostate cancer, the PSA level in the blood is proportionately related to the total prostatic mass. | <u> </u> | <u> </u> |
| | T | F |
| 4. Bilateral upper, outer quadrant breast pain is symptomatic of fibrocystic breast disease. | <u> </u> | <u> </u> |
| | T | F |
| 5. All males with testicular cancer can bank sperm prior to treatment and thus preserve reproductive capacity. | <u> </u> | <u> </u> |
| | T | F |
| 6. Radiation therapy for testicular cancer results in infertility. | <u> </u> | <u> </u> |
| | T | F |
| 7. Unilateral orchiectomy does not necessarily decrease virility. | <u> </u> | <u> </u> |
| | T | F |
| 8. Prostate cancer, in the early stages of the disease, produces urinary symptoms such as frequency, urinary retention, and decreased size of the stream. | <u> </u> | <u> </u> |
| | T | F |
| 9. Breast lumps associated with fibrocystic disease feel fixed to the chest wall when palpated and regress in size after menses. | <u> </u> | <u> </u> |
| | T | F |
| 10. The synthetic androgen (Danazol) is used for severe pain associated with fibrocystic disease. | <u> </u> | <u> </u> |
| | T | F |
| 11. Kegel exercises strengthen the muscles of the pelvic floor. | <u> </u> | <u> </u> |
| | T | F |
| 12. A course of estrogen therapy may be prescribed for a postmenopausal woman with a uterine prolapse. | <u> </u> | <u> </u> |
| | T | F |
| 13. Surgery is the treatment of choice for symptomatic cystocele. | <u> </u> | <u> </u> |
| | T | F |
| 14. Ovarian cancer may be linked to mutations in the <i>BRCA 1</i> or <i>BCRA 2</i> gene. | <u> </u> | <u> </u> |
| | T | F |
| 15. "Heaviness" of the scrotum, inguinal area, or lower abdomen is a symptom of testicular cancer. | <u> </u> | <u> </u> |
| | T | F |
| 16. Prostaglandin E injected directly into the corpus cavernosum is used to treat impotence and can induce an erection for 30–60 minutes in some men. | <u> </u> | <u> </u> |
| | T | F |
| 17. Preventing overdistention of the bladder can be an important part of the management of symptoms related to benign prostatic hypertrophy. | <u> </u> | <u> </u> |
| | T | F |
| 18. Prostate cancer metastasizes to the bones of the pelvis before visceral organs such as the lungs. | <u> </u> | <u> </u> |
| | T | F |
| 19. Low-grade fever and scant purulent vaginal drainage are symptoms of PID. | <u> </u> | <u> </u> |
| | T | F |
| 20. Chlamydial infection predisposes to epididymitis. | <u> </u> | <u> </u> |
| | T | F |

APPLICATION QUESTIONS

1. The nurse is taking a history of a client who has had benign prostatic hyperplasia (BPH) in the past. To determine whether the client currently is experiencing difficulty, which symptom would the nurse ask the client about?
 - a. Hematuria
 - b. Urinary incontinence
 - c. Urinary retention
 - d. Decreased force in the stream of urine
2. A client with prostatitis following a kidney infection has received instructions on management of the condition at home and prevention of recurrence. Which statement by the client indicates that the instructions have been understood?
 - a. "I need to keep fluid intake to a minimum to decrease the need to urinate."
 - b. "I should exercise as much as possible to stimulate circulation."
 - c. "I will take warm sitz baths and analgesics for comfort."
 - d. "I can stop taking antibiotics when the pain subsides."
3. The nurse is assessing a client with epididymitis. The nurse anticipates which findings on physical examination?
 - a. Fever, diarrhea, groin pain, and ecchymosis
 - b. Fever, nausea, vomiting, and painful scrotal edema
 - c. Nausea, vomiting, and scrotal edema with ecchymosis
 - d. Diarrhea, groin pain, and scrotal edema
4. A client complains of fever, perineal pain, and urinary frequency, urgency, and dysuria. To assess whether the client's problem is related to bacterial prostatitis, the nurse would look at the results of the prostate examination, which should reveal that the prostate gland is
 - a. tender and edematous with ecchymosis
 - b. reddened, swollen, and boggy
 - c. soft and swollen
 - d. tender, indurated, and warm to the touch
5. Which information about pelvic inflammatory disease (PID) would the nurse appropriately include when teaching sexually active young adults?
 - a. The single most obvious symptom of PID is severe pelvic pain.
 - b. PID is an infection of the uterus and Fallopian tubes.
 - c. Vaginal discharge is scant but with a foul odor.
 - d. PID can result in infertility due to inflammation and scarring.
6. Which treatments are used in the management of PID? (Select all that apply.)
 - a. Antibiotics
 - b. Analgesics
 - c. Bed rest
 - d. IV fluids
 - e. Douches
 - f. Sitz baths
 - g. Nasogastric intubation and suction
7. Which classes of drugs are used in the management of fibrocystic breast disease? (Select all that apply.)
 - a. Anti-inflammatory agents
 - b. Corticosteroids
 - c. Synthetic androgens
 - d. Oral contraceptives
 - e. Vasoconstrictors
8. Which is the most appropriate advice for the nurse to give to help a client with vulvitis cope with severe itch?
 - a. Soak in a warm tub
 - b. Take cool sitz baths
 - c. Wear cotton underwear
 - d. Pour water over the perineum after urinating
9. Which information should be included in a teaching plan for a client with prostatitis?
 - a. Massage prostate gland daily
 - b. Limit alcohol intake
 - c. Expect difficulty in initiating urination
 - d. Restrict fluid intake to 1500 ml daily
10. Which symptom should the nurse interpret as requiring a check for endometrial cancer?
 - a. Postmenopausal bleeding
 - b. Persistent leukorrhea
 - c. Painful sexual intercourse
 - d. Intermittent amenorrhea
11. How should the nurse interpret the leakage of fecal matter from the vagina of a client with advanced cancer?
 - a. Anal sphincter has been impaired
 - b. Cancer has metastasized to the GI tract

- c. Rectovaginal fistula has developed
d. Rectum is being compressed by the tumor mass
12. A woman attending a health fair tells the nurse that her breasts have always gotten very tender during the week before her period but that one breast has stayed sore for the last 2 months. Which is the most appropriate advice for the nurse to give?
- “Wear a good support bra to bed for a few nights and see if the pain is relieved.”
 - “Decrease the salt in your diet, the pain probably is due to fluid retention.”
 - “Try taking an OTC anti-inflammatory like ibuprofen for the pain.”
 - “You should see your health care provider and have the breast checked.”
13. When teaching about cancer detection, which factors should the nurse identify as predisposing a woman to breast cancer? (Select all that apply.)
- Family history of breast cancer, particularly in first-degree maternal relatives (mother, sister, and/or maternal aunt)
 - Positive tests for genetic mutations (*BRCA 1* and *BRCA 2*)
 - Long menstrual cycles
 - Early menarche, late menopause
 - Dysmenorrheas
 - Nulliparous or first pregnancy after the age of 30 years
 - Multiple sexual partners
 - Extended breast-feeding
14. Which assessment finding is characteristic of advanced ovarian cancer?
- Ascites
 - Purpura
 - Splenomegaly
 - Hypoactive DTRs
15. Which are risk factors for endometrial cancer? (Select all that apply.)
- Anovulation
 - Abnormal uterine bleeding
 - History of atypical endometrial hyperplasia
 - Multiparity
 - Polycystic ovarian syndrome
 - Obesity
 - Diabetes
16. Which client with breast cancer is a candidate for treatment with Tamoxifen?
- A 32-year-old client with a lumpectomy for a small tumor and no sign of spread
 - A 58-year-old client with negative estrogen receptor (ER) status
 - A 41-year-old client with metastatic disease
 - A 66-year-old client with estrogen sensitive disease
17. Following teaching about PID, which statement by a client indicates that clarification is needed?
- “Infertility and ectopic pregnancy are complications of PID.”
 - “A risk factor for PID is insertion of an intrauterine device (IUD).”
 - “Untreated PID can lead to septicemia.”
 - “PID is most often due to fungal overgrowth.”
18. When caring for a client with a uterine prolapse who is to have a pessary inserted, which information should the nurse make certain has been checked?
- Number of pregnancies
 - Time since menopause
 - Allergy to latex
 - Use of douches
19. Which factors predispose to uterine prolapse or the development of a cystocele? (Select all that apply.)
- Child bearing
 - Obesity
 - Heavy occupational work
 - Large pelvic cavity
 - Bronchitis
20. Which instruction should the nurse include when instructing a client on the use of Flagyl?
- “Do not drink alcohol while taking medication.”
 - “Douche daily while taking the medication.”
 - “Discontinue other medications until course of Flagyl is complete.”
 - “Do not use a spermicide while on the medication.”
21. Which is a sign of a trichomonas vaginal infection?
- Thick, white, cheesy discharge
 - Relapsing, low-grade fever
 - Vomiting without nausea
 - Thin, bubbly, green-tinged malodorous discharge

(continued)

22. Which test confirms the diagnosis of prostate cancer?
- PSA
 - Alkaline phosphatase
 - Ultrasound of the prostate
 - Prostate biopsy
23. Lupron is prescribed for a client with prostate cancer. Which assessment data best indicates that the medication is having the desired effect?
- Client reports pain is controlled
 - Vomiting has stopped
 - Urine is free of blood
 - PSA level has dropped
24. Which condition can pain in young women with ovarian cancer mimic?
- Appendicitis
 - Constipation
 - PMS
 - Urinary tract infection
25. Which finding on the physical examination of a 68-year-old, postmenopausal woman would cause suspicion of disease?
- Amenorrhea
 - Sparse pubic hair
 - Dry vaginal mucous membrane
 - Palpable ovary

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following:

- | | |
|---|--|
| 1. <u> n </u> Prostatitis | a. Result of injury and strain during childbirth |
| 2. <u> i </u> Uterine prolapse | b. Removable mechanical device that holds the uterus in position |
| 3. <u> a </u> Rectocele | c. Isometric exercises that strengthen the pubococcygeal muscle |
| 4. <u> f </u> Fibrocystic disease | d. Inability to voluntarily control the ejaculatory reflex once aroused |
| 5. <u> h </u> Breast cancer | e. Blood test to detect prostate cancer and monitor effectiveness of therapy |
| 6. <u> m </u> Testicular cancer | f. Most widely accepted term for benign changes in breast tissue |
| 7. <u> b </u> Pessary | g. Descent of a portion of the posterior bladder wall into the vaginal canal |
| 8. <u> c </u> Kegel | h. Most common cancer affecting women |
| 9. <u> g </u> Cystocele | i. Descent of the cervix or entire uterus into the vaginal canal |
| 10. <u> d </u> Premature ejaculation | j. Involuntary inhibition of the ejaculatory reflex |
| 11. <u> o </u> Symptom of PID | k. Laboratory test elevated in a variety of liver and bone disorders |
| 12. <u> j </u> Retrograde ejaculation | l. Inability to attain or maintain an erection |

- | | |
|-----------------------------------|---|
| 13. <u>e</u> PSA | m. Undescended testicles are a risk factor |
| 14. <u>l</u> Impotence | n. STIs and excessive alcohol intake are risk factors |
| 15. <u>k</u> Alkaline phosphatase | o. Pain on manipulation of the cervix |

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

- The most common type of gynecological cancer found in women is endometrial cancer.
- Ovarian cancer causes more deaths than any other cancer of the reproductive system.
- A predisposing factor for epididymitis in males under 35 years of age is chlamydia infection.
- Intermittent cold packs and then later heat application to the scrotum may help relieve the pain of epididymitis.
- Nursing care of the client with testicular cancer includes encouraging client to verbalize fears/concerns related to body image and sexuality.
- Noncancerous enlargement of the prostate gland is called benign prostatic hypertrophy.
- The most common causative organism of prostatitis is E coli.
- The most common type of cancer found in males 15–35-years old is testicular.
- Tumor specific antigens found in testicular cancer are alphafetoprotein (AFP) and beta subunit of human chorionic gonadotropin (HCG).

TRUE & FLASE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- Acute bacterial prostatitis may produce sudden fever, chills, and perineal, rectal, or low back pain. *True*
- Prostate cancer is the most commonly found cancer in men. *True*
- In prostate cancer, the PSA level in the blood is proportionately related to the total prostatic mass. *True*
- Bilateral upper, outer quadrant breast pain is symptomatic of fibrocystic breast disease. *True*
- All males with testicular cancer can bank sperm prior to treatment and thus preserve reproductive capacity. *False.*
Some men are not producing sperm or have low sperm counts at time of diagnosis and so are not candidates for sperm banking.
(continued)

6. Radiation therapy for testicular cancer results in infertility. *False.*
Infertility is not always a consequence of radiation therapy for testicular cancer.
7. Unilateral orchiectomy does not necessarily decrease virility. *True*
8. Prostate cancer, in the early stages of the disease, produces urinary symptoms such as frequency, urinary retention, and decreased size of the stream. *True*
9. Breast lumps associated with fibrocystic disease feel fixed to the chest wall when palpated and regress in size after menses. *False*
Breast lumps associated with fibrocystic disease are freely movable and regress after menses.
10. The synthetic androgen (Danazol) is used for severe pain associated with fibrocystic disease. *True*
11. Kegel exercises strengthen the muscles of the pelvic floor. *True*
12. A course of estrogen therapy may be prescribed for a postmenopausal woman with a uterine prolapse. *True.*
13. Surgery is the treatment of choice for symptomatic cystocele. *False*
Surgical repair (anterior repair) is done when other treatments have failed.
14. Ovarian cancer may be linked to mutations in the *BRCA 1* or *BCRA 2* gene. *True*
15. “Heaviness” of the scrotum, inguinal area, or lower abdomen is a symptom of testicular cancer. *False*
16. Prostaglandin E injected directly into the corpus cavernosum is used to treat impotence and can induce an erection for 30–60 minutes in some men *True*
17. Preventing overdistention of the bladder can be an important part of the management of symptoms related to benign prostatic hypertrophy. *True*
18. Prostate cancer metastasizes to the bones of the pelvis before visceral organs such as the lungs. *True*
19. Low-grade fever and scant purulent vaginal drainage are symptoms of PID. *False*
Profuse, purulent vaginal drainage and low-grade fever are two of the many symptoms of PID.
20. Chlamydial infection predisposes to epididymitis. *True*

APPLICATION ANSWERS

1. The nurse is taking a history of a client who has had benign prostatic hyperplasia (BPH) in the past. To determine whether the client currently is experiencing difficulty, which symptom would the nurse ask the client about?
 - a. Hematuria
 - b. Urinary incontinence
 - c. Urinary retention
 - d. Decreased force in the stream of urine

Rationale

Correct answer: a.

Decreased force of the stream of urine is an early sign of BPH. The stream later becomes weak and dribbling. Hematuria is a common presenting sign of cancer of the prostate. Urinary incontinence is not generally a problem with BPH. Retention occurs later in the disease.

2. A client with prostatitis following a kidney infection has received instructions on management of the con-

dition at home and prevention of recurrence. Which statement by the client indicates that the instructions have been understood?

- “I need to keep fluid intake to a minimum to decrease the need to urinate.”
- “I should exercise as much as possible to stimulate circulation.”
- “I will take warm sitz baths and analgesics for comfort.”
- “I can stop taking antibiotics when the pain subsides.”

Rationale

Correct answer: c.

Treatment of prostatitis includes medication with antibiotics, analgesics, and stool softeners. The nurse also teaches the client to rest, increase fluid intake, and use sitz baths for comfort. Antibiotic therapy is always continued until the prescription is finished although symptoms may have resolved.

- The nurse is assessing a client with epididymitis. The nurse anticipates which findings on physical examination?
 - Fever, diarrhea, groin pain, and ecchymosis
 - Fever, nausea, vomiting, and painful scrotal edema
 - Nausea, vomiting, and scrotal edema with ecchymosis
 - Diarrhea, groin pain, and scrotal edema

Rationale

Correct answer: b.

Typical signs and symptoms of epididymitis include scrotal pain and edema, which often are accompanied by fever, nausea, vomiting, and chills.

- A client complains of fever, perineal pain, and urinary frequency, urgency, and dysuria. To assess whether the client's problem is related to bacterial prostatitis, the nurse would look at the results of the prostate examination, which should reveal that the prostate gland is
 - tender and edematous with ecchymosis
 - reddened, swollen, and boggy
 - soft and swollen
 - tender, indurated, and warm to the touch

Rationale

Correct answer: d.

The client with prostatitis has a prostate gland that is swollen and tender but that is also warm to the touch, firm, and indurated. Systemic symptoms include fever with chills, perineal and low back pain, and signs of UTI.

- Which information about pelvic inflammatory disease (PID) would the nurse appropriately include when teaching sexually active young adults?
 - The single most obvious symptom of PID is severe pelvic pain.
 - PID is an infection of the uterus and Fallopian tubes.
 - Vaginal discharge is scant but with a foul odor.
 - PID can result in infertility due to inflammation and scarring.

Rationale

Correct answer: d.

PID can result in infertility due to inflammation and scarring. Severe pain is characteristic of PID but it is not the only obvious symptom—profuse vaginal drainage also occurs. PID affects the uterus and Fallopian tubes but can also involve the pelvic vasculature and peritoneum as well as the ovaries.

- Which treatments are used in the management of PID? (Select all that apply.)
 - Antibiotics
 - Analgesics
 - Bed rest
 - IV fluids
 - Douches
 - Sitz baths
 - Nasogastric intubation and suction

Rationale

Correct answers: a, b, c, d, and g.

Treatment of PID is intensive and involves all of these modalities. Douches, which can force bacteria and drainage upward, are not given. Sitz baths are used to ease external discomfort from conditions such as vulvitis, episiotomy, and hemorrhoids.

- Which classes of drugs are used in the management of fibrocystic breast disease? (Select all that apply.)
 - Anti-inflammatory agents
 - Corticosteroids
 - Synthetic androgens
 - Oral contraceptives
 - Vasoconstrictors

Rationale

Correct answers: a, c, and d.

Anti-inflammatory agents such as ibuprofen are used for pain. Synthetic androgens can be used to suppress ovarian function and estrogen stimulation of the breast tissue but because of undesirable side effects, use is reserved to unusually severe disease. Oral contraceptives are used to suppress oversecretion of estrogen. Vasoconstrictors and corticosteroids do not have a role in the management of fibrocystic breast disease.

(continued)

8. Which is the most appropriate advice for the nurse to give to help a client with vulvitis cope with severe itch?
- Soak in a warm tub
 - Take cool sitz baths
 - Wear cotton underwear
 - Pour water over the perineum after urinating

Rationale

Correct answer: b.

Cooling helps relieve itch. Soaking in a warm tub can soothe inflammation. Wearing cotton underwear helps to prevent vaginitis. Pouring cold water over the perineum after urinating effectively removes irritating urine from the genital area but is not as effective at relieving vulva itch as sitting in cold water.

9. Which information should be included in a teaching plan for a client with prostatitis?
- Massage prostate gland daily
 - Limit alcohol intake
 - Expect difficulty in initiating urination
 - Restrict fluid intake to 1500 ml daily

Rationale

Correct answer: b.

Alcohol intake should be limited because of its diuretic effect. An inflamed prostate should not be massaged. Difficulty in initiating urination is a symptom of BPH, not prostatitis. Fluids are not restricted. The man with prostatitis should drink at least 64–128 ounces of fluid per day.

10. Which symptom should the nurse interpret as requiring a check for endometrial cancer?
- Postmenopausal bleeding
 - Persistent leukorrhea
 - Painful sexual intercourse
 - Intermittent amenorrhea

Rationale

Correct answer: a.

Postmenopausal bleeding is the primary symptom of endometrial cancer. Persistent leukorrhea occurs with a variety of vaginal and cervical infections. Painful intercourse (dyspareunia) occurs with uterine prolapse. Amenorrhea has a variety of causes. The most frequent is pregnancy but endocrine disturbances, poor diet, excessive exercise, emotional shock, change in climate, etc., are other causes.

11. How should the nurse interpret the leakage of fecal matter from the vagina of a client with advanced cancer?
- Anal sphincter has been impaired
 - Cancer has metastasized to the GI tract
 - Rectovaginal fistula has developed
 - Rectum is being compressed by the tumor mass

Rationale

Correct answer: c.

Leakage of fecal matter from the vagina is a sign of rectovaginal fistula. It is not a sign of any of the conditions listed as other options.

12. A woman attending a health fair tells the nurse that her breasts have always gotten very tender during the week before her period but that one breast has stayed sore for the last two months. Which is the most appropriate advice for the nurse to give?
- “Wear a good support bra to bed for a few nights and see if the pain is relieved.”
 - “Decrease the salt in your diet, the pain probably is due to fluid retention.”
 - “Try taking an OTC anti-inflammatory like ibuprofen for the pain.”
 - “You should see your health care provider and have the breast checked.”

Rationale

Correct answer: d.

Soreness of a breast from fibrocystic disease disappears after menstruation. When soreness persists after menses, assessment by a health care provider is needed to determine the cause. Breast soreness associated with fibrocystic disease can be treated with measures to decrease fluid retention and/or taking an OTC anti-inflammatory. A good support bra can also help but it does not need to be worn at night.

13. When teaching about cancer detection, which factors should the nurse identify as predisposing a woman to breast cancer? (Select all that apply.)
- Family history of breast cancer, particularly in first-degree maternal relatives (mother, sister, and/or maternal aunt)
 - Positive tests for genetic mutations (*BRCA 1* and *BRCA 2*)
 - Long menstrual cycles
 - Early menarche, late menopause
 - Dysmenorrheas
 - Nulliparous or first pregnancy after the age of 30 years
 - Multiple sexual partners
 - Extended breast-feeding

Rationale

Correct answers: a, b, c, d, and f.

Family history of breast cancer, particularly in first-degree maternal relatives (mother, sister, and/or maternal aunt), positive test for mutated *BRCA 1* or *BRCA 2*, long menstrual cycles, early menarche, late menopause, and

nulliparity or first pregnancy after the age of 30 years are all risk factors for breast cancer. Multiple sexual partners predisposes to cervical cancer. Breast-feeding appears to exert a protective influence against breast cancer if done for a sufficient length of time.

14. Which assessment finding is characteristic of advanced ovarian cancer?
- Ascites
 - Purpura
 - Splenomegaly
 - Hypoactive DTRs

Rationale

Correct answer: a.

Ascites develops late in the course of ovarian cancer. Another sign of advanced ovarian cancer is pleural effusion, which is common with metastases to the lung. Purpura, splenomegaly, and hypoactive DTRs are not related symptoms.

15. Which are risk factors for endometrial cancer? (Select all that apply.)
- Anovulation
 - Abnormal uterine bleeding
 - History of atypical endometrial hyperplasia
 - Multiparity
 - Polycystic ovarian syndrome
 - Obesity
 - Diabetes

Rationale

Correct answers: a, b, c, e, f, and g.

Anovulation, abnormal uterine bleeding, a history of atypical endometrial hyperplasia, polycystic ovarian syndrome, obesity, and diabetes are all risk factors for endometrial cancer. Additional risk factors are nulliparity not multiparity, hypertension, and familial history of endometrial cancer.

16. Which client with breast cancer is a candidate for treatment with Tamoxifen?
- A 32-year-old client with a lumpectomy for a small tumor and no sign of spread
 - A 58-year-old client with negative estrogen receptor (ER) status
 - A 41-year-old client with metastatic disease
 - A 66-year-old client with estrogen sensitive disease

Rationale

Correct answer: d.

Tamoxifen is adjuvant therapy for early stage ER—positive breast cancer. Tamoxifen is an estrogen antagonist that blocks the ER sites on the tumor cells thus blocking tumor growth. It decreases the risk of metastasis or prolongs survival once metastasis occurs.

17. Following teaching about PID, which statement by a client indicates that clarification is needed?
- “Infertility and ectopic pregnancy are complications of PID.”
 - “A risk factor for PID is insertion of an intrauterine device (IUD).”
 - “Untreated PID can lead to septicemia.”
 - “PID is most often due to fungal overgrowth”

Rationale

Correct answer: d.

PID is most often bacterial in origin; it is not most often the result of fungal infection. Untreated PID can lead to septicemia. Infertility and ectopic pregnancy are complications of PID. Insertion of an IUD is a risk factor for PID. Other risk factors include abortion, pelvic surgery, infections during or after pregnancy, early age of first intercourse, multiple sexual partners, frequent intercourse, intercourse without condoms, sex with a partner with an STI, history of previous STI or previous pelvic infection, use of a biopsy curette or an irrigation catheter, and tubal insufflation.

18. When caring for a client with a uterine prolapse who is to have a pessary inserted, which information should the nurse make certain has been checked?
- Number of pregnancies
 - Time since menopause
 - Allergy to latex
 - Use of douches

Rationale

Correct answer: c.

If the client is allergic to latex, a rubber pessary cannot be used. Number of pregnancies, time since menopause, and use of douches are not relevant to the insertion of a pessary.

19. Which factors predispose to uterine prolapse or the development of a cystocele? (Select all that apply.)
- Child bearing
 - Obesity
 - Heavy occupational work
 - Large pelvic cavity
 - Bronchitis

Rationale

Correct answers: a, b, c, and e.

Problems with pelvic support such as uterine prolapse and cystocele can be the result of a congenital defect, prolonged increased intra-abdominal pressure, or traumatic injury to supporting structures. Thus pregnancy and vaginal delivery, obesity, job requiring heavy labor, and chronic cough all predispose to weakened pelvic supports and the development of uterine prolapse and cystocele.

(continued)

20. Which instruction should the nurse include when instructing a client on the use of Flagyl?
- “Do not drink alcohol while taking medication.”
 - “Douche daily while taking the medication.”
 - “Discontinue other medications until course of Flagyl is complete.”
 - “Do not use a spermicide while on the medication.”

Rationale

Correct answer: a.

Alcohol should be avoided because metronidazole (Flagyl) and alcohol together can cause severe nausea, vomiting, cramps, flushing, and headache. Metronidazole also can increase the blood thinning effects of warfarin (Coumadin) and increase the risk of bleeding. All other options are unrelated to the use of Flagyl.

21. Which is a sign of a trichomonas vaginal infection?
- Thick, white, cheesy discharge
 - Relapsing, low-grade fever
 - Vomiting without nausea
 - Thin, bubbly, green-tinged malodorous discharge

Rationale

Correct answer: d.

Trichomonas infection causes a thin, bubbly, green-tinged, malodorous vaginal discharge, irritation, itching, and urinary symptoms such as burning and/or frequency. Candida albicans infection causes a thick, white, cheesy discharge. Low-grade fever is a systemic manifestation of infection and is not seen with trichomonas vaginitis. Vomiting without nausea is seen in head injury.

22. Which test confirms the diagnosis of prostate cancer?
- PSA
 - Alkaline phosphatase
 - Ultrasound of the prostate
 - Prostate biopsy

Rationale

Correct answer: d.

Diagnosis of cancer can only be confirmed by microscopic examination of tissue. PSA is used for screening for prostate cancer but elevated levels (over 4 ng/ml) can be due to a variety of factors including benign prostatic hypertrophy and prostatitis; they are not specific to prostate cancer. Ultrasound of the prostate is used for follow-up when PSA levels are suspicious but its effectiveness is controversial. Alkaline phosphatase is an enzyme whose serum levels are elevated in hepatobiliary and bone disease.

23. Lupron is prescribed for a client with prostate cancer. Which assessment data best indicates that the medication is having the desired effect?
- Client reports pain is controlled
 - Vomiting has stopped
 - Urine is free of blood
 - PSA level has dropped

Rationale

Correct answer: d.

Lupron is a gonadotropin-releasing hormone agonist analog (GnRH), which suppresses pituitary release of LH and reduces serum testosterone levels. Since prostatic cancers require testosterone, reducing testosterone levels causes tumors to regress. Because the concentration of PSA in the blood is proportional to the total prostatic mass as the tumor regresses, PSA level drops. If a client has pain from metastases and these shrink in response to Lupron, pain can be relieved. However, this is not the best measure of Lupron's effectiveness since not all tumors are necessarily causing pain. Vomiting is not common with prostate cancer and hematuria is a late sign. Concentration of PSA in the blood is proportional to the total prostatic mass.

24. Which condition can pain in young women with ovarian cancer mimic?
- Appendicitis
 - Constipation
 - PMS
 - Urinary tract infection

Rationale

Correct answer: a.

Ovarian cancer can present in young women with pain similar to that of appendicitis. If pain accompanies constipation it is usually crampy pain or a sense of rectal discomfort. Urinary tract infection causes burning on urination or suprapubic discomfort from the bladder.

25. Which finding on the physical examination of a 68-year-old, postmenopausal woman would cause suspicion of disease?
- Amenorrhea
 - Sparse pubic hair
 - Dry vaginal mucous membrane
 - Palpable ovary

Rationale

Correct answer: d.

A palpable ovary in a postmenopausal woman raises suspicion of ovarian cancer. Normally ovaries are not palpable on pelvic examination after menopause. Amenorrhea is absence of menses so is normal postmenopause. Sparse pubic hair and dryness of the vaginal membranes are normal changes with advancing age.

Test Plan Category:

Physiological Integrity

Sub-category: Physiological Adaptation—Part 2

FLUID AND ELECTROLYTE IMBALANCES

BASIC CONCEPTS

Electrolytes are electrically charged ions.

- Cations are positively charged ions, e.g., sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}).

- Anions are negatively charged ions, e.g., chloride (Cl^-), bicarbonate (HCO_3^-), phosphate (HPO_4^{2-}), and sulfate (SO_4^{2-}).

Fluid compartments

- Intracellular fluid is the fluid within the cells. The main electrolytes are potassium, magnesium, phosphate⁻, and sulfate.

- Extracellular fluid is the fluid outside the cells. The main electrolytes in the ECF are sodium, chloride, and bicarbonate.
 - Intravascular fluid (plasma) is the fluid within the blood vessels. Protein-rich albumin is the main protein and is primarily responsible for creating the osmotic pull that holds fluid in the intravascular space.
 - Interstitial fluid contains no protein.
 - Lymph.
 - Transcellular fluid, e.g., synovial, cerebrospinal, intraocular, pericardial, pancreatic, biliary, peritoneal, and pleural.

Fluid balance—I&O:

- Fluid requirement per day for an average adult is 2500-ml intake.
- Average fluid loss per day is 2500 ml.
- Sources of fluid:
 - oral intake is 1200–1500 ml on average;
 - water in foods is 1000 ml;
 - by-product of metabolism water is 200 ml.
- Sources of fluid loss:
 - water loss through urine is 1400–1500 ml;
 - insensible water loss through skin and lungs (vapor in exhaled air) is 350–400 ml and 350–400 ml, respectively;
 - water loss through perspiration is 100 ml;
 - water loss through feces is 100–200 ml.

Clinical Alert

Obligatory water losses are essential to maintaining body function. For an adult, the obligatory water loss per day is 1300 ml which includes 500 ml of urine plus the insensible water loss plus water loss in feces).

FLUID IMBALANCES

- Isotonic imbalances occur when water and electrolytes are gained or lost in equal proportions and the osmolarity (concentration of solutes) remains the same.
- Osmolar imbalances occur when only water is gained or lost and the concentration of solutes is changed.

Isotonic Fluid Volume Deficit

- Equal proportions of water and electrolytes are lost from ECF.
- It is also called hypovolemia (decreased blood volume because loss first affects intravascular space).

Etiology: Abnormal loss through skin (fever, diaphoresis, or wound drainage), kidneys, or GI tract (diarrhea, vomiting, gas-

tric suction), bleeding, insufficient intake (anorexia, nausea, dysphagia, inability to access from confusion or immobility), third-spacing shift of fluid into an area where it is sequestered (essentially unavailable), e.g., edema or fluid in bowel.

S&S: Thirst, weakness, weight loss, decreased skin turgor, dry mucous membranes, sunken eyeballs, dry eyes, low-grade fever, weak rapid pulse, drop in blood pressure, orthostatic hypotension, flat neck veins, decreased capillary refill, decreased central venous pressure, decreased urine volume (<30 ml/hr), increased urine specific gravity (>1.030), increased hematocrit, and BUN.

Rx: Isotonic fluid replacement such as lactated Ringer's solution.

Nursing Process Elements

- Monitor VS
- Monitor weight
- Monitor skin turgor
- I&O
- Administer oral and IV fluids as ordered
- Provide mouth care
- Prevent skin breakdown
- Monitor lab values

Isotonic Fluid Volume Excess

- Equal proportions of water and sodium are retained by the body.
- It is also called hypervolemia (increased blood volume).

Etiology: Excessive oral intake of sodium chloride (overuse of sodium-based antacids such as soda bicarbonate or Alka-Seltzer or overuse of hypertonic enemas such as Fleet), too rapid administration of sodium-containing infusions, CHF, renal failure, cirrhosis, and Cushing's syndrome.

S&S: Edema, weight gain, full bounding pulse, tachycardia, increased blood and central venous pressures, distended neck and peripheral veins, slow vein emptying, moist crackles in lungs, dyspnea, and mental confusion.

Rx: Diuretics.

Nursing Process Elements

- Monitor vital signs
- Take daily weight
- Assess for edema
- Measure I&O
- Monitor lab results
- Maintain Fowler's position
- Restrict fluid intake as ordered
- Restrict sodium intake

Dehydration

Hyperosmolar imbalance develops when water is lost from the body and an excess of sodium results.

Etiology: Decreased sensation of thirst, enteral feedings with insufficient water intake, hyperventilation, prolonged fever, diabetes insipidus, diabetic ketoacidosis, and osmotic diuresis.

S&S: Dry sticky mucous membranes, flushed dry skin, thirst, fever, irritability, convulsions, and coma.

Rx: Hypotonic IV fluids such as 0.9% sodium chloride.

Nursing Process Elements

- Obtain daily weight
- Monitor I&O
- Monitor serum values
- Administer fluids as ordered

Overhydration

Hypo-osmolar imbalance develops due to the presence of excess water in the body, and low serum osmolality and low serum sodium result.

Etiology: Replacement of only water when loss of both water and electrolytes has occurred as with diaphoresis, SIADH, AIDS, and head injury.

S&S: Impaired neurological function as a result of cerebral edema—confusion, convulsions, and coma.

Rx: Restrict fluid to less than 1000 ml/d.

Nursing Process Elements

- Obtain daily weight
- Monitor I&O
- Monitor serum values
- Restrict fluids as ordered

ELECTROLYTE IMBALANCES

Sodium

- Sodium is the most abundant electrolyte found in ECF.
- Sodium controls water distribution and is the chief regulator of ECF volume; loss or gain of sodium means a loss or gain of water.
- Sodium maintains acid–base balance, transmission of nerve impulses, and osmotic pressure. Balance between dietary intake and renal secretion of sodium determines the sodium content of blood.
- Normal serum sodium is 135–145 mEq/l.

Hyponatremia (serum Na⁺ < 135 mEq/l)

- Hyponatremia develops due to the presence of excess water in relationship to sodium. It develops when
 - either there is too much water relative to the amount of sodium (too much water taken into body or not enough water excreted) or
 - too little sodium relative to the amount of water (too much sodium lost from the body or not enough taken in).

Etiology:

- Loss of fluids high in chloride as in vomiting and diarrhea and gastric suctioning
- Use of medications such as diuretics, lithium, cisplatin, heparin, and NSAIDs
- Decreased aldosterone as in adrenal insufficiency (Addison's disease)
- Water intoxication as from administration of excess volume of D5W
- CHF with decreased cardiac output that leads to fluid retention
- Chronic renal failure

S&S: Lethargy, anorexia, N&V, and muscle cramps. Confusion, muscle twitching, convulsions, and coma occur with serum sodium less than 120 mEq/l.

Dx: Measurement of serum sodium.

Rx:

- Varies with degree of hyponatremia
- Replace sodium orally or intravenously
- Treat underlying cause

Nursing Process Elements

- Monitor I&O and VS
- Obtain daily weight
- Monitor for CNS changes indicative of acute hyponatremia
- Encourage foods high in sodium content
- Administer sodium as ordered
- Restrict fluids as ordered
- Monitor for CHF: crackles, edema, and neck vein distention

Nursing Intervention Alert

Administer IV hypertonic solutions such as 3% and 5% NaCl carefully; inappropriate administration can cause death.

**Client teaching for self-care**

- Identification of sources of sodium
- Increase intake of salty foods and fluids
- Hold medications that induce hyponatremia when blood is to be drawn for electrolytes

Hypernatremia (serum Na^+ > 145 mEq/l)

- Hypernatremia develops due to the presence of excess sodium in relationship to water. It develops when
 - either there is too much sodium in relationship to water (too much sodium taken in or too little lost “sodium retention”) or
 - too little water in relationship to sodium (too little water taken in or too much lost—decreased total body water in relationship to sodium).
- Hypernatremia results in increased ECF volume.

Etiology:

- Insufficient fluid intake as a result of lack of awareness of thirst as in confusion or altered level of consciousness or inability to access fluids due to immobility.
- Dehydration
- Diabetes insipidus with its excessive water loss
- Lack of antidiuretic hormone
- Cushing’s disease
- Potassium depletion
- Hypovolemia
- High-sodium diet
- Excessive administration of IV sodium solution
- Ingestion of large amounts of salt as in salt water drowning
- Use of medications such as methyldopa, oral contraceptives, corticosteroids, and hydrolazine

S&S: Thirst, low-grade fever, sticky mucous membranes, dry swollen tongue, tachycardia, and altered mental status.

Dx: Measurement of serum sodium.

Rx:

- Varies with degree of hypernatremia, hypotonic fluid, sodium restriction, and diuretic
- Treat underlying cause

**Nursing Process Elements**

- Monitor I&O and VS
- Obtain daily weight
- Assess intake of sodium: dietary (water from a water softener, frozen foods, canned soups, etc.) and in home/OTC remedies such as Alka-Seltzer and baking soda and water
- Assess for excessive thirst, changes in mucous membrane, and fever

- Monitor for changes in behavior
- Restrict sodium
- Administer hypotonic solutions such as D5W as ordered

**Client teaching for self-care**

- Identification of sources of sodium
- Need to avoid salty foods and fluids
- Hold medications that induce hypernatremia when blood for electrolytes is to be drawn

Chloride

- Chloride is the major extracellular anion found mostly in combination with sodium or hydrogen as NaCl and HCl. Along with sodium, chloride maintains osmolarity of body fluids and acid–base balance.
- Absorption of chloride is controlled indirectly by aldosterone.
- Normal serum chloride is 90–110 mEq/l.
- Hyperchloremia or hypochloremia usually occurs along with shifts in Na^+ or HCO_3^- levels.
- Hyperchloremia is seen with hyperkalemia and hypernatremia, stomach cancer, kidney dysfunction, Cushing’s syndrome; medications as KCl, methyldopa, and cortisone preparations are used.
- Hypochloremia is seen with hypokalemia, hyponatremia, gastric suction, prolonged diarrhea, low-sodium diet, diabetic ketoacidosis, Addison’s disease; medications as bicarbonate, aldosterone, and thiazide diuretics are used.

Potassium

- Potassium is the most abundant intracellular cation.
- Potassium affects acid–base balance and osmotic pressure.
- Potassium is responsible for electrical conduction in muscle cells.
- Concentration of potassium is dependent on sodium reabsorption, aldosterone (increases loss of) level, and acid–base balance.
- Source of potassium is dietary intake; potassium is excreted or retained by kidneys depending on cellular needs.
- Normal serum potassium is 3.5–5.0 mEq/l.
- Potassium concentration has a narrow range; minor changes in levels have significant effects.
- Serum potassium levels are monitored with health problems such as cardiac dysrhythmias, renal disease, and use of medications such as thiazide diuretics.

Hypokalemia (serum K^+ < 3.5 mEq/l)

Hypokalemia develops when there is too little potassium in the body.

- Body does not conserve potassium so intake needs to compensate for loss.

- Intake of potassium can be insufficient and/or loss can be excessive.
- Potassium is secreted by the distal tubule—if secretion is increased, loss can be excessive.
- Loss of potassium can also occur through other routes in the presence of disease, e.g., GI tract with diarrhea.
- Serum K^+ levels can be low due to shift of K^+ to the intracellular space.

Etiology:

- Loss from GI tract: diarrhea, persistent vomiting, ileostomy drainage, GI suction, and overuse of laxatives
- Liver disease
- Diabetic acidosis
- Increased adrenal corticosteroid secretion (Cushing's syndrome)
- Use of medications as thiazide diuretics, aspirin, prednisone, laxatives, and cisplatin
- Anorexia and malnutrition
- Alcoholism
- Dehydration
- Alkalosis

S&S: Muscle weakness, cramps, anorexia, N&V, cardiac dysrhythmias, increased sensitivity to digoxin, lethargy, confusion, and decreased DTRs.

Dx: Measurement of serum potassium.

Rx:

- Administer potassium: dose 40–60 mEq/d
- Treat underlying cause

**Nursing Process Elements**

- Encourage increase in dietary potassium
- Administer potassium supplements as ordered
- Always dilute potassium when administered intravenously to prevent tissue damage

**Assessment Alert**

Hypokalemia can precipitate toxicity to digoxin. K^+ level should be greater than 3.5 mEq/l when taking digoxin.

**Client teaching for self-care**

- Eat foods rich in potassium when taking medications that are potassium depleting.

Hyperkalemia (serum $K^+ > 5.5$ mEq/l)

Hyperkalemia develops when there is too much potassium in the body due to inadequate excretion by the kidney or malfunctioning of the distal tubule or decreased renal blood flow with insufficient sodium to be exchanged for potassium or excessive intake or movement of potassium out of cells into ECF.

Etiology:

- Renal failure
- Medications such as tetracycline, antineoplastics, heparin, isoniazid, lithium, and potassium-conserving diuretics
- Acidosis
- Insulin deficiency
- Adrenal insufficiency (Addison's disease)
- High oral or IV intake
- Cell destruction: burns, trauma, and malnutrition

S&S: Weakness, paresthesias of face, tongue, feet and hands; flaccid muscle paralysis, hyperactive DTRs, nausea, confusion, ECG changes: tall, peaked t waves, wide QRS intervals, prolonged PR intervals, bradycardia, cardiac dysrhythmias, heart block, and cardiac arrest with K^+ greater than 7.0.

Dx: Measurement of serum K^+ .

**Clinical Alert**

Incorrect handling of blood samples can result in hemolysis of blood cells with release of intracellular potassium thereby giving a false, high serum K^+ measurement.

Rx:

- Varies with degree of hyperkalemia
- Restrict K^+ —no supplements, no transfusions of whole blood products
- IV sodium bicarbonate to alkalinize plasma causing a shift of K^+ into the cells
- Kayexalate (oral or rectal) to remove K^+
- Dialysis to remove K^+
- Treat underlying cause

**Clinical Alert**

Emergency management of hypokalemic cardiac effects: IV calcium gluconate antagonizes effect of K^+ on the heart.

Nursing Process Elements

- Stop any infusions containing potassium and withhold potassium supplements
- Monitor for neuromuscular S&S
- Monitor cardiac function
- Restrict potassium intake: avoid administering potassium supplements, potassium-sparing diuretics, high-potassium foods, and use of salt substitutes all of which are high in potassium

Client teaching for self-care

- Identification of sources of potassium
- Need to restrict intake if level is more than 6 mEq/l

Calcium

- Calcium is the cation primarily concentrated in the skeletal system.
- Concentration of calcium in the body is indirectly controlled by parathormone from the parathyroid gland.
- Calcium is excreted in urine, feces, and sweat.
- Normal serum calcium is 8.5–10 mg/dl.
- Controls transmission of nerve impulses and contraction of all types of muscle; maintains cellular permeability, and is essential for blood coagulation and formulation of teeth and bones.

Hypocalcemia (serum Ca^{2+} < 8.5 mg/dl)

Hypocalcemia develops when there is too little calcium in the body. It develops due to inadequate intake or inhibition of absorption from GI tract or excessive loss through GI tract or increased renal excretion.

Etiology:

- Lactose intolerance
- Malabsorption syndrome
- Vitamin D deficiency
- Acute pancreatitis
- Diarrhea
- Ileostomy drainage
- Intestinal suction
- Renal failure
- Removal or destruction of the parathyroid glands
- Medications such as corticosteroids, cisplatin, caffeine, and loop diuretics

S&S:

- Numbness and tingling of fingers and toes
- Hyperactive DTRs
- Positive Trousseau sign—BP cuff inflated on upper arm above systolic pressure for 2 minutes; if carpal spasm occurs, sign is positive.

- Positive Chvostek sign—facial nerve is tapped about 3 cm in front of ear lobe; if unilateral contraction of facial and eyelid muscles occurs, sign is positive.
- Carpo-pedal spasm
- Confusion
- Tetany

Dx: Measurement of serum calcium.

Rx: Medical IV calcium gluconate or calcium chloride for acute symptomatic hypocalcemic emergency.

Clinical Alert

Too rapid infusion of IV calcium gluconate or calcium chloride can cause digitalis toxicity and cardiac arrest.

Nursing Process Elements

- Seizure precautions for severe hypocalcemia
- Safety precautions if confused
- Monitor airway because laryngeal stridor can occur

Client teaching for self-care

- Need for high-calcium diet—1000–1500 mg/d
- Dietary sources of calcium: milk and milk products, grains, cereals, fruits, nuts, and greens
- Calcium supplements
- Avoid cigarette smoking since even moderate smoking can increase urinary excretion of Ca^{2+}

Hypercalcemia (serum Ca^{2+} > 10 mg/dl; severe >1 mg/dl)

Hypercalcemia develops when there is too much calcium in the body. It occurs due to increased mobilization from bone or increased intake or increased intestinal reabsorption related to excess vitamin D or decreased renal excretion.

Etiology:

- Hyperparathyroidism
- Bone metastases from solid cancers (breast, prostate, lung, head, neck, melanoma), lymphoma, leukemia, and myeloma
- Prolonged immobilization
- Excessive oral intake of calcium supplements
- Excessive intake of vitamin D supplements
- Renal failure
- Use of thiazide diuretics

S&S:

- Muscular weakness
- Tiredness

- Anorexia
- N&V
- Constipation
- Decreased memory span and confusion
- Polyuria
- Polydipsia
- Renal calculi (stones)
- ECG change: shortened QT interval
- Cardiac arrest at >18 mg/dl

Dx: Measurement of serum calcium

Rx:

- Lasix to increase calcium excretion
- IV fluid of 0.45% NS or 0.9% NaCl to dilute serum calcium and promote renal excretion
- Oral, NGT, or IV inorganic phosphate salts: phosphosoda or neutrophos
- Calcitonin for clients with heart or renal damage who cannot manage a large sodium load
- Treat underlying cause

Nursing Process Elements

- Monitor cardiac function
- Assess for signs of toxicity if client is on digoxin
- Administer medications and fluids as ordered and assess for effect on symptoms
- Increase mobilization if possible
- Maintain good fluid intake to decrease risk of renal calculi
- Discourage ingestion of dairy products and other foods high in calcium
- Withhold calcium supplements

Phosphorus

- Phosphorus is essential for function of muscles, nerves, RBCs, and the metabolism of carbohydrates, proteins, and fats.
- Normal serum phosphorus is 2.5–4.5 mg/dl.

Hypophosphatemia (serum level <2.5 mg/dl)

Hypophosphatemia occurs as a result of increased cellular uptake with hyperventilation or poor absorption from the GI tract or excess renal loss.

Etiology:

- Malnutrition or starvation
- Alcohol withdrawal
- Diabetic ketoacidosis
- Recovery phase of severe burns
- Overuse of laxatives
- Hyperalimentation

S&S:

- Memory loss
- Muscle weakness
- Muscle pain and tenderness
- Confusion
- Apprehension
- CHF

Dx: Measurement of serum phosphorus.

Rx: IV phosphorous for serum levels <1 mg/dl; oral otherwise.

Nursing Process Elements

- Monitor for infection because of effect on WBCs
- Begin hyperalimentation slowly in malnourished clients to decrease the risk of a rapid shift of phosphate into the cells
- Encourage intake of phosphorous rich foods: beef, pork, beans, and other legumes
- Stop antacids and calcium supplements

Hyperphosphatemia (serum level >4.5 mg/dl)

Hyperphosphatemia develops when there is too much phosphorous in the body. It occurs due to impaired renal excretion or decreased glomerular filtration rate.

Etiology:

- Renal failure
- Chemotherapy
- Large intake of milk
- Overuse of phosphate-containing cathartics
- Large vitamin D intake
- Overuse of Fleet enemas

S&S:

Same as for hypocalcemia because the problems result from the hypocalcemia associated with hyperphosphatemia.

Dx: Measurement of serum phosphorus.

Rx:

- Treatment of the underlying hypocalcemia
- Low-phosphate diet
- Phosphate-binding gels and dialysis for renal failure

Nursing Process Elements

- Same as for hypocalcemia

Client teaching for self-care

- Low-phosphate diet

Magnesium (normal serum magnesium is 1.6–2.5 mEq/l)

- Magnesium is essential to neuromuscular function.
- Concentration of magnesium in the body is regulated by parathormone which increases or decreases reabsorption of magnesium from the renal tubules.
- Magnesium is absorbed from GI tract.
- If Mg^{2+} level is low, the kidney excretes more K^+ .

Hypomagnesemia (serum level <1.6 mEq/l)

Hypomagnesemia develops when there is too little magnesium in the body. It occurs as a result of decreased reabsorption from the GI tract or increased excretion from the kidneys.

Etiology:

- Malnutrition or starvation
- Prolonged gastric suction
- Diarrhea
- Alcoholism
- Alcohol withdrawal
- Drugs such as diuretics, aminoglycosides, cisplatin, excessive doses of vitamin D, and calcium
- Pancreatitis
- Hyperparathyroidism

S&S:

- Neuromuscular irritability: difficulty swallowing, tremors, seizures, positive Chvostek, and Trousseau signs
- CNS changes: mood change and disorientation
- Tachycardia

Dx: Measurement of serum magnesium.

Rx: IV magnesium sulfate or oral magnesium.

**Nursing Process Elements**

- Assess for symptoms
- Aspiration precautions if difficulty swallowing
- Monitor clients on digoxin for signs of toxicity

**Client teaching for self-care**

- Dietary sources of magnesium: green vegetables, nuts, legumes, bananas, and oranges

Hypermagnesemia (serum level >2.5 mEq/l)

Hypermagnesemia develops when there is too much magnesium in the body. It occurs due to decreased excretion or excessive intake of magnesium.

Etiology:

- Renal failure
- Excessive use of antacids with a high concentration of magnesium
- Untreated diabetic ketoacidosis

S&S:

- Flushing and sense of skin warmth
- Hypotension
- ECG changes: prolonged PR interval and widened QRS
- Bradycardia
- Altered consciousness: drowsiness and lethargy progressing to coma
- Diminished or absent DTRs
- Depressed respirations

Dx: Measurement of serum magnesium

Rx:

- Hemodialysis with Mg^{2+} free dialysate results in safe serum levels in hours
- IV administration of calcium
- Magnesium-free IV fluids with a diuretic
- Ventilatory support for respiratory depression

**Nursing Process Elements**

- Monitor VS for drop in blood pressure, bradycardia, and slow, shallow respirations
- Monitor change in consciousness

**Clinical Alert**

Tumor lysis syndrome is an oncologic emergency characterized by hyperphosphatemia, hyperkalemia, hyperuricemia, and hypocalcemia. It is seen with some rapidly growing cancers such as leukemias and lymphomas and following chemotherapy-induced rapid tumor cell destruction. Symptoms include oliguria, azotemia, lethargy, N&V with the release of intracellular contents.

ACID–BASE IMBALANCE**Basic Concepts**

- The most important acids and bases in body are
 - acids such as carbonic acid (H_2CO_3) which dissolves in plasma into carbon dioxide (pCO_2) and water and
 - bases such as bicarbonate (HCO_3^-).
- Normal acid–base balance is 1 part acid to 20 parts base.
- pH is the concentration of hydrogen ions—a measure of the acidity or alkalinity of a fluid.
 - Range of pH: The lower the pH, the greater the number of hydrogen ions and the more acidic the fluid; the higher the pH, the fewer the number of hydrogen ions and the more alkaline the fluid.

- Acidosis is a condition in which $\text{pH} < 7.40$.
 - Respiratory acidosis develops when retention of the volatile gas CO_2 takes place due to inability to blow it off through the lungs.
 - Metabolic acidosis develops when retention of non-volatile acids or loss of base takes place.
- Alkalosis is a condition in which $\text{pH} > 7.40$.
 - Respiratory alkalosis develops when there is an excessive loss of CO_2 .
 - Metabolic alkalosis-develops when retention of non-volatile bases or loss of nonvolatile acids takes place.
- Regulation of acid–base balance takes place through
 - chemical buffers: these instantaneously combine with acids or bases in cells and ECF to maintain pH at 7.40. The most important buffer is bicarbonate that accepts a hydrogen ion forming carbonic acid which then becomes CO_2 and H_2O with the CO_2 able to be blown off through the lungs.
 - respiratory system: it regulates CO_2 in the ECF by changing rate and depth of respiration and therefore the amount of CO_2 blown off. This takes minutes to hours to have effect.
 - kidneys: these control amount of sodium bicarbonate in the ECF by combining bicarbonate or hydrogen with other substances and excreting them in the urine. This takes hours to days to have effect.
- Measures of acid–base balance: arterial blood gases (see Chapters 16 and 21), serum electrolytes.

Respiratory acidosis

Respiratory acidosis develops due to decreased alveolar ventilation with resulting carbon dioxide retention. Compensatory effects: Kidney retains HCO_3^- , increases elimination of acid, and increased production of ammonia.

Etiology:

- Pulmonary disease: ARDS, pneumonia, flail chest, pneumothorax, smoke inhalation, massive pulmonary embolism, pulmonary edema, COPD, cystic fibrosis, and kyphoscoliosis
- Neuromuscular problems: drugs, toxins, Guillain-Barre syndrome, high spinal cord injury
- Airway obstruction: aspiration, laryngospasm
- CNS depression: sedative overdose, anesthesia, cerebral trauma, brain tumor, polio, multiple sclerosis, ALS, and muscular dystrophy
- Other: cardiac arrest, inadequate tidal volume, or respiratory rate on ventilator

S&S: Dyspnea, tachypnea, restlessness, confusion, diaphoresis, anxiety, headache, tachycardia progressing to lethargy, ventricular dysrhythmia, dilated facial and conjunctival blood vessels, cyanosis, and coma.

Rx: Suction and chest PT to clear airway; intubation and mechanical ventilation for $\text{PaCO}_2 > 50\text{--}60$ mm Hg; low-flow oxygen.

Nursing Process Elements

- Monitor respiratory status: rate, depth, rhythm, and effort
- Encourage coughing or suction to clear airway
- Maintain semi-Fowler's position to promote chest expansion unless contraindicated; sidelying position for mechanically ventilated clients

Respiratory alkalosis

Carbon dioxide is lost as a result of increased alveolar ventilation.

Etiology:

- Stimulation of the respiratory center: anxiety, fever, pain, salicylates, hyperventilation, intracerebral trauma, gram-negative sepsis, pregnancy, and hepatic insufficiency
- Hypoxemia: high altitude, hypotension, severe anemia, and CHF
- Pulmonary disease: pneumonia, pulmonary emboli, inhalation of irritants, and interstitial fibrosis
- Excessive TV or respiratory rate on a ventilator

S&S: Increased rate and depth of respiration, anxiety, lightheadedness, paresthesias, circumoral numbness progressing to confusion, cardiac dysrhythmias, tetany, syncope, and seizures.

Rx: Treat underlying cause.

Nursing Process Elements

- Institute measures to relieve pain or anxiety
- Encourage normal breathing by coaching
- Have client breathe into a paper bag
- Monitor for cardiac dysrhythmias

Metabolic acidosis

Etiology:

- Loss of bicarbonate: diarrhea, ileostomy drainage, biliary and pancreatic drainage, renal tubular disease, and acetazolamide
- Excess production of acid: ketoacidosis, diabetes, alcohol-induced starvation, lactic acidosis, and rhabdomyolysis
- Excess acid ingestion: salicylates, cocaine, ecstasy, and methamphetamine
- Renal inability to excrete hydrogen ions: renal failure, renal tubular type 1 acidosis, hyperaldosteronism, and potassium-sparing diuretics

Clinical Alert

Chronic renal failure is the most common cause of chronic metabolic acidosis.

S&S: Increased rate and depth of respiration, fatigue/lethargy, hypotension, tachypnea, cold clammy skin, N&V, diarrhea, confusion, fruity breath odor progressing to Kussmaul's respirations, dry warm flushed skin, dysrhythmias, stupor, and coma.

Rx:

- Treat underlying disorder and correct fluid and electrolyte imbalances; dialysis when renal failure is the cause
- For severe acidosis, IV sodium bicarbonate may be cautiously given especially to clients with CHF or pulmonary edema

Nursing Process Elements

- Monitor for cardiac dysrhythmias
- Check for pulse deficit that indicates weak contractions or cardiac failure
- Monitor ABGs and electrolytes to evaluate treatment

Metabolic alkalosis

Etiology:

- Loss of hydrogen ions: vomiting, nasogastric suctioning, thiazide diuretics, excess mineralocorticoid, hypercalcemia, and hypoparathyroidism
- Hydrogen ion intracellular shift: hypokalemia, refeeding after starvation

- Bicarbonate retention: bicarbonate ingestion or infusion and massive blood transfusion

S&S: Decreased rate and depth of respirations, irritability, restlessness, muscle weakness, hyporeflexia, polyuria/polydipsia, dysrhythmias progressing to tetany, apathy, confusion, convulsions, and stupor.

Rx:

- Correct underlying disease.
- Hypokalemia is usual and is corrected with oral or IV potassium, isotonic saline IV to correct volume deficiencies when cause is diuretics or loss of gastric secretions

Nursing Process Elements

- Monitor for dysrhythmias
- Check for pulse deficits
- Monitor lab data especially pH, serum bicarbonate, and serum potassium
- Weigh daily
- Record I&O including stomach contents removed by suction
- Use isotonic saline to irrigate nasogastric tubes to prevent removal of electrolytes
- Notify physician if serum potassium drops to <3.5 mEq/l

MEDICAL EMERGENCIES

GENERAL PRINCIPLES OF EMERGENCY CARE—REFERS TO CARE GIVEN TO CLIENTS WITH URGENT AND CRITICAL NEEDS

Goal: Preserve life and prevent deterioration before more definitive treatment can be given.

Principles of Assessment and Emergency Management

- Treat the potentially life-threatening problems
- Stabilize the pulmonary cardiovascular and central nervous systems
- Maintain a patent airway and provide adequate ventilation, employing resuscitation measures when necessary
- Assess for chest injuries with subsequent airway obstruction
- Control hemorrhage and its consequences
- Evaluate and restore cardiac output
- Prevent and treat shock; maintain or restore effective circulation

- Perform a rapid initial physical assessment and reassess frequently
- Perform a Glasgow Coma Scale; evaluate best motor, verbal, and pupil response
- Monitor with ECG if appropriate
- Splint suspected fractures; and stabilize c-spine
- Protect wounds with sterile dressings
- Check to see if client has medic-alert identification
- Assess VS frequently
- Provide IV access with large-bore needles

Obtaining Assessment Data

- Obtain a brief history of the accident/illness from the client or accompanying person; include the following questions:
 - What were the circumstances, precipitating events, location, and time of injury/illness?
 - When did symptoms appear?
 - Was the client unconscious after the injury?

- How did the client get to the hospital?
- What was the health status before the client reached the hospital?
- Is there a past history of illness or past admissions?
- Is the client currently taking medications?
- Are there any drug or food allergies?
- Does the client have bleeding tendencies?
- Is the client under a physician's care
- Name of the physician.
- What time was the last meal eaten?
- What is the date of the last tetanus immunization?

Recording of Data

Consent to examine and treat the client is part of the emergency department record. The client must consent to invasive procedures. If the client is unconscious and brought to the emergency department without family or friends, this fact should be documented. Monitoring of the client's conditions and all instituted treatment modalities must be documented. After treatment, a notation is made on the record about the client's condition on discharge or transfer and instructions given to the patient and family for follow-up care.

Psychological Management of Clients and Families in Emergencies

- Understand and accept anxieties
- Keep family members informed
- Provide honest and realistic outcomes
- Help family members cope with impending death or death
- Offer spiritual counseling
- Provide privacy
- Allow immediate family to visit per hospital protocol

CARDIAC ARREST

- Heart ceases to produce an effective pulse and blood circulation.
- Cardiac arrest may follow respiratory arrest.

Etiology:

- Cardiac electrical event: heart rate too fast (especially ventricular tachycardia or ventricular fibrillation), too slow (bradycardia or AV block), or absent (asystole)
- Ventricular fibrillation is the major cause with precipitating factors such as
 - myocardial infarction (MI),
 - congenital heart disease,
 - heart failure,
 - anesthetics and antiarrhythmic drug overdose,
 - electrical shock,

- electrolyte imbalances,
- near drowning,
- hypothermia,
- ventricular irritation due to cardiac pacing during cardiac catheterization or angiography,
- acute hemorrhage,
- hypoxia or acidosis, and
- myocarditis.
- Precipitating causes of asystole are
 - drug overdose,
 - hemorrhage,
 - anaphylaxis,
 - respiratory acidosis or hypercapnia,
 - left ventricular heart failure, and
 - electromechanical dissociation associated with severe MI, heart wall rupture, and cardiac tamponade.

Assessment Alert

Emergency treatment such as CPR must restore circulation within approximately 4 minutes after the onset of cardiac arrest to prevent irreversible brain damage.

S&S:

- Clinical manifestations of cardiac arrest include
 - immediate loss of consciousness,
 - absence of pulses,
 - apnea or gasping respirations, and
 - Ashen-gray skin.

Dx:

Assessment Alert

Absence of carotid pulses is the most reliable sign.

Nursing Process Elements

- Assess ABCs (airway, breathing, circulation)
- Begin resuscitation measures immediately to prevent irreversible brain damage
- Call for assistance
- Establish a patent airway
- Provide artificial ventilation by mouth-to-mouth resuscitation or with an Ambu bag
- Give oxygen as soon as possible

- Provide artificial circulation through external cardiac compression
- Defibrillate using direct-current countershock for ventricular fibrillation or tachycardia
- Establish a patent IV line if not already in place
- Administer emergency drugs as ordered
- Provide emotional support to family members or significant others

Assessment Alert

Cardiac arrest may occur when electrical activity is present but there is an ineffective cardiac contraction or circulating volume (pulseless electrical activity [PEA]).

Client teaching for self-care

- Teach family members or significant others
 - Steps of CPR
 - Basic pathophysiology of the underlying disease process

RESPIRATORY ARREST

Etiology:

- Airway obstruction, decreased respiratory drive, or respiratory muscle weakness
- Upper airway obstruction: posterior tongue displacement into the oropharynx secondary to a loss of muscular tone in unconscious clients (most common), blood, mucus, vomitus, or foreign body, spasm or edema of the vocal cords, pharyngolaryngeal inflammation, neoplasm, or trauma
- Lower airway obstruction: aspiration of gastric contents, widespread severe bronchospasm, extensive airspace-filling processes (e.g., pneumonia, pulmonary edema, pulmonary hemorrhage)
- Airway obstruction may be partial or complete.

S&S:

- Absence of spontaneous ventilation, cyanosis; if respiratory arrest is prolonged, cardiac arrest quickly ensues as a result of the effect of hypoxemia on cardiac function.
- Impending respiratory arrest: depressed sensorium and feeble, gasping, or irregular respirations, often with tachycardia, diaphoresis, and relative hypertension due to agitation and CO₂ accumulation

Rx:

- Establish patent airway
- Give two rescue breaths (insufflations—mechanical forcing of air into the respiratory system).

- Give artificial respiration if spontaneous respiration is not resumed after rescue breaths.

—Do only when heart is still beathing

—Do only for respiratory arrest; not if client is weakly breathing

—Use a barrier device (even a cotton handkerchief) to protect against exposure to bodily fluids such as blood or vomit.

—Start by giving two insufflations. These can help a nearly breathing client recover spontaneous respiration.

—Tilt back the head of the client to extend his airways; the head will remain in this position on itself, you do not have to maintain it so.

—Open the jaw of the client by pulling on his chin. In some cases (like some cases of epilepsy), the muscles of the clients are so contracted that it is impossible to open the mouth. Contrary to urban legend, the client will not “swallow” tongue. In this situation, it may not be possible to blow into the mouth. Instead, seal the lips together and breathe into the nose while keeping the head tilted back.

—Close the nose of the client with your free hand.

—Take a deep breath, put your mouth on the mouth of the client in an airtight manner, and blow into the mouth of the client. These breaths should be gentle and last no longer than 2 seconds to prevent air from entering the stomach.

—When you have given two insufflations, check the carotid pulse of the client, while keeping an eye on his respiration. Chances are that

—the client might have recovered spontaneous respiration thanks to “your insufflations” or

—the client might be in a state of cardio-respiratory arrest.

If the client has recovered spontaneous respiration, put him in *recovery position*, cover him, and monitor his respiration on a regular basis until a mobile medical unit arrives.

If the client is in a state of cardio-respiratory arrest, you will have to perform cardiopulmonary resuscitation (CPR).

- Use a 100% mask (airtight mask) and an air balloon. Ventilate the client with pure oxygen. A client whose lungs are full of pure oxygen can stay in *apnea* for nearly 30 minutes (half an hour).

- Intubate

- ABGs

Nursing Process Elements

- Verify tube placement
- Assess respiratory status
- Monitor cardiac status

SHOCK

- A life-threatening condition which is characterized by inadequate blood flow to the tissues and cells of the body to meet metabolic needs.
- A cellular hypofunction state exists when the body consumes its oxygen more rapidly, and compensatory mechanisms are initiated to meet the increased demands of the body and restore oxygen and perfusion to cells.
- Compensatory mechanisms are the same regardless of the type of shock.
- Shock affects all body systems.
- Cellular hypoperfusion states include hypovolemia, cardiogenic shock, anaphylaxis, neurogenic shock, and septic shock.

Hypovolemic Shock

Etiology: Decreased intravascular volume.

Predisposing factors:

Absolute hypovolemia

- Loss of whole blood (e.g., hemorrhage from trauma, surgery, GI bleeding.)
- Loss of plasma (e.g., burn injuries)
- Loss of body fluids (e.g., vomiting, diarrhea, excessive diuresis, diaphoresis, diabetes insipidus, diabetes mellitus)

Relative hypovolemia

- Pooling of blood or fluids (e.g., ascites, peritonitis, bowel obstruction)
- Internal bleeding (e.g., fracture of long bones, ruptured spleen, hemothorax, severe pancreatitis)
- Massive vasodilation (e.g., sepsis)

S&S:

- Vary with the amount and rate of loss and effectiveness of compensatory mechanisms
- Altered mentation, ranging from lethargy to unresponsiveness
- Rapid, deep respirations that gradually become labored and shallower as the client's condition deteriorates.
- Cool, clammy skin
- Weak and thready pulses
- Tachycardia due to activation of the sympathetic nervous system
- Decreased urine output; urine is dark and concentrated because kidneys are conserving fluid.

Dx:

- Determination of serum lactate
- Arterial pH
- Base deficit to assess the presence of anaerobic metabolism
- Hemoglobin and hematocrit
- Serum potassium

Rx:

- Optimize oxygenation
- Correct the underlying cause of fluid loss as quickly as possible (e.g., bleeding, GI loss)
- Restore intravascular volume to reverse the sequence of events leading to inadequate tissue perfusion
- Administer warmed fluids, blood/blood products, crystalloids, colloids rapidly using two large-bore (14–16 gauge) peripheral IVs
- Goals of resuscitation:
 - CVP 15 mm Hg
 - PAWP 10–12 mm Hg
 - Cl >3 L/min/m²
 - Blood lactate <4 mmol/l
 - Base deficit -3 to $+3$ mmol/l

Clinical Alert

Military antishock trousers (MAST) are a garment designed to correct internal bleeding and hypovolemia by the application of counterpressure around the legs and abdomen creating artificial peripheral resistance and helping sustain coronary perfusion.

Nursing Process Elements

- Administer ordered fluids
- Maintain adequate IV access with large-bore needle/catheter
- Assess pulmonary and renal status
- Observe for fluid overload
- Monitor I&O
- Weigh daily

Assessment Alert

Position the client who shows signs of shock with the lower extremities elevated approximately 20 degrees; knees straight, trunk horizontal, and head slightly elevated.

Cardiogenic Shock

Etiology: Loss of ventricular contractile force, which results in decreased stroke volume and decreased cardiac output.

Precipitating factors:

- Systolic dysfunction: inability of the heart to pump blood forward (e.g., MI, cardiomyopathy).

- Diastolic dysfunction: inability of the heart to fill during diastole (e.g., cardiac tamponade).
- Arrhythmias (e.g., bradycardia, tachycardia).
- Structural factors: valvular abnormality (e.g., stenosis or regurgitation), papillary muscle dysfunction, and acute ventricular septal defect.

S&S: Change in mental status, weak, thready pulse of >100 bpm, diminished S1 and S2 heart sounds, pale cool skin, concentrated urine progressively decreasing in amount until <30 ml/hr, tachypnea with auscultatory crackles and wheezes, elevated BUN, and serum creatinine.

Hemodynamic Findings

- Systolic blood pressure <90 mm Hg with increased diastolic pressure resulting in a narrowed pulse pressure
- Mean arterial pressure <70 mm Hg
- Cardiac index <2.2 l/min/m²
- Pulmonary artery wedge pressure >18 mm Hg

Noninvasive Findings

- Thready, rapid pulse
- Narrow pulse pressure
- Distended neck veins
- Arrhythmias
- Chest Pain (recurrent chest pain suggests extension of infarct)
- Cool, pale, moist skin
- Oliguria
- Decreased mentation

Pulmonary Findings

- Dyspnea
- Increased respiratory rate
- Inspiratory crackles, possible wheezing
- Arterial blood gases show decrease in PaO₂

Assessment Alert

The cumulative amount of infarcted muscle is directly related to the risk of developing shock.

Dx:

- Left ventricular damage
- Decreased cardiac output
- Dysrhythmias
- Increased left ventricular end-diastolic pressure (LVEDP)
- Decreased arterial blood pressure

Rx:

- Improve O₂ status by decreasing demand
- Reestablish blood flow with thrombolytics, angioplasty, and emergency revascularization to reestablish blood flow
- Increase O₂ supply by providing supplemental O₂
- Vasoactive drug therapy to increase cardiac output
 - Dilate coronary arteries (e.g., nitrates)
 - Improve contractility (e.g., inotropes)
 - Reduce preload (e.g., nitrates, morphine, diuretics, ACE inhibitors)
 - Reduce afterload (e.g., ACE inhibitors, phosphodiesterase inhibitors, B-adrenergic agonists, vasodilators)
 - Reduce heart rate (e.g., B-adrenergic blockers, calcium channel blockers)
 - Reduce contractility (e.g., B-adrenergic blockers [Contraindicated with decreased ejection fraction])
- Correct arrhythmias
- Circulatory assist devices: IABP, VAD

Nursing Process Elements

- Prevention
- Intra-aortic balloon counter-pulsation (IABC)
- Hemodynamic monitoring
- Fluid administration
- Safety and comfort

Circulatory Shock or Distributive Shock (Neurogenic, Septic, and Anaphylactic Shock)

Neurogenic shock

Etiology: Massive vasodilation resulting from loss of sympathetic vasoconstrictor tone.

Precipitating factors:

- Hemodynamic consequences of injury and/or disease to the spinal cord at or above T5
- Spinal anesthesia
- Vasomotor center depression (e.g., severe pain, drugs, hypoglycemia, injury)

S&S:

- Dry, warm skin
- Syncope
- Bradycardia
- Hypotension
- Loss of the ability to sweat below the level of the injury

Clinical Alert

An unconscious client is treated as though a spinal cord injury has occurred until proven otherwise.

Dx:

- Radiographs of the spine, chest, and other structures
- CT scan
- MRI
- Somatosensory-evoked potentials
- CBC, electrolytes, glucose, BUN, creatinine, blood type, and crossmatch
- ABGs
- Coagulation studies

Rx:

- Treat underlying cause
- Minimize spinal cord trauma with stabilization
- Careful administration of fluids
- Drug therapy
 - Dopamine for hypotension and bradycardia
 - Phenylephrine or norepinephrine to increase SVR
 - Epinephrine for vasoconstrictive action
- Heparin or low-molecular-weight heparin (Lovenox)

Nursing Process Elements

- Elevate and maintain the head of the bed at least 30 degrees for clients receiving spinal or epidural anesthesia
- Immobilize the client to prevent further damage to the spinal cord
- Apply elastic compression stockings or pneumatic compression hose
- Elevate the foot of bed to minimize pooling of blood
- Check skin for redness, tenderness, and warmth of the calves
- Assess Homans' sign
- Perform passive range of motion
- Monitor for hypothermia and internal bleeding

Septic shock

- Complex and generalized process that involves all organ systems

Etiology: Initiated by infection—most often gram-negative bacterial infection, but can also result from gram-positive bacterial, viral, fungal, or parasitic infection.

Risk Factors:

- Invasive procedure
- Indwelling lines and catheters

- Old age
- Presence of chronic disease (e.g., diabetes mellitus, chronic renal failure, congestive heart failure)
- Immunosuppression
- Malnourishment
- Debilitation
- Malnutrition

S&S:

- Increased cardiac output progressing to low cardiac output
- Decreased urinary output
- Hyperthermia
- Warm flushed skin initially, progressing to cool and pale
- Bounding pulse
- Nausea, vomiting, diarrhea, or decreased bowel sounds
- Confusion or agitation
- Increased heart and respiratory rate

Clinical Alert

Fluid replacement must be instituted to correct the hypovolemia that results from the incompetent vasculature and inflammatory response.

Dx:

- Presence of bacteria in the blood
- Urine, blood, and sputum culture
- WBC with differential leukocyte count
- Hgb and Hct
- Activated protein C
- Changes in plasma D-dimer

Rx:

- Optimize oxygen delivery by increasing supply/decreasing demand
- Fluid resuscitation
- Optimize cardiac output
 - Volume
 - Positive inotropes (e.g., dobutamine)
- Vasopressors (increase blood pressure) (e.g., norepinephrine, phenylephrine)
- Correct acidosis
- Obtain culture before beginning antibiotics
- Antibiotics as ordered
- Debride wounds to remove necrotic tissue
- Institute infection control practices

**Nursing Process Elements**

- Ensure patent airway
- Start or maintain an established IV catheter
- Administer oxygen
- Administer antibiotics
- Obtain specimens of blood, urine, wound drainage, and sputum for culture
- Observe for overt bleeding
- Administer medications as prescribed

**Client teaching for self-care**

- Avoid crowds and large gatherings of people
- Do not share eating utensils or personal toilet articles
- Report S&S of infection
- Practise good bodily hygiene
- Do not change pet litter boxes
- Refrigerate and prepare food appropriately
- Take medications as prescribed

Anaphylactic shock

Anaphylactic shock is an immediate, systemic, normovolemic vasogenic reaction that occurs when an antigen interacts with the preformed antibody found on the surface of mast cells and basophils.

Etiology: Result of a systemic antigen–antibody reaction in a client who has preexisting antibodies to an offending antigen.

Precipitating factors:

- Contrast media
- Blood/blood products—transfusion reaction
- Drugs—penicillin sensitivity
- Insect bites—bee stings
- Anesthetic agents
- Food/food additives
- Vaccines
- Environmental agents
- Latex

S&S:

- Uneasiness
- Apprehension
- Weakness
- Impending doom
- Anxious
- Frightened
- Itching and urticaria
- Angioedema

- Crackles, wheezing, and reduced breath sounds
- Congestion, rhinorrhea, dyspnea, and respiratory distress
- Respiratory failure and cardiac dysrhythmias

**Nursing Intervention Alert**

An emergency anaphylaxis kit or an epinephrine injector such as the EpiPen automatic injector should be readily available at all times.

Dx:

- History of severe allergic reaction/anaphylaxis
- Severe bronchospasms
- ABGs
- Angioedema
- Intense itchy skin

Rx:

- Premedication when a history of prior sensitivity (e.g., contrast media) exists
- Identify and remove offending cause if possible, e.g., latex tube
- Maintain patent airway
- Intubation/mechanical ventilation
- Drug therapy
 - Epinephrine: subcutaneous, IV, nebulized
 - Bronchodilators: nebulized, IV
 - Antihistamines
 - Corticosteroids (if hypotension persists)
- Fluid Resuscitation

**Nursing Process Elements**

- Assess history of allergens
- Institute emergency management of airway
- Start IV access
- Medications as prescribed
- Respiratory support with mechanical ventilation and oxygenation as needed

**Client teaching for self-care**

- Wear identification that identifies sensitivities
- Prevent further exposure to antigens
- Instructions concerning emergency use of medications to treat anaphylaxis
- Teach S&S of anaphylaxis

DISSEMINATED INTRAVASCULAR COAGULATION (DIC)

Etiology: Inappropriate stimulation of clotting.

Precipitating factors:

- Intrinsic pathway—injury to or alteration of vascular endothelium
- Extrinsic pathway—entry into circulation of procoagulant released from damaged tissue
- Common pathway—platelet adherence to abnormal vascular endothelium or aggregates of platelets or WBCs, which stimulate fibrinogen or prothrombin

S&S:

- CNS changes—restlessness, malaise, confusion, disorientation, and altered level of consciousness
- Cardiovascular—tachycardia, hypotension, nonspecific ST changes on ECG, and increased pulmonary artery pressure
- Pulmonary—hemoptysis, ARDS, tachypnea, orthopnea, dyspnea, hemorrhage, and cyanosis
- Renal—decreased urine output, oliguria, hematuria, urethral bleeding, severe back pain, ↑ BUN and creatinine
- Skin—petechiae, purpura, ecchymosis, oozing from venipuncture sites, bruising under site of BP cuff, hemorrhagic bullae, wound hematomas, cold mottled fingers and toes, and gangrene
- Gastrointestinal—N&V, abdominal pain, hematemesis, or NG drainage with blood, rectal bleeding and hematochezia, GI hemorrhage, and melena
- Musculoskeletal—severe muscle pain
- Legs—severe mottling of skin on lower legs, absent popliteal, posterior tibial, or pedal pulses, calf swelling, pain in foot with dorsiflexion, blood pooling, and cyanosis
- Toes—cool, mottled skin, and gangrenous changes in tips of toes
- Eyes—conjunctival or retinal hemorrhage and blurred vision
- Nasopharyngeal—gingival bleeding, epistaxis, bleeding from NG or endotracheal tube insertion site

Dx:

- Prothrombin time (PT)—prolonged
- Activated partial thromboplastin time (APTT or PT)—prolonged
- Thrombin time—excessively sensitive—20–40 seconds
- Fibrinogen levels—decreased
- Fibrin degradation product—elevated
- d-dimer—specific for fibrin monomer in DIC
- Antithrombin III—decreased
- Ethanol test—positive 1+ and 3+
- Platelets—decreased

- RBC—decreased
- Reticulocytes >4%
- Hgb & Hct—decreased

Rx:

- Correct the primary or underlying disorder if possible (i.e., prompt delivery of dead fetus and placenta or administration of IV antibiotics for sepsis).
- Control the major symptoms, either bleeding or thrombosis—stop hemorrhage—terminate the accelerated coagulation process—minimize development of microthrombi—resolve established thrombi
- Provide prophylaxis to prevent recurrence: heparin accelerates the rate at which antithrombin 3 neutralizes thrombin and activated factor X. This action blocks the coagulation cascade at the common pathway and ultimately prevents conversion of fibrinogen to fibrin.

Nursing Process Elements

- Assess for bloody drainage
- Observe for signs of thrombosis
- Check for petechiae, ecchymosis, or cyanosis
- Provide meticulous care to avoid infection
- Assess for fluid volume
- Assess for respiratory and cardiovascular problems
- Provide gentle care to avoid trauma
- Attend to IV therapy line and heparin infusion
- Provide psychosocial support

CARDIAC TAMPONADE

- Medical emergency
- Rising intracardiac pressure, decreased diastolic filling time, and decreased cardiac output

Etiology: Accumulation of excess pericardial fluid compresses the heart resulting in diminished cardiac filling and decreased cardiac output.

Precipitating factors: Chest trauma (blunt or penetrating) or chest tumor (cancer of esophagus or lung).

S&S:

- Dyspnea
- Chest pain or pressure
- Falling blood pressure
- Rapid, weak pulse
- Increased JVD and CVP
- Distant heart sounds
- Pericardial friction rub

- Diminishing pulse pressure (difference between systolic and diastolic BP)
- Ankle and sacral edema
- Ascites
- Lethargy
- Pulsus paradoxus (lose systolic blood pressure during inspiration)

Clinical Alert

Cardiac Tamponade is a life-threatening condition that requires immediate intervention. Pericardial sac normally contains about 50 cc of fluid so even a small increase in fluid causes compression of the heart within the pericardial sac.

Dx: Echocardiogram, chest X-ray (cardiac enlargement), and ECG (nonspecific abnormalities).

Rx: Treat cause; administer oxygen (mechanical ventilation may be needed), drain fluid via pericardiocentesis, if tumor related. Chemotherapy or radiation may be used to decrease tumor size; vasopressors to increase blood pressure and cardiac output.

Nursing Process Elements

- Administer oxygen and position to facilitate breathing
- Treat for signs of shock but avoid fluid overload as cardiac output is already compromised
- Assist with pericardiocentesis
- Check for murmurs
- Assess for signs of fluid reaccumulation after pericardiocentesis

Client teaching for self-care

- Teach client signs of reoccurrence if related to malignancy.

PULMONARY EDEMA

- Acute heart failure
- Usually the result of left heart failure
- Causes severe tissue hypoxia leading to organ system failure and death
- Volume overload increases left atrial, pulmonary vein and capillary pressures; this high pressure forces fluid from the blood into pulmonary interstitial spaces and ultimately into the alveoli.

Etiology: Inadequate left ventricular function with cardiac disease can also result from hypervolemia, pulmonary disorders, and certain cancer-related conditions.

S&S:

- Profound dyspnea, tachypnea, cyanosis, wheezing, production of pink (blood tinged) frothy secretions, and orthopnea
- Wheezing, rales, and crackles
- Severe anxiety and sense of impending doom, restlessness, and confusion
- Tachycardia and hypotension
- Pallor, decrease in oxygen saturation levels, and abnormal ABGs.
- Elevated JVD and CVP

Assessment Alert

Severe life-threatening complication. Client presents in acute respiratory distress and sense of suffocation or “drowning” in secretions. Crackles are heard in the lung bases due to movement of air through the alveolar fluid.

Dx: Clinical manifestations and chest X-ray demonstrate pulmonary congestion

Rx: Reduce excess fluid and improve gas exchange by means of MOIST.

- M—morphine to reduce anxiety and pain, and to reduce peripheral resistance and venous return
- O—oxygen to respond to hypoxemia; intubation may be needed
- I—IV medications to improve ventricular function including inotropes (dopamine or dobutamine), diuretics (furosemide), aminophylline to relieve bronchospasms, vasodilators (nitroglycerine) to dilate vessels thereby decreasing afterload and preload
- S—suction as needed
- T—treat underlying cause

Nursing care

- Position the client for comfort and support of ventilation and circulation: semi to high Fowler’s with legs dangling and arms supported and away from the chest as in leaning on an over-the-bed table
- Maintain airway patency
- Administer oxygen at high concentrations
- Monitor VS, pulse oximetry, ABGs, and hemodynamic status
- Provide emotional support—assume a calm, reassuring manner
- Monitor effects of medications—especially for changes in electrolyte levels

- Accurate I&O
- Prepare for emergency treatments (rotating tourniquets, intubation, phlebotomy)

Client teaching for self-care

- Treatment for underlying cause
- Promote activity without adding to fatigue, so pace and prioritize daily activities
- Avoid extremes in temperature that tax cardiac function
- Stop activity if experiencing light-headedness or shortness of breath
- Plan for periods of rest alternating with periods of activity
- Maintain low-sodium diet
- Potassium replacement if taking a potassium-depleting diuretic and/or include foods high in potassium in the diet. This includes orange and tomato juice, bananas, raisins, figs, prunes, apricots, spinach, cauliflower, and potatoes
- Take diuretics at times that allow for uninterrupted sleep
- Importance of adherence to medical regime
- Weigh self daily and report to physician a greater than 3-lbs weight gain (1 liter = 2.2 lbs; “a pint is a pound the world around”)
- How to take pulse and report to physician if pulse is <60 bpm or >120 bpm
- S&S of complications or onset of condition to be reported

ACUTE RESPIRATORY DISTRESS SYNDROME

- Acute respiratory failure
- Clinical syndrome of noncardiogenic pulmonary edema and progressive decrease in arterial oxygen content

Etiology: Always occurs after serious illness or injury either directly to the lungs or after indirect insult to the body.

Precipitating factors:

- Aspiration
- Drug overdose
- Prolonged inhalation of high concentrations of oxygen, smoke, or corrosive substances
- Shock
- Trauma such as pulmonary contusion, multiple fractures, and head injury
- Systemic infection

S&S: Clinical S&S usually 12–48 hours after a serious injury or illness include

- anxiety,
- decreased level of consciousness,

- dyspnea,
- tachypnea,
- auscultated crackles,
- decreased functional residual capacity,
- hypocapnia,
- severe hypoxia, or
- marked buccal peripheral cyanosis.

Dx: Clinical presentation.

- Low partial pressure of arterial oxygen (PaO₂)
- Chest X-ray showing dense pulmonary infiltrates with a white out or ground glass appearance to the lung
- Decreased pulmonary compliance

Assessment Alert

ABG analysis: decreased PaO₂ (below 60 mm Hg despite administration of oxygen at a high flow rate (10 l/min)

Rx:

- Oxygen
- Mechanical ventilation
- Extracorporeal lung-assist technology
- Partial liquid ventilation
- Positioning
- Pharmacological therapy
- Nutritional support

Nursing Process Elements

- Assist with endotracheal intubation and mechanical ventilation; as prescribed, institute positive end-expiratory pressure (PEEP) to keep alveoli distended, stretch stiff lungs, and increase oxygen–carbon dioxide diffusion
- Administer corticosteroids as prescribed, to decrease inflammation surrounding the alveoli and to stabilize the capillary membrane
- Encourage semi-Fowler’s or high Fowler’s position
- Assess for S&S of fluid volume overload including peripheral edema and jugular vein distention (JVD)
- Provide adequate nutritional support that is not high in carbohydrates, which metabolize to form excess CO₂. The diet should include 35–45 kcal/kg a day to meet normal requirements, with enteral or parental feeding support if necessary
- Reassure client, explain all procedures, and remain calm to reduce client’s anxiety and thereby decrease oxygen need
- Monitor ABG levels

- Maintain effective tracheobronchial hygiene
- Monitor hemodynamic status

Assessment Alert

Identify clients at high risk for pulmonary hypertension such as COPD, pulmonary emboli, congenital heart disease, and mitral valve disease.

CHOKING

To assist a client who is choking on a foreign object, perform the abdominal thrust maneuver (sometimes called the Heimlich maneuver).

Assessment Alert

Hands crossed at the neck are the universal sign for choking.

- Stand behind the person who is choking
- Place both arms around the person's waist
- Make a fist with one hand with the thumb outside the fist
- Place thumb side of fist against the person's abdomen above the navel and below the xiphoid process
- Grasp fist with other hand
- Quickly and forcefully exert pressure against the person's diaphragm, pressing upward with quick, firm thrusts.
- Apply thrusts 6–10 times until the obstruction is cleared.
- The pressure from the thrusts should lift the diaphragm, force air into the lungs, and create an artificial cough powerful enough to expel the aspirated object.

POISONING

- Exposure to poisons can occur by ingestion, inhalation, or skin or mucous membrane contact.
- Typically occurs in children younger than age 6 years, with a peak incidence between 12 and 24 months.

Etiology:

- Improper or dangerous storage of potentially toxic substances
- Poor lighting resulting in errors in reading
- Human factors are
 - failure to read label properly;
 - failure to return poisons to their proper place;
 - failure to recognize the material as poisonous;
 - lack of supervision of a child.

S&S:

- Vary with poison
- Toxin may have a limited local effect or continue to a stage of absorption and interference with metabolic processes and organ function.
- Acute poisoning may result in arrhythmias or permanent multiorgan damage due to initial loss of airway, breathing, circulation, and specific organ toxicity.

Rx: Emergency management

- Establish and maintain airway, ventilation, and oxygenation. In the absence of cerebral or renal damage, prognosis depends largely on successful management of respiratory and circulatory systems.
- Blood gas analysis or spirometry is used to determine adequacy of ventilation.
- Assess pulse, blood pressure, central venous pressure, and temperature (core and peripheral).
- Mechanical ventilation if respirations are depressed. Positive expiratory pressure applied to the airway (bag mask) may help keep the alveoli inflated.
- Oxygen for respiratory depression, unconsciousness, cyanosis, and shock
- Prevent aspiration of gastric contents by positioning client on side with head down, using an oropharyngeal airway, and suctioning
- Stabilize cardiovascular function and monitor ECG
- Indwelling urinary catheter to monitor renal function
- Obtain blood specimen to test for concentration of drug or poison
- Monitor neurologic status (including cognitive function) and VS for change and direction of change over time
- Determine what product was taken, the amount, time since ingestion, symptoms, age and weight of the client, and pertinent health history.
- Contact poison control center in the area if an unknown toxic agent has been taken or if it is necessary to identify an antidote for a known toxic agent.
- Treatment of shock based on cause: cardiodepressant action of a drug ingested, venous pooling in lower extremities, or reduction in circulating blood volume as a result of increased capillary permeability.
- Remove the toxin or decrease its absorption by emptying the stomach
 - Syrup of ipecac to induce vomiting in the alert client (do not induce vomiting after ingestion of caustic substances or petroleum distillates)
 - Gastric lavage. Save gastric aspirate for toxicology screens.
 - Activated charcoal administration if poison is one that is absorbed by charcoal
 - Cathartic, when appropriate

Table 31–1 Acetaminophen, Salicylate, and Lead Poisoning

| Substance | Mechanism of Action | Treatment |
|--|---|--|
| Acetaminophen | Can cause fetal hepatonecrosis Toxic dose: 140 mg/kg | O ₂ , IV, monitor, emesis/lavage, charcoal, cathartic, <i>N</i> -acetylcysteine (oral dose: 140 mg/kg, then 70 mg/kg every 4 hours for 17 doses, dilute to 5% solution and add to juice) |
| Salicylate poisoning aspirin (present in compound analgesic tablets) | <p>Uncouples oxidative phosphorylation; inhibits Krebs cycle</p> <ul style="list-style-type: none"> • Restlessness, tinnitus, deafness, blurring of vision • Hyperpnea, hyperpyrexia, sweating • Epigastric pain, vomiting, dehydration • Respiratory and metabolic acidosis • Disorientation, coma, cardiovascular collapse <p>Phase I (first 24 hours after ingestion)</p> <ul style="list-style-type: none"> • May be asymptomatic • Anorexia • N&V • Diaphoresis • Malaise • Pallor <p>Phase II (24–48 hours after ingestion)</p> <ul style="list-style-type: none"> • Symptoms of phase I diminish or disappear • Right upper quadrant pain due to liver damage • Liver enlargement with elevated bilirubin and hepatic enzymes and prolonged prothrombin time • Oliguria <p>Phase III (days 3 to 5 after ingestion)</p> <ul style="list-style-type: none"> • Signs of hepatic failure such as jaundice, hypoglycemia, coagulopathy, encephalopathy • Peak liver function abnormalities • Anorexia, nausea, vomiting, malaise may reappear • Renal failure and cardiomyopathy may occur <p>Phase IV</p> <ul style="list-style-type: none"> • Associated with recovery or progression to completed liver failure and death <ul style="list-style-type: none"> —Pain, vomiting, dehydration —Respiratory and metabolic acidosis —Disorientation, coma, cardiovascular collapse | <p>O₂, IV, monitor, emesis/lavage, charcoal, cathartic, alkalinization of urine, replace potassium, dialysis</p> <ul style="list-style-type: none"> • Treat respiratory distress • Induce gastric emptying emesis or lavage • Give activated charcoal to absorb aspirin: a cathartic may be administered with charcoal to help assure intestine cleaning. <ul style="list-style-type: none"> • Support client with intravenous infusions as prescribed to establish hydration and correct electrolyte imbalances <ul style="list-style-type: none"> • Enhance elimination of salicylates as directed by forced diuresis, alkalinization of urine, peritoneal dialysis, or hemodialysis, according to severity of intoxication. • Monitor serum salicylate level for efficacy of treatment <ul style="list-style-type: none"> • Administer specific prescribed pharmacologic agent for bleeding and other adverse effects |
| Lead Poisoning | <ul style="list-style-type: none"> • Toxic to CNS, bone marrow, kidneys • Lead attaches to RBCs • Stores in bone and soft tissue • Twice as long to excrete than absorb • Kidneys injured | <ul style="list-style-type: none"> • Remove lead from environment • Remove child from environment during lead abatement process |

- Administer any specific chemical antagonist or physiologic antagonist as early as possible to reverse or diminish effects of the toxin
- Support the client having seizures: poisons may excite the CNS or the client may have seizures from oxygen deprivation.
- Procedures to promote the removal of the ingested substance if the above are not effective:
 - Diuresis for agents excreted by the renal route

—Dialysis

—Hemoperfusion (process of passing blood through an extracorporeal circuit and a cartridge containing an adsorbent [such as charcoal or resins], after which the detoxified blood is returned to the client).

—Multiple doses of charcoal

See Table 31-1 for specific information related to acetaminophen, salicylate, and lead poisoning.

Nursing Process Elements

- Monitor central venous pressure as indicated
- Monitor fluid and electrolyte imbalance
- Reduce elevated temperature
- Cautiously give analgesics as prescribed for pain; severe pain causes vasomotor collapse and reflex inhibition of normal physiologic functions
- Assist in obtaining specimens of blood, urine, stomach contents, and vomitus
- Provide constant nursing surveillance and attention to the client in a coma; coma from poisoning results from interference with brain cell function or metabolism
- Monitor and treat for complications such as hypotension, cardiac dysrhythmias, and seizures
- If the client is discharged, give written material indicating S&S of potential problems and procedures for call-back or return
- Request a psychiatric consultation if poisoning was a suicide attempt
- In cases of accidental poison ingestion, provide poison prevention and home poison-proofing instructions to the client or family

EYE INJURY

Etiology: Trauma to the eye may be caused by blunt or sharp injury, chemical, or thermal burns. The eyelids, protective layers, surrounding soft tissue, or the globe itself may be injured. Vision may be impaired by direct injury or latent scarring. See Table 31-2 for information on specific types of eye injuries and their treatment.

Nursing Process Elements

- Medicate for pain as directed
- Provide ice and cool compresses to relieve swelling and pain
- Provide additional comfort measures such as positioning, dimmed lights, and quiet environment
- Irrigate and patch eye as directed
- Monitor VS and neurological status as indicated
- Watch for and report signs of infection such as fever, drainage, increased pain, warmth, and redness

Client teaching for self-care

- Teach client how to administer medications such as topical antibiotics
- Instruct on use of patch or shield

- Advise client to report increase in pain, decrease in vision, redness, and fever
- Teach safety measures with decreased visual acuity
- Advise use of corrective lenses as prescribed
- Stress follow-up care
- Attempt to prevent future trauma with protective eyewear

WOUND DEHISCENCE AND EVISCERATION

Wound dehiscence—disruption of surgical incision or wound

Evisceration—protrusion of wound contents after dehiscence. These are serious surgical complications.

Etiology: Sutures give way as a result of increased stress related to marked distention or strenuous coughing, infection, or failure of the wound closure technique, e.g., broken sutures, slipped knot, or inadequate muscle bites.

Predisposing factors: Increasing age, poor nutritional status, weak or pendulous abdominal walls, and pulmonary or cardiovascular disease in clients undergoing abdominal surgery.

S&S:

- Gush of bloody peritoneal fluid from the wound
- Something gave way as reported by client
- Pain
- Vomiting
- Protrusion of intestines from an abdominal wound
- Warning signs of dehiscence related to infection: redness or swelling of, or around, incision line, excessive pain and tenderness on palpation, purulent, or odorous drainage

Dx: Clinical presentation.

Rx:

- Opiate for pain
- Sterile dressing to wound
- Fluid resuscitation
- Return to or for resuturing under general anesthesia

Nursing Intervention Alert

When disruption of a wound occurs, the client is placed in low Fowler's position and instructed to lie quietly. These actions minimize protrusion of body tissues. Protruding coils of intestine are covered with a sterile dressing moistened with sterile saline solution, and the surgeon is notified at once.

Table 31–2 Eye Trauma

| Condition | Signs and Symptoms | Treatment |
|---|--|---|
| Blunt Contusion—bruising of periorbital soft tissue | <ul style="list-style-type: none"> • Swelling and discoloration of the tissue • Bleeding into the tissue and structures of the eye • Pain • Increased intraocular pressure | <ul style="list-style-type: none"> • Treatment to reduce swelling • Pain management dependent on structures involved |
| Hyphema—presence of blood in the anterior chamber | <ul style="list-style-type: none"> • Pain • Blood in anterior chamber • Increased intraocular pressure | <ul style="list-style-type: none"> • Usually spontaneous recovery • If severe, bed rest or chair rest with bathroom privileges, eye shield, anterior chamber paracentesis, topical steroids, cycloplegics |
| Orbital fracture—fracture and dislocation of walls of the orbit, orbital margins, or both | <ul style="list-style-type: none"> • May be accompanied by other signs of head injury • Rhinorrhea • Contusion • Diplopia • Diagnosis: X-ray, computed tomography (CT) | <ul style="list-style-type: none"> • May heal on own if no displacement or infringement on other structures • Surgery (repair the orbital floor with plate freeing entrapped orbital tissue) |
| Foreign body—on cornea (25% all ocular injuries), conjunctiva Intraocular particles penetrate sclera, cornea, globe | <ul style="list-style-type: none"> • Severe pain • Lacrimation • Foreign body sensation • Photophobia • Redness • Swelling | <ul style="list-style-type: none"> • Medical emergency • Removal of foreign body through irrigation, cotton-tipped applicator, or magnet • Treatment of intraocular foreign body depends on size, magnetic properties, tissue reaction, location • Surgical removal |
| Laceration/Perforation cutting or penetration of soft tissue of globe | <ul style="list-style-type: none"> • Pain • Bleeding • Lacrimation • Photophobia | <ul style="list-style-type: none"> • Medical emergency • Surgical repair—method depends on severity of injury • Antibiotics—topically and systemically |
| Ruptured globe concussive injury to globe with tears in the ocular coats, usually the sclera | <ul style="list-style-type: none"> • Pain • Altered intraocular pressure • Limitation of gaze in field of rupture • Hyphema • Hemorrhage • Diagnosis: CT, ultrasound | <ul style="list-style-type: none"> • Medical emergency • Surgical repair • Vitrectomy • Scleral buckle • Antibiotics • Steroids • Enucleation |
| Burns Chemical—caused by alkali or acid agent | <ul style="list-style-type: none"> • Pain • Burning • Lacrimation • Photophobia | <ul style="list-style-type: none"> • Medical emergency • Copious irrigation until pH 7.0 • Severe scarring may require keratoplasty • Antibiotics |
| Thermal—usually burn to eyelids may be first, second, or third degree | <ul style="list-style-type: none"> • Pain • Burned skin • Blisters | <ul style="list-style-type: none"> • First aid—apply sterile dressings • Pain control • Fluid blebs left intact • Eyelids sutured together to protect eye if perforation a possibility • Skin grafting with severe second-, and third-degree burns |
| Ultraviolet—excessive exposure to sunlight, sunlamp, snow blindness, welding | <ul style="list-style-type: none"> • Pain—delayed several hours after exposure • Foreign body sensation • Lacrimation • Photophobia | <ul style="list-style-type: none"> • Pain relief • Condition self-limiting • Bilateral patching with antibiotic ointment and cycloplegics |

BURNS

Etiology:

- Burns are caused by a transfer of energy from a heat source to the body.
- Types of burns:
 - Thermal
 - Dry heat—flame, flash
 - Contact—tar, metals, grease
 - Moist heat—steam, scald
 - Chemical
 - Acids
 - Alkalis
 - Inhalation
 - Smoke
 - Hot air
 - Chemicals
 - Electrical
 - Lightning
 - Electric current
 - Radiation
 - Sunburn
 - Radiation therapy
 - Accidental exposure

Risk factors/groups: Children particularly boys; disabled; older adults with impaired mobility, coordination, judgment; substance abusers, smokers.

S&S:

- Tissue destruction results from coagulation, protein denaturation, or ionization of cellular contents.
- Amount of tissue damage is determined by type, temperature, and amount of causative agent such as flame or scalding liquid, duration of contact, and thickness of the skin.
- Classification of burns:
 - First-, second-, or third-degree based on depth of the injury. See Table 31-3.
 - Severity of burn injury: minor, moderate uncomplicated, or major burn injuries (classified according to the American Burn Association criteria). See Table 31-4.
 - Thermal, chemical, radiation burns.
- Localized effects:
 - Area of coagulation surrounded by an area of damaged blood vessels and decreased perfusion surrounded by an area of hyperemia
 - Area of damaged blood vessels is at great risk for necrosis in days following injury
- Systemic effects of major burns—“burn shock”
- Hypovolemia—result of fluid lost from wound and release of vasoactive substances, which cause a massive fluid shift from the intravascular to interstitial space.
- Edema: peaks in 12–24 hours after injury and resolves by 72 hours.
- Results from fluid shift in response to release of vasoactive mediators as above

Table 31–3 Depth of Burn Injury

| Depth of Burn and Causes | Skin Involvement | Symptoms | Wound Appearance | Recuperative Course |
|--|--|---|---|---|
| First degree Superficial Partial-thickness Sunburn Low-intensity flash | Epidermis; possibly a portion of the dermis | Tingling Hyperesthesia (supersensitivity) Pain soothed by cooling | Reddened; blanches with pressure; dry Minimal or no edema Possible blisters | Complete recovery within a week; no scarring. Peeling. |
| Second degree Deep partial-thickness Scalds Flash flames | Epidermis, upper dermis, portion of deeper dermis | Pain Hyperesthesia Sensitive to cold air | Pale, mottled, pearly white, mostly dry, often insensate; difficult to differentiate from full-thickness injury | Recovery in 2–4 weeks. Some scarring and depigmentation contractures. Infection may convert it to full thickness. |
| Third degree Full-thickness Flame Prolonged exposure to hot liquids Electric current Chemical | Epidermis, entire dermis, and sometimes subcutaneous tissue; may involve connective tissue, muscle, and bone | Pain free Shock Hematuria (blood in the urine) and possibly hemolysis (blood cell destruction) Possible entrance and exit wounds (electrical burn) | Dry, pale white, leathery, or charred broken skin with fat exposed Edema | Eschar sloughs Grafting necessary Scarring and loss of contour and function; contractures Loss of digits or extremity possible |

Table 31–4 Classification of Burns According to the American Burn Association

| Minor Burn | Moderate Uncomplicated Burn | Major Burn |
|--|---|---|
| <ul style="list-style-type: none"> • Second-degree burns of <15% TBSA in adults or <10% TBSA in children | <ul style="list-style-type: none"> • Second-degree burns of 15–25% TBSA in adults or 10–20% TBSA in children | <ul style="list-style-type: none"> • Second-degree burns of >25% TBSA in adults or >20% TBSA in children |
| <ul style="list-style-type: none"> • Third-degree burns of <2% TBSA not involving special care areas (eyes, ears, face, hands, feet, perineum) | <ul style="list-style-type: none"> • Third-degree burns of <10% TBSA not involving special care areas | <ul style="list-style-type: none"> • All third-degree burns of 10% TBSA or greater |

TBSA, total body surface area

- Other systemic effects—hypermetabolism, myocardial depression, damage to the renal tubules, pulmonary hypertension, pulmonary edema, suppression of cellular immunity, catabolism of fat and muscle, clotting abnormalities, anemia from early destruction of RBCs, decreased hepatic, and intestinal perfusion
- Decreased cardiac output secondary to vasoconstriction
- Inhalation burns—soot around the mouth, singed eye lashes, brows, nasal hair; respiratory distress
- Electrical burns—cardiac and respiratory arrest due to disruption of electrical conduction throughout body

Rx: Emergent Phase

- First priority: Stop the burning process.
 - For dry powder burns, brush the powder off first.
 - For scald, rinse affected area with a large amount of clean water. Never use cold water on extensive burns because of the potential effect on body temperature.
 - For flash or flame burns, use water or wrap client in a blanket, coat, or other material; then roll on the ground to smother flames; move client to a safe area; cool burn with water; remove clothing and jewelry that is not adherent to the body.
 - For chemical burns, irrigate with large amounts of water or saline (water for eyes).

Nursing Intervention Alert

Use litmus paper to test water that has been used to irrigate an eye for acidity or alkalinity; if the injurious chemical has been completely washed out, the pH will be neutral.

- Assess airway, breathing, and circulation. If the client was involved in a fire, assume inhalation injury until proven otherwise, and manage accordingly. Oxygen, suctioning, postural drainage, or endotracheal intubation may be needed.

Assessment Alert

Carbon monoxide is probably the most common cause of inhalation injury because it is a by-product of the combustion of organic materials and is therefore present in smoke. Carbon monoxide combines with hemoglobin to form carboxyhemoglobin, which competes with oxygen for available hemoglobin binding sites. The affinity of hemoglobin for carbon monoxide is 200 times greater than for oxygen.

- Perform a quick assessment of neurological status; check for spinal cord injury.
- Remove jewelry and clothing not stuck to burned areas.
- Cover wounds loosely with sterile (if available) or clean dressings dampened with normal saline or water to ease pain and prevent evaporation of body fluids.
- If hands or feet are burned, separate fingers or toes with sterile gauze pads moistened with sterile water. Keep hand in a position of function.
- Do not open eyelids if they are burned; apply moist gauze pads to both eyes. Be certain burn is thermal and not chemical.
- Do not open blisters.
- Do not apply any salves or ointments.
- Wrap entire body in something dry to prevent heat loss.
- Begin volume resuscitation with large bore needle (16–18 gauge) and lactated Ringer's solution or normal saline. If burn is large, keep client NPO to avoid the risk of vomiting and aspiration.
 - Fluid requirement for 24 hours is based on a formula such as the Parkland or the Brooke; both use isotonic or hypertonic IV solutions and calculate amount to be infused for 24 hours with one-half infused in the first 8 hours and one-fourth infused in each of the next 8-hour blocks.

—Using the Parkland formula, the amount of lactated Ringer’s solution (volume expander) to deliver in the first 24 hours after time of injury is calculated as follows:

Clinical Alert

Fluid requirements are calculated from the time the burn injury occurred, not from the time fluid resuscitation is being started.

$$\text{Fluid} \times 4 \text{ cc} \times \% \text{TBSA} \times \text{weight in kg}$$

%TBSA excludes any first-degree burn

Example: 70-kg client with 50% second-degree burn
 $4 \text{ ml} \times 70 \text{ kg} \times 50\% = 14,000 \text{ ml of IV fluid/24 hr.}$
 7000 ml of IV fluid/8 hr

Clinical Alert

The formula is a guide only and infusions must be tailored to urinary output and central venous pressure; if not adjusted to the individual client, under- or over-hydration can result.

Half of this fluid is given in the first 8 hours post injury and the rest in the subsequent 16 hours.

TBSA in the formula is the percentage of body surface area affected by partial thickness or full-thickness burns (superficial thickness burns are not counted). TBSA can be estimated quickly by using the rule of nines (see Table 3-5)

—For smaller or irregular burns, size is estimated by using the surface of the client’s hand as about 1% of the TBSA.

- Tetanus toxoid given when immunization status is in doubt.
- Acute phase: focus is treatment of burn wound and prevention of complications
- Medications: analgesics (morphine sulfate, fentanyl, codeine), ranitidine, sucralfate, or other agent to prevent

Table 31–5 Rule of Nines

| | |
|--------------------|-----|
| Head | 9% |
| Anterior torso | 18% |
| Posterior | 18% |
| Each leg | 18% |
| Each arm | 9% |
| Genitalia/Perineum | 1% |

stress ulcers, topical antimicrobial (silver sulfadiazine or mafenide acetate for deep burns; bacitracin or the like for superficial burns) to prevent infection of the burn wound

- Wound care: hydrotherapy to cleanse wound; debridement (surgical or enzymatic) and dressing (closed method) or no dressing (open method)
- Skin grafts
 - Used for full-thickness burns
 - Types of grafts are as follows:
 - autografts: from client’s own body
 - allograft: from a live or deceased donor; may be fresh or frozen
 - heterograft: from another species
 - synthetic substitutes
 - biosynthetic dressings
 - Autografts are permanent; all others temporary and are rejected with healing but reduce water, protein and electrolyte loss; decrease pain; and allow mobility.
 - Split thickness grafts: epidermis and part of dermis; allows regeneration of skin at donor site
 - Full-thickness grafts: better cosmetic result so used for face, hands, and neck
- Nutrition: metabolism after a burn injury can be two to three times normal so burn clients are in catabolic state until caloric intake exceeds metabolic demand.
 - Baseline nutritional assessment with anthropometric measurements followed by urea nitrogen and prealbumin measures two to three times weekly
 - Protein requirements increased from 0.8 gm/kg to 1.5–3.0 gm/kg body weight to replace nitrogen lost through wound and urine and to allow healing
 - Caloric need can range from 3500–5000 cal/d and is given as 20% protein, 50% carbohydrate, and 30% fat.
 - Most burn clients require enteral feedings and they are begun as early as possible after burn.

Nursing Process Elements

- Assess severity of injury
 - Depth of burn
 - Extent of burn
 - Age of the client
 - Pulmonary injury
 - Associated trauma
 - Special considerations – electrical, chemical
 - Preexisting illness
- Assess VS frequently
- Assess clients with inhalation burns or burns of the face or neck for signs of laryngeal edema and airway obstruction: severe, brassy cough; stridor, hoarseness, anxiety, confusion, coma and give 100% oxygen by mask

- Protect from hypothermia: keep covered to prevent heat loss from exposure to air; keep room warm; avoid drafts; use warming devices such as heat lamps or warming blankets
- Assess for adequate fluid resuscitation: urinary output of 30–50 ml/hr or 1–2 ml/kg of body weight/hr in children; normal LOC; systolic BP >100 mm Hg with pulse of <100 bpm; pH of 7.35–7.45 and base excess of 6 or greater

Clinical Alert

Urinary output is used as a guide to fluid resuscitation until edema begins to resolve in 48–72 hours, then serum and urinary electrolyte levels are used to guide fluid administration.

- Maintain cardiac monitoring of clients with electrical burns for 2 hours after dysrhythmias cease
- Maintain indwelling catheter drainage to obtain hourly output, which is used to guide fluid resuscitation
- Monitor urinary output and color or urine

Assessment Alert

Burgundy-colored urine suggests the presence of hemochromogen and myoglobin resulting from muscle damage.

- Weigh daily: gain occurs because of fluid retention; loss occurs as fluid is lost.
- Monitor for glucosuria
- Maintain nasogastric suction if client is nauseated and in absence of peristalsis
- Protect from infection: cleanse dirt from wound; use protective precautions; hair shaved or clipped around area of burn; culture wound after cleaning for baseline and then once or twice per week; encourage as much mobility as possible and deep breathing to prevent pneumonia
- Assess for impaired peripheral tissue perfusion: decreased or absent distal pulses, pallor, coldness, paresthesias, lack of feeling, slow capillary refill. Impaired perfusion can result from edema occurring under areas of eschar because eschar is inelastic
- Assess for respiratory distress resulting from constriction of chest wall by eschar in clients with chest burns
- Control pain: skin anesthetics for first-degree burns, gentle handling, keeping wounds covered to prevent contact with air, and administration of opioids such as morphine sulfate IV in small doses every 5–10 minutes for 24–48 hours

Nursing Intervention Alert

Subcutaneous and intramuscular pain medications are avoided for burn clients because of problems related to absorption from the administration site due to edema and vasoconstriction.

- Administer tetanus toxoid if there is any question about the client's immunization status
- Monitor wound and donor site if applicable, for signs of infection

Assessment Alert

Sepsis can occur with serious even deadly consequences. Signs of sepsis are change in mental status, fever, tachypnea, tachycardia, paralytic ileus, abdominal distention, and oliguria.

- Provide wound care:
 - Medicate for pain and time wound care when medication is most effective
 - Provide hydrotherapy (tub immersion, spray table, or shower) to remove topical medications and wound debris:
 - tub immersion: not more than 30 minutes to prevent excess heat loss; promotes range of motion
- Provide graft care:
 - Prevent movement of the graft: maintain immobilizing devices such as bulky dressings or splints for 48–72 hours
 - Remove graft dressings slowly and gently so as not to disturb graft
 - Check full thickness and graft sheets every 24 hours for areas of fluid collection beneath them: collected fluid can be removed by rolling with a q-tip or by making slits in the graft
- Maintain nutrition
- Coordinate with physical and occupational therapists
- Maintain range of motion
- Promote coping
- Support hope
- Provide information for realistic planning for future
- Support client's and family's coping style
- Recognize that anxiety, irritability, sleep, and body image disturbances are common emotional reactions

**Client teaching for self-care**

- Report: opening of a healed area, blister formation, signs of infection (fever $>100.4^{\circ}\text{F}$, increased or foul drainage, redness, pain, swelling, hardness or warmth of an area), problems with pressure garment or elastic bandages used to prevent thick, rigid scarring, which is disfiguring and leads to contractures
- Healed burned areas may be hypersensitive to fabric softeners, dyes, detergents: wash new clothing before wearing, use mild soap and no fabric softeners, rinse twice; wash clothes separately if open wound areas exist

PULMONARY EMBOLISM

- Pulmonary embolism is an obstruction of the pulmonary arterial bed. The embolus travels from the venous circulation to the right side of the heart and to the pulmonary artery. Obstruction of blood flow leads to pulmonary hypertension and infarction.
- Can manifest itself as one large clot, several tiny clots, or a shower of clots in the lungs.

Etiology:

- Nondissolved substance such as air, fat, or thrombus in the pulmonary vessels.
 - Most often: dislodged thrombus from leg veins
 - Thrombi may also originate in the pelvic vein, hepatic vein, right side of the heart, or arm vein.

Precipitating/risk factors:

- DVT following orthopedic or abdominal surgery, use of oral contraceptives, pregnancy, prolonged immobility, any conditions characterized by venous stasis, hypercoagulability, and vein wall damage (Virchow's triad)
- Trauma especially with long bone fracture
- Clot dissolution
- Sudden muscle spasm
- Intravascular pressure changes
- IV therapy

S&S:

Symptoms vary depending on the size and location of the emboli.

- Sudden onset of dyspnea, tachypnea, localized, sharp pleuritic chest pain, apprehension, cyanosis, and crackles
- Restlessness
- Cough and hemoptysis
- Splinting of the chest
- Tachycardia
- If DVT is present there will be calf swelling, warmth at site, mild fever

- Signs of shock such as hypotension and cardiac arrhythmia

Dx:

- Chest X-ray shows wedge-shaped infiltrate.
- Lung scan shows V/Q mismatch perfusion defects in areas beyond occluded vessels.
- Pulmonary angiography is the most definitive test (check for dye allergy).
- ECG helps rule out MI versus pulmonary emboli.
- ABGs show alkalosis and hypoxemia.

Rx:

- Oxygen therapy
- Drug therapy: for acute episode IV heparin and thrombolytic agents (urokinase, streptokinase) to inhibit coagulation and prevent further clots; proactive treatment of clients at risk for DVT with low dose SQ heparin and then oral anticoagulants
- If heparin contraindicated may insert inferior vena cava filter, very rarely pulmonary embolectomy
- Pain medication such as morphine (monitor respiratory status before administering)

**Assessment Alert**

PE is difficult to diagnosis therefore the nurse needs to monitor any client at risk for S&S.

**Nursing Intervention Alert**

Primary nursing goals are to maintain adequate cardiovascular and pulmonary function as the obstruction resolves and to prevent reoccurrence. Most emboli resolve in about 10 days, therefore care should be given to dissolve the existing emboli and to prevent further formation.

**Nursing Process Elements**

- Monitor cardiopulmonary status
- Monitor ABGs
- Maintain bed rest in acute stage
- Administer oxygen via nasal cannula
- Place client in high Fowlers position
- Monitor V/S, LOC, and respiratory status
- Auscultate heart and lung sounds

- Controlled breathing technique
- Prepare for endotracheal intubation if need arises
- Administer pain medication as needed
- Monitor coagulation lab results, adjust therapy, give prn medication
- Monitor CVP
- Once client is stable, encourage frequent movement and assist with isometric and ROM exercise
- Reduce anxiety
- No massaging of legs
- Maintain hydration
- Apply elastic stockings (antiembolic) and pneumatic compression devices

Client teaching for self-care

- Deep breathing and coughing exercises using incentive spirometry
- Avoid crossing legs because this can impede circulation and promote thrombus formation
- Anticoagulant therapy regimen if prescribed long-term
- Precautions related to bleeding as a side effect of anticoagulant therapy
- Advise the client to stay away from OTC medication or check with his/her physician before taking OTC medications
- Importance of follow-up care and lab test monitoring for anticoagulant therapy

WORKSHEET

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|-------|-------|
| 1. PEEP is used for clients with ARDS to keep alveoli distended, stretch stiff lungs, and increase oxygen-carbon dioxide diffusion. | _____ | _____ |
| | T | F |
| 2. The burned client needs 2 or 4 ml of lactated Ringer's solution/normal saline per kg of body weight per percent of body surface burn in the first 24 hours to maintain blood volume and urinary output. | _____ | _____ |
| | T | F |
| 3. When the rule of nines is used to calculate area of a burn, all body areas that have been burned are calculated into the formula. | _____ | _____ |
| | T | F |
| 4. When performing the Heimlich maneuver, the thumb side of fist is placed against the person's abdomen above the navel and below the xiphoid process. | _____ | _____ |
| | T | F |
| 5. The fluid that lubricates the pleural space is intracellular fluid. | _____ | _____ |
| | T | F |
| 6. An electrolyte imbalance associated with decreased aldosterone is hyponatremia. | _____ | _____ |
| | T | F |
| 7. Administration of hypotonic IV solutions would be an expected part of therapy for a client with hypernatremia. | _____ | _____ |
| | T | F |
| 8. The most common cause of septic shock is infection with gram-positive bacteria. | _____ | _____ |
| | T | F |
| 9. Heparin is used prophylactically in the management of DIC because it blocks the coagulation cascade at the common pathway and ultimately prevents conversion of fibrinogen to fibrin. | _____ | _____ |
| | T | F |
| 10. The first priority of the emergent phase of burn care is checking the airway. | _____ | _____ |
| | T | F |

MATCHING QUESTIONS

Match the value in column B that is realistically consistent with the abnormality named in column A:

Column A

Column B

- | | |
|-------------------------|---------------|
| 1. ____ Hyponatremia | a. 1.2 mEq/l |
| 2. ____ Hypokalemia | b. 2.2 mEq/l |
| 3. ____ Hypomagnesemia | c. 3.2 mEq/l |
| 4. ____ Hypochloremia | d. 3.4 mEq/l |
| 5. ____ Hypocalcemia | e. 4.1 mEq/l |
| 6. ____ Hyponatremia | f. 5.4 mEq/l |
| 7. ____ Hyperkalemia | g. 8.2 mEq/l |
| 8. ____ Hypermagnesemia | h. 9.7 mEq/l |
| 9. ____ Hyperchloremia | i. 10.2 mEq/l |
| 10. ____ Hypercalcemia | j. 87 mEq/l |
| | k. 102 mEq/l |
| | l. 114 mEq/l |
| | m. 126 mEq/l |
| | n. 142 mEq/l |
| | o. 160 mEq/l |

MATCHING QUESTIONS

Match the following:

Column A

Column B

- | | |
|----------------------------|--------------------------|
| 1. ____ sedative overdose | a. Respiratory acidosis |
| 2. ____ hyperventilation | b. Metabolic acidosis |
| 3. ____ diabetes mellitus | c. Respiratory alkalosis |
| 4. ____ gastric suctioning | d. Metabolic alkalosis |
| 5. ____ renal failure | |

6. ____ pain
7. ____ vomiting
8. ____ emphysema
9. ____ flail chest
10. ____ diarrhea

MATCHING QUESTIONS

Match the following:

Column A

1. ____ sweet(acetone) odor to breath
2. ____ decreased rate and depth of respirations
3. ____ tetany
4. ____ light-headedness
5. ____ warm, flushed skin
6. ____ increased respiratory rate and depth
7. ____ headache
8. ____ lethargy
9. ____ tingling in the extremities
10. ____ hyporeflexia

Column B

- a. Respiratory acidosis
- b. Metabolic acidosis
- c. Respiratory alkalosis
- d. Metabolic alkalosis

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The two general types of fluid imbalance are _____ and _____.
2. Cardiac tamponade is best diagnosed based on the results of a(n) _____.
3. PaO₂ below 60 mm Hg despite administration of oxygen at 10 l per minute would be expected in a client with _____.
4. Venous stasis, hypercoagulability, and venous endothelial disease are risk factors for _____.
5. When doing a gastric lavage on a client with an accidental poisoning, the gastric aspirate is saved to allow for a _____.

(continued)

6. The substance that plays the greatest role in holding fluid in the intravascular space is _____.
7. _____ is the predominant cation in the extracellular space.
8. A urine volume of <30 ml/hr and a urine specific gravity of >1.030 are suggestive of isotonic fluid volume _____.
9. Kayexalate is used in the treatment of _____.
10. Morphine is used in the treatment of cardiogenic shock for its effect in reducing _____.

APPLICATION QUESTIONS

1. Which is the most reliable indicator of cardiac arrest?
 - a. Loss of consciousness
 - b. Apnea of 4-minutes duration
 - c. Inaudible blood pressure
 - d. Absence of a palpable carotid pulse
2. Which intervention would be expected in the plan of care for a client with hypercalcemia?
 - a. Fluid restriction
 - b. Low-phosphate diet
 - c. Lasix injection
 - d. IV calcium gluconate
3. When teaching a client with hypokalemia secondary to decreased intake, which foods would be included in the dietary recommendations?
 - a. Cashews and walnuts
 - b. Spinach and broccoli
 - c. Bananas and apricots
 - d. Milk and yogurt
4. A client with which S&S is a candidate for artificial respiration?
 - a. No heartbeat or measurable respiration
 - b. Barely discernible respirations and a weak carotid pulse
 - c. Absence of spontaneous ventilation and tachycardia
 - d. Shallow gasping and apical heart rate of 48
5. In which situation would the nurse check Chvostek and Trousseau signs?
 - a. Client complains of calf pain
 - b. Client complains of headache and photophobia
 - c. Client complains of weakness and dysphagia
 - d. Client complains of tingling in the feet
6. Which type of treatment would be appropriate for a client with a serum potassium level of 3.3 mEq/l?
 - a. Kayexalate
 - b. IV sodium bicarbonate
 - c. KCl
 - d. Dialysis
7. A client has a temperature of 99.4 °F and a urine specific gravity of 1.035. Further assessment discloses poor skin turgor and flat neck veins. Which problem should the nurse suspect?
 - a. Isotonic fluid volume deficit
 - b. Hypo-osmolar overhydration
 - c. Hyponatremia
 - d. Hypokalemia
8. A client's laboratory reports show a serum potassium of 3.2 mEq/l. For which symptoms would the nurse assess the client?
 - a. Hyperactive DTRs
 - b. Flaccid paralysis
 - c. Cardiac dysrhythmia
 - d. Paresthesias in the extremities
9. A client presents expectorating pink-tinged, frothy respiratory secretions. The nurse would immediately gather additional assessment data related to the possibility of which disorder?
 - a. Cardiac tamponade
 - b. Pulmonary tuberculosis
 - c. Pulmonary edema
 - d. Bacterial pneumonia
10. Asking a client about amount and frequency of Alka-Seltzer use would be included in the assessment of a client with which problem?
 - a. Hypermagnesemia
 - b. Hypernatremia

- c. Hypovolemia
d. Hypophosphatemia
11. It is calculated that a burn client needs 1800 ml of fluid in the first 24 hours in order to maintain blood volume and urinary output. How many ml would the nurse plan to infuse in the first 8 hours based on the Parkland formula?
a. 450
b. 600
c. 900
d. 1200
12. What does right upper quadrant pain that develops 48 hours after an overdose of aspirin indicate?
a. Diaphragmatic irritation
b. Lower esophageal ulceration
c. Biliary colic
d. Liver damage
13. When speaking to a group of junior high school students about first aid, the nurse explains there is a universal sign indicating choking and asks if any of the students knows what it is. Which student's response is correct?
a. Mouth open, index finger pointing in
b. Hand on neck over throat area
c. Hands crossed at the neck
d. Mouth open, index fingers pointing at each side of neck.
14. A client, 36 hours after an intestinal resection moves into a sitting position in bed and immediately tells the nurse "Something just 'gave way' under my dressing." On examination, the nurse discovers that the incision has dehisced and a loop of intestine is protruding. Which is the first action the nurse should take?
a. Notify the surgeon
b. Cover the protruding intestine with a sterile dressing wet with normal saline.
c. Assist the client to low Fowler's position.
d. Obtain a wound culture
15. How should the finding of mahogany-colored urine in a burned client be interpreted?
a. Muscle damage has occurred
b. Kidney failure is developing
c. Hemoglobin is being released from the spleen
d. Bladder mucosa has ulcerated
16. A client is admitted with a serum sodium of 128 mEq/l. Which order would the nurse question if it was written on the order sheet for this client?
a. High-protein, low-sodium diet.
b. Restrict fluids to 1500 ml/d
c. IV infusion of 5% NaCl
d. Daily electrolytes
17. Which S&S occurring in a client with burns are indicative of developing sepsis? Mark all that apply.
a. ___ Change in mental status
b. ___ Fever
c. ___ Tachypnea
d. ___ Bradycardia
e. ___ Hepatomegaly
f. ___ Abdominal distention
g. ___ Oliguria
18. Which is a priority goal of nursing care for a client with a burn during the first 48–72 hours after skin grafting?
a. Maintain range of motion
b. Ensure adequate caloric intake
c. Prevent displacement of the graft
d. Suppress an immune reaction
19. What is used as a guide to fluid resuscitation in a client with burns after the edema has resolved?
a. hourly urinary output
b. serum albumin and prealbumin
c. daily weight
d. serum and urinary electrolytes
20. Which client is at risk for metabolic acidosis?
a. A 17-year old with cystic fibrosis
b. A 35-year old pregnant woman
c. A 48-year old with hypoparathyroidism
d. A 65-year old with an ileostomy
21. A client with COPD complains of headache and a "racing" heart; he is also restless and somewhat confused. Which problem would the nurse suspect?
a. Respiratory acidosis
b. Respiratory alkalosis
c. Metabolic acidosis
d. Metabolic alkalosis
22. A 61-year-old client with a history of chronic renal failure is admitted with a possible appendicitis. Based on this history, which acid–base imbalance is most likely to be found when laboratory test results are assessed?
a. Respiratory acidosis
b. Respiratory alkalosis
c. Metabolic acidosis
d. Metabolic alkalosis
23. The plan of care for which client would involve monitoring for respiratory acidosis?
a. A 24-year old with Guillain-Barre syndrome
b. A 37-year old with pancreatic drainage

(continued)

- c. A 50-year old who required a massive blood transfusion following a motor vehicle accident
 d. A 70-year old with chronic congestive heart failure
24. Which intervention would the nurse expect to be ordered for a client with dehydration?
 a. Isotonic IV fluid infusion
 b. Hypotonic IV fluid infusion
 c. Sodium restriction
 d. Diuretic therapy
25. When evaluating fluid resuscitation for a 12-year-old child with a burn injury, which outcome would be one indicator that the client was receiving adequate fluid?
 a. Urinary output of 3–5 ml/kg of body weight/hr
 b. Normal mentation
 c. pH of 7.25–7.35 and base excess of 8 or greater
 d. Respiratory rate of 14–20

ANSWERS & RATIONALES

TRUE AND FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- PEEP is used for clients with ARDS to keep alveoli distended, stretch stiff lungs, and increase oxygen-carbon dioxide diffusion. *True*
- The burn client needs 2 or 4 ml of lactated Ringer's solution/normal saline per kg of body weight per percent of body surface burn in the first 24 hours to maintain blood volume and urinary output. *True*
- When the rule of nines is used to calculate area of a burn, all body areas, which have been burned, are calculated into the formula. *False*
Only body surface areas that have partial or full-thickness burns are included; those with superficial thickness burns are not counted.
- When performing the Heimlich maneuver, the thumb side of fist is placed against the person's abdomen above the navel and below the xiphoid process. *True*
- The fluid that lubricates the pleural space is intracellular fluid. *False*
It is transcellular fluid that is part of the extracellular fluid. Other examples of transcellular fluid are synovial, cerebrospinal, intraocular, pericardial, pancreatic, biliary, and peritoneal fluid.
- An electrolyte imbalance associated with decreased aldosterone is hyponatremia. *True*
- Administration of hypotonic IV solutions would be an expected part of therapy for a client with hypernatremia. *True*
- The most common cause of septic shock is infection with gram-positive bacteria. *False*
The most common cause of septic shock is infection with gram-negative bacteria although it can be due to gram-positive as well as to viral, fungal, or parasitic infection.
- Heparin is used prophylactically in the management of DIC because it blocks the coagulation cascade at the common pathway and ultimately prevents conversion of fibrinogen to fibrin. *True*
- The first priority of the emergent phase of burn care is checking the airway. *False*
The first priority is to stop the burning; the next concern is airway followed by breathing and circulation.

MATCHING ANSWERS

Match the value in column B that is realistically consistent with the abnormality named in column A:

Column A

Column B

- | | |
|-----------------------------|---------------|
| 1. <u>m</u> Hyponatremia | a. 1.2 mEq/l |
| 2. <u>d</u> Hypokalemia | b. 2.2 mEq/l |
| 3. <u>a</u> Hypomagnesemia | c. 3.2 mEq/l |
| 4. <u>j</u> Hypochloremia | d. 3.4 mEq/l |
| 5. <u>g</u> Hypocalcemia | e. 4.1 mEq/l |
| 6. <u>o</u> Hypernatremia | f. 5.4 mEq/l |
| 7. <u>f</u> Hyperkalemia | g. 8.2 mEq/l |
| 8. <u>c</u> Hypermagnesemia | h. 9.7 mEq/l |
| 9. <u>l</u> Hyperchloremia | i. 10.2 mEq/l |
| 10. <u>i</u> Hypercalcemia | j. 87 mEq/l |
| | k. 102 mEq/l |
| | l. 114 mEq/l |
| | m. 126 mEq/l |
| | n. 142 mEq/l |
| | o. 160 mEq/l |

MATCHING ANSWERS

Match the following:

Column A

Column B

- | | |
|-------------------------------|--------------------------|
| 1. <u>a</u> sedative overdose | a. Respiratory acidosis |
| 2. <u>c</u> hyperventilation | b. Metabolic acidosis |
| 3. <u>b</u> diabetes mellitus | c. Respiratory alkalosis |

(continued)

4. d gastric suctioning d. Metabolic alkalosis
5. b renal failure
6. c pain
7. d vomiting
8. a emphysema
9. a flail chest
10. b diarrhea

MATCHING ANSWERS

Match the following:

Column A

Column B

- | | |
|--|--------------------------|
| 2. <u> b </u> sweet(acetone) odor to breath | a. Respiratory acidosis |
| 2. <u> d </u> decreased rate and depth of respirations | b. Metabolic acidosis |
| 3. <u> c,d </u> tetany | c. Respiratory alkalosis |
| 4. <u> c </u> light-headedness | d. Metabolic alkalosis |
| 5. <u> b </u> warm, flushed skin | |
| 6. <u> b,c </u> increased respiratory rate and depth | |
| 7. <u> a </u> headache | |
| 8. <u> e,f </u> lethargy | |
| 9. <u> g </u> tingling in the extremities | |
| 10. <u> h </u> hyporeflexia | |

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The two general types of fluid imbalance are isotonic and osmolar.
2. Cardiac tamponade is best diagnosed based on the results of a(n) echocardiogram.

3. PaO₂ below 60 mm Hg despite administration of oxygen at 10 l per minute would be expected in a client with acute respiratory distress syndrome.
4. Venous stasis, hypercoagulability, and venous endothelial disease are risk factors for pulmonary embolism.
5. When doing a gastric lavage on a client with an accidental poisoning, the gastric aspirate is saved to allow for a toxicity screen.
6. The substance that plays the greatest role in holding fluid in the intravascular space is albumin.
7. Potassium is the predominant cation in the extracellular space.
8. A urine volume of <30 ml/hr and a urine specific gravity of >1.030 are suggestive of isotonic fluid volume excess.
9. KayExalate is used in the treatment of Hyperkalemia.
10. Morphine is used in the treatment of cardiogenic shock for its effect in reducing pre-load.

APPLICATION ANSWERS

1. Which is the most reliable indicator of cardiac arrest?
 - a. Loss of consciousness
 - b. Apnea of 4-minutes duration
 - c. Inaudible blood pressure
 - d. Absence of a palpable carotid pulse

Rationale

Correct answer: d.

Absence of a carotid pulse is a good indicator of cardiac arrest because it is the closest palpable artery to the heart so even a very weak pump can be felt. Loss of consciousness occurs for a variety of reasons—one of the most basic being lack of oxygen to the brain. Lack of oxygen to the brain does result from cardiac arrest but it also occurs from other factors including orthostatic hypotension and blockage or disruption of blood flow through the cerebral arteries. Apnea is not necessarily indicative of cardiac arrest. Cardiac arrest results in apnea or cessation of breathing and apnea, which causes a lack of oxygen, ultimately causes cardiac arrest. Inability to hear blood pressure is not a reliable indicator of cardiac arrest because when the heart pumps very weakly, blood pressure can become inaudible (may still be palpable).

2. Which intervention would be expected in the plan of care for a client with hypercalcemia?
 - a. Fluid restriction
 - b. Low-phosphate diet
 - c. Lasix injection
 - d. IV calcium gluconate

Rationale

Correct answer: c.

Lasix is a diuretic that increases calcium excretion. Fluid restriction is inappropriate. Low-phosphate diet is used for hypophosphatemia. IV calcium gluconate is given for the emergency management of hypocalcemia.

3. When teaching a client with hypokalemia secondary to decreased intake, which foods would be included in the dietary recommendations?
 - a. Cashews and walnuts
 - b. Spinach and broccoli
 - c. Bananas and apricots
 - d. Milk and yogurt

Rationale

Correct answer: c.

Bananas and apricots are good sources of potassium and therefore are recommended for clients who need to increase intake of potassium.

4. A client with which S&S is a candidate for artificial respiration?
 - a. No heartbeat or measurable respiration
 - b. Barely discernible respirations and a weak carotid pulse
 - c. Absence of spontaneous ventilation and tachycardia
 - d. Shallow gasping and apical heart rate of 48.

(continued)

Rationale

Correct answer: c.

Artificial respiration is used for clients who have no spontaneous respiration but whose hearts are still beating. Cardiopulmonary resuscitation is required for clients with neither heartbeat nor spontaneous ventilation. Artificial respiration is not done for clients who have spontaneous breathing. Neither is it done if there is no heartbeat.

5. In which situation would the nurse check Chvostek and Trousseau signs?
 - a. Client complains of calf pain
 - b. Client complains of headache and photophobia
 - c. Client complains of weakness and dysphagia
 - d. Client complains of tingling in the feet

Rationale

Correct answer: d.

Positive Chvostek and Trousseau signs are indicative of hypocalcemia that can lead to tetany. Tingling in the hands and feet is an early sign of hypocalcemia but can also have other causes. Chvostek and Trousseau are unrelated to complaints of calf pain, headache, photophobia, weakness, and dysphagia.

6. Which type of treatment would be appropriate for a client with a serum potassium level of 3.3 mEq/l?
 - a. Kayexalate
 - b. IV sodium bicarbonate
 - c. KCl
 - d. Dialysis

Rationale

Correct answer: c.

Normal serum potassium is 3.5 to 5.0 mEq/l so a client with a serum potassium of 3.3 mEq/l is hypokalemic and needs potassium. Therefore, administration of KCl would be appropriate. Kayexalate and dialysis are used to remove potassium and IV sodium bicarbonate is given to alkalinize the plasma and cause a shift of potassium into the cells.

7. A client has a temperature of 99.4 °F and a urine specific gravity of 1.035. Further assessment discloses poor skin turgor and flat neck veins. Which problem should the nurse suspect?
 - a. Isotonic fluid volume deficit
 - b. Hypo-osmolar overhydration
 - c. Hyponatremia
 - d. Hypokalemia

Rationale

Correct answer: a.

Symptoms of isotonic fluid deficit are thirst, weakness, weight loss, decreased skin turgor, dry mucous mem-

branes, sunken eyeballs, dry eyes, low-grade fever, weak rapid pulse, drop in blood pressure, orthostatic hypotension, flat neck veins, decreased capillary refill, decreased central venous pressure, decreased urine volume (<30 ml/hr), increased urine specific gravity (>1.030), increased hematocrit, and BUN. Hypo-osmolar overhydration causes impaired neurological function as a result of cerebral edema: confusion, convulsions, and coma. Symptoms of hyponatremia are lethargy, anorexia, N&V, and muscle cramps. Confusion, muscle twitching, convulsions, and coma occur with serum sodium of less than 120 mEq/l. Hypokalemia causes muscle weakness, cramps, anorexia, N&V, cardiac dysrhythmias, increased sensitivity to digoxin, lethargy, confusion, and decreased DTRs.

8. A client's laboratory reports show serum potassium of 3.2 mEq/l. For which symptoms would the nurse assess the client?
 - a. Hyperactive DTRs
 - b. Flaccid paralysis
 - c. Cardiac dysrhythmia
 - d. Paresthesias in the extremities

Rationale

Correct answer: c.

The range of normal for serum potassium is 3.5–5.0 mEq/l so 3.2 mEq/l is indicative of hypokalemia. Cardiac dysrhythmias occur with both hypokalemia and hyperkalemia. DTRs are hypoactive with hypokalemia but hyperactive with hyperkalemia. Muscle weakness occurs with hypokalemia but paralysis occurs with hyperkalemia. Paresthesias are a symptom of hyperkalemia.

9. A client presents expectorating pink-tinged, frothy respiratory secretions. The nurse would immediately gather additional assessment data related to the possibility of which disorder?
 - a. Cardiac tamponade
 - b. Pulmonary tuberculosis
 - c. Pulmonary edema
 - d. Bacterial pneumonia

Rationale

Correct answer: c.

A sign of pulmonary edema is the production of pink-tinged, frothy sputum. Cardiac tamponade is not characterized by any type of expectoration. Clients with tuberculosis first develop a slight cough productive of scant mucoid sputum. If cavitation develops, sputum becomes purulent and blood tinged. Bacterial pneumonia is characterized by the production of rust-colored sputum.

10. Asking a client about amount and frequency of Alka-Seltzer use would be included in the assessment of a client with which problem?
- Hypermagnesemia
 - Hypernatremia
 - Hypovolemia
 - Hypophosphatemia

Rationale

Correct answer: b.

Alka-Seltzer is high in sodium and can be a source of high oral intake leading to hypernatremia.

11. It is calculated that a burn client needs 1800 ml of fluid in the first 24 hours in order to maintain blood volume and urinary output. How many ml would the nurse plan to infuse in the first 8 hours based on the Parkland formula?
- 450
 - 600
 - 900
 - 1200

Rationale

Correct answer: c.

One-half of the total fluid required in the first 24 hours is infused in the first 8 hours. One half of the total 1800 ml is 900 ml. The remaining half of the total is infused over the remaining 16 hours.

12. What does right upper quadrant pain that develops 48 hours after an overdose of aspirin indicate?
- Diaphragmatic irritation
 - Lower esophageal ulceration
 - Biliary colic
 - Liver damage

Rationale

Correct answer: d.

Right upper quadrant pain due to liver damage is characteristic of the second phase of salicylate poisoning that occurs 24–48 hours after ingestion. Other symptoms of this phase are hepatomegaly, elevated bilirubin and hepatic enzymes, prolonged prothrombin time, and oliguria.

13. When speaking to a group of junior high school students about first aid, the nurse explains there is a universal sign indicating choking and asks if any of the students knows what it is. Which student's response is correct?
- Mouth open, index finger pointing in
 - Hand on neck over throat area
 - Hands crossed at the neck
 - Mouth open, index fingers pointing at each side of neck

Rationale

Correct answer: c.

The universal sign indicating choking is hands crossed at the neck.

14. A client, 36 hours after an intestinal resection moves into a sitting position in bed and immediately tells the nurse "Something just 'gave way' under my dressing". On examination, the nurse discovers that the incision has dehiscenced and a loop of intestine is protruding. Which is the first action the nurse should take?
- Notify the surgeon
 - Cover the protruding intestine with a sterile dressing wet with normal saline
 - Assist the client to low Fowler's position
 - Obtain a wound culture

Rationale

Correct answer: c.

A low Fowler's position takes stress off the suture line and prevents further disruption. The intestine is then protected with a sterile, wet with N/S dressing, and the surgeon notified.

15. How should the finding of mahogany-colored urine in a burned client be interpreted?
- Muscle damage has occurred
 - Kidney failure is developing
 - Hemoglobin is being released from the spleen
 - Bladder mucosa has ulcerated

Rationale

Correct answer: a.

Muscle damage releases component chemicals that are excreted by the kidneys and turn the urine mahogany in color.

16. A client is admitted with serum sodium of 128 mEq/l. Which order would the nurse question if it was written on the order sheet for this client?
- High-protein, low-sodium diet
 - Restrict fluids to 1500 ml/d
 - IV infusion of 5% NaCl
 - Daily electrolytes

Rationale

Correct answer: b.

The normal serum sodium range is 135–145 mEq/l so 128 mEq/l is low so it would not be appropriate to order a low-sodium diet because the client needs sodium. Restricting fluids would help equalize the proportions of sodium and water so the relative amount of sodium in the serum would increase. Infusing a hypertonic solution of 5% NaCl would increase sodium. Daily electrolytes would allow monitoring of electrolyte status.

(continued)

17. Which S&S occurring in a client with burns are indicative of developing sepsis? Mark all that apply.
- ___ Change in mental status
 - ___ Fever
 - ___ Tachypnea
 - ___ Bradycardia
 - ___ Hepatomegaly
 - ___ Abdominal distention
 - ___ Oliguria

Rationale

Correct answers: a, b, c, f, and g.

Tachycardia not bradycardia is a sign of developing sepsis. Hepatomegaly is unrelated to sepsis.

18. Which is a priority goal of nursing care for a client with a burn during the first 48–72 hours after skin grafting?
- Maintain range of motion.
 - Ensure adequate caloric intake
 - Prevent displacement of the graft
 - Suppress an immune reaction

Rationale

Correct answer: c.

The graft must stay firmly in contact with the graft bed for the first 48–72 hours so immobilization devices such as bulky dressings or splints are left intact for that period of time and when dressings are removed, they are removed slowly and gently.

19. What is used as a guide to fluid resuscitation in a client with burns after the edema has resolved?
- Hourly urinary output
 - Serum albumin and prealbumin
 - Daily weight
 - Serum and urinary electrolytes

Rationale

Correct answer: d.

Serum and urinary electrolyte levels are used to guide fluid administration after edema begins to resolve 48–72 hours after the burn injury occurs. Until that time, urinary output is used as a guide to fluid resuscitation. Serum albumin and prealbumin are measures of nutritional status. Daily weight is a measure of fluid retention or loss.

20. Which client is at risk for metabolic acidosis?
- A 17-year old with cystic fibrosis
 - A 35-year old pregnant woman
 - A 48-year old with hypoparathyroidism
 - A 65-year old with an ileostomy

Rationale

Correct answer: d.

Ileostomy drainage places a client at risk for metabolic acidosis. Risk associated with cystic fibrosis is for respira-

tory acidosis. Risk associated with pregnancy is for respiratory alkalosis. Hypoparathyroidism is a risk factor for metabolic alkalosis.

21. A client with COPD complains of headache and a “racing” heart; he is also restless and somewhat confused. Which problem would the nurse suspect?
- Respiratory acidosis
 - Respiratory alkalosis
 - Metabolic acidosis
 - Metabolic alkalosis

Rationale

Correct answer: a.

Headache, tachycardia, restlessness, and confusion are S&S of respiratory acidosis for which a client with COPD is at risk. Other S&S include dyspnea, tachypnea, diaphoresis, and anxiety progressing to lethargy, ventricular dysrhythmia, dilated facial and conjunctival blood vessels, cyanosis, and coma.

22. A 61-year-old client with a history of chronic renal failure is admitted with a possible appendicitis. Based on this history which acid–base imbalance is most likely to be found when laboratory test results are assessed?
- Respiratory acidosis
 - Respiratory alkalosis
 - Metabolic acidosis
 - Metabolic alkalosis

Rationale

Correct answer: c.

Chronic renal failure is the most common cause of chronic metabolic acidosis.

23. The plan of care for which client would involve monitoring for respiratory acidosis?
- A 24-year old with Guillain-Barre syndrome
 - A 37-year old with pancreatic drainage
 - A 50-year old who required a massive blood transfusion following a motor vehicle accident
 - A 70-year old with chronic congestive heart failure

Rationale

Correct answer: a.

Guillain-Barre syndrome because it can affect the muscles of respiration decreasing alveolar ventilation, results in the retention of carbon dioxide, which leads to respiratory acidosis. Pancreatic drainage places the client at risk for metabolic acidosis because of the loss of base. Massive blood transfusion is a risk factor for metabolic alkalosis and CHF is a risk factor for respiratory alkalosis.

24. Which intervention would the nurse expect to be ordered for a client with dehydration?
- Isotonic IV fluid infusion
 - Hypotonic IV fluid infusion

- c. Sodium restriction
- d. Diuretic therapy

Rationale

Correct answer: b.

A hypotonic solution such as 0.9% sodium chloride solution would be given as dehydration is a hyperosmolar imbalance in which water is lost in excess of sodium. Isotonic IV infusions are used in the treatment of hypovolemia.

25. When evaluating fluid resuscitation for a 12-year-old child with a burn injury, which outcome would be one indicator that the client was receiving adequate fluid?

- a. Urinary output of 3–5 ml/kg of body weight/hr
- b. Normal mentation
- c. pH of 7.25–7.35 and base excess of 8 or greater
- d. Respiratory rate of 14–20

Rationale

Correct answer: b.

One indicator of adequate fluid resuscitation is normal mentation. Other indicators of adequate fluid include urinary output of 30–50 ml/hr or 1–2 ml/kg of body weight/hr in children; and a pH of 7.35–7.45 and base excess of 6 or greater.

INFECTIOUS DISEASES

GONORRHEA

- Sexually transmitted infection with *Neisseria gonorrhoeae*, a gram-negative *Diplococcus*

- One of the most common STIs
- Over 1 million cases are reported in the United States each year
- Major cause of PID, tubal infertility, ectopic pregnancy, and chronic pelvic pain

- If untreated, it may cause severe disseminated infection: arthritis, dermatitis, pericarditis, endocarditis, and meningitis
- If a pregnant woman is affected, stillbirth, neonatal death, and premature labor can occur
- Infants born to infected mothers may experience prematurity, conjunctivitis, and pneumonia

Etiology: Localized, sexually transmitted infection affecting urethra, endocervix, and/or rectum.

Risk factors: Young, sexually active, multiple sexual partners.

S&S:

- Asymptomatic to mildly symptomatic (50% of women with gonorrhea have no symptoms)
- Dysuria
- Urinary frequency
- Cervical discharge
- Conjunctivitis

Dx:

- Endocervical, oral, or rectal cultures
- Gram stain

Rx:

- Ceftriaxone 125 mg, IM and Cefixime 400 mg p.o.
- Partners must also be treated

Clinical Alert

Clients who present having been sexually assaulted should be treated prophylactically; repeat cultures should be done in 2 weeks.

Nursing Process Elements

- Assist client in assessing risk for STIs
- Discuss safer sexual practices
- Help clients develop communication skills to initiate discussions with their partners

Client teaching for self-care

- Encourage client to initiate discussions about sex with their partners
- Reinforce the need for client to abstain from sexual intercourse until after all sexual partners are treated
- Reinforce the need for annual screening for STIs

CHLAMYDIA

- Sexually transmitted infection with *Chlamydia trachomatis*
- Most common STI
- An estimated 3–4 million cases occur annually in the United States
- Most commonly found in young, sexually active people with more than one partner
- Up to 40% of untreated women develop PID

OB

Increases risk for ectopic pregnancy and infertility

- Chlamydia and gonorrhea often coexist

OB

An estimated 30% of pregnant women are affected

Etiology: Sexually transmitted infection.

Predisposing factors: Young, sexually active people with multiple sexual partners; nonbarrier contraceptive methods

S&S:

- Chlamydial infections of the cervix often produce no symptoms
- Cervical discharge
- Dyspareunia
- Dysuria
- Bleeding (friable cervix)
- Conjunctivitis
- Perihepatitis
- Postpartum endometritis

OB

If a pregnant woman is affected, stillbirth, neonatal death, or premature birth may occur

- Infants born to infected mothers may experience prematurity, conjunctivitis, and pneumonia

Dx:

- Tissue culture
- Endocervical and urethral culture

Rx:

- Erythromycin or amoxicillin (when pregnant)
- Doxycycline (postpartum)
- Tetracycline (nonpregnant)
- Erythromycin ophthalmic ointment for newborn
- Partners must also be treated

Nursing Process Elements

- Assist client in assessing risk of STIs
- Discuss safer sexual practices
- Help client develop communication skills to initiate discussion with her partners

**Client teaching for self-care**

- Repeat testing needs to be done 2 weeks posttreatment (test of cure)
- Importance of abstaining from sexual intercourse until all sexual partners have been treated
- Importance of using condoms with all new or noninfected partners
- Annual routine gynecological care, including a PAP test and testing for STIs

SYPHILIS

- Complex, curable sexually transmitted bacterial infection caused by the spirochete *Treponema pallidum*
- Leads to disability and death if left untreated

OB

Fetal/neonatal effects: stillbirth, developmental delay, seizures, or neonatal death, symptoms of infection may not be present at birth but develop in a few weeks.

Etiology: Sexually transmitted infection.

Predisposing factors: Young adults, multiple sex partners, inadequate knowledge of transmission and prevention, and unprotected sex.

S&S:

- Divided into primary, secondary, and tertiary stages of infection
 - Primary: the first sign of primary syphilis is a painless chancre that develops on the genitalia, anus, lips, or in the oral cavity; if untreated, the chancre heals within 6 weeks; the disease is highly infectious during the primary phase.
 - Secondary: although the chancre disappears, the spirochete lives and is carried by the blood to all parts of the body; about 2 months after the initial infection, symptoms of secondary syphilis appear, which include enlargement of the liver and spleen, headache, anorexia, and a generalized maculopapular skin rash; if left untreated, the disease enters a latent phase that may last several years.
 - Tertiary: may have heart, blood vessel, and nervous system involvement; general paralysis and psychosis may result.

Dx:

- Primary stage: dark-field microscopy from sample scraped from the base of the chancre; serologic tests are usually negative at this time
- Secondary stage: serologic (VDRL) tests are positive at this time; the rapid plasma regain (RPR) and fluorescent treponemal antibody absorption (FTA-ABS) tests are more

specific and are often done to confirm a positive test of VDRL

Rx:

- Best treatment for all stages is with penicillin; doxycycline can be used if client is allergic to penicillin
- Reevaluation should be done at 6 and at 12-month post-treatment

**Nursing Process Elements**

- Assist client in identifying STI preventive measures that are compatible with age, language, male–female relationships within the client's culture
- Teach the S&S that require medical care
- Refer to support groups

**Client teaching for self-care**

- Importance of abstaining from sexual intercourse during the prodromal period when lesions are present
- Use of condoms with all new or noninfected partners
- All partners must be treated in order to prevent reinfection
- Comfort measures such as wearing nonconstricting clothing, wearing cotton underwear, taking Sitz baths, and air-drying lesions
- Need for strict hand washing with soap and water
- Importance of returning for follow-up care

HERPES

- Herpes simplex virus (HSV) is an enveloped, double-stranded DNA virus that occurs in two forms: herpes simplex type 1 and type 2
- HSV-1 is transmitted via oral and respiratory secretions; HSV-2 is transmitted via sexual contact
- Transmission is more likely to occur from men to women

Etiology: Herpes simplex virus.

Risk factors: Female sex. African-American ethnic background, Mexican-American ethnic background, older age, poverty, low educational level, cocaine use, multiple sexual partners, unprotected sex, and having a sexual partner with genital herpes.

S&S:

- Painful genital vesicular lesions
- Vesicles can be on cervix, vagina, or external genitalia
- Primary infection is commonly associated with fever, malaise, myalgia; numbness, tingling, burning, itching, redness, swelling, and pain with lesions; urinary retention; lymphadenopathy

Dx:

- Tissue culture (swab specimen from vesicles)
- Immunofluorescent staining of the cell can differentiate HSV-1 from HSV-2

Rx:

- Currently no cure for HSV-2 infection
- Treatment aimed at relieving symptoms
- Acyclovir (Zovirax), valacyclovir (Valtrex), and famciclovir (Famvir)—antiviral agents used to suppress symptoms and shorten the course of infection

OB In pregnant women, acyclovir has been used near date of expected delivery to suppress outbreak

Clinical Alert

OB If a pregnant woman presents to deliver and has active lesions, delivery by cesarean section is the current standard of care because herpes can cause potentially fatal infection in newborns.

Nursing Process Elements

- Listen to client's concerns to reduce anxiety
- Client may need assistance and support in discussing the infection and its implications with partner(s)
- Provide information and instruction
- Encourage use of analgesics as ordered
- Encourage proper hygiene practices (especially hand washing with soap and water)
- Encourage use of Sitz baths for comfort
- Encourage use of clean, soft, loose fitting, and absorbent clothing
- Discourage use of powders, lotions, and occlusive ointments because they prevent lesions from drying
- Encourage client to avoid stress, sunburn, and other stress-producing situations, which can precipitate an outbreak
- Discomfort with urination can be reduced by pouring water over the vulva during voiding
- When oral antiviral agents are taken, client needs to know when to take medication and to alert provider to side effects such as headache and/or rash

Client teaching for self-care

- Disease process:
 - Herpes is transmitted by direct sexual contact
 - Abstinence from sex is required for a brief period during treatment

—Intercourse during a herpes outbreak not only increases the risk of transmission but also increases the likelihood of contracting HIV and other STIs; makes HIV more infective

—Transmission is possible even in the absence of lesions

—Condoms may provide some protection against viral transmission

—Control of the condition may require a change in sexual behavior and medication use

- Appropriate hygiene practices
- Practices to avoid self-infection
- Health promotion activities such as eating a well-balanced diet, avoiding stress, and getting enough rest
- Importance of taking medications as prescribed, keeping follow-up appointments, and informing health care provider when outbreaks occur
- Support groups and the possible benefits of joining a group where experiences and solutions can be shared

HIV/AIDS

- Human immunodeficiency virus (HIV-1) is a retrovirus transmitted by contact with infected blood or body fluids
- HIV infection may cause acquired immunodeficiency syndrome (AIDS)
- AIDS is the fifth leading cause of death in American women aged 25–44 years; black and Hispanic women make up three-fourth of that statistic
- Women and men are much more likely to get HIV from men than from women
- Heterosexual transmission accounts for the majority of all new cases of HIV in women

OB Seropositive women can transmit HIV to their fetuses across the placenta, at birth when the infant is exposed to maternal blood and vaginal secretions and after birth by breast milk.

Etiology:

- Infection by the HIV retrovirus that affects helper T cells bearing the CD4⁺ antigen.
- Through the action of reverse transcriptase, HIV produces DNA from its viral RNA. The viral DNA enters the nuclei of affected cells and is incorporated into their DNA, where it's transcribed into more viral RNA. If the host (affected) cells reproduce, the HIV DNA is duplicated along with their own DNA and it is passed on to the daughter cells.
- When activated, host cells replicate the virus. The virus buds out of the cell membrane and emerges from the host cell free to infect other cells.
- HIV replication may lead to cell death or the virus may become latent.
- HIV infection causes pathological effects in two ways: directly through destruction of CD4⁺ cells, other immune

cells, and/or neuroglial cells, or indirectly through the effects of CD4⁺ T-cell dysfunction and resulting immunosuppression

Risk factors/at-risk populations: Homosexual or bisexual men, IV drug users, women who exchange sex for drugs, recipients of contaminated blood or blood products, heterosexual partners of those in high-risk groups, neonates of infected women, females in age group 25–44 years old, women who have anal intercourse, unprotected sex, and intercourse during menses

S&S:

- Latency phase: mononucleosis-like syndrome, which may be attributed to flu or another virus; followed by an asymptomatic period which may last for years.
- Symptomatic phase: persistent generalized lymphadenopathy; nonspecific symptoms including weight loss, fatigue, night sweats; fevers related to altered function of CD4⁺ cells, immunodeficiency, and infection of other CD4⁺ antigen-bearing cells; neurologic symptoms; opportunistic infections (see Table 32-1); cancer

PEDS

Assessment Alert

HIV/AIDS in children are often manifested by failure to thrive and developmental delays. The child may have recurrent oral candidiasis and chronic diarrhea.

Dx:

- Laboratory studies reveal CD4⁺ T cell count less than 200 cells per μ l and the presence of HIV antibodies
- T cell subsets CD4 and CD8 counts and ratios stage the infection and establish a prognosis.
- Antibody assay tests (ELISA, Western blot, rapid tests including oral fluid HIV-1 antibody test that can be done on plasma or oral fluid obtained by swabbing around gums) take 3 weeks to 3–6 months to be positive after exposure because the body has to have time to produce antibodies to the virus. “Window period”: time between exposure and the presence of detectable antibodies.

OB At birth, the infant may have a positive antibody titer as maternal antibodies readily cross the placenta. This does not indicate HIV infection.

PEDS The ELISA and Western blot immunoassay are used to determine HIV infection in children. Infants born to HIV-positive mothers will have positive results due to the presence of maternal antibodies that have crossed the

placenta. These antibodies may persist until the child is 18-months old so antibody testing is unreliable until after this age. HIV polymerase chain reaction (PCR) can detect the infection allowing diagnosis by the time the infant is 1-month old.

Rx:

- Protease inhibitors, nucleoside reverse transcriptase inhibitors, and nonnucleoside reverse transcriptase inhibitors
- Highly active antiretroviral therapy (HAART) “cocktail”—combination of a protease inhibitor and two reverse transcriptase inhibitors, which interrupt HIV replication at different places in the cycle, e.g., Lamivudine, Zidovudine, and Nelfinavir
- Additional treatments may include immunomodulatory agents; human granulocyte colony-stimulating growth factor; anti-infective and antineoplastic agents; nutritional support; fluid and electrolyte replacement therapy; treatment of opportunistic infections (See Table 32-1)

OB All pregnant women should be given ZDV orally starting at 14-weeks gestation and continued through pregnancy, intravenously during labor, and to the newborn for the first 6 weeks of life (reduces the risk of maternal–newborn transmission by 66%)

Clinical Alert

Viral load—amount of virus in the serum; measured by Plasma HIV RNA. Used to monitor disease progression and response to antiretroviral therapy.

OB The risk of teratogenic effects of the HIV medications are not known at this time. Some HIV-positive pregnant women choose to suspend therapy during the first 3 months of pregnancy.

OB Although this is a high-risk pregnancy, invasive procedures such as amniocentesis are avoided if possible to reduce the risk of contamination of the fetus. Noninvasive procedures such as nonstress testing and serial ultrasounds are performed at a more frequent rate.

PEDS The child with HIV/AIDS should receive the normal immunizations recommended for all children. Attenuated live virus can be administered when there is no evidence of severe immunocompromise. Children receiving active intravenous gamma globulins (IVIG) may not develop full immunity due to the presence of passive antibodies.

Table 32–1 Common Opportunistic Infections Associated with AIDS

| Type of Infection | S&S | Treatment | Comments |
|---|--|---|--|
| M. avian complex (MAC) (bacterial infection) | High fever, night sweats, fatigue, anorexia, weight loss, abdominal pain, diarrhea, enlarged lymph nodes, liver, and spleen. | Prophylaxis: Azithromycin or clarithromycin Rx: Antimycobacterial agents | Most common opportunistic infection in AIDS clients. |
| <i>Mycobacterium tuberculosis</i> | See TB in Chapter 21 | See TB in Chapter 21 | Annual PPD needed if HIV positive. |
| Candidiasis—oral, rectal, vaginal (fungal disease) | White, curd-like patches on erythematous mucous membrane, itching and irritation. White, cheesy vaginal drainage. | Fluconazole, ketoconazole | No prophylaxis given—if client has chronic esophageal infection may be on long-term suppressive therapy. |
| Disseminated candidiasis | High fever, chills, and hypotension.. | Amphotericin B may be needed. | |
| Cryptococcosis (fungal disease) | Most effects on lungs and CNS: dyspnea, cough, chest discomfort, fever, headache, blurred vision, dizziness, loss of memory,, irritability, fatigue, N&V, and convulsions. | Amphotericin B—primary prophylaxis and long-term suppressive therapy with Fluconazole if CD4 cell counts are less than 50 cells/mm ³ . | Dx: fungus in CSF or blood. Source of fungus: pigeon droppings. |
| Histoplasmosis (fungal infection) | Acute pulmonary symptoms or disseminated disease that is fatal if not treated effectively. | Amphotricin B or fluconazole | Prophylaxis with Itraconazole if CD4 cell count less than 100 cells/mm ³ . |
| Cryptosporidium (protozoan infection) | GI infection: fever, N&V, abdominal pain, cramps, severe watery diarrhea, fluid and electrolyte imbalances, and malnutrition. | No effective cure. Reduce stool volume, decrease peristalsis, and relieve pain. | |
| <i>Pneumocystis carinii</i> (protozoan infection) | Primarily causes pneumonia: dyspnea on exertion, nonproductive cough, productive cough. Arterial O ₂ tension less than 70 mmHg, low respiratory diffusing capacity, or increased alveolar—arterial oxygen tension gradient; no evidence of bacterial pneumonia. | IV pentamidine isethionate or IV or PO or PO trimethoprim-sulfamethoxazole. | Without treatment leads to respiratory insufficiency and death. |
| <i>Toxoplasma gondii</i> | Encephalitis in AIDS clients: headache, confusion, fever, vomiting, hemiparesis, loss of vision, and seizures. | trimethoprim-sulfamethoxazole (TMP-SMX). | |
| CMV | Retinitis common in AIDS clients. | Ganciclovir | See individual sections on CMV and Herpes in this chapter |
| Herpes simplex type 1 and 2 | Disseminated effects brain, liver, and lungs. | Acyclovir | |

Nursing Process Elements

- Assess for risk factors and S&S of HIV disease
- Assess nutritional status that ranges from normal early in disease to extreme cachexia: weight, appetite, stomatitis, dysphagia, and food tolerance
- Assess fatigue level and ability to perform ADLs

Assessment Alert

Assess carefully persons already infected with HIV for signs of opportunistic infection since opportunistic infections are the major complications of HIV disease.

- Protect clients with AIDS from exposure to other infection
- Promote recognition and discussion of feelings; recognize that clients often are angry or guilty about the diagnosis
- Provide access to counseling for client and partner
- Provide appropriate information to enable informed decisions about care and lifestyle
- For nausea, suggest dry crackers and a beverage half hour before meals; antiemetics if needed.
- Provide high-calorie, high-protein diet divided into six small meals if anorexic or difficulty eating.
- See nutrition section in Chapter 13—for other interventions to support nutrition
- Encourage 8 hours of sleep a night; rest periods as needed during the day; and provide assistance as needed
- Recommend use of appropriate assistive devices

Client teaching for self-care

- For the uninfected, focus on prevention of contracting the virus; for the infected, focus on ways of preventing transmission of the virus
- Provide factual information and correct misconceptions related to diagnosis
- Importance of routine screening
- Safe sexual practices including consistent use of condoms
- Importance of regular follow-up care
- Importance of taking medications as prescribed

Clinical Alert

Health care workers are at increased risk of exposure to HIV. It is critical that health care workers

adhere to protective guidelines meticulously and follow through with postexposure procedures. Basic postexposure procedures are as follows:

- Wash wounds thoroughly with soap and water and irrigate with disinfectant solution; irrigate eyes with water or sterile saline; rinse mucous membranes with water.
- Obtain baseline laboratory tests including serologies.
- Have follow-up testing every 3 months for a year.

PEDS

ROSEOLA (EXANTHEM SUBITUM)

Etiology: Human herpes virus type 6 infection.

- At-risk population: children 6 months to 3 years of age
- Incubation period: 5–15 days

S&S: Persistent high fever in apparently well child for 2–3 days; when fever drops nonpruritic, rosy macular rash that fades with pressure appears on trunk and spreads to neck, face, and extremities, and lasts 2–3 days; enlarged cervical and postauricular lymph nodes, cough, pharyngitis, and coryza.

Complications: Febrile seizures.

Rx: Antipyretics for fever.

Nursing Process Elements

- No isolation

Client teaching for self-care

- Measures to control fever
- Febrile seizure precautions if child is at risk

FIFTH DISEASE (ERYTHEMA INFECTIOSUM)

Etiology: Human parvovirus B19 infection from infected person.

- Incubation period: 4–21 days

S&S: Rash occurring in three distinct phases: erythema on cheeks giving an appearance of a “slapped face” lasting 1–4

days; followed in 24 hours by a maculopapular, symmetrical rash, which develops proximally to distally on upper and lower extremities and lasts a week or more. The rash then subsides but reappears if skin is exposed to sun, heat, cold, friction, or other irritant.

Complications: Self-limited arthritis and arthralgia, aplastic crisis in immunosuppressed clients or those with hemolytic disease.

Rx: Antipyretics, analgesics, and anti-inflammatories.

Nursing Process Elements

- Respiratory isolation for hospitalized immunosuppressed child or child with aplastic crisis; otherwise isolation not needed

CHICKEN POX (VARICELLA)

Etiology: Varicella zoster virus infection from direct contact with respiratory secretions or skin lesions of infected persons, from droplet spread or contaminated objects. Communicable 24 hours before rash appears to days after; incubation period: 2–3 weeks.

S&S: Low-grade fever, malaise, and anorexia for 24 hours followed by a severely itchy rash that goes through stages of macule, papule, vesicle, and crust, and begins on the trunk and spreads to face and extremities, enlarged lymph nodes.

Complications: Bacterial infection in skin, pneumonia, and encephalitis.

Rx: Acyclovir (Zovirax); varicella zoster immunoglobulin after exposure for high-risk clients; antihistamines or diphenhydramine hydrochloride for itch.

Nursing Process Elements

- Isolation of hospitalized children; isolate at home until vesicles have dried; isolate high-risk children from infected children
- Prevent scratching and risk of secondary infection
 - Give soothing baths
 - Apply calamine lotion
 - Keep child's fingernails short and smooth
 - Put mittens on child
 - Keep child cool
 - Keep child occupied
 - Remove loose crusts
 - Teach child to put pressure on itchy areas rather than scratching
- Do not give aspirin because of risk of Reye's syndrome

MEASLES (RUBEOLA)

Etiology: Viral infection from direct contact with droplets of respiratory secretions, blood or urine of infected person

- Communicable mainly during prodromal period but also 5 days after rash appears; incubation period: 10–20 days

S&S: Fever, malaise, cough, coryza, conjunctivitis, Koplik spots (small, irregular, red spots with a pinpoint blue—white center on oral mucosa opposite molars), red maculopapular rash that starts on face and spreads down over body appearing confluent on upper body and more discrete on lower; turns brownish in 3–4 days and is followed by fine desquamation, anorexia, and generalized lymphadenopathy.

Complications: Otitis media, pneumonia, bronchiolitis, obstructive laryngitis, and encephalitis.

Rx: Supportive care; antipyretics for fever; antibiotics for those at high risk of secondary infection.

Nursing Process Elements

- Respiratory isolation if hospitalized
- Isolation until fifth day of rash at home
- Bed rest while febrile
- Dim lights if photophobia is a problem
- Keep child from rubbing eyes
- Monitor for signs of corneal ulceration
- Use cool mist vaporizer
- Lubricate skin around nares

GERMAN MEASLES (RUBELLA)

Etiology: Rubella virus infection contracted through direct contact with nose or throat secretions of symptomatic or nonsymptomatic infected person, droplet airborne transmission, or indirect contact with articles freshly soiled with secretions from the nose or throat and is communicable for about a week before and 5 days after appearance of rash. Incubation period: 14–21 days.

S&S: Low-grade fever, headache, malaise, anorexia, mild conjunctivitis, coryza, sore throat, cough, lymphadenopathy followed in 1–5 days by discrete, rosy, maculopapular rash which starts on the face and spreads rapidly down over body. Rash disappears in same order it developed and is usually gone in 3 days.

Assessment Alert

PEDS Children exhibit no symptoms before onset of rash.

Complications: Rare.

Clinical Alert

OB

Rubella virus has a teratogenic effect.

Rx: No specific treatment; antipyretics for fever; and analgesics for discomfort.

Nursing Process Elements

- Provide comfort measures
- Assess knowledge of the disease and immunization

Client teaching for self-care

OB

Isolate from pregnant women because of teratogenic effect

MUMPS

Etiology: Paramyxovirus from saliva of infected persons transmitted by direct contact or droplet spread. Communicable from just before to just after swelling begins. Incubation period: 14–21 days.

S&S: Malaise, headache, fever followed in 24 hours by an earache aggravated by chewing; swelling and tenderness of one or both parotid glands by the end of 72 hours.

Complications: Sensorineural deafness, encephalitis, myocarditis, arthritis, hepatitis, epididymo-orchitis with or without sterility, and meningitis.

Rx: Analgesics and antipyretics.

Nursing Process Elements

- Isolation and respiratory precautions if hospitalized
- Isolate at home during communicable stage
- Bed rest until swelling subsides
- Provide soft, bland foods
- Encourage fluids
- Apply hot or cold compresses to swollen parotids for comfort

POLIOMYELITIS

- Poliomyelitis occurs as following three distinct disease forms:
 - Abortive or inapparent
 - Nonparalytic
 - Paralytic

Etiology: Enterovirus type 1 (most often causes paralysis), 2, or 3 (least often causes paralysis) infection contracted by direct contact with oropharyngeal secretions or feces of symptomatic or nonsymptomatic infected persons. Incubation period: 5–35 days.

S&S:

- Abortive disease: fever, sore throat, headache, anorexia, vomiting, abdominal pain for a few hours or days
- Nonparalytic disease: pain and stiffness in neck, back, and legs along with above symptoms in more severe form.
- Paralytic: symptoms of nonparalytic, recovery, then onset of CNS paralysis

Complications: Respiratory arrest, hypertension, and renal calculi from immobilization.

Rx: No specific treatment. Supportive care including mechanical ventilation and physical care, sedatives, and analgesics according to individual needs.

Nursing Process Elements

- Maintain complete bed rest during acute phase
- Monitor for signs of respiratory paralysis: difficulty talking, ineffective cough, inability to hold breath, shallow, and rapid respirations
- Keep tracheostomy tray at the bedside
- Maintain good body alignment
- ROM and footboard to prevent contractures

SEVERE ACUTE RESPIRATORY SYNDROME (SARS)

Etiology: Infection with SARS-associated coronavirus (SARS-CoV), which is spread by respiratory droplets or by touching contaminated objects and then touching own eyes, nose, or mouth.

S&S: Onset: high fever (temperature greater than 100.4°F [$>38.0^{\circ}\text{C}$]), headache, overall discomfort and aching, occasional mild respiratory symptoms, diarrhea; dry cough after 2–7 days progressing to pneumonia in most clients.

Rx: No effective drug therapy available; symptomatic, supportive treatment may include antiviral medications (such as ribavirin), antibiotics, steroids, IV fluids, and ventilatory assistance.

Nursing Process Elements

- Maintain contact and airborne isolation precautions for persons with SARS or a high suspicion thereof

- Promote respiratory hygiene and coughing/sneezing etiquette among all clients
 - Provide tissues and hands-free container for disposal of used tissues
 - Provide accessible alcohol-based hand cleanser
 - Provide soap and disposable towels for hand washing where sinks are available
- Provide mask for clients with symptoms of a respiratory infection and make them sit apart from other clients in waiting areas
- Use droplet precautions in addition to standard precautions when examining clients with symptoms of respiratory infection

Client teaching for self-care

- Cover mouth when coughing or sneezing
- Use tissues and dispose of in nearest disposal container
- Wash hands after touching respiratory secretions or objects contaminated with them

EASTERN EQUINE ENCEPHALITIS (EEE)

Etiology: Mosquito-borne viral disease

- Occurs in eastern half of the United States
- Incubation period: 3–10 days
- Over age 50 and younger than 15 at greatest risk
- Working or playing outdoors in endemic areas places people at risk

S&S: Many persons who are infected with the virus develop no apparent illness. In those who do develop illness, symptoms range from mild and flu-like to full-blown encephalitis, coma, and death in about one-third of those affected. (See Chapter 22 for S&S of encephalitis.)

Complications: Mild to severe permanent neurologic damage in about 50% of survivors.

Rx: No specific treatment; hospitalization and supportive care, e.g., respiratory support, prevention of secondary bacterial infections, and physical therapy, depending on individual need.

Nursing Process Elements

- Assess for signs and symptoms of complications

Client teaching for self-care

Avoid mosquito bites

- Use an EPA-registered repellent according to manufacturers' instructions

- Wear protective clothing
- Avoid outdoor activity during peak mosquito-biting hours (dusk to dawn) if possible; if not, use double protection: wear long sleeves, and spray repellent directly onto clothes
- Do not apply repellents containing permethrin directly to skin
- Do not spray repellent on the skin under clothing
- Remove standing water that can provide mosquito breeding sites
 - At least once or twice a week, empty water from flowerpots, pet food, and water dishes, birdbaths, swimming pool covers, buckets, barrels, and cans
 - Check for clogged rain gutters and clean them out
 - Remove discarded tires and other items that could collect water
 - Be sure to check for containers or trash in places that may be hard to see such as under bushes or under your home

WEST NILE VIRUS

Etiology: Infection with West Nile virus from bite of an infected mosquito.

S&S:

- Many infected persons develop no symptoms; about 20% develop mild symptoms and less than 1% develop severe symptoms
- Mild: fever, headache, and body aches, nausea, vomiting, occasional swollen lymph glands or rash on chest, stomach, and back
- Severe: high fever, headache, neck stiffness, stupor, disorientation, coma, tremors, convulsions, muscle weakness, vision loss, numbness, and paralysis
- May last days to several weeks

Complications: Neurological effects may be permanent

Rx: No specific treatment; hospitalization with supportive treatment with IV fluids and ventilatory assistance for severe symptoms.

Nursing Process Elements

Assessment Alert

People over the age of 50 are more likely to develop serious symptoms.

**Client teaching for self-care**

- Prevention of mosquito bites (See section EEE.)

RABIES

- Rabies occurs primarily in wild animals like raccoons, skunks, bats, and foxes.
- It can affect domestic animals such as cats, cattle, and dogs.
- It infects the CNS causing encephalopathy and death

S&S: Fever, headache, and general malaise followed by neurological symptoms such as insomnia, anxiety, confusion, slight or partial paralysis, excitation, hallucinations, agitation, hypersalivation, difficulty swallowing, and hydrophobia (fear of water); death usually occurring in few days.

Dx: No single diagnostic test; saliva is tested for virus; serum and spinal fluid are tested for antibodies to the rabies virus; and skin biopsies of hair follicles at the nape of the neck are tested for rabies antigen.

Rx:

- No treatment after symptoms appear
- Rabies vaccine regimen provides immunity when administered after an animal bite or mucous membrane contamination with infectious material such as saliva (postexposure prophylaxis [PEP]) or for protection (preexposure prophylaxis)
- Preexposure prophylaxis: three doses of vaccine given on days 0, 7, and 21 or 28
- PEP begins as soon as possible after exposure: one dose of immunoglobulin and five doses of rabies vaccine over a 28-day period (days 3, 7, 14, and 28 after the first vaccination)

CYTOMEGALOVIRUS (CMV) INCLUSION DISEASE

Etiology: CMV infection from direct contact with saliva, urine, blood, tears, semen, or breast milk of an infected person; virus is absorbed through the mucous membranes of the nose or mouth.

- Fifty to eighty percent of adults in the United States are infected by age 40

OB

High-risk groups are

- fetuses of infected mothers, especially mothers first infected while pregnant; fetal effects include lung infection, excessive bleeding, anemia, liver damage, vision impairment, or neurological conditions that include seizures, hearing loss, varying degrees of mental impairment, or problems with physical coordination;
- immunocompromised clients.

S&S: Most infected individuals have no or very mild symptoms and no health consequences. Others have prolonged fever, fatigue, mild hepatitis, and tender lymph nodes. Severe forms of infection, which include CMV retinitis and encephalitis, occur in transplant recipients. Neuromuscular impairments in the form of leg weakness and bladder or bowel dysfunction may occur in end-stage AIDS clients. Symptoms reappear at intervals for life as the virus becomes active after a period of dormancy.

Rx: No cure. Antivirals such as ganciclovir and acyclovir to prevent infection or reduce “viral load” in the immunocompromised. High-titer immunoglobulin (IVIG, CytoGam) for acutely infected individuals with some impaired immunity.

**Nursing Process Elements**

- Assess client’s understanding of the disease course
- Monitor for complications

**Client teaching for self-care**

- Good hygiene especially hand washing to avoid contracting or spread
- Avoid sharing drinking glasses and utensils
- Carefully dispose of diapers, tissues, and other items contaminated with body fluids

INFECTIOUS MONONUCLEOSIS

Etiology: Infection with Epstein—Barr virus (EBV), a member of the herpes virus family, during adolescence or young adulthood from contact with the saliva of an infected person. EBV infection in children is asymptomatic or not distinguishable from other mild childhood illness.

Following symptomatic infection, EBV remains dormant in some cells of the immune system, throat, and blood, and periodically reactivates asymptotically and appears in the saliva.

S&S: Fever, sore throat, swollen lymph glands, occasional splenomegaly or liver involvement. No known effect of active EBV infection on pregnancy. Symptoms resolve in 1 or 2 months.

Complications: Burkitt’s lymphoma and nasopharyngeal carcinoma occur as a late development in a few carriers of EBV.

Dx: Clinical presentation of fever, sore throat, swollen lymph glands, and client’s age, elevated WBC count, greater than 10% atypical lymphocytes, and a positive reaction to a “mono spot” test; positive Paul—Bunnell heterophile antibody test.

Rx: No antiviral drugs, vaccines, or other specific treatment; symptomatic treatment only. Five-day course of steroids to control swelling of the throat and tonsils is sometimes prescribed.

Nursing Process Elements

No special precautions or isolation is needed because transmission only occurs through saliva and most individuals exposed to clients with infectious mononucleosis have previously been infected with EBV and are not at risk for infectious mononucleosis.

TOXOPLASMOSIS

Etiology: Infection with protozoan intracellular parasite, *Toxoplasma gondii* as a result of ingestion of contaminated soil, careless handling of cat litter, ingestion of raw or undercooked meat (lamb, pork, and beef), transmission from a mother to a fetus through the placenta (congenital infection), or by blood transfusion or solid organ transplantation.

S&S:

- Asymptomatic in most people otherwise mild sore throat, headache, muscle pain, lymphadenopathy, and fever
- Immunosuppressed clients: fever, headache, confusion, seizures, and abnormal neurological findings from brain lesions and blurred vision from retinal inflammation

Congenital infection: CNS impairments, hepatic and splenic enlargement, rash, fever, jaundice, anemia, blindness from inflammation of the retina, and mental retardation; may be present at birth or develop over the first few months of life

Dx: Serologic titers for toxoplasmosis, MRI of the head, cranial CT scan, brain biopsy, slit lamp examination for retinal lesions.

Rx: Anti-infectives for symptomatic cases: pyrimethamine, sulfonamide drugs, folinic acid, clindamycin, and trimethoprim-sulfamethoxazole. Asymptomatic children are treated to prevent retinal inflammation. Pregnant women are treated despite toxicity of medications. AIDS clients are treated until the CD4 count is over 100 to prevent reactivation of disease.

Nursing Process Elements

- Provide supportive care as necessary

Client teaching for self-care

Prevention:

- Avoid undercooked meats, or freeze meat to -20°C for 2 days.
- Protect children's play areas from cat and dog feces.
- Keep children away from cat litter boxes.
- Wash the hands thoroughly after contact with soil that may be contaminated with animal feces; after cleaning a litter box, and after handling raw meat.

SCARLET FEVER

Etiology: Group A beta-hemolytic streptococci from nose and throat secretions of infected persons or carriers contracted through direct contact, droplets, or contaminated articles or foods. Communicable both during incubation period of 1–7 days and during clinical illness phase. Carriers are communicable for 2 weeks to months.

S&S: Abrupt high fever with disproportionate tachycardia, vomiting, headache, chills, malaise, abdominal pain. Red, swollen tonsils with patchy exudates, beefy-red throat, swollen, white strawberry tongue (white coated with prominent red papillae) followed by red strawberry tongue (white coating sloughs off), red punctuate lesions on palate; red punctate rash most marked in intertriginous areas and absent on face; marked circumoral pallor; subsequent fine skin desquamation sheets on trunk, palms and soles.

Complications: Otitis media, peritonsillar abscess, sinusitis, glomerulonephritis, carditis, and polyarthrititis.

Rx: Penicillin; erythromycin if allergic to penicillin; analgesics for sore throat.

Nursing Process Elements

- Respiratory precautions for first 24 hours of antibiotics
- Bed rest while febrile
- Provide quiet activities
- Provide nonirritating liquids and soft foods
- Institute measures to relieve sore throat: gargles, throat spray, cool mist vaporizer, and analgesics
- Client teaching for self-care
- Correct administration of antibiotic and importance of compliance
- Notify health care provider if fever persists with antibiotic therapy

LYME DISEASE

Etiology: *Borrelia burgdorferi* (spirochete) transmitted to humans by ticks.

S&S:

- Headache
- Stiff neck
- Fever
- Muscle aches
- Fatigue
- Rash (may appear up to 1 month after bite)
- Regional lymphadenopathy

Assessment Alert

- Rash looks like a bull's eye and is called erythema migrans.

Dx: Appearance of erythema migrans, laboratory testing, and at least one of the following: arthritis, facial palsy, meningitis, and carditis.

Rx: Doxycycline (Vibramycin), ceftriaxone (Rocephin), and azithromycin for 3–4 weeks.

Complications:

- Arthritis
- Permanent joint damage
- Meningitis
- Bell's palsy
- Encephalopathy
- Encephalomyelitis
- Severe and/or persistent fatigue
- Hepatitis
- Heart abnormalities
- Eye inflammations
- Muscle aches
- Memory and concentration problems

OB

Difficulties with pregnancy including prenatal infection, miscarriage, and still birth

Nursing Process Elements

- Monitor for complications

Client teaching for self-care

- Continue medication to resolve infection

ROCKY MOUNTAIN SPOTTED FEVER

Etiology: *Rickettsia rickettsii* infection transmitted to humans by bite of or exposure to crushed tissues or feces of infected ticks who acquire the infective organism from eating off of rabbits, field mice, and dogs. Occurs spring and summer primarily in the Rocky Mountain and Mid-Atlantic states.

S&S: Sudden onset of fever that typically lasts 14 days, headache, conjunctival infection followed 3 days later by a maculopapular rash, which appears first on the extremities and rapidly spreads to the rest of the body including the palms and soles and subsequently becomes petechial.

Dx: History and clinical presentation.

Rx: Antibiotics, such as tetracycline or chloramphenicol until two or three days after temperature returns to normal for a full 24-hour period. Late or no treatment can result in death.

Nursing Process Elements

- No isolation needed
- Supportive care

Client teaching for self-care

- Avoid known tick-infested areas when possible
- Protect hands when removing ticks from persons or animals
- Remove ticks without crushing them

TETANUS (LOCKJAW)

Etiology: Infection with *Clostridium tetani*.

- Spore-forming organism found in soil, dust, and animal feces
- In puncture or other deep—flesh wounds, spores produce a powerful neurotoxin and tetanospasmin
- Incubation period: 3–21 days with an average of 8

S&S:

- Stiffness of jaw, neck, and other muscles
- Muscular irritability
- Spasms of jaw (lockjaw), neck, throat, chest, and other muscles that cause symptoms such as difficulty swallowing and breathing
- Fever

Complications: Death from constriction of airways, pneumonia, or instability in the autonomic nervous system; permanent brain damage from hypoxemia if muscle spasms have closed the airway.

Rx: Supportive care may include mechanical ventilation, sedation, and pharmacologically maintained muscle paralysis; tetanus antitoxin, such as tetanus immune globulin (TIG) which neutralizes toxin, but only that which hasn't yet combined with nerve tissue; antibiotics; tetanus vaccine to prevent future tetanus infection.

Clinical Alert

- Tetanus infection dose not confer immunity; tetanus vaccination/boosters still are needed throughout life

**Nursing Process Elements**

- Monitor signs and symptoms with special attention to respiratory status
- Provide supportive care in accord with treatments ordered

**Client teaching for self-care****Preventing Tetanus**

- Get tetanus toxoid boosters
- Take proper care of wounds
 - Clean wound with soap and a washcloth; rinse thoroughly with water
 - Apply thin layer of a multi-ingredient antibiotic such as Neosporin or Polysporin
 - Cover the wound to keep clean; change dressing daily or when wet or dirty
 - See health care provider for deep, dirty wounds or animal bites especially if immunization not up to date

E. COLI FOODBORNE ILLNESS

Etiology: Infection with *E. coli* O157:H7 from intestines of healthy cattle, deer, goats, and sheep through ingestion of undercooked, contaminated ground beef (most common cause); bean sprouts; fresh, leafy vegetables or raw milk; person-to-person contact; swimming in or drinking sewage-contaminated water.

S&S: Severe, bloody diarrhea; abdominal cramping; little or no fever.

Complications: Hemolytic uremic syndrome (HUS)

- Red blood cells are destroyed and kidneys fail
- Most often occurs in children under age 5 and the elderly

- Principal cause of acute kidney failure in children

Dx: Stool culture.

Rx:

- Most people recover without specific treatment
- Antibiotics are avoided as no benefit is documented and risk of renal disease
- Antidiarrheals such as loperamide are avoided

**Nursing Process Elements**

- Assess signs and symptoms
- Monitor for fluid and electrolyte imbalance

**Client teaching for self-care**

- Prevent infection
 - Thoroughly cook ground beef—contaminated meat looks and smells normal
 - Avoid unpasteurized milk
 - Wash hands carefully before preparing or eating food
- Wash well all utensils and counters that have been in contact with raw meat or other food sources of the bacteria
- Keep raw meat and other potential food source separate from other foods
- Wash fruits and vegetables well
- Remove outer leaves from vegetable such as lettuce or cabbage
- Avoid foods as advised by public health officials during outbreaks
- If one has a diarrheal illness,
 - wash hands thoroughly after using the toilet or changing a diaper of an infected child;
 - avoid swimming in public pools or lakes;
 - avoid sharing baths with others;
 - avoid preparing food for others.

WORKSHEET**TRUE & FALSE QUESTIONS**

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Pregnant women do not have to be treated for STIs.

T F

2. Douching is necessary for the prevention of STIs and other bacterial infections.

T F

- | | | |
|---|------------------|------------------|
| 3. Client should be aware that any pelvic pain and/or abnormal discharge, especially after sexual exposure, childbirth, or pelvic surgery, should be evaluated as soon as possible. | <u> </u> T | <u> </u> F |
| 4. Clients who have been sexually assaulted should be treated prophylactically with repeat cultures done in 2 weeks. | <u> </u> T | <u> </u> F |
| 5. Chlamydia is the most commonly found STI in the United States. | <u> </u> T | <u> </u> F |
| 6. Pelvic inflammatory disease (PID), if untreated, can cause infertility. | <u> </u> T | <u> </u> F |
| 7. Syphilis is a serious systemic disease that can lead to disability and death. | <u> </u> T | <u> </u> F |
| 8. The best treatment for all stages of syphilis is doxycycline. | <u> </u> T | <u> </u> F |
| 9. Acyclovir is the only known cure for herpes. | <u> </u> T | <u> </u> F |
| 10. Clients infected with HIV may remain asymptomatic for years. | <u> </u> T | <u> </u> F |
| 11. The HIV organism can be spread by casual contact. | <u> </u> T | <u> </u> F |
| 12. The placenta provides protection for the fetus in the HIV-positive pregnant woman. | <u> </u> T | <u> </u> F |
| 13. A person cannot get the AIDs virus from anal sex. | <u> </u> T | <u> </u> F |
| 14. HIV is considered a bloodborne pathogen. | <u> </u> T | <u> </u> F |
| 15. Clients with the HIV infection should be counseled to avoid all sexual contact. | <u> </u> T | <u> </u> F |
| 16. HIV is a retrovirus. | <u> </u> T | <u> </u> F |
| 17. Many tests for HIV are looking for antibodies produced by the host against the virus. | <u> </u> T | <u> </u> F |
| 18. Individuals who become infected with the HIV organism will be seropositive within days of infection. | <u> </u> T | <u> </u> F |
| 19. AIDS-defining conditions are opportunist infections not normally seen in healthy individuals. | <u> </u> T | <u> </u> F |
| 20. Antibiotics will not work on an individual with HIV. | <u> </u> T | <u> </u> F |
| 21. Amniocentesis may be performed on the pregnant HIV-positive woman at 32 weeks to determine if the fetus is infected. | <u> </u> T | <u> </u> F |
| 22. Only IV drug users are at risk for HIV. | <u> </u> T | <u> </u> F |
| 23. Gonorrhea is a localized infection of the reproductive organs and pelvic cavity. | <u> </u> T | <u> </u> F |
| 24. Cervical discharge, which is mucoid and often blood tinged, is the classic sign of chlamydial infection | <u> </u> T | <u> </u> F |
| 25. The best treatment for all stages of syphilis is penicillin. | <u> </u> T | <u> </u> F |
| 26. The VDRL test can be used as a screening test for clients with first-stage syphilis. | <u> </u> T | <u> </u> F |

(continued)

- | | | |
|--|------------------|------------------|
| 27. A nonpruritic rash that appears first on the trunk and faded with pressure is characteristic of roseola. | <u> </u> T | <u> </u> F |
| 28. An immunosuppressed child diagnosed with Fifth disease must be monitored for aplastic crisis. | <u> </u> T | <u> </u> F |
| 29. The age group most likely to develop the severe form of West Nile virus are those over age 50. | <u> </u> T | <u> </u> F |
| 30. The risk of tetanus infection is greatest when a wound is deep. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Matching the following:

Column A

1. ___ Rabies
2. ___ EEE
3. ___ SARS
4. ___ Varicella
5. ___ Scarlet fever
6. ___ Chlamydia
7. ___ Rocky Mountain spotted fever
8. ___ Toxoplasmosis
9. ___ *E.-coli*
10. ___ West Nile virus

Column B

- a. Undercooked pork
- b. Cat feces
- c. Contact with respiratory secretions
- d. Infected animal bite
- e. Blood transfusion
- f. Contaminated vegetables
- g. Sex with an infected partner
- h. Mosquito bite
- i. Contact with skin lesions
- j. Tick bite

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The disease that Koplik spots are a sign of is _____.
2. An antibiotic used in the treatment of a pregnant woman with chlamydia is _____.

3. Neuromuscular impairments in the form of leg weakness and bladder or bowel dysfunction caused by CMV infection may occur in clients with _____.
4. A child with scarlet fever needs to be on respiratory precautions for _____ hours after antibiotic therapy is started.
5. List four risk factors associated with the development of HIV infections: _____.
6. Name two nonspecific symptoms that are associated with HIV infections in children: _____.

APPLICATION QUESTIONS

1. Which advice would be appropriate for the nurse to give a client who is concerned about preventing EEE?
 - a. Avoid swimming in fresh water
 - b. Remove ticks from the skin without crushing them
 - c. Apply a permethrin-based insect repellent to the skin
 - d. Drain standing water from around home
2. Which instruction should the nurse give to a client who is treated for chlamydia?
 - a. Use birth control for 30 days after treatment
 - b. Do not use tampons for at least months
 - c. Return for repeat testing in 2 weeks
 - d. Take showers not tub baths
3. Which STIs present a risk to the health of fetuses or neonates? Mark all that apply.
 - a. Chlamydia
 - b. Syphilis
 - c. Gonorrhea
 - d. Herpes
4. A client states he was told that one should take care to protect the hands when removing ticks from a dog or cat and asks why this is important. On which fact should the nurse's response be based?
 - a. Contact with ticks can cause a desquamation reaction of the skin.
 - b. Contact with crushed tick tissues or feces presents a risk of contracting Rocky Mountain spotted fever.
 - c. Contact with tick antigens can result in an anaphylactic reaction.
 - d. Contact with blood from an engorged tick can transmit the West Nile virus
5. The parents of a child just diagnosed with scarlet fever asks "When we know if our other child is going to get this as well?" Which information should serve as the basis for the nurse's response? Mark all that apply.
 - a. The incubation period of scarlet fever is up to a week.
 - b. Scarlet fever is communicable both during the incubation and clinical illness phase.
 - c. Carriers can be communicable for months.
 - d. Transmission is via the fecal-oral route.
 - e. Infection is transmitted by tick bites.
6. The nurse is talking to a group of teenagers about the risks involved with drug use. One teenager asks about the relationship between drug abuse and HIV. The student states: "As long as I don't inject the drugs, I won't be at risk of developing HIV." The nurse's best response would include
 - a. true, but drugs are not good for you in other ways.
 - b. sniffing cocaine can also place you at risk for HIV.
 - c. you are right, IV drug use is the only way you can acquire HIV.
 - d. it is possible that the drug you are using has been handled by someone with HIV and you could get it from him or her.
7. A pregnant woman who is seropositive for HIV is planning on breast-feeding her infant. As the prenatal nurse, you would explain that
 - a. it is a good idea as the baby will receive the HIV antibodies that are in her body.
 - b. The HIV virus could be in the breast milk and the mother could give her baby her disease.
 - c. The mother should stop taking her HIV drugs if she is going to breast-feed as it could be hazardous to the infant.

(continued)

- d. As long as the mother continues to take her HIV drugs, it is OK as the baby will get the drugs at the same time as he/she gets the virus.
8. As a nurse, you should wear gloves for the following activities: (Select all that apply.)
- Starting an IV
 - Hanging a unit of blood
 - Changing a newborn's diaper
 - Giving the newborn a first bath
 - Shaking hands with a new client.
9. While teaching a newly diagnosed HIV client about safe practices, the nurse would teach the client to
- avoid kissing his children on the cheek.
 - use a separate set of dishes for himself.
 - avoid sharing toothbrushes and razor blades.
 - wash his clothes separately from the rest of the family.
10. A client says to the nurse: "I sometimes wonder if I should be tested for HIV. What do you think?" The nurse's best response would be
- "You wonder if you should be tested?"
 - "If you are worrying about having HIV, then of course you should be tested."
 - "The testing for HIV doesn't hurt, so you should go ahead with it."
 - "Are you worried the information will get out if you are tested?"
11. A woman seropositive for HIV delivers a term infant. While in the newborn nursery, the infant is tested and is found to have HIV antibodies. The mother asks the nurse what this means. The nurse's best response would be based on the knowledge that the antibodies
- mean that the baby will develop HIV.
 - mean that the baby will not develop HIV.
 - indicate that the baby is infected with HIV.
 - are maternal antibodies that crossed the placenta.
12. A man is seen in the clinic and asks to be tested for AIDS (HIV). The testing determines that the man's HIV status is negative. The nurse would
- congratulate the man on his negative status.
 - report the man to his employer as a high-risk employee.
 - explain that the HIV-negative status only provides immunity for 6 months.
 - provide information about lifestyle changes that may be needed to protect against infection.
13. A 3-month-old infant is showing symptoms of failure to thrive. Because the mother has tested positive for HIV, the physician is planning to test the infant for infection. The nurse would expect the physician to order which HIV test?
- PCR
 - ELISA
 - Western blot
 - WBC differential
14. A child is HIV-positive and his immune system is severely compromised. Which vaccination type should be avoided in this child?
- Killed vaccine
 - Toxoid vaccine
 - Attenuated vaccine
 - Passive immunization
15. A woman in early pregnancy, asks the nurse whether the HIV drugs she is taking will harm the baby. The nurse's response would be based on the knowledge that
- these drugs will harm the baby but without them the mother might die.
 - nurses should not provide the client with drug-related information.
 - these drugs do not harm the fetus and may be health promoting for the fetus.
 - it is not known whether these drugs place the fetus at risk and mothers need to make an informed decision about taking them.
16. Which direction should be given to a client for whom Flagyl is prescribed?
- Do not drink alcohol while taking Flagyl
 - Douche daily while taking Flagyl
 - Discontinue all other medications while taking Flagyl
 - Expect gray-green vaginal drainage while taking Flagyl
17. Which is a clinical manifestation of a vaginal trichomonas infection?
- thick, white, cheesy discharge
 - high fever
 - vomiting
 - thin, bubbly, green-tinged malodorous discharge
18. Which is an important aspect of care for any client with an STI?
- Maintenance of HIPAA standards
 - Ensuring that both client and partner(s) receive treatment.

- c. Reporting the disease to the Department of Health
d. Provision of information on birth control
19. When caring for a client with herpes, which information should be included in the plan for teaching self-care?
a. The risk of contracting HIV is increased during a herpes outbreak.
b. Antibacterial powder or lotion can be used to relieve soreness or itch.
c. Sitz baths should be avoided until lesions heal.
d. Clean, snug, absorbent underwear should be worn.
20. Which intervention would the nurse expect to be ordered for a woman in labor who has active herpes lesions?
a. Delivery by cesarean section
b. IV antibiotics
c. Stat non-stress test
d. Buccal pitocin
21. Which STI is the major cause of PID, infertility, ectopic pregnancy, and chronic pelvic pain?
a. Herpes
b. Chlamydia
c. Gonorrhea
d. Monilia
22. When explaining the importance of treatment, the nurse tells the client that arthritis, dermatitis, pericarditis, endocarditis, or meningitis can result from which STI if it is not treated?
a. Chlamydia
b. Herpes
c. Gonorrhea
d. PID
23. A client for whom a FTA-ABS test is ordered asks the purpose of the test. The nurse's response should be based on the fact that this test is used to confirm the diagnosis of which STI?
a. Gonorrhea
b. Syphilis
c. Chlamydia
d. Herpes
24. Which statement made by a client in a clinic waiting room requires correction? Mark all that apply.
a. You only have to worry about tetanus if you injure yourself on a rusty nail.
b. Even if you have tetanus, you still need immunizations for the rest of your life.
c. Tetanus occurs today only in underdeveloped countries.
d. TIG reverses or prevents the S&S of tetanus.
25. Which instructions should be given to clients when prevention of infection with *E. coli* O157:H7 is the goal? Mark all that apply.
a. Cook all hamburger to medium or well done
b. Wash green, leafy vegetables carefully
c. Stay away from persons with the disease
d. Avoid contact with sick farm animals
e. Do not swim where sewage may have escaped into the water
f. Drink pasteurized, not raw, milk
g. Wear gloves when changing cat litter boxes

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Pregnant women do not have to be treated for STIs. *False*
All women, pregnant or not, need to be treated for STIs.
2. Douching is necessary for the prevention of STIs and other bacterial infections. *False*
Douching destroys the natural flora that combats infecting organisms and may introduce bacteria upward.

(continued)

3. Clients should be aware that any pelvic pain and/or abnormal discharge, especially after sexual exposure, childbirth, or pelvic surgery, should be evaluated as soon as possible. *True*
4. Clients who have been sexually assaulted should be treated prophylactically with repeat cultures done in 2 weeks. *True*
5. Chlamydia is the most commonly found STI in the United States. *True*
6. PID, if untreated, can cause infertility. *True*
7. Syphilis is a serious systemic disease that can lead to disability and death. *True*
8. The best treatment for all stages of syphilis is doxycycline. *False*
The best treatment for all stages of syphilis is penicillin; doxycycline can be used if client is allergic to penicillin.
9. Acyclovir is the only known cure for herpes. *False*
There is no cure for herpes, which is a virus; acyclovir, an antiviral agent, can suppress the symptoms and shorten the course of the infection.
10. Clients infected with HIV may remain asymptomatic for years. *True*
11. The HIV organism can be spread by casual contact. *False*
The HIV virus cannot be spread by casual contact.
12. The placenta provides protection for the fetus in the HIV-positive pregnant woman. *False*
The placenta does not prevent the transmission of the HIV virus to the fetus.
13. A person cannot get the AIDS virus from anal sex. *False*
The AIDS virus can be transmitted from anal sex.
14. HIV is considered a bloodborne pathogen. *True*
15. Clients with the HIV infection should be counseled to avoid all sexual contact. *False*
Clients with the HIV infection do not need to avoid all sexual contact; they need to be counseled regarding safer sexual practices.
16. HIV is a retrovirus. *True*
17. Many tests for HIV are looking for antibodies produced by the host against the virus. *True*
18. Individuals who become infected with the HIV organism will be seropositive within days of infection. *False*
Individuals who become infected with the HIV organism are not seropositive within days of infection; it takes 3 weeks to 3–6 months for the client to become seropositive.
19. AIDS-defining conditions are opportunist infections not normally seen in healthy individuals. *True*
20. Antibiotics will not work on an individual with HIV. *False*
Antibiotics are effective for individuals with HIV provided the organism causing the infection being treated is sensitive to the antibiotic used.
21. Amniocentesis may be performed on the pregnant, HIV-positive woman at 32 weeks to determine if the fetus is infected. *False*
Amniocentesis does not determine if a fetus is infected with HIV.

22. Only IV drug users are at risk for HIV. *False*
IV drug users are at risk for HIV if dirty needles are used but since HIV can be transmitted by infected blood or blood products or other infected body fluids, anyone including health care workers who has contact with these substances is at risk.
23. Gonorrhea is a localized infection of the reproductive organs and pelvic cavity. *False*
Gonorrhea can cause severe disseminated infection: arthritis, dermatitis, pericarditis, endocarditis, and meningitis.
24. Cervical discharge which is mucoid and often blood-tinged is the classic sign of chlamydial infection. *False*
Chlamydial infection is often asymptomatic. When symptoms do occur discharge or bleeding from the cervix can be among them.
25. The best treatment for all stages of syphilis is penicillin. *True*
26. The VDRL test can be used as a screening test for clients with first-stage syphilis. *False*
The VDRL does not become positive until the second stage of the disease.
27. A nonpruritic rash that appears first on the trunk and faces with pressure is characteristic of roseola. *True*
28. An immunosuppressed child diagnosed with Fifth disease must be monitored for aplastic crisis. *True*
29. The age group most likely to develop the severe form of West Nile virus are those over age 50. *True*
30. The risk of tetanus infection is greatest when a wound is deep. *True*

MATCHING ANSWERS

Matching the following:

Column A

1. d Rabies
2. h EEE
3. c SARS
4. i Varicella
5. a Tetanus
6. g Chlamydia
7. j Rocky Mountain spotted fever
8. b Toxoplasmosis
9. f *E. coli*
10. h West Nile virus

Column B

- a. Deep flesh wound
- b. Cat feces
- c. Contact with respiratory secretions
- d. Infected animal bite
- e. Blood transfusion
- f. Contaminated vegetables
- g. Sex with an infected partner
- h. Mosquito bite
- i. Contact with skin lesions
- j. Tick bite

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The disease that Koplik spots are a sign of is measles.
2. An antibiotic used in the treatment of a pregnant woman with chlamydia is erythromycin or amoxicillin.
3. Neuromuscular impairments in the form of leg weakness and bladder or bowel dysfunction caused by CMV infection may occur in clients with end-stage AIDS.
4. A child with scarlet fever needs to be on respiratory precautions for 24 hours after antibiotic therapy is started.
5. List four risk factors associated with the development of HIV infections: sexual contact with an infected person, contaminated blood or blood products, drug abuse, particularly IV drug use, and infants born to infected mothers.
6. Name two nonspecific symptoms that are associated with HIV infections in children: failure to thrive and developmental delays.

APPLICATION ANSWERS

1. Which advice would be appropriate for the nurse to give a client who is concerned about preventing EEE?
 - a. Avoid swimming in fresh water
 - b. Remove ticks from the skin without crushing them
 - c. Apply a permethrin-based insect repellent to the skin
 - d. Drain standing water from around home

Rationale

Correct answer: d.

EEE is a mosquito-borne disease. Mosquitos breed in still water so draining plant pots and other containers of standing water decreases the number of mosquitos and helps prevent exposure to the EEE virus. Ticks cause Rocky Mountain spotted fever. Swimming in fresh water does not affect exposure to EEE but can be the source of other disease such as infections of the outer ear. Repellents with permethrin are effective in keeping mosquitos away but cannot be applied directly to the skin.

2. Which instruction should the nurse give to a client who is treated for chlamydia?
 - a. Use birth control for 30 days after treatment
 - b. Do not use tampons for at least months
 - c. Return for repeat testing in 2 weeks
 - d. Take showers not tub baths

Rationale

Correct answer: c.

Test of cure needs to be done 2 weeks after treatment. Birth control is not needed but sexual activity should be avoided until all sexual partners have been treated. Use of tampons and showers are unrelated.

3. Which STIs present a risk to the health of fetuses or neonates? Mark all that apply.
 - a. Chlamydia
 - b. Syphilis
 - c. Gonorrhea
 - d. Herpes

Rationale

Correct answers: a, b, c, and d.

Chlamydia and gonorrhea are associated with neonatal conjunctivitis and pneumonia as well as premature labor, stillbirth, and neonatal death. Syphilis can cause still birth, developmental delay, seizures, or neonatal death.

4. A client states he was told that one should take care to protect the hands when removing ticks from a dog or cat and asks why this is important. On which fact should the nurse's response be based?
 - a. Contact with ticks can cause a desquamation reaction of the skin.

- b. Contact with crushed tick tissues or feces presents a risk of contracting Rocky Mountain spotted fever.
- c. Contact with tick antigens can result in an anaphylactic reaction.
- d. Contact with blood from an engorged tick can transmit the West Nile virus.

Rationale

Correct answer: b.

Ticks are the vectors responsible for the transmission of Rocky Mountain spotted fever. Desquamation of the skin is seen in Toxic shock syndrome, measles, radiation therapy, and in many other situations; however, it is not characteristic of contact with ticks. Anaphylactic shock from contact with a tick is not documented in the literature. West Nile virus is a mosquito-borne illness.

5. The parents of a child just diagnosed with scarlet fever asks “When we know if our other child is going to get this as well?” Which information should serve as the basis for the nurse’s response? Mark all that apply.
- a. The incubation period of scarlet fever is up to a week.
 - b. Scarlet fever is communicable both during the incubation and clinical illness phase.
 - c. Carriers can be communicable for months.
 - d. Transmission is via the fecal—oral route.
 - e. Infection is transmitted by tick bites.

Rationale

Correct answers: a, b, and c.

Scarlet fever is communicable both during the incubation phase of 1–7 days and the clinical illness phase. Carriers are communicable from weeks to months. Transmission is by direct contact with nasopharyngeal secretions of infected persons, contact with contaminated items, or by droplet spread. Scarlet fever is not transmitted by ticks, Rocky Mountain spotted fever is.

6. The nurse is talking to a group of teenagers about the risks involved with drug use. One teenager asks about the relationship between drug abuse and HIV. The student states: “As long as I don’t inject the drugs, I won’t be at risk of developing HIV.” The nurse’s best response would include
- a. true, but drugs are not good for you in other ways.
 - b. sniffing cocaine can also place you at risk for HIV.
 - c. you are right, IV drug use is the only way you can acquire HIV.
 - d. it is possible that the drug you are using has been handled by someone with HIV and you could get it from him or her.

Rationale

Correct answer: b.

Drug abusers use a straw to sniff the cocaine from the counter into their nares. The nares becomes fragile and

bleeds readily. If blood gets on the straw and then the straw is shared with another drug user, that individual may acquire HIV from the straw.

7. A pregnant woman who is seropositive for HIV is planning on breast-feeding her infant. As the prenatal nurse, you would explain that
- a. it is a good idea as the baby will receive the HIV antibodies that are in her body.
 - b. the HIV virus could be in the breast milk and the mother could give her baby her disease.
 - c. the mother should stop taking her HIV drugs if she is going to breast-feed as it could be hazardous to the infant.
 - d. as long as the mother continues to take her HIV drugs, it is OK as the baby will get the drugs at the same time as he gets the virus.

Rationale

Correct answer: b.

HIV is found in all blood and body fluids. It is recommended that HIV-positive women should not breast-feed.

8. As a nurse, you should wear gloves for the following activities: (Select all that apply.)
- a. Starting an IV
 - b. Hanging a unit of blood
 - c. Changing a newborn’s diaper
 - d. Giving the newborn a first bath
 - e. Shaking hands with a new client

Rationale

Correct answers: a, b, c, and d.

Any time there could be exposure to blood or body fluid, gloves should be worn. Casual contact does not spread the HIV virus.

9. While teaching a newly diagnosed HIV client about safe practices, the nurse would teach the client to
- a. avoid kissing his children on the cheek.
 - b. use a separate set of dishes for himself.
 - c. avoid sharing toothbrushes and razor blades.
 - d. wash his clothes separately from the rest of the family.

Rationale

Correct answer: c.

Shared toothbrushes and razor blades will lead to exposure to blood and body fluids and should be avoided. All other interventions are not necessary.

10. A client says to the nurse: “I sometimes wonder if I should be tested for HIV. What do you think?” The nurse’s best response would be
- a. “You wonder if you should be tested?”
 - b. “If you are worrying about having HIV, then of course you should be tested.”

(continued)

- c. "The testing for HIV doesn't hurt, so you should go ahead with it."
- d. "Are you worried the information will get out if you are tested?"

Rationale

Correct answer: a.

This is an open-ended question that encourages the client to respond with more information. More information about the client's concerns are needed before intervening.

11. A woman seropositive for HIV delivers a term infant. While in the newborn nursery, the infant is tested and is found to have HIV antibodies. The mother asks the nurse what this means. The nurse's best response would be based on the knowledge that the antibodies
- a. mean that the baby will develop HIV.
 - b. mean that the baby will not develop HIV.
 - c. indicate that the baby is infected with HIV.
 - d. are maternal antibodies that crossed the placenta.

Rationale

Correct answer: c.

This is passive immunity that crossed the placenta from the mother and provides no indication of the infant's future HIV status.

12. A man is seen in the clinic and asks to be tested for AIDS (HIV). The testing determines the man's HIV status is negative. The nurse would
- a. congratulate the man on his negative status.
 - b. report the man to his employer as a high-risk employee.
 - c. explain that the HIV-negative status only provides immunity for 6 months.
 - d. provide information about lifestyle changes that may be needed to protect against infection.

Rationale

Correct answer: d.

The fact that the man seeks HIV testing indicates he feels he may have been exposed. In addition to providing information about his current status, it is imperative that information about lifestyle changes be included. It is illegal to provide information about HIV status to outside entities.

13. A 3-month-old infant is showing symptoms of failure to thrive. Because the mother has been tested positive for HIV, the physician is planning to test the infant for infection. The nurse would expect the physician to order which HIV test?
- a. PCR
 - b. ELISA
 - c. Western blot
 - d. WBC differential

Rationale

Correct answer: a.

PCR test can be used as early as 1 month of age. The ELISA and Western blot results would be confused by the maternal antibodies in the baby's blood. The WBC differential would not be helpful.

14. A child is HIV-positive and his immune system is severely compromised. Which vaccination type should be avoided in this child?
- a. Killed vaccine
 - b. Toxoid vaccine
 - c. Attenuated vaccine
 - d. Passive immunization

Rationale

Correct answer: c.

Attenuated vaccine contains live but weakened organisms. Because the child's immune system is compromised, these live vaccines may cause illness.

15. A woman in early pregnancy, asks the nurse whether the HIV drugs she is taking will harm the baby. The nurse's response would be based on the knowledge that:
- a. These drugs will harm the baby but without them the mother might die.
 - b. Nurses should not provide the client with drug-related information.
 - c. These drugs do not harm the fetus and may be health promoting for the fetus.
 - d. It is not known whether these drugs place the fetus at risk and mothers need to make an informed decision about taking them.

Rationale

Correct answer: d.

The teratogenic properties of these drugs are not fully known. The clients should be involved in making informed decisions about the health of themselves and their fetus.

16. Which direction should be given to a client for whom Flagyl is prescribed?
- a. Do not drink alcohol while taking Flagyl
 - b. Douche daily while taking Flagyl
 - c. Discontinue all other medications while taking Flagyl
 - d. Expect gray-green vaginal drainage while taking Flagyl

Rationale

Correct answer: a.

Alcoholic beverages should be avoided while taking Flagyl and for 3 days after the last dose. Mixing alcohol

with Flagyl can result in abdominal cramps, nausea, vomiting, headaches, and flushing. Caution must be used to avoid accidental ingestion of alcohol from sources such as over the counter cough suppressants or cold products. Douching is unrelated to taking Flagyl. It is not necessary to discontinue all medications and Flagyl does not cause gray-green vaginal drainage.

17. Which is a clinical manifestation of a vaginal trichomonas infection?
- thick, white, cheesy discharge
 - high fever
 - vomiting
 - thin, bubbly, green-tinged malodorous discharge

Rationale

Correct answer: d.

A thin, bubbly, green-tinged, foul-smelling vaginal discharge is characteristic of trichomonas infection. A thick, white, cottage cheese like discharge is characteristic of monilia (*Candida albicans*) infection. High fever and vomiting may accompany infections which involve other organisms and more generalized infections such as PID.

18. Which is an important aspect of care for any client with an STI?
- Maintenance of HIPAA standards
 - Ensuring that both client and partner(s) receive treatment
 - Reporting the disease to the Department of Health
 - Provision of information on birth control

Rationale

Correct answer: a.

Maintaining client's privacy as regulated by HIPAA is a critical aspect of care of all clients including those with any type of STI. Not all STIs require both the client and partner to be treated and not all are reportable diseases. Information on birth control may be desirable but it is not an essential aspect of care for all clients with STIs as the possibility of pregnancy does not apply to all clients and it is not essential to the cure or prevention of STIs.

19. When caring for a client with herpes, which information should be included in the plan for teaching self-care?
- The risk of contracting HIV is increased during a herpes outbreak.
 - Antibacterial powder or lotion can be used to relieve soreness or itch.
 - Sitz baths should be avoided until lesions heal.
 - Clean, snug, absorbent underwear should be worn.

Rationale

Correct answer: a.

The risk of contracting HIV and other STIs is increased during an outbreak of herpes lesions. Use of powders, lotions, or ointments should be avoided; analgesics can be taken as ordered for pain and discomfort on urination can be eased by pouring plain water over the perineum. Sitz bath should be encouraged as they also provide comfort; they do not need to be avoided until the lesions heal. Under clothing covering involved areas should be clean, absorbent, and loose fitting, not snug.

20. Which intervention would the nurse expect to be ordered for a woman in labor who has active herpes lesions?
- Delivery by cesarean section
 - IV antibiotics
 - Stat nonstress test
 - Buccal pitocin

Rationale

Correct answer: a.

A woman with active herpes lesions is delivered by caesarean section to avoid exposing the fetus to the herpes virus during passage through the birth canal. Acyclovir is sometimes ordered as the EDC approaches in an attempt to prevent an outbreak at the time of labor so that a C-section is not necessary. IV antibiotics are not administered because herpes is caused by a virus and there is no cure. An immediate non-stress test is ordered to determine fetal well-being and so is not required by the presence of a maternal herpes outbreak. Pitocin is used to induce labor or strengthen contractions and so would be considered for use only with a vaginal delivery.

21. Which STI is the major cause of PID, infertility, ectopic pregnancy, and chronic pelvic pain?
- Herpes
 - Chlamydia
 - Gonorrhea
 - Monilial vaginitis*

Rationale

Correct answer: c.

Gonorrhea is the major cause of PID, infertility, ectopic pregnancy, and chronic pelvic pain. Chlamydia also increases the risk of infertility and ectopic pregnancy but not with the aggressiveness of gonorrhea. *Monilial vaginitis* is a relatively harmless overgrowth of normal vaginal flora brought about by factors such as antibiotic use, changes in hormone levels as in pregnancy, and stress. Herpes is a lifelong problem because there is no cure but it is not a major cause of PID, infertility, ectopic pregnancy, or chronic pelvic pain.

22. When explaining the importance of treatment, the nurse tells the client that arthritis, dermatitis, pericarditis,

(continued)

endocarditis, or meningitis can result from which STI if it is not treated?

- a. Chlamydia
- b. Herpes
- c. Gonorrhea
- d. PID

Rationale

Correct answer: c.

Gonorrhea, if not effectively treated, can cause severe disseminated infection causing problems such as arthritis, dermatitis, pericarditis, endocarditis, or meningitis. Chlamydia is the most common STI and it increases the risk of ectopic pregnancy and infertility. Herpes is not curable; antiviral medications are used to suppress outbreaks of the disease and to shorten their duration. PID can be caused by gonorrhea and hence lead to the infections noted but it is not necessarily the cause of PID. Therefore, it cannot be said that untreated PID can lead to these complications.

23. A client for whom a FTA-ABS test is ordered asks the purpose of the test. The nurse's response should be based on the fact that this test is used to confirm the diagnosis of which STI?
- a. Gonorrhea
 - b. Syphilis
 - c. Chlamydia
 - d. Herpes

Rationale

Correct answer: b.

VDRL is a basic serologic screening test for syphilis. Because the VDRL can be positive for reasons other than syphilitic infection, a more specific serologic test such as a FTA-ABS or a rapid plasma regain (RPR) test is done to confirm the diagnosis. Gonorrhea, chlamydia, and herpes are all diagnosed based on culture.

24. Which statement made by a client in a clinic waiting room requires correction? Mark all that apply.
- a. You only have to worry about tetanus if you injure yourself on a rusty nail.
 - b. Even if you have tetanus you still need immunizations for the rest of your life.

- c. Tetanus occurs today only in underdeveloped countries.
- d. TIG reverses or prevents the S&S of tetanus.

Rationale

Correct answers: a, c, and d.

Clostridium tetani, the organism that causes tetanus, is found in soil and dust. Getting a puncture wound from a rusty nail does put one at risk for tetanus, particularly if the nail was in the soil, because the resulting wound is a deep flesh wound and the organism is an anaerobe and therefore more likely to infect a deep wound. Tetanus occurs everywhere in the world even developed countries because the organism forms spores, which can lie dormant for long lengths of time and people do not all receive the required immunizations to protect against the disease. TIG neutralizes the neurotoxin, which causes the S&S of tetanus but only the toxin that has not already attached to nerve cells. Therefore, it does not prevent all S&S or reverse existing S&S.

25. Which instructions should be given to clients when prevention of Infection with *E. coli* O157:H7 is the goal? Mark all that apply.
- a. Cook all hamburgers to medium or well done.
 - b. Wash green, leafy vegetables carefully.
 - c. Stay away from persons with the disease.
 - d. Avoid contact with sick farm animals.
 - e. Do not swim where sewage may have escaped into the water
 - f. Drink pasteurized, not raw, milk.
 - g. Wear gloves when changing cat litter boxes.

Rationale

Correct answers: a, b, c, e, and f.

E. coli O157:H7 can be transmitted by ingestion of undercooked contaminated hamburger, contaminated green, leafy vegetables, direct contact with infected persons, by swimming in or drinking sewage contaminated water, or by drinking contaminated raw milk. The organism is found in the GI tracts of healthy cattle, goats, and deer so avoiding contact with sick farm animals does not prevent transmission. The organism is not found in cat urine or feces so precautions in handling soiled litter do not prevent transmission.

Test Plan Category:

Physiological Integrity

| ▶ Infection | 1043 | | |

CELL INJURY

The three most basic causes of cell injury are

- deficiency—lack of a substance essential to the cell,
- intoxication or poisoning—presence of a substance (toxin) which impairs cell function; toxins may be endogenous (made within the body) or exogenous (from outside the body), and
- trauma or physical injury—damage to the cell's structure.

These in turn may be the result of factors such as hypoxia, chemicals, physical agents such as heat, cold, radiation, electric current, and mechanical force, infectious agents, immune injury, genetic defects, nutritional imbalances, and aging.

EFFECTS OF CELL INJURY

Reversible Effects

- Water accumulation in the cell.
- Fat accumulation in the cell and enlargement of the organ—commonly seen in liver, heart, and kidney.
- Residual body accumulation in the cell—remains of phagosomes (that ingest invading microorganisms and damaged cell organelles, number increases with age).
- Hyaline change in cell—presence of hyaline in or between cells—commonly seen in damaged arterioles, renal tubule cells, liver, and nerves.

- Use of an alternate metabolic pathway: when glucose is lacking; cells burn protein for energy.
- Change in cell size or number
 - Hypertrophy: Enlargement of cells and organs as a result of increased demand, for example, cardiac hypertrophy and muscle hypertrophy.
 - Hyperplasia: Increase in the number of cells through cell division, in response to demand.
 - Atrophy: Shrinking of cells and organs as a result of decreased demand. Types of atrophy are
 - disuse atrophy (due to reduced workload, neurological or hormonal stimuli) and
 - pressure atrophy (decrease in size due to long-term pressure).
 - Apoptosis: Decrease in the number of cells as a result of self-destruction.
 - Organelle changes: Increase in the number of specific organelles to meet a functional demand; this occurs over the long term.

Irreversible Effects

Damage to the cell membrane or the membranes of the organelles is a primary cause of irreversible cell injury.

Irreversible cell injury can result in either the cell continuing to function at less than a normal level or in necrosis (cell death).

Types of necrosis

- Coagulation necrosis: This is characterized by initial appearance of a firm area with the structure of normal tissue even though cells are dead; subsequently the area is broken down and cleared by phagocytes. It is common when cells die due to anoxia or toxic injury except in the brain. Examples: gangrene, caseous necrosis seen in TB.
- Liquefaction necrosis: This is characterized by an initial liquid area of dead cells. It is seen in the death of nervous system cells due to anoxia and in death of cells associated with bacterial infections.

Calcification

- Calcification refers to the deposition of calcium in cells.
- It occurs at the sites of necrosis regardless of type; can cause tissue to be brittle and rigid; can interfere with function, for example, calcification of heart valves can prevent proper opening and closing and in arteries can result in loss of elasticity.
- It may occur in normal tissues such as lung, kidney, gastric mucous membranes, and arteries due to hypercalcemia. No effects are seen unless the deposits are very large.

Variation in tissue susceptibility to damage

- Ischemia (decreased blood flow)—CNS 5–10 minutes, Liver and kidney 60 minutes.

- Ionizing radiation—actively dividing cells' DNA in most susceptible.
- Viruses only affect certain types of cells.

Clinical Alert

The time for which a tissue can withstand ischemia without damage determines the window within which a problem with blood flow needs to be identified and corrected and in which transplants must be done.

INDICATORS OF CELLULAR INJURY

- Decreased function: e.g. change in urine specific gravity when kidneys cannot concentrate urine.
- Release of cell constituents such as potassium and intracellular enzymes such as CPK, GGT.
- Change in electrical activity as on an ECG, EEG, and EMG.
- Direct examination of tissues/cells.

INFLAMMATION

Acute Inflammation

- An acute inflammation is a nonspecific response, i.e., a variety of different initiators (triggering events) produce same vascular and cellular responses.
- Initiators include substances released from injured cells, direct stimulation of mast cells such as from cold or trauma, microbial products, complement activation, exposure of basement membrane or connective-tissue components, deposition of antigen—antibody complexes, and disruption of vascular integrity.
- Initiators activate a variety of chemical mediators, which in turn elicit the vascular and cellular events that comprise the inflammatory response.
- Chemical mediators can be either cell-derived or plasma-derived:
 - Cell-derived chemical mediators include histamine, which is released from mast cells and promotes vasodilation and increased vascular permeability, and also leukotrienes and prostaglandins, which are released from phagocytes and mast cells in the damaged area.
 - Plasma-derived mediators are mostly formed from inactive proteins circulating in the plasma as a result of a cascade (sequence of activation events). The one cascade involved solely with inflammation is the kinin cascade. Bradykinin, one of its components, contributes to pain.

- Acute inflammation is a local response with five classic signs: redness, heat, swelling, pain, and loss of function.
- Components of the inflammatory response
 - Vascular component: increased blood flow to damaged tissue and an increase in capillary and venule permeability.
 - Cellular component—movement of leukocytes, which can inactivate bacteria and remove debris, into the tissue spaces of damaged area.

These two components result in exudate formation, which is the movement of fluid with suspended substances and cells into the tissue spaces of the damaged area.

Process of exudate formation

- Hyperemia—increased blood flow occurs as a result of dilation of arterioles and precapillary sphincters, which reduces vascular resistance. Hyperemia causes the area to become red and hot.
- Tissue fluid formation (movement of fluid out of the vascular system into the tissues) increases along the capillary because of the increase in pressure from the increased blood flow. Two other factors that further contribute to formation of tissue fluid are:
 - stasis of blood flow in the capillaries as a result of increased viscosity of blood secondary to fluid being lost into tissue and
 - increased vascular permeability as a result of contraction of the endothelial cells of the venules, which results in spaces between them through which fluid can pass out of the venule.
- Formation of tissue fluid causes swelling and pain.

Benefits of exudate formation

The formation of exudate

- dilutes toxins,
- increases pain as a result of swelling thereby limiting use and preventing further damage,
- allows antibodies to enter the tissues from the blood stream, and
- brings proteins to the damaged tissues, which facilitate phagocytosis.

Types of exudates

Exudates range from thin, and consisting mostly of water, to thick, and consisting of large amounts of fluid, proteins, cellular debris, and blood. The type of exudate formed depends on the nature of the inflammation. Some inflammations and the type of exudates formed in them are:

- Serous—inflammation in response to mild injury; exudate is watery because the vascular permeability is not increased enough to permit the escape of protein from the capillaries. Example, fluid in blisters of a mild sunburn
- Purulent or suppurative—inflammation associated with more severe injury, exudate is thick, white or greenish pus;

when localized called an abscess and when diffused called cellulitis.

- Hemorrhagic—inflammation seen in severe injury; capillary damage allows RBCs to escape into tissue spaces.

Leukocytes and the acute inflammatory response

- Initially large numbers of neutrophils arrive at the site of injury; peak at 6–12 hours; then the number declines over the next 12–24 hours.
- Meanwhile mononuclear cells (monocytes) or macrophages begin to increase until they peak at about 5 days.
- In viral rickettsial infections and acute dermatitis—lymphocytes predominate
- Allergies and some parasites—eosinophils predominate

Phagocytosis

- Kills microorganisms.
- Destroys or inactivates toxic agents.
- Degrades macromolecules.

Opsonization enhances phagocytosis—opsonins coat particles to be phagocytized and ease binding to the phagocyte.

Systemic effects of inflammation

S&S: Fever, anorexia, increase in deep sleep, rapid weight loss, residual weakness. Leukocytosis is caused by two- to threefold rapid increase in WBCs on differential with bacterial infection; ischemic damage causes neutrophilia, viral infections cause lymphocytosis, and allergic reactions cause eosinophilia.

Although the inflammatory response is protective, it can also cause tissue damage as in glomerulonephritis in which immune complexes are deposited in the renal basement membrane and cause an inflammatory response. Since the immune complexes cannot be phagocytized because of their attachment to the basement membrane, the result is release of substances from the phagocyte that can damage the membrane and can lead to renal failure. Thus, the challenge is to limit the response sufficiently to prevent tissue damage while maintaining its protective function.

Chronic Inflammation

- Chronic inflammation differs from acute in terms of time and nature of response
 - subacute lasts for more than 1 week while
 - chronic lasts for more than 6 weeks.
- It begins with an acute inflammatory response but the injurious agent is not destroyed. Its long-term presence appears to stimulate the immune response.
- Types of chronic inflammation are
 - nonspecific: diffuse accumulation of macrophages and lymphocytes at site of injury and
 - granulomatous: granulomas form (round masses of transformed macrophages surrounded by lymphocytes and fibroblasts; may be central mass of necrotic tissue

containing the injurious agent (foreign body or bacterium); seen in TB. Cellular response dominates; not the fluid exudative response. There is massive buildup of cells, usually macrophages and lymphocytes. Injurious agent may be minimally invasive bacteria, fungi, parasites, or foreign bodies insoluble in body fluids such as talc.

- Chronic inflammation causes progressive tissue destruction, loss of function, and scarring.

HEALING

Four components of the healing process:

- Regeneration—replacement of parenchyma (functional cells of an organ)
- Repair—replacement of damaged tissue with fibrous scar tissue
- Revascularization—development of vessels to provide bloodflow to new tissue
- Reepithelialization—growth of protective epithelium over damaged surfaces

Regeneration

- Regeneration occurs by mitosis.
- The ability to regenerate varies according to the tissue type.
 - Labile tissues: Cells are continually dividing to replace those lost through normal processes, for example, epithelia of skin and mucous membranes, red bone marrow, and lymphoid tissues; regeneration is easy and rapid.
 - Stable tissues: Cells divide slowly after growth is complete but can increase the rate of mitosis if damage occurs, for example, liver, and fibroblasts and osteoclasts of connective tissue. Regeneration leads to return of function if there is undamaged stroma (supportive connective tissue and blood vessels). If stroma is damaged, regeneration may be disorganized resulting in some functional loss.
 - Permanent tissues: No cell division after growth is complete. Examples nervous, cardiac, and skeletal muscle tissue; lost cells are replaced with scar tissue leaving functional impairment.

Repair

- Repair refers to the formation of scar tissue by fibrosis.
- The main event is the production of collagen fibers by fibroblasts. Collagen formation occurs in the exudates of the acute inflammatory response changing it into ground substance or matrix, which is the intercellular material of the scar. Clots must be removed by phagocytosis before healing can be completed. Organization refers to both phagocytosis of the clot and its replacement with scar tissue.
- Collagen is weak until about 5 days postinjury, then rapidly and steadily increases in strength by means of cross-links between fibers. By 3 months its maximum strength is achieved which is 70–80% of normal.

Revascularization

Revascularization is also called angiogenesis. As new blood vessels develop, the exudate in which they form appears pink and granular and is called granulation tissue; it is essential to scar formation. New vessels develop from intact vessels adjacent to the damaged site. They begin as endothelial buds which gradually grow into channels through which blood can flow; finally, they differentiate into arterioles, venules, or true capillaries. Lymphatic drainage is also reestablished although later and more slowly than blood supply. Finally, the number of blood vessels in the damaged area is reduced as the metabolic demands associated with healing end. Thus, the scar appears pink and then gradually fades as the blood flow diminishes.

Reepithelialization

A zone of active mitosis develops just at the back of the wound edge and newly formed cells and older cells in front of them slide over the wound surface. When cells from the sides of the wound meet, the newly divided cells begin to move upward and then differentiate into specialized cell types that were lost.

Types of Wound Healing in the Skin

- Primary healing or healing by first intention—Occurs in incision-type wounds with minimal damage and closely approximated edges. Melanocytes are not replaced, so area over scar is pale and does not tan.
- Secondary healing or healing by second intention—Occurs in wounds whose edges are not closely approximated, for example, an ulcer. Secondary healing is similar to primary but it takes longer; much more granulation tissue is needed to fill the wound; and wound contraction occurs. Wound contraction is the drawing in of the wound edges toward the center after granulation tissue forms. This process starts 2–3 days postinjury and can continue for weeks reducing the size of the wound up to 80%.

Table 33–1 discusses the healing characteristics of the tissues in the body.

Conditions Essential for Good Healing

- Site of injury must be free of debris.
- Wound edges need to be immobilized to allow tissues to join across area of injury.
- Adequate blood supply to site of healing.
- Adequate protein, zinc, and vitamin C.

Complications of Healing

- Contracture
 - Exaggerated contraction of maturing collagen, mostly affecting large wounds which results in distortion and limited mobility. Example: contracture following burns of the

Table 33–1 Tissue and Healing Characteristics

| Tissue | Healing Characteristics |
|--|--|
| Epithelial | Readily regenerates except for respiratory epithelium in which scar tissue forms if the damage is more than superficial |
| Connective tissue | Healing is slow because of limited blood supply |
| <ul style="list-style-type: none"> • <i>Bone</i> | There are 3 stages: Stage 1—Phagocytes clear debris; granulation tissue forms; osteoblasts (bone formers) migrate to site. Takes 4–5 d Stage 2—Osteoblasts form collagen and cartilage (soft callus) in the break and then ossify it into hard callus, which is structurally weak. Takes 3 wks Stage 3—Osteoblasts and osteoclasts (bone dissolvers) work together to model the large mass of hard callus into normal shape. May take many months/years; bone has normal strength during remodeling |
| <ul style="list-style-type: none"> • <i>Tendons and ligaments</i> | Requires close approximation of wound edges; if not held tightly together or edges are irregular scar tissue forms resulting in a weak area with reduced function |
| <ul style="list-style-type: none"> • <i>Cartilage</i> | Heals by fibrous repair and the result is some degree of reduced function |
| <ul style="list-style-type: none"> • <i>Adipose tissue</i> | Fat cells do not divide but precursor cells differentiate to form replacement tissue |
| Glandular tissue | Most regenerate well although with extensive injury, new tissue may be disorganized with some impairment of function. Parathyroids have limited ability to regenerate; cells of the glomerulus, Bowman's capsule, adrenal medulla, and posterior pituitary do not regenerate |
| Nervous tissue | No replacement of neurons occurs; injured cells are replaced with nonfunctional neuroglia. If part of a myelinated neuron is lost in the peripheral nervous system, regeneration occurs slowly over weeks if supporting tissue and Schwann cells remain intact but no sensory receptors are replaced so motor function may be restored but there is sensory loss |
| Muscular tissue | Cardiac and skeletal muscle cells do not divide and produce new cells; healing is by fibrous repair resulting in loss of contraction strength but this is compensated for by hypertrophy of remaining cells. If only a portion of a muscle fiber is injured some regeneration may occur |

skin of the ankle can result in reduced motion of these parts.

Contracture causes stricture or narrowing in tubular organs, for example, healing following gonorrheal infection in the oviducts can cause narrowing which prohibits an ovum from reaching the uterus.

- Adhesions

Joining of serous membranes, which normally move freely against each other, due to organization of inflammatory exudates. Risk is greatest with trauma to abdominal organs, heart, and lungs.

- Dehiscence

Breaking open of a healing wound usually as a result of pressure on the wound.

Abdomen is the most common site of dehiscence with paroxysms of coughing, vomiting, or diarrhea increasing risk.

- Keloids

Irregular masses of scar tissue protruding from the skin that result from overproduction of collagen.

Most common among young female blacks from Africa or the Caribbean and occur most frequently on the upper body.

INFECTION

Infection is the invasion and proliferation of microorganisms (bacteria, fungi, viruses, and parasites) in body tissues. All infections cause inflammation but not all inflammations are due to infections.

Terminology Related to Infection

- *Virulence*—ability of a microorganism to produce infection.
- *Pathogen*—microorganism that causes infection in a healthy person.
- *Opportunistic pathogen*—microorganism that causes infection only in a susceptible person.
- *Resident flora*—microorganisms that normally live in a specific area of the body, for example, *Escherichia coli* are normal in the gut; *Candida albicans* are normal in the vagina; *Staphylococcus aureus* are normal in the nasal passages and on the skin. Resident flora cause infection when they move to other parts of the body.
- *Transient flora*—microorganisms that attach loosely to the skin and can be removed by washing.

- *Colonization*—process by which strains of microorganisms become resident flora in an area of the body.
- *Local infection*—infection limited to a specific area of the body.
- *Systemic infection*—microorganisms spread and damage a variety of body areas.
- *Bacteremia*—microorganisms found in the blood when it is cultured.
- *Septicemia*—bacteremia with a systemic infection.
- *Nosocomial infection*—infection associated with health care provided in a health care facility; endogenous if the infection spreads from one area of a client to another; exogenous if the source of the infection is the health care environment or personnel.
- *Iatrogenic infection*—type of nosocomial infection that is the direct result of a diagnostic or therapeutic procedure.

Practice Alert

Most common sites of nosocomial infection: urinary tract, respiratory tract; bloodstream; and wounds.

Most common infecting organisms: *Escherichia coli*, *Staphylococcus aureus*, and *Enterococci*.

Most common type of source: exogenous.

Proper hand washing by health care providers is essential to prevent exogenous infection; proper washing of client's hands is essential to the prevention of endogenous infection.

Chain of Infection

- *Etiologic agent* (causative microorganism).
- *Reservoir* (source of microorganism; carrier is a human or animal source that does not have signs of disease).
- *Portal of exit from the reservoir* (respiratory tract via coughing, sneezing, breathing, and talking; GI tract via saliva, vomit, and feces; urinary tract via urine; reproductive tract via vaginal or penile discharge and semen; blood via open wounds, needle puncture sites; tissue via drainage from a cut or wound).
- *Modes of transmission*

There are three methods of transmission:

- Direct transfer of microorganisms from person to person through body contact or direct droplet spray.
- Indirect by vehicle (any substance that serves as an intermediate means to transport and introduce a microorganism into a susceptible host; examples include water, blood, serum and fomites (inanimate objects such as tissues, toys, and hospital equipment) or by vector (animal or insect that transports infectious agent).

—Airborne by droplets or dust, which travel on air currents to susceptible host.

- *Portal of entry*—breaks in the skin as well as the usual routes of exit.
- *Susceptible host*—one at risk for infection; compromised host is one at increased risk. Risk results from very young or very old age, chronic illness, suppressed immunity due immunosuppressant drugs, radiation, immunodeficiency diseases; stress with prolonged blood cortisone levels, which suppress inflammatory response and deplete energy, and inadequate nutrition.

Factors Determining the Likelihood of Getting an Infection

- Number of microorganisms—the greater the number, the more likely it is that infection will occur.
- Virulence of the microorganism—the greater the virulence, the more likely the occurrence of infection.
- Ability of the microorganism to enter the body—the greater the ability, the more likely the occurrence of infection.
- Susceptibility of the host—the more susceptible, the greater the likelihood of infection.
- Ability of the microorganism to live in the host's body.

Defenses Against Infection

- Nonspecific defenses
 - Intact skin and mucous membranes: first line of defense
 - Cilia and moist membranes that trap microorganisms and other foreign particles
 - Body fluids such as saliva, highly acidic gastric secretions, acidic vaginal secretions after puberty, and tears
 - Inflammatory response
- Specific defenses
 - Antibody-mediated defenses (humoral immunity based on B lymphocytes and mediated by antibodies [immunoglobulins] produced by B cells).
 - Cell-mediated defenses (cellular immunity based on the T-cells [helper T cells (help immune system), cytotoxic T cells (kill microorganisms), suppressor T cells (suppress function of helper and cytotoxic)] released by lymphoid tissues on exposure to an antigen).

Specific defenses are based in the immune system.

Protection from immunoglobulins from mother protects infants for only 2–3 months.

Signs of Local Infection

- Swelling
- Redness
- Pain or tenderness on touch or movement
- Heat

- Loss of function depending on site and extent
(Note: These are the five classic signs of inflammation because inflammation always accompanies infection but infection is not always present with inflammation.)

Signs of Systemic Infection

- Fever
- Increased pulse and respiratory rates if fever is high
- Malaise
- Anorexia and sometimes nausea and vomiting
- Enlarged, tender lymph nodes that drain infected area
- Elevated WBC count ($>11,000/\text{ml}$)
- Increase in specific WBCs on differential depending on type of infection
- Elevated ESR
- Positive cultures

NEOPLASIA

CELL CYCLE

- The cell cycle describes the life of a cell.
- It starts at the midpoint of mitosis when a given new cell is being formed and ends at the point when two daughter cells are being formed from that cell.
- The five phases of the cell cycle are
 - G1: postmitotic period of cell growth characterized by development of RNA and protein.
 - G0: resting stage.
 - S: period of DNA synthesis resulting in two sets of chromosomes in the nucleus.
 - G2: premitotic time of RNA and protein synthesis.
 - M: cell splits into two daughter cells.
- From G1 phase, the cell may enter either G0 phase or S phase.
- Length of cycle varies with type of tissue, from 1 hour to 400 hours (liver)—difference results from time spent in G1 and G0.
- Permanent cells such as neurons never enter the cell cycle because they do not replicate.
- Chemotherapeutic drugs act at different stages of the cell cycle.

NORMAL AND ABNORMAL GROWTH

- Aplasia (aplastic growth)—Lack of organ development.
- Hypoplasia (hypoplastic growth)—Inadequate development resulting in immature structure and deficient function.
- Atrophy—Reduction in cell size due to decreased use or demand.
- Hypertrophy—Enlargement of cells that cannot divide in response to use or demand.
- Regeneration—Production of new cells to replace those lost to injury.

- Hyperplasia—Production of new cells by mitosis in response to increased demand, for example, after a nephrectomy, some cells of remaining kidney become hypertrophied and others become hyperplastic and with infection, lymph nodes become hyperplastic and hence lymphadenopathy occurs.
- Metaplasia and dysplasia—Structurally or functionally abnormal tissue due to altered tissue growth in response to intense or prolonged demand, most often affect epithelial tissues.
 - Metaplasia: Conversion of one cell type to another, for example, respiratory epithelium of smokers changes from ciliated pseudostratified to a thicker, well-organized stratification free of cilia and goblet cells that produce mucus so it is more resistant to chronic irritation but does not clear the respiratory tract of inhaled particles and microorganisms as well.
 - Dysplasia: Occurs with more severe and prolonged irritation; dysplastic tissue is disordered and cells vary in size and shape; often precedes neoplasia; some forms of dysplasia are known as precancerous lesions.
- Neoplasia—Overgrowth of tissue resulting in a neoplasm, which is a group of cells with an irreversible abnormal growth pattern. May be benign or malignant.

CHARACTERISTICS OF A BENIGN NEOPLASM

- Benign neoplasm is composed of cells resembling the tissue of origin.
- It grows slowly by expansion.
- It does not recur or metastasize.
- It does not destroy tissue unless it compromises blood supply by pressure.
- It does not cause systemic symptoms or death unless its location interferes with the function of a vital organ such as the brain or the heart.

CHARACTERISTICS OF MALIGNANT NEOPLASMS (CANCER)

- Malignant neoplasms are composed of primitive, undifferentiated cells with limited resemblance to the tissue of origin (anaplastic cells).
- They grow rapidly expanding at periphery and invading and destroying surrounding tissues.
- They tend to recur.
- They metastasize (spread by blood and lymph to distant sites) to create secondary tumors, which in some cases may result in the first signs/symptoms of disease.
- They cause systemic symptoms such as altered taste, anorexia, weight loss, weakness, and ultimately death.

Clinical Alert

Cancers vary in their degree of anaplasia. Generally, the greater the anaplasia, i.e., the more primitive and undifferentiated the cells are, the more malignant the tumor is.

Cancers are not necessarily invasive and metastatic to the same degree—a tumor may be highly metastatic but minimally invasive, minimally metastatic but highly invasive, highly invasive and highly metastatic, or minimally invasive and minimally metastatic.

CLASSIFICATION OF NEOPLASIA

- *Carcinoma*—malignant tumor arising in tissues derived from the ectoderm or endoderm, for example, cancers of the skin, epithelial lining of the respiratory tract or GI tract, or breast.
- *Sarcoma*—malignant tumor arising in tissues derived from the mesoderm, for example, cancers of muscle, bones, or connective tissue.

Specific terminology indicating additional information about the tumor:

- Basal cell carcinoma—cancer of the deepest layer of the skin.
- Squamous cell carcinoma—cancer of skin cells nearer to the surface.
- Adenocarcinoma—cancer of gland cells.
- Leukemia—cancer of the blood.
- Myelomas—cancer of the bone marrow.
- Lymphomas—cancer of the lymphatic system.
- Chondrosarcoma—cancer of cartilage.

CHARACTERISTICS OF MALIGNANT CELLS

- Cell membrane lacks contact inhibition (continues to grow even when touches another cell).
- It does not form intercellular connections.
- Number of free ribosomes is increased.
- Proteins normally synthesized during fetal development are synthesized.
- Fewer enzymes are produced.
- Simpler metabolic pathways are utilized.
- Nucleus is enlarged with abnormal chromosomes and increased amounts of DNA.
- Cells are anaplastic, i.e., primitive and undifferentiated.
- They replicate more quickly than normal—often do not enter the G₀ phase of the cell cycle—just keep dividing until blood or nutrient supply runs out.
- They cannot perform functions of the tissue of origin.
- They do not “age” or “die” on time.

CARCINOGENESIS (ONCOGENESIS)

Carcinogenesis refers to the change of normal cells into malignant cells.

Two distinct processes are involved in carcinogenesis:

- *Initiation*—Occurrence of a reversible basic change in the cell, probably in DNA, that creates the potential for tumor development.
- *Promotion*—Exposure to factors which greatly favor tumor growth when initiation has occurred; promoters do not result in tumors in the absence of initiation.

INITIATORS AND PROMOTERS

- Genetic factors
- Environmental chemical and toxic substances
 - nitrosamines in food preservatives
 - benzopyrene in cigarette smoke
 - methylaminobenzene in fabric dyes and food coloring
 - aflatoxin from fungi on improperly stored peanuts and corn
 - asbestos, cobalt, lead, and cadmium
- Tobacco
- Alcohol
- Diet
- Radiation
 - solar radiation (sun)
 - ionizing radiation (radioactive materials, X-ray)

- Viruses
 - Hepatitis B and C viruses are associated with liver cancer
 - Human papilloma virus (HPV) causes cervical cancer
 - Epstein-Barr virus is associated with nasopharyngeal cancer and AIDS-related Burkitt's lymphoma
 - Human T-cell leukemia virus is associated with some leukemias
 - Cytomegalovirus is associated with Kaposi's sarcoma
- Immunologic defects
- Psychosocial factors

Most tumors occur in tissues with a high rate of cell reproduction such as epithelia and bone marrow. Permanent tissues such as skeletal muscle and neurons almost never develop tumors.

TUMOR-SPECIFIC ANTIGENS

Tumor-specific antigens (TSAs) form a unique set of antigens found on a tumor's cells. Presence of TSAs suggests "immune surveillance," i.e., that the immune system is capable of recognizing and destroying tumor cells.

TUMOR STAGING

- Tumor staging is the categorization of a cancer based on its potential for invasion and metastasis.
- It is used to describe solid tumors.
- It aids in assessing prognosis and selecting treatment.
- There are many staging systems; in all of them, stage I means growth restricted to primary site and stage IV indicates extensive invasion and metastasis.
- TNM is an international staging system in which T (tumor size), N (regional lymph node involvement), and M (presence of metastasis) are described by subscript numbers from 0 to 3 with 0 meaning none and 1, 2, and 3 meaning increasing disease. Example: for a client with a T1N0M0 breast cancer, there is a single small primary tumor with no involvement of lymph nodes and no metastasis; a T3N2M1 tumor is a large primary tumor with multiple lymph nodes involved and one area of metastasis such as to the bone.

TUMOR GRADING

- Tumor grading is the categorization of a tumor based on histological characteristics of the tumor identified after biopsy.
- Grade 1 has highly differentiated cells with few mitoses and a good prognosis, grades 2, 3, and 4 are progressively less differentiated with more mitoses and a poorer prognosis.

TUMOR EFFECTS

- Tissue destruction secondary to pressure on adjacent cells or blood vessels, release of destructive enzymes, or invasion of adjacent structures, for example, cervical cancer causing kidney failure.
- Obstruction from growth of tumor within a lumen as in esophageal mucosal cancer or from external pressure as in ureteral obstruction from prostate, rectal, or cervical tumors.
- Infection secondary to general suppression of immune system with some cancers; bone marrow suppression that decreases neutrophils and monocytes; disruption of skin or mucous membrane by the tumor; blockage of ureters, GI tract, or respiratory passages causing stagnation which favors bacterial growth.
- Anemia secondary to chronic bleeding from the tumor; bone marrow suppression which also causes clotting deficits due to decreased platelets; autoimmune destruction of circulating RBCs with some tumors and particularly in the elderly; decreased availability of vitamin B12 with GI tumors; or decreased stimulation of RBC production due to decreased erythropoietin with renal tumors.
- Pain, intermittent or constant, due to invasion and destruction of tissue especially bone with fractures, stretching of hollow organs by obstruction, or compression of tissue.
- Cachexia—Syndrome of generalized weakness, fever, wasting, anorexia, and pallor seen in advanced malignancy.
- Hormonal effect
 - Hypersecretion of affected glands occurs with benign tumors and with well-differentiated malignant tumors; hyposecretion with anaplastic tumors.
 - Ectopic secretion may occur, i.e., tumors of nonendocrine tissue can develop ability to secrete functional hormone.

Assessment Alert

Symptoms of hormone excess will present in clients with ectopic secretion of hormones.

Lung cancers may secrete insulin, parathormone, ADH, and ACTH.

Breast, ovarian, and renal cancers may secrete parathormone.

Parathyroid and renal cancers may secrete ACTH.

- Paraneoplastic syndromes—Tumor-related effects that are not well understood, for example, the occurrence of leg vein thrombosis with pancreatic or lung tumors; muscle and peripheral nerve problems with particular lung or breast tumors; increased intracranial pressure from cancers not within the skull.

TUMOR TREATMENT

- **Surgery**—most successful when tumor is encapsulated and can be removed with minimal disruption of normal tissue; tumors with irregular edges require more removal of normal tissue. If there is node involvement, lymph channels and nodes that drain the tumor site are removed progressively away from the site until no further tumor is detected. Surgical removal of detectable tumor does not guarantee that no microscopic amounts of tumor remain; surgical manipulation may result in embolization of tumor cells.
- **Radiation therapy**—uses destructive doses of ionizing radiation from radioactive isotopes such as cobalt-60 and devices that produce X-rays to irradiate and destroy tumor cells; also destroys normal cells especially those that are rapidly dividing; produces heat in skin as it passes through and can cause burns (see section “radiation therapy”).

- **Chemotherapy**—toxic chemical substances or hormones, which interfere with the cell’s metabolism or division are used to destroy the tumor. Tumors can manifest tolerance to chemotherapy, i.e., antitumor effects are good initially and then diminish (see section “chemotherapy”).
- **Immunotherapy**—uses the immune system to destroy the tumor.
- **Combination therapy**—uses two or more of the above types of treatment to maximize tumor kill and ideally minimize side effects by limiting the amount of each.

Clinical Alert

Each tumor type differs in its susceptibility to the different types of therapies; therapies used depend on the tumor’s susceptibility.

PATHOPHYSIOLOGY OF IMMUNITY

Types of hypersensitivity reactions

- Type I: immediate or anaphylactic hypersensitivity
- Type II: antibody-dependent hypersensitivity
- Type III: immune-complex-mediated hypersensitivity
- Type IV: cell-mediated, delayed-type hypersensitivity

IMMEDIATE OR ANAPHYLACTIC HYPERSENSITIVITY

The first exposure to the antigen, which is usually through skin or mucous membrane, causes no symptomatic reaction but the antigen has been recognized and IgE antibodies specific to it have been produced and have bound to mast cells throughout the body. This is called sensitization and can last for months. When the sensitized system next encounters the antigen, allergen binds to the antibodies causing release of chemical mediators from the mast cells. The result is a two-phase reaction: immediate and late.

- **Immediate phase**
 - Primarily due to histamine.
 - Occurs in 5–30 minutes and can be over in an hour.
 - Effects: increased vascular permeability; constriction of bronchial muscles and narrowed airways; increased secretion from nasal, bronchial, and gastric glands; hives, conjunctivitis, and rhinitis.

—Antihistamines can lessen early-phase effects by blocking the effects of histamine; epinephrine can block the actual response of mast cells.

- **Late phase**
 - Involves mediators that attract eosinophils and neutrophils, leukotrienes, prostaglandins, platelet-activating factor, and protein-digesting enzymes resulting in cellular infiltration and tissue damage.
 - Occurs in 2–8 hours and may last 2–3 days.
 - Corticoid steroids and NSAIDs block the late phase while leaving the early phase unaffected.

Localized Anaphylaxis

- Forms of localized anaphylaxis include allergic asthma, hay fever, eczema, and urticaria (hives).
- It develops after repeated exposure to low-dose antigen at a mucosal barrier.
- It is controlled by avoiding allergen or desensitization (injections of low but increasing doses of allergen, which increase IgG that removes antigen from the body fluids before it can interact with the mast cells).

Systemic Anaphylaxis

- Within minutes, widespread mast cell release of histamine causes pruritus, urticaria, wheezing, dyspnea,

which can progress to laryngospasm and suffocation. Circulatory shock from loss of fluid from the vascular tree also occurs.

- Triggers include drugs, especially antibiotics such as penicillin, insect venoms such as from bee or wasp stings, foods such as shellfish or peanuts, and desensitization injections of allergens.
- Rx: Parenteral histamine competitors such as epinephrine or isoproterenol.

ANTIBODY-DEPENDENT HYPERSENSITIVITY

Antibodies attach to the surface of cells such as RBCs or the glomerular basement membrane of the kidney and initiate a series of cytotoxic mechanisms involving K cells, the complement cascade, and antibody Fc components which destroy the cells.

This reaction in which antibodies are turned against self-cells is the mechanism underlying autoimmune diseases such as myasthenia gravis.

IMMUNE-COMPLEX-MEDIATED HYPERSENSITIVITY

Immune complexes are aggregations of antigens and their antibodies. Large immune complexes, which are removed from the bloodstream by the liver and the spleen, are formed when there are equal amounts of antigen and antibody. When the amounts are unequal, smaller complexes are formed which are deposited in the vascular walls resulting in microthrombi formation and endothelial damage as well as an inflammatory response with basement membrane damage. If the problem is excessive amounts of antibody specific to a tissue, the immune complexes tend to be deposited in that tissue as seen in rheumatoid arthritis. If the problem is excessive antigen, they tend to be deposited in the area of exposure as with the lung in the pneumoconiosis.

CELL-MEDIATED, DELAYED-TYPE HYPERSENSITIVITY

Cell-mediated hypersensitivity is the primary cause of tissue damage in TB, contact dermatitis, acute and chronic transplant rejection, and in many fungal, viral, and parasitic infections.

The reaction requires antigen presentation and helper-T-cell sensitization to begin and then involves cytotoxic T cells, activated macrophages, K cells with their

antibody-dependent cellular toxicity (ADCC) action, and NK cells.

IMMUNE DEFICIENCY

PRIMARY DEFICIENCIES

- Primary deficiencies are often genetic.
- They manifest as chronic or recurrent infections in infants over a few months of age because of the inability to replace passive immunity received from mother during pregnancy with active immunity.
- B-cell deficiency: low or absent gamma globulin resulting in infections with viruses such as rubella, which are normally neutralized by antibody, or bacteria such as *H. influenzae* that require opsonization to be phagocytized.
- T-cell deficiency: results in chronic or repeated infections due to viruses, yeasts/fungi such as *Candida*, and/or intracellular bacteria such as *M. tuberculosis*.
- Severe combined immunodeficiency: autosomal recessive or X-linked inherited disorder in which both T-cell and immunoglobulin production and function are deficient.
- Without successful bone-marrow transplant, death occurs before 1 year of age from opportunistic infection due to the same organisms as in AIDS (*Pneumocystis carinii*, *Candida*, *Pseudomonas*, cytomegalovirus, and herpes simplex virus).

SECONDARY DEFICIENCIES

- T-cell-mediated immune response decreases with increasing age.
- Immune deficiency occurs with severe malnutrition.
- Severe burns result in diminished ability to combat bacteria such as *H. influenzae* or *Staphylococcus* that require opsonization for phagocytosis.
- Diabetes results in reduced inflammatory and specific immune responses.
- Leukemias, lymphomas as well as infections such as cytomegalovirus, TB, and coccidiomycosis can suppress immune function.
- Iatrogenic deficiencies (related to medical treatment) occur with immunosuppressant drugs used to prevent graft rejection, chemotherapy or radiation used to treat cancer, use of drugs such as some anticonvulsants, tranquilizers, antimicrobials, analgesics, which are toxic to immune system components, surgery and anesthesia which can depress B-and T-cell function and cause lymphocyte deficiency for up to a month, stress, and corticosteroids.
- HIV infection (see Chapter 32).

RADIATION THERAPY

- Radiation therapy is used as a curative or palliative treatment for cancer alone or in combination with surgery and/or chemotherapy.
- The goal is to kill tumor cells without damaging normal cells; therefore, total radiation dose is divided and given in varying patterns to allow normal cells to recoup. However, there is always some damage to normal cells.
- Different body tissues have different levels of radiosensitivity (potential susceptibility to injury from ionizing radiation and time needed for damage to occur). Tissues that are highly proliferative are most affected by radiation. Thus, effects are first seen in bone marrow, skin, and GI tract.
- Hypoxic tissues are resistant to radiation.
- Radiosensitizers are drugs that enhance the effect of radiation; radioprotectors help protect normal cells from damage.
- Side effects of radiation primarily affect tissues at the site of therapy and may be acute (affect tissues with rapid cell division and occur within days) or late (due to blood vessel or connective tissue damage and occur after months or years, e.g., skin atrophy, fibrosis or ulceration, cataracts, and pulmonary fibrosis). Most common acute side effects are port-area skin reactions (erythema which increases over 2–3 weeks and then fades or progresses to dry then moist desquamation along with temporary alopecia), fatigue, and bone-marrow suppression (occurs with almost all ports with recovery time dependent on the size of port and dose of radiation).

Practice Alert

Skin folds (intertriginous areas) such as axilla and groin are at high risk for skin reactions.

- Postradiation malignancies such as skin cancer, leukemia, non-Hodgkin's lymphoma, and sarcoma can develop.
- Monitoring for signs of bone-marrow depression (changes in laboratory values, infection, anemia, or bleeding) and for changes in weight at least weekly are critical nursing responsibilities.

INTERNAL RADIOTHERAPY (BRACHYTHERAPY)

- In internal radiotherapy, the radioactive source is placed in the body; the source may be sealed, for example, radioactive seeds inserted in prostate tumors, radioactive needles

placed in breast tumors, or unsealed, for example, radioactive iodine (I^{131}) ingested/injected for thyroid tumors.

- Sealed radiation source may be inserted and removed at each treatment or afterloaded and left in place for duration of treatment.
- Afterloading: The container is placed in the body in the OR with its position confirmed by X-ray; client is placed in a private room; and radioactive substance is inserted. Exact positioning of the implant is essential to radiate tumor and prevent damage to normal tissue.
- Both sealed and unsealed sources require radiation precautions to protect others from exposure. Exposure risk of unsealed sources varies with the specific isotope used and its mode of excretion from the body; for example, I^{131} is excreted from body fluids so there is exposure risk both from client and from contact with body discharges.

Practice Alert

- Time, distance, and shielding are the three essential elements in protection from hazardous radiation exposure. Minimize time with and maximize distance from clients with internal radiation sources.
- Remember a lead shield is not adequate protection against gamma rays.
- Follow guidelines from radiation safety officer carefully.
- Always wear dosimetry badge to measure radiation exposure.
- Rotate care of brachytherapy clients among the team of nurses.
- Never assign a pregnant nurse to care for a brachytherapy client.
- Trace doses of radiation used for diagnosis do not require special precautions.

EXTERNAL RADIOTHERAPY

- In external radiotherapy, the port (anatomic area that will receive the radiation) is marked in ink or tattoos.
- It is preoperatively used to decrease tumor size and eliminate stray cancer cells outside the operative area but

results in delayed healing of the parts of the surgical wound in the radiation-treated area.

- It is used postoperatively to eradicate any remaining tumor or subclinical disease.

Client teaching for self-care

Teach client to

- prevent irritation of skin over treated area: Cleanse area daily with mild soap and water (do not erase markings and take care to dry skin folds carefully); avoid irritating, rubbing clothes (cotton against skin is least irritating), use of per-

fumed soaps, ointments, powders, lotions, deodorants, heating pads, and hot or cold packs; use only an electric shaver; avoid scratching, vigorous rubbing or massage; also to avoid sun exposure when possible otherwise use sunscreen

- plan rest periods during the day and adequate sleep at night to combat fatigue
- eat a high-protein, high-CHO, and high-calorie diet and check weight weekly for loss
- take antiemetics and antidiarrheals as prescribed and eat a low-residue diet, for nausea and diarrhea associated with an abdominal port

For mucositis or xerostomia due to radiation involving the mouth or throat, teach as indicated under chemotherapy.

CHEMOTHERAPY

- Chemotherapy is used for the cure of cancer, long-term control of tumor growth, or for palliative shrinking of the tumor.
- Adjuvant chemotherapy (chemotherapy given along with either surgery or radiation) is designed to destroy any micrometastases.
- Chemotherapeutic agents that act on dividing cells are most effective when tumors are small and many cells are dividing; larger, slower growing tumors respond best to agents that act whether or not the cells are dividing.
- Mostly, chemotherapy involves a combination regimen because
 - different drugs attack tumor cells in different ways thereby increasing effectiveness,
 - risk of the tumor becoming resistant to therapy is decreased, and
 - different drugs produce toxicity in different organs and at different times after administration so larger amounts of chemotherapy can be given.
- Classifications of chemotherapeutic drugs include alkylating agents, antimetabolites, plant (vinca) alkaloids, antitumor antibiotics, and steroids.
- Doses of chemotherapy are usually based on body surface area (BSA), which is calculated using height and weight.
- Routes of administration are po, sc, IM, IV, topical, or direct instillation into bladder, peritoneum, CSF, or tumor bed, which allows high doses with less severe systemic effects. IV route often through a central VAD is most common.
- Side effects of chemotherapy, like those of radiotherapy, are seen first in tissues with rapid growth rates: bone mar-

row, GI epithelium, hair follicles, and the germinal epithelium of the testes. Fatigue and organ toxicities that are drug specific are also common. Table 33–2 discusses the side effects of chemotherapy.

- Some chemotherapy drugs are vesicants, i.e., cause severe tissue ulceration if they leak out of the vein into soft tissues

Practice Alert

Monitoring for IV infiltration when vesicant drugs are being administered is critical as is immediate treatment with appropriate antidotes and hot and cold applications to minimize tissue damage.

- Some chemotherapy drugs are associated with hypersensitivity reactions and specific precautions must be taken during administration.

Assessment Alert

The most serious complication of bone-marrow suppression (specifically neutropenia) is infection, with the most common sites being oropharynx, lungs, urinary tract, and skin.

Table 33–2 Side Effects of Chemotherapy

| Affected Tissue/Organ | Symptoms | Notes | Management |
|-------------------------|---|---|--|
| Bone-marrow suppression | Neutropenia (neutrophil count <1000/mm ³) | Each drug has a particular time at which maximum suppression occurs—for many drugs it is 7–10 d after drug administration | <p>Implement regimen to maintain skin and mucous membrane integrity</p> <p>Avoid injections, rectal treatments, and other invasive procedures such as urinary catheterization</p> <p>Avoid medications that mask pain and other signs of infection</p> <p>Minimize exposure to sources of infection: Good hand washing by staff; restrict contact with persons with colds or other infection; avoid or thoroughly wash and cook fruits and vegetables; avoid obviously infected items such as litter boxes, and used tissues</p> <p>Monitor WBC and neutrophil count and for signs of infection</p> <p>Report stat fever over 101 F or other signs of infection</p> <p>Obtain bacterial and fungal cultures of body fluids before giving antibiotics</p> <p>Administer antibiotics and colony-stimulating factors as ordered</p> |
| | Thrombocytopenia (Platelets <50,000/mm ³) | May be mild such as bruising or a nosebleed or major hemorrhage into brain or GI tract | <p>Minimize trauma by avoiding injections, rectal treatments, and other invasive procedures</p> <p>Avoid drugs which increase bleeding (ASA and NSAIDs)</p> <p>After venipuncture, apply pressure for 5 min to site</p> <p>Monitor platelet count</p> <p>Monitor for signs of bleeding</p> <p>Administer platelet Tx as ordered for count below 10,000/mm³, for active bleeding or before invasive procedures</p> <p>Use soft toothbrush; avoid flossing and dental procedures</p> <p>Use only electric shaver</p> <p>Avoid activities that present risk of trauma</p> |
| | Anemia | Signs of decreased tissue perfusion in any organ: fatigue, decreased endurance, headache, dizziness, tachycardia, and dyspnea | <p>Administer EPO and/or Tx as ordered</p> <p>Design energy-conserving plan with client</p> |
| GI tract | Stomatitis | Timing usually parallels bone-marrow suppression, i.e., 7–10 d after treatment | <p>Remove and clean dentures or brush teeth with soft brush after eating and at bedtime, then rinse with salt and water or a mouthwash containing <6% alcohol</p> <p>Floss daily unless contraindicated</p> |

(continued on next page)

Table 33–2 (continued from previous page)

| Affected Tissue/Organ | Symptoms | Notes | Management |
|--|--|--|--|
| | | | Do not wear dentures if they rub or are rough or if mouth is sore Lubricate lips and avoid irritants such as alcohol or tobacco Rinse every 2–4 hrs, increase fluid intake and use artificial saliva PRN for dry mouth Avoid spicy or acidic foods and use topical anesthetics and systemic analgesics PRN for sore mouth |
| | N&V | Typically peaks in first 12 hrs; may be followed by delayed nausea lasting 2–5 d Anticipatory N&V may also occur | Administer antiemetics Monitor fluid and electrolyte status |
| | Constipation and diarrhea | May be directly caused by drug but can be exacerbated by altered diet, opioid use, etc. | |
| Hair follicles | Alopecia | Amount of hair loss is dose and route-dependent; ranges from thinning of scalp hair to complete loss of all body hair; begins 2–3 wks after start of Rx; reversible with regrowth starting 1–2 mo after Rx and taking up to a year | |
| Ovaries/testes | Altered fertility: amenorrhea in young and menopause in older females; decreased sperm production and sperm and semen abnormalities in men | Most common with alkylating agents; fertility can be recovered but length and time for recovery depends on the drug and the dose; younger women more likely to recover than older | |
| Specific drug-related organ toxicities | | | Cryoprotectant drugs protect normal tissue and prevent some toxicities |
| Heart (cardiac cells) | EKG changes, heart failure over long term | Occurs with anthracycline agents | |
| Lungs | Pulmonary fibrosis | Occurs with bleomycin | |
| Liver | Hepatic toxicity | Occurs with high doses of many drugs | |
| Kidney | Nephrotoxicity | Occurs with cisplatin and high dose of methotrexate | |
| Urinary bladder | Hemorrhagic cystitis | Occurs with cyclophosphamide and ifosfamide | |

Practice Alert

Health care workers who handle chemotherapeutic drugs can be exposed to low doses and be at risk for their side effects including carcinogenicity and teratogenicity so following OSHA guidelines for safe handling of chemotherapeutic drugs is critical.

Most cytotoxic agents are metabolized or excreted within 48 hours although stool excretion can take a week.

Assessment Alert

Neutropenic clients do not exhibit a normal inflammatory response. Mild localized tenderness and fever over 101 F may be the only signs of severe infection and represent a medical emergency.

Client teaching for self-care

- Clarify goal of chemotherapy: cure, palliation, and adjuvant therapy
- Reinforce planned protocol, i.e., treatment intervals and duration
- Teach client about expected side effects and supportive interventions as shown in Table 33–2

HEMODYNAMICS

The heart, large blood vessels, and the microcirculation (capillary circulation) interact to keep all body tissues perfused with blood. Effective perfusion requires good cardiac pumping ability, an adequate amount of blood to be pumped, and ability of blood vessels to constrict and to dilate to maintain blood pressure.

- Heart rate
 - Increased by sympathetic and decreased by parasympathetic nervous system stimulation.
 - Sustained rate of >180 bpm increases work of heart and decreases time of diastole so there is less time for ventricular filling.
 - Cardiac muscle receives oxygenated blood during diastole so at high heart rates the heart muscle becomes ischemic.
- Stroke volume
 - Volume of blood ejected by the ventricle with each heartbeat.
 - Normal: 60–70 ml.
- Cardiac output (CO)
 - Volume of blood pumped by the ventricle per minute. (Heart rate \times stroke volume).
 - Normal: 4–6 l/min.
- Central venous pressure (CVP)
 - Pressure created by blood volume in the right side of the heart.
 - Normal: 2–4 mmHg.
- Systemic vascular resistance (SVR)
 - Resistance in the arteries and the arterioles against which the left ventricle must pump. As SVR increases, CO decreases.
 - Normal: 900–1400 dynes/sec/cm⁻⁵.
- Pulmonary vascular resistance
 - Resistance in the pulmonary arteries and the arterioles against which the right ventricle must pump.
 - Normal: 30–100 dynes/sec/cm⁻⁵
- Preload
 - As the amount of blood filling the ventricle during diastole increases, the force of contraction increases up to a critical point after which effective contraction decreases.
 - Preload is a function of the volume of blood filling the ventricle and the ability of the ventricle to stretch (ventricular compliance).
 - Right ventricular preload is measured by CVP (normal range 2–4 mmHg).

- Left ventricular preload volume pressure is measured as the pulmonary artery wedge pressure (PAWP) (normal range 5–12 mmHg).
- Afterload
 - Tension in the ventricular wall during systole.
 - As afterload increases, work required for the heart to pump blood increases.
 - Afterload is increased by any factor that opposes the ejection of blood from the ventricle, e.g., aortic or pulmonary stenosis, septal hypertrophy, vasoconstriction, and increase in blood volume or viscosity.
- Contractility (contractile force of the heart or inotropy)
 - Inotropy is increased by sympathetic nervous system stimulation and by drugs such as digoxin, dopamine, and amrinone.
 - Inotropy is decreased by factors such as acidosis and hypoxia.
- Hemodynamic parameters which reflect these functions are
 - CVP,
 - pulmonary artery pressure (PAP), and
 - intra-arterial blood pressure.

CVP MEASUREMENT

- CVP is the pressure of the blood in the right atrium.
 - It reflects right ventricular heart function and venous blood return.
 - It indicates the heart's ability to manage fluid load.
- Uses:** CVP is a hemodynamic measure to manage a client's fluid volume status; it is used as a guide to the safe administration of intravenous fluid volume.
- Elevated CVP is indicative of hypervolemia: CHF, pulmonary edema, and cardiac tamponade.
 - Decreased CVP is indicative of hypovolemia: dehydration and shock.

Assessment Alert

Normal range may be measured as 2–8 mmHg or 5–10 cm of CVP of H₂O depending on the equipment used.

The zero point of the manometer or the transducer must be at the level of the right atrium (phlebostatic axis—fourth intercostal space midaxillary line)

Preparation: CVP catheter is inserted and connected to either a water manometer or a pressure-monitoring system.

Procedure: Procedure is generally done at the bedside. Equipment is prepared; insertion site is selected, shaved if necessary and cleansed with antiseptic solution; the physician inserts and threads a CVP catheter into the superior vena cava just above the right atrium.

Complications: Infection and air embolism.

Nursing Process Elements

- Provide client education concerning CVP monitoring
- Make sure the catheter is secure and a dry sterile occlusive dressing is in place
- Obtain portable chest X-ray to confirm placement
- Inspect site for signs of infection
- Perform dressing change per protocol
- Change lines per protocol
- Take CVP readings as ordered noting that trends are more important and accurate than individual readings
- Be sure to correctly zero prior to readings

PAP MEASUREMENT

- Pulmonary artery catheter is often referred to as Swan-Ganz catheter.
- It has four to five lumens to measure various cardiac pressures.
 - CVP or right atrial pressure
 - Reading is from the proximal lumen with normal CVP 0–5 mmHg.
 - PAP
 - Normal mean pressure is 15 mmHg.
 - PAWP
 - Balloon is inflated with 1 ml of air and becomes wedged in a pulmonary artery so that pressure of the left ventricle end diastolic pressure is obtained when the mitral valve is open, normal mean pressure is 10 mmHg.
 - CO
 - Amount of blood pumped by the heart in 1 minute. Normal 4–8 lpm and is measured by thermodilution method where fluid is injected into the proximal lumen and the temperature change of the blood is recorded in the pulmonary artery by a thermistor and calculated by a computer.
- It may also have pacing capabilities.

Uses: PAP measurement is used in hemodynamic monitoring to provide information about the efficiency of the right and left sides of the heart and evaluating a client's response to medical treatment.

Preparation: PAP catheter is a balloon-tipped catheter which is inserted through a large vein and then attached to a pressure-monitoring system (300 mmHg heparinized pressure solution). It requires continuous ECG monitoring during insertion.

Procedure: Procedure is generally done at the bedside. Equipment is prepared; insertion site is selected, shaved if necessary and cleansed with antiseptic solution; the physician inserts and threads a PAP catheter into the superior vena cava → right atrium → right ventricle → pulmonary artery.

Complications: Infection, air embolism, thromboembolism, dysrhythmias, hemorrhage, pulmonary artery infarct, and pulmonary artery rupture.

Nursing Process Elements

- Provide client education concerning PAP monitoring
- Make sure the catheter is secure and a dry sterile occlusive dressing is in place
- Obtain portable chest X-ray to confirm placement
- Inspect site for signs of infection
- Perform dressing change per protocol using aseptic technique (every 48 hours is standard)
- Change lines per protocol (every 72 hours for line and 24 hours for IV solution is standard)
- Take PAP readings as ordered noting that trends are more important and accurate than individual readings
- Take readings between breaths to avoid effects of intrathoracic pressure
- Be sure balloon is completely deflated after PAWP is obtained
- Be sure that the catheter is correctly calibrated and zeroed prior to readings
- Keep pressure at 300 mmHg at all times to ensure a continuous flow of flush solution to prevent clot formation and catheter occlusion
- Know procedures for immediate treatment if complications occur

INTRA-ARTERIAL BLOOD PRESSURE MEASUREMENT

- Intra-arterial blood pressure measurement refers to the continuous measurement of systolic, diastolic, and mean arterial blood (MAP) pressure.

- It provides continuous assessment of arterial perfusion to the major organs.
- MAP represents perfusion pressure throughout the cardiac cycle. Normal range 70–100 mmHg

Uses: It is used to obtain direct and continuous BP monitoring when Kirchoff sounds are not heard, when client is hemodynamically unstable, when client is receiving potent vasoactive medications, and may also be used when frequent arterial blood gas measurements are required.

Preparation: Prepare client for procedure and gather materials including catheter, tubing, heparinized pressure solution, and monitor.

Procedure: Procedure is generally done at the bedside. Allen test is performed to determine that collateral circulation is adequate. Equipment is prepared; insertion artery site is selected and cleansed with antiseptic solution; the physician cannulates an artery and attaches the pressure-monitoring system.

Complications: Infection, air embolism, thromboembolism, and hemorrhage.

Nursing Process Elements

- Provide client education concerning intra-arterial BP monitoring
- Make sure the catheter is secure and a dry sterile occlusive dressing is in place
- Make sure site is visible
- Inspect site for signs of infection
- Assess peripheral perfusion by checking extremity for color, temperature, sensation, pulses, and movement
- Perform dressing change per protocol
- Change lines per protocol
- Monitor BP readings as ordered noting that trends are more important and accurate than individual readings
- Know procedures for immediate treatment if complications occur
- Compare monitor BP readings with manual readings per shift

Assessment Alert

Intra-arterial BP readings may be 5–10 mmHg higher than manual cuff BP readings.

WORKSHEET

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The three most basic causes of cell injury are
 - a. _____
 - b. _____
 - c. _____
2. The five classic signs of infection are
 - a. _____
 - b. _____
 - c. _____
 - d. _____
 - e. _____
3. The two major components of the inflammatory response are
 - a. _____
 - b. _____
4. The three types of exudates are
 - a. _____
 - b. _____
 - c. _____
5. The four components of the healing process are
 - a. _____
 - b. _____
 - c. _____
 - d. _____
6. Collagen fibers in scar tissue are weak for _____ days.
7. The four most common sites of nosocomial infection are
 - a. _____
 - b. _____
 - c. _____
 - d. _____
8. Cancers arising in tissues derived from mesoderm such as muscles, bones, or connective tissue are called _____.
9. The two distinct processes involved in carcinogenesis are
 - a. _____
 - b. _____
10. Another name for the contractile force of the heart is _____.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|-------|-------|
| 1. Calcification occurs only in necrotic tissue. | _____ | _____ |
| | T | F |
| 2. Chronic inflammation progressively destroys tissue and results in loss of function and scarring. | _____ | _____ |
| | T | F |
| 3. Once regeneration occurs, function is restored to damaged organs. | _____ | _____ |
| | T | F |
| 4. If a child cuts his hand on a piece of broken glass and has eight sutures to close the wound, healing will occur by second intention. | _____ | _____ |
| | T | F |
| 5. To facilitate healing of a wound across the middle knuckle of the index finger, the joint needs to be immobilized. | _____ | _____ |
| | T | F |
| 6. Signs of systemic infection include swollen lymph nodes, fever, and elevated ESR. | _____ | _____ |
| | T | F |
| 7. Total length of the cell cycle is the same for all cells; what differs is the length of time spent in each phase. | _____ | _____ |
| | T | F |
| 8. A characteristic of a benign tumor is that it is composed of cells that resemble the tissue of origin. | _____ | _____ |
| | T | F |
| 9. Malignant tumors cause systemic symptoms such as altered taste and weight loss. | _____ | _____ |
| | T | F |
| 10. The initial effect of an increase in heart rate is a decrease in cardiac output. | _____ | _____ |
| | T | F |

MATCHING QUESTIONS

Match the following:

- | | |
|------------------------------|--|
| 1. _____ Adhesions | a. Type of nosocomial infection, which is the direct result of a diagnostic or therapeutic procedure |
| 2. _____ Hypertrophy | b. Angiogenesis |
| 3. _____ Serous exudates | c. Ability of a microorganism to produce infection |
| 4. _____ Dehiscence | d. Enlargement of cells and organs as a result of increased demand |
| 5. _____ Apoptosis | e. Number of cells increased through cell division in response to demand |
| 6. _____ Contracture | f. Fluid in blisters of a mild sunburn |
| 7. _____ Suppurative exudate | g. Microorganism that causes infection only in a susceptible person |

- | | |
|---------------------------------|---|
| 8. ____ Necrosis | h. Tissue death |
| 9. ____ Granuloma | i. Process by which strains of microorganisms become resident flora in an area of the body |
| 10. ____ Keloid | j. Tissue is disordered and cells vary in size and shape |
| 11. ____ Hyperplasia | k. Shrinking of cells and organs as a result of decreased demand |
| 12. ____ Phagocytosis | l. Lack of organ development |
| 13. ____ Revascularization | m. Exaggerated contraction of maturing collagen, mostly affecting large wounds which results in distortion and limited mobility |
| 14. ____ Colonization | n. Joining of serous membranes which normally move freely against each other due to organization of inflammatory exudates. Risk is greatest with trauma to abdominal organs, heart, and lungs |
| 15. ____ Atrophy | o. Breaking open of a healing wound usually a result of pressure on the wound |
| 16. ____ Opportunistic pathogen | p. Irregular masses of scar tissue protruding from the skin that result from overproduction of collagen |
| 17. ____ Iatrogenic infection | q. Decreased number of cells as a result of self-destruction |
| 18. ____ Virulence | r. Round masses of transformed macrophages surrounded by lymphocytes and fibroblasts |
| 19. ____ Aplastic | s. Shortening of a muscle or scar tissue causing distortion or deformity |
| 20. ____ Dysplasia | t. Ingestion of particles by cells |
| | u. Material that passes through vessels into adjacent tissues in inflammation |

APPLICATION QUESTIONS

- Of which process is gangrene an example?
 - Coagulation necrosis
 - Liquefaction necrosis
 - Autolysis
 - Phagocytosis
- Which is the primary factor that determines the time interval that can elapse between removal of an organ from a donor and its transplantation into a recipient?
 - Time an organ can survive ischemia
 - Ability of the organ to withstand temperature change
 - Amount of DNA present in the organ's cells
 - Number of organelles in the organ's cells
- Which factors can initiate an inflammatory response? (Select all that apply.)
 - Heat or cold
 - Trauma
 - Infection
 - Antigen–antibody-complex deposition
 - Complement activation

(continued)

4. What type of diet should be encouraged for a client having radiation through an abdominal port who complains of nausea and vomiting? (Select all that apply.)
 - a. High-protein
 - b. High-carbohydrate
 - c. High-fat
 - d. High-residue
 - e. High-calorie
 - f. Low-protein
 - g. Low-calorie
 - h. Low-carbohydrate
 - i. Low-residue
 - j. Low-fat
5. When caring for a client having radiation therapy the nurse receives a report that the client's laboratory values are normal and there are no signs of anemia, infection, or bleeding. Which conclusion should the nurse draw from this information?
 - a. Radiation has not yet reached a therapeutic level.
 - b. The client is free of side effects of radiation.
 - c. Nutritional status is normal.
 - d. Bone-marrow suppression is not a problem.
6. The father of a 9-month-old boy just diagnosed with a primary immune deficiency says to the nurse "I don't understand it. Why did my son seem healthy until he was 6-months old and then start getting all these infections?" On which fact should the nurse's response be based?
 - a. Under 6-months of age, most babies do not show signs of active infection.
 - b. It takes about 6 months for babies to be exposed to enough pathogens for infection to readily occur.
 - c. Until about 6 months, babies are protected from infection by immunity from their mothers.
 - d. Before 6 months, babies are only susceptible to bacterial infections.
7. When assessing skin of a client having external radiation therapy, which fact should the nurse keep in mind?
 - a. Skin damage is preceded by changes in oral mucous membranes.
 - b. Most skin changes occur 4–8 weeks after the start of radiation.
 - c. Skin areas with poor blood flow are at greatest risk for injury.
 - d. Intertriginous areas are at particular risk for skin reactions.
8. How should the care of a client undergoing brachytherapy be assigned?
 - a. To male nurses whenever possible
 - b. On a rotating basis among nonpregnant nursing staff
 - c. Consistently to the same nurses
 - d. Never to a nurse with a history of cancer
9. A client having radiation therapy asks the nurse if his blood cells are going to be affected. Which fact should form the basis of the nurse's answer?
 - a. Bone marrow and therefore blood cells is affected with almost all ports of radiation.
 - b. If radiation is delivered to the hip or leg, no effect should occur.
 - c. It depends on whether or not medications are being taken that sensitize blood cells to radiation.
 - d. Speed and volume of blood to tissues of the port will determine the effect.
10. Which direction should be given to a client with a platelet count of $45,000 \text{ mm}^3$, a WBC count of $1250/\text{mm}^3$, and an RBC count of 4.8 million/ mm^3 ?
 - a. Cook vegetables well.
 - b. Use an electric razor.
 - c. Rest at regular intervals.
 - d. Increase vitamin B12 intake.
11. A client having chemotherapy for breast cancer reports a temperature of 101.4 F. How should the nurse interpret this fact?
 - a. Sign of infection, which needs to be reported right away
 - b. Side effect of chemotherapy, not requiring intervention
 - c. Sign of infection, which needs monitoring and reporting if it persists for 48 hours
 - d. Indicator of dehydration requiring client teaching regarding fluid intake
12. A client who had a dose of chemotherapy at 8 a.m. calls the clinic at 2:30 p.m. complaining of nausea and vomiting despite having taken the prescribed medication. She asks how much worse the nausea and vomiting is going to get. On which fact should the nurse's answer be based?
 - a. Nausea and vomiting is totally unpredictable.
 - b. Nausea and vomiting typically peak in the first 12 hours.
 - c. Nausea and vomiting will ease on going to bed.
 - d. Vomiting should cease in about 36 hours but nausea may persist for 7–10 days.

13. For which type of toxicity would the nurse plan to monitor a client who is being treated with cisplatin?
- Neurotoxicity
 - Cardiotoxicity
 - Nephrotoxicity
 - Hepatotoxicity
14. Which class of chemotherapy drugs is most likely to affect fertility?
- Alkylating agents
 - Antimetabolites
 - Cytotoxic antibiotics
 - Mitotic inhibitors
15. Which information could be correctly included in the teaching plan for a client receiving chemotherapy?
- Scalp hair may be lost but body hair is unaffected.
 - Hair loss usually occurs 6–8 weeks after chemotherapy starts.
 - Regrowth usually starts 1–2 months after chemotherapy is completed.
 - Hair regrowth can be expected to take 24–36 months.
16. Which comment about measuring pulmonary artery wedge pressure indicates a correct understanding of at least one aspect of the procedure?
- The pressure-monitoring system must be calibrated at least every 12 hours.
 - Normal mean pressure is 15 mmHg.
 - The balloon must be completely deflated after each pressure measurement is obtained.
 - The catheter is passed through the right heart and into the right pulmonary artery.
17. Which statement is an appropriate practice guideline when CVP is being monitored?
- A pressure greater than 6 mmHg must be reported immediately.
 - A CVP of greater than 10 mmHg indicates the need for immediate fluid.
 - Overall trend is more important than any individual measure.
 - A CVP of 1–3 mmHg requires immediate intervention to prevent pulmonary edema.
18. Which statement made by a client receiving radiation therapy indicates a need for further teaching?
- “Today is my last treatment so by next week I will know if I am going to have any side effects from the radiation.”
 - “I’m tired of having blood drawn but I know I need it to check my bone marrow.”
 - “I need to check my skin for redness, especially in the skin folds.”
 - “I’m awfully fatigued all the time but I understand it is expected.”
19. When caring for a client with a Swan–Ganz catheter, for which complications would the nurse monitor? (Select all that apply.)
- Heart failure
 - Thromboembolism
 - Hypervolemia
 - Cardiac dysrhythmia
 - Infection
20. A client who has received a biopsy report indicating dysplasia asks the nurse if this means she has cancer. Which is the most appropriate response?
- “Yes, it is cancer but an early form that is usually treatable.”
 - “It may be cancer. More tests have to be done and you will know in about 5 days.”
 - “No, it is not cancer but the tissue is abnormal and sometimes it becomes cancerous.”
 - “No, it is not cancer and it doesn’t turn into cancer.”
21. Which complication must the nurse be alert for when caring for a client on intra-arterial blood pressure monitoring?
- Ventricular tachycardia
 - Myocardial infarct
 - Pulmonary artery rupture
 - Hemorrhage

Think Smart/Test Smart

This question is looking for a correct statement because it asks which statement shows that the person making it correctly understands some aspect of the procedure. Thus, three distractors are going to be incorrect statements about the procedure and one is going to be correct and will be the answer.

(continued)

22. The spouse of a client who is to have intra-arterial blood pressure monitoring initiated, tells the nurse he heard someone say that an Allen test would be done and asks what it is for. Which fact should form the basis of the nurse's response?
- To make sure there is collateral circulation sufficient to keep tissue supplied with oxygenated blood.
 - To check for abnormal clotting because of the risk of thromboembolism.
 - To check if the volume of bloodflow is sufficient to provide an accurate measurement.
 - To determine if the artery has a diameter great enough to allow passage of the catheter.
23. When measuring CVP, which is the reference point or the zero point of the manometer or the transducer?
- Fourth intercostal space at the left midclavicular line
 - Fourth intercostal space at the left sternal border
 - Sixth intercostal space at the right sternal border
 - Sixth intercostal space at the left midclavicular line
24. A client having a Swan–Ganz catheter inserted asks how the MD will know when it is in the right place. What is the most accurate reply to the client's question?
- A chest X-ray shows the position.
 - It is inserted under fluoroscopy so it can be seen on a television screen.
 - The pressure in the artery changes depending on where the catheter is located.
 - The distance from the point of entry to the heart is measured and the catheter is marked off in centimeters.
25. When preparing a client for insertion of a pulmonary artery catheter, the nurse's explanation of the procedure could include information based on which fact?
- Procedure is usually done in an operating room or treatment room.
 - EKG is monitored continuously during insertion.
 - Insertion is basically a risk-free procedure.
 - Light, general anesthesia is used for client comfort.

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

- The three most basic causes of cell injury are
 - deficiency
 - intoxication/poisoning
 - trauma/physical injury
- The five classic signs of infection are
 - redness
 - heat
 - pain
 - swelling
 - loss of function
- The two major components of the inflammatory response are
 - vascular
 - cellular

4. The three types of exudates are
 - a. serous
 - b. purulent/suppurative
 - c. hemorrhagic
5. The four components of the healing process are
 - a. regeneration
 - b. repair
 - c. revascularization
 - d. reepithelialization
6. Collagen fibers in scar tissue are very weak for 6–8 days.
7. The four most common sites of nosocomial infection are
 - a. urinary tract
 - b. respiratory tract
 - c. bloodstream
 - d. wounds
8. Cancers arising in tissues derived from mesoderm such as muscles, bones, or connective tissue are called sarcomas.
9. The two distinct processes involved in carcinogenesis are
 - a. initiation
 - b. promotion
10. Another name for the contractile force of the heart is inotropy.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Calcification occurs only in necrotic tissue. *False*
Deposits of calcium can occur in normal tissues as a result of marked hypercalcemia.
2. Chronic inflammation progressively destroys tissue and results in loss of function and scarring. *True*
3. Once regeneration occurs, function is restored to damaged organs. *False*
Function is restored if the stroma is undamaged; if stroma is damaged then regeneration may be disorganized and some degree of functional loss results.
4. If a child cuts his hand on a piece of broken glass and has eight sutures to close the wound, healing will occur by second intention. *False*
Healing is by first intention when the edges of the wound are approximated; it is second intention when the wound is not closed but is left to granulate in.
5. To facilitate healing of a wound across the middle knuckle of the index finger, the joint needs to be immobilized. *True*
6. Signs of systemic infection include swollen lymph nodes, fever, and elevated ESR. *True*

(continued)

7. Total length of the cell cycle is the same for all cells; what differs is the length of time spent in each phase. *False*
Total length of cell cycle varies with the type of cell ranging from 1 hour to 100 hours with the difference a result of time spent in G0 and G1.
8. A characteristic of a benign tumor is that it is composed of cells that resemble the tissue of origin. *True*
9. Malignant tumors cause systemic symptoms such as altered taste and weight loss. *True*
10. The initial effect of an increase in heart rate is a decrease in cardiac output. *False*
The initial effect is an increase in heart rate because cardiac output equals heart rate x stroke volume. When the heart rate reaches 180 bpm and is sustained there is less time for the ventricle to fill with blood so the stroke volume starts to decrease and ultimately the cardiac output decreases even though the rate is high.

MATCHING ANSWERS

Match the following:

APPLICATION ANSWERS

- Of which process is gangrene an example?
 - Coagulation necrosis
 - Liquefaction necrosis
 - Autolysis
 - Phagocytosis

Rationale

Correct answer: a.

Gangrene is an example of coagulation necrosis and is characterized by initial appearance of a firm area with the structure of normal tissue even though cells are dead; subsequently, the area is broken down and cleared by phagocytes. Gangrene is common when cells die due to anoxia or toxic injury except in the brain.

Liquefaction necrosis is characterized by an initial liquid area of dead cells. It is seen in death of nervous-system cells due to anoxia and in death of cells associated with bacterial infections.

- Which is the primary factor that determines the time interval that can elapse between removal of an organ from a donor and its transplantation into a recipient?
 - Time an organ can survive ischemia
 - Ability of the organ to withstand temperature change
 - Amount of DNA present in the organ's cells
 - Number of organelles in the organ's cells

Rationale

Correct answer: a.

Oxygen, which is essential to cell survival, is brought to the tissues by the blood. Once an organ is removed from the donor its cells no longer have a source of oxygenated blood until it is implanted in the recipient. Different types of cells/tissues can withstand ischemia for different lengths of time. Hence, how long the organ can survive until implanted depends on this ability of the cells to withstand ischemia.

- Which factors can initiate an inflammatory response? (Select all that apply.)
 - Heat or cold
 - Trauma
 - Infection
 - Antigen–antibody-complex deposition
 - Complement activation

Rationale

Correct answers: a, b, c, and d.

Inflammation is a nonspecific response that occurs when there is damage to skin or mucous membranes, which serve as the body's first line of defense against infection. Anything that can damage these tissues can cause inflammation. Thus, factors such as prolonged exposure to the sun, surgery, exposure to irritating chemicals, and accidental cuts and scrapes are all initiators of the inflammatory response. The inflammatory response is nonspecific because it occurs as a result of many different kinds of damage and is the same regardless of the specific initiating factor.

(continued)

4. What type of diet should be encouraged for a client having radiation through an abdominal port who complains of nausea and vomiting? (Select all that apply.)
- High-protein
 - High-carbohydrate
 - High-fat
 - High-residue
 - High-calorie
 - Low-protein
 - Low-calorie
 - Low-carbohydrate
 - Low-residue
 - Low-fat

Rationale

Correct answers: a, b, and e.

Clients having radiation therapy need a high-protein, high-carbohydrate, and high-calorie diet. Radiation causes tissue damage so extra protein is needed for tissue repair. Carbohydrates and calories are needed to provide the energy for tissue repair and to combat the fatigue associated with radiation therapy. Fat is high in calories but is harder to digest; neither a low-fat nor a high-fat diet is recommended. Amount of residue is unrelated.

5. When caring for a client having radiation therapy the nurse receives a report that the client's laboratory values are normal and there are no signs of anemia, infection, or bleeding. Which conclusion should the nurse draw from this information?
- Radiation has not yet reached a therapeutic level.
 - The client is free of side effects of radiation.
 - Nutritional status is normal.
 - Bone-marrow suppression is not a problem.

Rationale

Correct answer: d.

Some effect on bone marrow occurs with almost all radiation therapy regardless of port. Bone-marrow suppression becomes a significant problem when RBC and WBC counts and platelet count drop below critical levels. This drop is seen in laboratory values and can result in the development of anemia, infection, or bleeding. Therefore, normal laboratory values and the absence of signs/symptoms of anemia, infection, and bleeding indicate that bone-marrow suppression is not a problem at this time.

6. The father of a 9-month-old boy just diagnosed with a primary immune deficiency says to the nurse "I don't understand it. Why did my son seem healthy until he was 6-months old and then start getting all these infections?" On which fact should the nurse's response be based?

- Under 6 months of age, most babies do not show signs of active infection.
- It takes about 6 months for babies to be exposed to enough pathogens for infection to readily occur.
- Until about 6 months, babies are protected from infection by immunity from their mothers.
- Before 6 months, babies are only susceptible to bacterial infections.

Rationale

Correct answer: c.

In utero, fetuses are protected against infection by passive immunity received from the mother via the placenta. This passive protection against pathogens that the mother has immunity to lasts for approximately 6 months at which time the infant becomes dependent on his or her own immune system for protection against infection. Therefore, it is not until the passive immunity has "worn off" that immunodeficiency in the infant manifests itself in chronic or recurrent infections. Infants develop signs of infection. Infection can occur at any time; it can even be present at birth. The cause of infection can be any type of microorganism.

7. When assessing skin of a client having external radiation therapy, which fact should the nurse keep in mind?
- Skin damage is preceded by changes in oral mucous membranes.
 - Most skin changes occur 4–8 weeks after the start of radiation.
 - Skin areas with poor blood flow are at greatest risk for injury.
 - Intertriginous areas are at particular risk for skin reactions.

Rationale

Correct answer: d.

Skin fold areas are at particular risk for developing a reaction to radiation therapy.

It is important to keep these areas clean, dry, and free of irritation to help decrease the risk. Changes in oral mucous membranes do not always occur with radiation therapy; it depends on the port. This is different from chemotherapy, which is administered systemically. Acute skin reactions consist of erythema which increases over 2–3 weeks and then either fades or progresses to dry or moist desquamation.

Areas of poor bloodflow are less well-oxygenated and hypoxic tissues are resistant to radiation not at greater risk for injury.

8. How should the care of a client undergoing brachytherapy be assigned?
- To male nurses whenever possible
 - On a rotating basis among nonpregnant nursing staff
 - Consistently to the same nurses
 - Never to a nurse with a history of cancer

Rationale

Correct answer: b.

To limit exposure to specific individuals, care of clients undergoing brachytherapy should be rotated among staff members with the exception of those who are pregnant because of the risk of damage to the developing fetus. Male gender or cancer history are not considered influencing factors. Assigning the same nurses would support consistency and efficiency of care but these benefits do not outweigh the risk of exposure.

9. A client having radiation therapy asks the nurse if his blood cells are going to be affected. Which fact should form the basis of the nurse's answer?
- Bone marrow and therefore blood cells are affected with almost all parts of radiation.
 - If radiation is delivered to the hip or leg, no effect should occur.
 - It depends on whether or not medications are being taken that sensitize blood cells to radiation.
 - Speed and volume of blood to tissues of the part will determine the effect.

Rationale

Correct answer: a.

Radiation therapy exerts its greatest effect on well-oxygenated, actively dividing cells. As a result, bone-marrow cells are almost always affected. The hip and long bones of the leg contain large amounts of bone marrow so effects on the blood from radiation to these areas do occur. The effect on the blood occurs because the active cells in the bone marrow are affected, not because of any sensitizing drug.

10. Which direction should be given to a client with a platelet count of $45,000 \text{ mm}^3$, a WBC count of $1250/\text{mm}^3$, and an RBC count of 4.8 million/ mm^3 ?
- Cook vegetables well.
 - Use an electric razor.
 - Rest at regular intervals.
 - Increase vitamin B12 intake.

Rationale

Correct answer: b.

A platelet count of $45,000 \text{ mm}^3$ is significantly below the normal of $150,000\text{--}400,000/\text{mm}^3$ and so the client is at risk for bleeding. A basic bleeding precaution is to use an electric razor to avoid cutting the skin. The WBC and RBC

counts are within normal range so do not require precautions. Cooking vegetables well is a direction given to neutropenic clients. Rest at regular intervals is needed by clients with anemia and other sources of fatigue. Increased vitamin B12 intake is needed by clients with pernicious anemia.

11. A client having chemotherapy for breast cancer reports a temperature of 101.4 F . How should the nurse interpret this fact?
- Sign of infection, which needs to be reported right away
 - Side effect of chemotherapy, not requiring intervention
 - Sign of infection, which needs monitoring and reporting if it persists for 48 hours
 - Indicator of dehydration requiring client teaching regarding fluid intake

Rationale

Correct answer: a.

Any temperature over 101 F is considered a sign of infection and needs to be reported right away. Clients having radiation therapy are immunosuppressed because of the effect of the radiation on the bone marrow and so infection poses a particular risk for this population.

12. A client who had a dose of chemotherapy at 8 a.m. calls the clinic at 2:30 p.m. complaining of nausea and vomiting despite having taken the prescribed medication. She asks how much worse the nausea and vomiting is going to get. On which fact should the nurse's answer be based?
- Nausea and vomiting is totally unpredictable.
 - Nausea and vomiting typically peak in the first 12 hours.
 - Nausea and vomiting will ease on going to bed.
 - Vomiting should cease in about 36 hours but nausea may persist for 7–10 days.

Rationale

Correct answer: b.

Nausea and vomiting typically peak in the first 12 hours so in this case the nausea and vomiting should begin to subside after 8 p.m. The degree of nausea and vomiting can vary from person to person and with different types of chemotherapy but broad patterns are evident; it is not totally unpredictable. Going to bed does not ease nausea and vomiting and its absolute duration is not known.

13. For which type of toxicity would the nurse plan to monitor a client who is being treated with cisplatin?
- Neurotoxicity
 - Cardiotoxicity
 - Nephrotoxicity
 - Hepatotoxicity

(continued)

Rationale

Correct answer: c.

Cisplatin is associated with nephrotoxicity and as a result, the nurse must monitor for signs of renal tubule damage. Intake and output must be monitored. The client must be well-hydrated before administration of cisplatin and encouraged to maintain a fluid intake of 2–3 l daily for the duration of therapy. Cisplatin can also cause ototoxicity (deafness) and should be monitored for tinnitus.

14. Which class of chemotherapy drugs is most likely to affect fertility?
- Alkylating agents
 - Antimetabolites
 - Cytotoxic antibiotics
 - Mitotic inhibitors

Rationale

Correct answer: a.

Alkylating agents are the type of chemotherapeutic agents that most commonly affect the ovaries and testes resulting in changes in fertility. Amenorrhea is common in young females and induced menopause common in older females. Decreased sperm production as well as sperm and semen abnormalities occur in men. In some cases, fertility returns after treatment but this varies with the age of the client and the specific drug and dose of drug received.

15. Which information could be correctly included in the teaching plan for a client receiving chemotherapy?
- Scalp hair may be lost but body hair is unaffected.
 - Hair loss usually occurs 6–8 weeks after chemotherapy starts.
 - Regrowth usually starts 1–2 months after chemotherapy is completed.
 - Hair regrowth can be expected to take 24–36 months.

Rationale

Correct answer: c.

Regrowth of hair usually starts 1–2 months after chemotherapy is completed. Both scalp and body hair may be lost and loss usually starts 2–3 weeks after treatment starts. Regrowth takes about a year.

16. Which comment about measuring pulmonary artery wedge pressure indicates a correct understanding of at least one aspect of the procedure?
- The pressure-monitoring system must be calibrated at least every 12 hours.
 - Normal mean pressure is 15 mmHg.
 - The balloon must be completely deflated after each pressure measurement is obtained.
 - The catheter is passed through the right heart and into the right pulmonary artery.

**Think Smart/Test Smart**

This question is looking for a correct statement because it asks which statement shows that the person making it correctly understands some aspect of the procedure. Thus, three distractors are going to be incorrect statements about the procedure and one is going to be correct and will be the answer.

Rationale

Correct answer: c.

The balloon must be completely deflated after each pressure measurement is obtained. This is correct. The other statements are incorrect because calibration should be checked before each reading; normal mean pressure is 10 mmHg not 15; and the catheter passes through the left ventricle into the left pulmonary artery because it provides a measure of left ventricle end diastolic pressure, which is increased in left ventricular failure and pericardial tamponade and decreased in hypovolemia.

17. Which statement is an appropriate practice guideline when CVP is being monitored?
- A pressure greater than 6 mmHg must be reported immediately.
 - A CVP of greater than 10 mmHg indicates the need for immediate fluid.
 - Overall trend is more important than any individual measure.
 - A CVP of 1–3 mmHg requires immediate intervention to prevent pulmonary edema.

Rationale

Correct answer: c.

Trend in CVP change is more significant than any individual measurement. Normal range of CVP is 0–8 mmHg or 5–10 cm H₂O depending on equipment used; so, a pressure of 6 mmHg is within normal range and would not need to be reported immediately. A CVP 10 mmHg is the upper limit of normal and does not indicate need for immediate fluid; elevated CVP is associated with hypervolemia not hypovolemia. Risk of pulmonary edema is indicated by an elevated CVP.

18. Which statement made by a client receiving radiation therapy indicates a need for further teaching?
- “Today is my last treatment so by next week I will know if I am going to have any side effects from the radiation.”
 - “I’m tired of having blood drawn but I know I need it to check my bone marrow.”
 - “I need to check my skin for redness, especially in the skin folds.”
 - “I’m awfully fatigued all the time but I understand it is expected.”

Rationale

Correct answer: a.

There are late as well as immediate effects of radiation therapy. Late effects are due to blood vessel or connective tissue damage and occur months or years after therapy. Examples of late effects include skin atrophy, fibrosis or ulceration, pulmonary fibrosis, and cataracts.

19. When caring for a client with a Swan–Ganz catheter, for which complications would the nurse monitor? (Select all that apply.)
- Heart failure
 - Thromboembolism
 - Hypervolemia
 - Cardiac dysrhythmia
 - Infection

Rationale

Correct answers: b, d, and e.

Thromboembolism, cardiac dysrhythmia, and infection are risks associated with a Swan–Ganz catheter. Thromboembolism is a risk because the catheter is a foreign object in the circulatory system that interferes with bloodflow. Cardiac dysrhythmia is a risk because the catheter is threaded through the heart. Infection is a risk because the catheter enters through the skin and thus provides a potential source of entry for bacteria into normally sterile areas of the body.

20. A client who has received a biopsy report indicating dysplasia asks the nurse if this means she has cancer. Which is the most appropriate response?
- “Yes, it is cancer but an early form that is usually treatable.”
 - “It may be cancer. More tests have to be done and you will know in about 5 days.”
 - “No, it is not cancer but the tissue is abnormal and sometimes it becomes cancerous.”
 - “No, it is not cancer and it doesn’t turn into cancer.”

Rationale

Correct answer: c.

Dysplastic tissue is characterized by disorder and cells that vary in size and shape. It results from severe and prolonged irritation and often precedes neoplasia. Some forms are known as precancerous lesions.

21. Which complication must the nurse be alert for when caring for a client on intra-arterial blood pressure monitoring?
- Ventricular tachycardia
 - Myocardial infarct
 - Pulmonary artery rupture
 - Hemorrhage

Rationale

Correct answer: d.

Hemorrhage is a potential complication because the catheter is inserted directly into a pulsating artery. Other complications are infection, air embolism, and thromboembolism. The arterial line called an art line or A line does not pass through the heart so dysrhythmias are not a major risk nor do they enter or affect the pulmonary artery so pulmonary artery rupture is not a concern. Occurrence of MI is unrelated.

22. The spouse of a client who is to have intra-arterial blood pressure monitoring initiated, tells the nurse he heard someone say that an Allen test would be done and asks what it is for. Which fact should form the basis of the nurse’s response?
- To make sure there is collateral circulation sufficient to keep tissue supplied with oxygenated blood.
 - To check for abnormal clotting because of the risk of thromboembolism.
 - To check if the volume of bloodflow is sufficient to provide an accurate measurement.
 - To determine if the artery has a diameter great enough to allow passage of the catheter.

Rationale

Correct answer: a.

An Allen test is done to ascertain that inserting a catheter into one of the large arteries of an extremity will not result in a decrease in oxygenated blood to the part such that tissue damage occurs. When performing the Allen test on an upper extremity, both the radial and ulna arteries are compressed until the pulses are obliterated while the client is making a fist. The client is then asked to open the fist and pressure is released on one of the arteries and the palm is observed for flushing. This procedure is then repeated for the other artery.

(continued)

23. When measuring CVP, which is the reference point or the zero point of the manometer or the transducer?
- Fourth intercostal space at the left midclavicular line
 - Fourth intercostal space at the left sternal border
 - Sixth intercostal space at the right sternal border
 - Sixth intercostal space at the left midclavicular line

Rationale

Correct answer: a.

The reference level for the transducer is the right atrium, whose filling pressure is measured by CVP. The right atrium is located below the fourth intercostal space at the left midclavicular line.

24. A client having a Swan–Ganz catheter inserted asks how the MD will know when it is in the right place. What is the most accurate reply to the client's question?
- A chest X-ray shows the position.
 - It is inserted under fluoroscopy so it can be seen on a television screen.
 - The pressure in the artery changes depending on where the catheter is located.
 - The distance from the point of entry to the heart is measured and the catheter is marked off in centimeters.

Rationale

Correct answer: a.

A chest X-ray is done to confirm the position of a Swan–Ganz catheter once it is inserted. It is inserted usually as a bedside procedure; it is not done under fluoroscopy. Pressure in the arterial system does change in different locations but this is not how placement is confirmed nor is it confirmed by the length of catheter inserted. No IV fluid is run into a central line until placement is confirmed by X-ray.

25. When preparing a client for insertion of a pulmonary artery catheter, the nurse's explanation of the procedure could include information based on which fact?
- Procedure is usually done in an operating room or treatment room.
 - EKG is monitored continuously during insertion.
 - Insertion is basically a risk-free procedure.
 - Light, general anesthesia is used for client comfort.

Rationale

Correct answer: b.

EKG is monitored continuously due to the risk of the catheter triggering a dysrhythmia as it passes through the right ventricle. The procedure is typically done at the bedside and general anesthesia is not needed. However, the procedure is not without risk. Air embolism, thromboembolism, pulmonary artery rupture or infarct, dysrhythmia, and infection can all occur.

Part III

TAKING THE TEST

This page intentionally left blank

Practice Test for NCLEX-RN®

HEALTH PROMOTION AND MAINTENANCE

Human Sexuality

Counsel client/family/significant others on sexuality issues

1. A client who has experienced a myocardial infarction is being discharged from the hospital. The client questions when he can resume sexual activity with his spouse. The nurse's best response is:
 - A. sex is no longer possible after your surgery.
 - B. you must avoid foreplay but sex is acceptable as long as it is of a short duration.
 - C. sex can be resumed when you can climb stairs without becoming short of breath.
 - D. masturbation is the only allowable form of sexual expression after the surgery.

The answer is C. Sex can be resumed when the client can climb two flights of stairs without becoming short of breath or the client can walk more than 2 miles without shortness of breath.

A is incorrect—Sex is possible after a myocardial infarction. B is incorrect—Foreplay is encouraged to slowly prepare the body for the changes in heart rate and respiratory rate that accompany sex. D is incorrect—Masturbation is acceptable after a myocardial infarction but it is not the only form of sexual expression allowed.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Disaster Planning

Identify nursing roles in disaster planning

2. What is the most important nursing role in disaster planning?
 - A. Knowing the policy for disasters in the facility.
 - B. Maintaining contact with community resources.

- C. Making a list of the most frequent contacts in the hospital.
- D. Attending meetings that discuss the potential for disasters in the community.

The answer is A. Knowing the policy for disasters in the facility is the most important role for the nurse. This allows the nurse to function within the policies of the hospital, which aids in maintaining patient and staff safety.

B is incorrect—Maintaining contact with community resources will benefit the nurse in a disaster situation, but is not the most important role. C is incorrect—Making a list of frequent contacts is helpful but not the most important nursing role. D is incorrect—Attending meetings on the disasters that can occur in the community will not prepare the nurse for how to handle the disaster in the facility.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Medical and Surgical Asepsis

Evaluate whether aseptic technique is performed correctly

3. A nurse is working with a physician on the insertion of a central line. What action performed by the physician requires the nurse to stop the procedure due to a breach in asepsis?
 - A. The kit is opened toward the physician last.
 - B. The physician drops his or her gloved hands below the level of the chest.
 - C. The physician touches two sterile hands together.
 - D. The physician turns his or her back to the sterile field.

The answer is D. A person who is working in a sterile field should not turn his or her back to the sterile field or it is considered contaminated.

A is incorrect—A sterile kit is opened toward the outside first and toward the individual last to avoid contamination

of the sterile contents. B is incorrect—The sterile field is from the chest to below the level of the sterile field. C is incorrect—A person wearing sterile gloves is allowed to touch two sterile gloved hands together without causing contamination to the field.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Identify expected physical, cognitive, psychosocial, and moral stages of development

4. Which verbal complaint during the assessment of a 55-year-old female client is considered abnormal and requires further investigation?
 - A. Absence of menstrual cycle
 - B. Thinning of hair
 - C. Periods of sweating and feeling warm
 - D. Lumps in axilla area

The answer is D. Lumps in the axilla area could be lymph nodes, which could be a sign of cancer and needs further attention.

A is incorrect—The loss of menses is normal at the age of 55. B is incorrect—The thinning of hair is secondary to a drop in estrogen levels and is considered normal in the 55-year-old woman. C is incorrect—Periods of sweating and feeling warm are a response to the body's hormonal changes.

PSYCHOSOCIAL INTEGRITY

Coping Mechanisms

Assess client response to illness (rationalization, hopefulness, anger)

5. A client receives a diagnosis of cancer after a biopsy of a suspicious lymph node. The client states, "You must have made a mistake, I want a second opinion." Which stage of grief is the client experiencing?
 - A. Denial
 - B. Anger
 - C. Bargaining
 - D. Despair

The answer is A. The client is denying that the diagnosis is correct and desires a second opinion. This is a normal response and the client should be allowed to work through it with support from staff.

B is incorrect—The client is not yet angry but may encounter this response as time progresses. The client who is angry will blame others or himself as to why the health crisis occurred. C is incorrect—The client will begin to bargain with God or others whom he or she feels holds the key to healing.

D is incorrect—The client will exhibit signs of depression in despair and will become disorganized with daily activities.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Elimination

Perform irrigations

6. A nurse is performing continuous bladder irrigation at 1 L/h. Which assessment is the priority?
 - A. The amount of fluid being returned.
 - B. The size of the indwelling catheter.
 - C. The client's knowledge level of the procedure.
 - D. The percentage of formalin ordered for irrigation.

The answer is A. The amount of fluid being returned is priority since a decrease in output without a decrease in the input may indicate clot formation or catheter malfunction and needs to be addressed immediately.

B is incorrect—The size of the catheter is important but not priority in bladder irrigation. C is incorrect—The client should have his knowledge level assessed prior to the beginning of the procedure. D is incorrect—Formalin is used in the operating room under anesthesia due to the pain it causes and the need to prevent ureteral reflux.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Educate client/family/staff on infection control measures

7. A nurse is discharging a client who has been undergoing chemotherapy. When discussing at home care, the priority instruction should be to:
 - A. avoid public places.
 - B. include fresh fruits and vegetables in your diet.
 - C. limit visitors in the home.
 - D. wash your hands often.

The answer is D. Hand washing is the number one method of preventing infection and should be taught to all clients who are immunosuppressed.

A is incorrect—While avoiding public places is important and should be taught, it is not the priority teaching. B is incorrect—While fresh fruits and vegetables will aid in including vitamin C and other essential nutrients in the diet, this is not the priority. C is incorrect—Limiting visitors is important but not the priority.

HEALTH PROMOTION AND MAINTENANCE

Self-Care

Assess and intervene in client performance of instrumental activities of daily living

8. When planning the care of a client with rheumatoid arthritis, which plan would be best to assist with activities of daily living?
 - A. Teach the client methods of energy conservation.
 - B. Provide the client with a shower chair.
 - C. Encourage family members to take over challenging activities.
 - D. Provide the client with large handled instruments for eating.

The answer is A. The client should learn which activities are the most tiresome and limit the activities to conserve energy. The client with rheumatoid arthritis needs rest to limit increased inflammation in joints.

B is incorrect—The client can benefit with a shower chair but it is not the best plan to assist with activities of daily living. C is incorrect—The client needs to be able to perform the activities of daily living and delegate the activities that he or she is unable to perform. The nurse should not encourage family members to take over these activities. D is incorrect—The client does need instruments for eating but it is not the best plan to assist with activities of daily living.

PSYCHOSOCIAL INTEGRITY

Sensory/Perceptual Alterations

Evaluate client with altered ability to communicate effectively and intervene to promote successful adaptation

9. A client has undergone a total laryngectomy due to cancer. The nurse should plan on assisting the client with communicating by:
 - A. providing an interpreter.
 - B. providing a sheet explaining sign language.
 - C. providing a tablet and pencil.
 - D. talking to the client's face, accentuating words through lip movement.

The answer is C. The client should be given a tablet and pencil for communication postop.

A is incorrect—An interpreter is not needed unless the client does not speak English. B is incorrect—The client should be allowed to communicate through the written word unless he requests a sheet about sign language. D is incorrect—The client should not be expected to read lips to communicate with the nurse due to the possibility of miscommunication.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Apply knowledge of nursing procedures and psychomotor skills when caring for a client with potential for complications

10. A client is 24 hours postop from gastric bypass surgery. Which of the following nursing actions is best in preventing thrombus formation?
 - A. The application of sequential compression devices.
 - B. Ambulating the client.
 - C. Administering salicylate (Aspirin).
 - D. Massaging of lower extremities.

The answer is B. The best method of preventing thrombus formation is ambulation. This will prevent a deep vein thrombosis as well as a pulmonary embolism.

A is incorrect—Sequential compression devices are beneficial in preventing thrombus formation but the best method is ambulation. C is incorrect—Aspirin is known for decreasing platelet aggregation and reduction in inflammation. It is not the best method of prevention of thrombus formation. D is incorrect—Massaging extremities is not appropriate in the postop client. Massaging of extremities may dislodge clots that have formed.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Monitoring Conscious Sedation

Assist with preparing client for conscious sedation

11. Prior to administering conscious sedation the nurse must first:
 - A. verify informed consent.
 - B. perform ABGs.
 - C. assess vital signs.
 - D. place high-flow oxygen on the client.

The answer is A. Prior to initiating conscious sedation, the nurse must ensure informed consent has been obtained and is on the chart.

B is incorrect—ABGs are not performed on a client before conscious sedation. C is incorrect—Vital signs are taken prior to medication administration but the first action is to verify consent has been obtained. D is incorrect—The client is not routinely placed on high-flow oxygen prior to conscious sedation. The client has a loss of protective reflexes but will breathe and the assessment of the client's oxygen saturation should occur.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

12. A client presents to the ED complaining of acute low back pain, which is unrelieved with over the counter pain medications. The client is pacing the room, diaphoretic and grimacing. Which assessment data is most indicative of renal calculi?
- Hematuria
 - Hypertension
 - Vomiting
 - Groin pain

The answer is A. A client with renal calculi will have hematuria or numerous red blood cells in the urine upon examination.

B is incorrect—Hypertension is not an indicative sign of renal calculi. Hypertension is common in a client who is experiencing severe pain. C is incorrect—While the client with renal calculi may experience vomiting, this is a side effect of the pain and not an indicative sign. D is incorrect—Some clients experience pain in the groin with renal calculi while some only experience unilateral flank pain making this not an indicative sign.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Apply knowledge needed to perform related nursing procedures and psychomotor skills when assessing vital signs

13. The nurse will plan to avoid performing which nursing actions on the left arm of a client with an arteriovenous fistula?
- Blood pressure monitoring
 - Oxygen saturation monitoring
 - Blood glucose monitoring
 - Assessment of capillary refill

The answer is A. A client with an arteriovenous fistula for hemodialysis should not have a blood pressure taken in that area to prevent damage and thrombosis formation inside the fistula.

B is incorrect—Oxygen saturation monitoring is acceptable in the site where a fistula is placed. C is incorrect—Blood glucose monitoring is appropriate in the affected arm as long as dialysis is not in progress. D is incorrect—Assessment of capillary refill is possible and safe for the client with an arteriovenous fistula.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Identify cardiac rhythm strip abnormalities

14. What is the most appropriate action for a rapidly occurring wide QRS complex with no discernable p-waves?
- Shock the client with 200 J
 - Perform chest compressions
 - Administer oxygen
 - Take a manual blood pressure

The answer is C. The client has a rhythm known as ventricular tachycardia and needs to have oxygen applied to meet the standards of ABC.

A is incorrect—The client will not require a shock of the rhythm. B is incorrect—Chest compressions should not be initiated until it is determined if a pulse is present. D is incorrect—A blood pressure is measured after a pulse is obtained.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Identify cardiac rhythm strip abnormalities

15. The nurse is assessing his or her patients at the beginning of the shift. One of the client's exhibits a rhythm that displays p waves occurring regularly, a p-r interval of 0.20 and a QRS complex for every p wave measuring <0.12 with a rate of 70 and the t wave is upright. The nurse would document this rhythm as:
- normal sinus rhythm
 - sinus bradycardia
 - first-degree AV block
 - second-degree AV block type I

The answer is A. The rhythm is regular since the rate is regular with a p-r interval and QRS complex measures within normal limits and the rate is above 60 and below 100.

B is incorrect—The rhythm is not below 60 beats per minute. C is incorrect—The p-r interval is not elongated making this a normal sinus rhythm. D is incorrect—The relationship between the p wave and the QRS is consistently occurring.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

16. When responding to a code in the hospital, the nurse finds a client who is being bagged with high flow oxygen by a fellow nurse. The client is pulseless and

CPR was begun less than 1 minute ago; there is no doctor on scene. Which action is next?

- A. Reassess for a pulse
- B. Attach the echocardiogram electrodes to the client
- C. Begin a fluid bolus of normal saline
- D. Ask another nurse for a history of the client

The answer is B. If CPR is in progress, the staff that arrives on scene should attach the electrodes to the client to prevent interruption of CPR.

A is incorrect—Reassessment for a pulse occurs after two full minutes of CPR. C is incorrect—Normal saline boluses must be ordered by the physician in the event the client has a history of heart failure. D is incorrect—A history regarding the client can occur after the electrodes are attached and the physician takes over the code.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Provide postoperative care

17. A client is in the recovery room following a carotid endarterectomy. Place the following assessments in priority order
- ___ neurological status
 - ___ signs of hemorrhage
 - ___ intracranial pressure
 - ___ blood pressure

The nurse's first priority is to assess the area for signs of hemorrhaging. This is most important since hemorrhage indicates that the brain is not receiving much needed oxygen and a stroke could occur as a result. Blood loss will affect the blood pressure and could cause the client to rapidly deteriorate. The second priority is the client's blood pressure. This is important since fluctuations are common during the first 24 hours postprocedure. The blood pressure should be monitored for hypertensive emergencies and hypotension, which will lead to poor perfusion of vital organs. The client's neurological status is the third assessment to monitor for changes consistent with a stroke. The last assessment is the intracranial pressure. The first three assessments will help identify if there is an increase in the intracranial pressure.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Error Prevention

Ensure proper identification of client when providing care

18. Which of the following is the best method of identifying an infant before providing care?

- A. Verify the information on the armband with the chart.
- B. Ask the mom if the armband information is correct.
- C. Ask the client if the information on the armband is correct.
- D. Ask the previous nurse the client's name and date of birth.

The answer is B. Verifying the information on the armband with the mom will ensure that the correct armband was placed on the correct client before treatment is rendered.

A is incorrect—While verifying the chart against the band does demonstrate that the order for the client matches the client's armband, it does not ensure that the correct client is wearing the correct armband. Not verifying the information with a family member could still lead to a treatment error. C is incorrect—An infant will not be able to speak and so this is not an appropriate method. D is incorrect—Each nurse providing care should verify the correct client each time that care is provided during a shift.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Ethical Practices

Intervene to promote ethical practice

19. A client returns from surgery with a diagnosis of cancer. The physician informs the staff to avoid telling the client the diagnosis. Upon awakening the client asks if he has cancer. Which response by the nurse is best?
- A. I will call the physician and have him speak with you.
 - B. I do not know the results of the test.
 - C. You need to ask your family if they know the results.
 - D. The surgeon found what he feels is cancer; he will speak with you later.

The answer is A. Calling the physician is the best answer to this ethical dilemma. The physician is responsible for informing the client of the diagnosis; questions will be asked that the nurse may not be able to answer. By calling the physician, the nurse is not compromising fidelity and/or veracity.

B is incorrect—This is a violation of veracity, which is the principle that a nurse will not knowingly lie to a client. C is incorrect—The family is not responsible for informing a client of the results of a surgery performed. Informing a family member may fall into a HIPAA violation if the client does not want the family to know the results. D is incorrect—Informing the client of the diagnosis is a violation of fidelity. Fidelity is when a health care provider must maintain a professional loyalty to those in the profession, which in this case is the physician.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Advocacy

Act as a client advocate

20. A client presents to the emergency department complaining of pain. The physician refuses to prescribe narcotic pain medication after stating the client is drug seeking. Which action by the nurse would be most appropriate?
- Report the physician to nursing administration for unethical behavior.
 - Ask the physician why he or she believes the client is drug seeking.
 - Discuss with the physician the client's chief complaint and ask if another type of pain reliever can be ordered.
 - Go to the charge nurse, tell her of the physician's actions and ask if another physician can assess the client.

The answer is C. The nurse is responsible for acting as a client advocate. If the nurse feels that the physician is not addressing the client's pain due to a fear of narcotic addiction, the nurse is responsible for discussing alternative methods of pain relief with the physician.

A is incorrect—It does not address the needs of the client. B is incorrect—It only questions the physician and does not allow for a solution to the client's needs. D is incorrect—It does not address the issue that is with the physician and is not cost-effective to have another physician see the client.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Confidentiality/Information Security

Maintain client confidentiality/privacy

21. You are working in an intensive care unit when an individual approaches you to ask about the unresponsive client in the bed you are assigned to. Before giving out information regarding the client you should first:
- verify that the individual is a family member by asking for the name of the client.
 - ask the individual about his or her relationship to the client.
 - ask the individual what is the personal identification number for the client.
 - ask to see a driver's license and compare it to the information listed on the chart as the next of kin.

The answer is C. According to HIPPA laws, a person requesting information on a client must present the personal identification number before information can be distributed. In this case, the client is unresponsive; therefore, the nurse must ensure that a HIPPA violation does not occur.

A is incorrect—Knowing the name of the individual does not authorize information to be distributed. B is incorrect—Regardless of the relationship of the individual to the client, information cannot be distributed without the PIN. D is incorrect—It does not follow the policy for identification and distribution of medical information.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Referrals

Assess the need to refer clients for assistance with actual or potential problems

22. While developing the clinical pathway of four clients, which client will need a referral to speech therapy based on the nurse's assessment?
- A client who experienced a fractured hip.
 - A client who underwent a laryngectomy.
 - A client who underwent a cholecystectomy.
 - A client who was admitted for congestive heart failure.

The answer is B. A client who underwent a laryngectomy may require therapy to regain voice function or consume food.

A is incorrect—A client with a fractured hip will not require speech therapy. C is incorrect—A client who underwent a cholecystectomy will not require speech therapy. D is incorrect—A client with congestive heart failure will not require speech therapy.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Safe Use of Equipment

Remove malfunctioning equipment from client care area and report the problem to appropriate personnel

23. While performing a morning check on the crash cart and defibrillator, the nurse notices the defibrillator does not charge and discharge as expected. Which action by the nurse is most appropriate?
- Place a repair tag on the equipment for biomedical services to pick up.
 - Notify the charge nurse and page biomedical services to check the equipment.

- C. Notify the house supervisor and request a temporary cart and defibrillator.
- D. Ask the nursing assistant to take the cart to the biomedical department and ask for an immediate repair.

The answer is C. If a defibrillator is found to be nonfunctioning, then the nursing supervisor needs to replace the equipment immediately to cover the area in the event a code occurs.

A is incorrect—Placing a tag on the equipment does not resolve the problem, which leaves the clients on the floor vulnerable if cardiac arrest occurs. B is incorrect—Paging biomedical services is not a resolution to the need for a new defibrillator. D is incorrect—Although asking for an immediate repair is possible, it may not be repaired. The need to replace the defibrillator is immediate and a replacement is needed while repairs are being completed.

HEALTH PROMOTION AND MAINTENANCE

Health Screening

Perform targeted screening exams

24. A school nurse should schedule which type of screening exam for all 12-year-olds enrolled in the school?
- A. Scoliosis
 - B. Diabetes
 - C. Hypertension
 - D. Hearing

The answer is A. Scoliosis screening occurs when a child reaches the age of puberty and should be conducted in the school setting with referrals made as needed.

B is incorrect—Diabetes is not a screening exam that needs to be performed in the school setting. C is incorrect—Hypertension screenings are not needed in the school setting. D is incorrect—Hearing exams are performed before school and if a child complains of difficulty hearing in class.

PSYCHOSOCIAL INTEGRITY

End-of-Life Care

Assist client/family/significant others in resolution of end-of-life issues

25. During the initial meeting with a client who has been referred for palliative care for a terminal illness, what is the primary nursing goal?
- A. To determine the client's religious preference.
 - B. To determine the client's goals for the care to be provided.
 - C. To form a trusting relationship with the client.
 - D. To form a list of support systems that the client can use.

The answer is C. The primary goal of the nurse during the first encounter with a client who is in need of palliative care is to form a trusting relationship. The trusting relationship is the bridge to begin planning care that will focus on the level of care he or she desires and to ensure that the end of life is met with the client having a sense of control.

A is incorrect—The client's religious preference is important but is not the goal of the initial meeting. B is incorrect—The nurse will determine the client's goals for care after a trusting relationship has been formed with the client. D is incorrect—A list of support systems for the client will be formed after an analysis is performed of the client's goals, current financial situation, family members, physical abilities, religious preferences, and psychosocial status.

PSYCHOSOCIAL INTEGRITY

Unexpected Body Image Changes

Assess client/family/significant other's reactions to a change in body image

26. Which statement made by a client indicates that acceptance of a new colostomy has not occurred?
- A. "My husband will never want to be intimate with me again."
 - B. "I will experiment with various pouches to see which one controls odor the best."
 - C. "I plan on beginning elimination training for my colostomy as soon as the doctor says it is okay."
 - D. "I will teach my spouse how to work with the colostomy in the event I ever need assistance."

The answer is A. The client is feeling despair that her spouse will not accept the changes she has undergone and will not desire her in a way he once did. She has not accepted the colostomy and assumes her spouse has not either.

B is incorrect—The client has accepted the colostomy and is ready to work with it so that it fits into her life. C is incorrect—The client has accepted the colostomy and is open to working with it to fit her needs. D is incorrect—The client has accepted the colostomy and is ready to teach others how to work with it as she does.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Monitor client's hydration status

27. Which of the following is the best indicator of a negative hydration status in a client who weighed 200 pounds on admission and has been vomiting for 3 days after being diagnosed with diabetic ketoacidosis?
- A. Daily weight of 170 pounds on day 3.
 - B. Serum glucose 100 mg/dL.

- C. Ketones negative in urine.
- D. Potassium level 4.0 mEq/L.

The answer is A. The client who is dehydrated will have a decrease in daily weights. This is a reflection of a negative fluid volume status.

B is incorrect—The serum glucose will rise in a client who is dehydrated due to insulin deficiency and glycogen breakdown to glucose of which cannot be eliminated by the body. C is incorrect—Ketones are positive due to free-floating fatty acids. The ketones are not eliminated due to low urine output and fluid volume deficit leading to ketones being in the urine. D is incorrect—As the client vomits and the potassium leaves the cell and goes to circulation, the level will rise; 4.0 mEq/L is considered a normal potassium level and therefore is an incorrect response.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Central Venous Access Devices

Access implanted venous access devices

28. A client has a medi-port for chemotherapy administration. The nurse has an order to access the medi-port for a blood draw and the administration of normal saline at 125mL/hr. The nurse will plan on obtaining which of the following to access the device?
- A. A 20-gauge 1.5-inch Huber needle
 - B. A 20-gauge 1.5-inch jelco
 - C. A butterfly needle
 - D. A needleless syringe system

The answer is A. A Huber needle is required to access a medi-port system so that damage will not occur to the structure of the system.

B is incorrect—A jelco is not the correct needle to access a medi-port. The use of a jelco would damage the implanted device and possibly the client. C is incorrect—A butterfly needle is small and used for lab collection only. It does not contain a catheter for fluid administration. D is incorrect—A needle is required to access the medi-port. A needleless system can be used after the medi-port is accessed by the appropriate needle.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Administer/maintain/discontinue total parenteral nutrition

29. Which site is the best for administering total parenteral nutrition to a client whose feeding contains greater than 10% glucose?

- A. PEG tube
- B. NG tube
- C. Peripheral site
- D. Central catheter site

The answer is D. The preferred site for the administration of parenteral nutrition is to use a central catheter site to prevent damage to the peripheral areas.

A is incorrect—Parenteral nutrition is administered intravenously not in a PEG tube site; tube feedings are reserved for PEG tube sites. B is incorrect—TPN is an intravenous form of feeding a client and an NG tube goes directly to the stomach, which requires tube feeding solutions. D is incorrect—Placing a high concentration of glucose in a peripheral site will irritate the vein and can cause damage to the client's surrounding tissues. TPN with greater than 10% glucose should use a central site.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Alterations in Body Systems

Monitor client output for changes from baseline

30. The client's output trend from a chest tube drainage system is as follows:

| | 0700 | 1500 | 2200 |
|-------|--------|--------|--------|
| Day 1 | 600 mL | 750 mL | 648 mL |
| Day 2 | 500 mL | 425 mL | 400 mL |
| Day 3 | 400 mL | 380 mL | 400 mL |
| Day 4 | 500 mL | 600 mL | 700 mL |

Based on the data trended, which initial action by the nurse would be best?

- A. Report the trend to the physician.
- B. Continue to monitor the client's drainage.
- C. Review the chart to see what the acceptable parameters are.
- D. Increase the suction on the chest tube.

The answer is C. On day 4 the output is similar to day 1, the nurse should verify with the chart what parameters are acceptable before consulting the physician.

A is incorrect—Before calling the physician, the nurse should verify the parameters with the chart to see what the physician considers acceptable. B is incorrect—Continuing to monitor the client comes after ensuring that the output is within expected limits. D is incorrect—The suction should never be increased unless a physician writes an order.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Identify signs and symptoms of client fluid and/or electrolyte imbalance

31. A client's serum calcium level is 7 mg/dL. What would be the clinical manifestations of for this laboratory result?
 - A. Abdominal cramps
 - B. Depressed DTRs and dysrhythmias
 - C. Lethargy and weakness
 - D. Numbness and tingling in the extremities

The answer is D. Normal serum calcium range is 8.5–10.5 mg/dL and so the client has hypocalcemia. Symptoms of hypocalcemia include numbness and tingling in the extremities, carpedal spasm, and ultimately tetany.

A, B, and C are incorrect—Lethargy and weakness as well as depressed deep tendon reflexes, anorexia, nausea, vomiting, constipation and dysrhythmias are symptoms of hypercalcemia. Abdominal cramping occurs with hyponatremia.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Implement procedures to counteract adverse effects of medications and parental therapy

32. A client who takes digoxin (Lanoxin) at home has presented with a digoxin level of 4 ng/mL and a heart rate of 38. What is the priority nursing action?
 - A. Set up the client for external pacing.
 - B. Administer Atropine 1 mg IV.
 - C. Administer Digibind 228 mg IV.
 - D. Assess the client for visual changes and nausea/vomiting.

The answer is C. The therapeutic digoxin level is 0.5–2 ng/mL. The client who has digitalis toxicity will require a dose of Digibind, which binds to the digoxin in the serum and removes it from the circulating system.

A is incorrect—The client does not need external pacing for digoxin toxicity. B is incorrect—While Atropine will raise the heart rate, it will not remove digoxin from the serum, which is the cause of the bradycardia. D is incorrect—The client may have visual changes and nausea/vomiting but the priority nursing action is to remove the digoxin from the system. The nurse understands the client is has digoxin toxicity by the level in the serum and the client's heart rate.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Radiation Therapy

Implement interventions to address side/adverse effects of radiation therapy

33. What is the priority of care in a client that is undergoing external radiation therapy?
 - A. Washing the markings off of the face.
 - B. Maintaining a 6-ft distance.
 - C. Grouping client care to minimize exposure to the radiation.
 - D. Assessing the skin for burned areas.

The answer is D. The client should be assessed for areas that are burned so that treatment can occur to prevent further damage to the skin and underlying tissues. Fluid volume status should also be addressed due to the body's response to the burn.

A is incorrect—The markings placed on the body for radiation therapy should not be removed to ensure that alignment of the radiation can occur with preciseness. B is incorrect—Only with internal radiation should a distance be kept from the patient. C is incorrect—Grouping client care to minimize exposure to radiation is not necessary with external radiation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Apply knowledge of nursing procedures and psychomotor skills when caring for a client experiencing a medical emergency

34. A client presents to the emergency department after being involved in a vehicular accident. The client has obvious facial fractures and a head injury. The nurse should refrain from:
 - A. placing a nasogastric tube.
 - B. inserting a urinary catheter.
 - C. cleaning the blood from the face.
 - D. bagging the client with a bag valve mask and high flow oxygen.

The answer is A. With obvious facial fractures, the client should not receive a nasogastric tube through the nose.

B is incorrect—A urinary catheter is safe as long as there is not any blood at the meatus. C is incorrect—The nurse should clean blood from the face to see what injuries are present. D is incorrect—The client can be bagged with BVM until an artificial airway is placed by the physician.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Understand communicable disease and the modes of organism transmission

35. A client is admitted with active tuberculosis. Which form of isolation should the client be placed on?
- Contact
 - Droplet
 - Airborne
 - Standard

The answer is C. Airborne isolation includes particles transmitted by droplet or airborne particles. By placing the client on airborne isolation, the client receives a room with negative airflow; mask are worn by staff while in the patient room and by the patient if out of the room for test.

A is incorrect—Contact isolation is for pathogens that are transmitted through direct or indirect contact with the client or items the client may have touched. B is incorrect—Droplet transmission is when the client coughs or the mucous membranes of the client are touched. Droplet transmission does not mean the client will need negative air pressure in his or her room since the particles are not suspended in the air as they are with airborne. D is incorrect—Standard is used for blood or body fluid pathogen transmission.

HEALTH PROMOTION AND MAINTENANCE

Family Systems

Assess impact of change on family system

36. Which statement made by a parent would indicate a need for immediate evaluation and counseling after the birth of the fifth child?
- “I just don’t know how I will pay for college for all of the children.”
 - “I have thoughts of throwing the baby in a dumpster.”
 - “The four oldest siblings argue constantly over the remote.”
 - “I wish I made more money so my family would be happier.”

The answer is B. The parent making the statement of the desire to throw the baby in the dumpster is indicative of a need for counseling. The parent could be experiencing depression or psychosis that needs intervention.

A is incorrect—Wondering how a parent will pay for college is a normal concern and does not pose an immediate

threat to the parent or children. C is incorrect—A sibling arguing with another is normal and does not pose a threat to the children or parent. D is incorrect—A parent wishing he or she made more money is normal and does not pose an immediate threat.

HEALTH PROMOTION AND MAINTENANCE

Lifestyle Choices

Assess client lifestyle choices

37. Which statement made by a parent indicates that a child may need to be evaluated every year by a health care provider?
- “My children are home schooled to avoid societal influences.”
 - “I allow my children to attend private schools only.”
 - “We encourage our children to take a multivitamin at bedtime every night.”
 - “We don’t allow our children to go outside alone.”

The answer is A. The parents in this situation have chosen to teach the children at home to avoid societal influences. The children need a yearly screening to note for developmental delays and issues associated with a lack of social interaction with other children. The children are also at risk for being victims of abuse by not having outside observers to notice signs or symptoms of abuse leading for the need of the parents to participate in a yearly evaluation of the children by a health care professional.

B is incorrect—The parents have chosen to place their children in private schools, which still allows for health screenings by the school nurse and evaluations for signs of abuse. C is incorrect—Taking a multivitamin is not a reason for yearly visits to the physician. D is incorrect—By not allowing children to go outside alone, the children are being protected from external dangers; furthermore, this is not a reason for yearly visits by a health care provider.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

Assess client for drug-/alcohol-related dependencies, withdrawal, or toxicities

38. A client presents with a history of illegal use of prescription narcotics. Which assessment data is the earliest sign of withdrawal?
- BP 90/60, HR 100
 - Anxiety, irritability
 - Insomnia, diarrhea
 - Nausea, vomiting

The answer is B. Anxiety and irritability is one of the first signs of opioid withdrawal with salivation, diaphoresis, and other symptoms following.

A is incorrect—The client presents with hypertension and tachycardia with an opioid withdrawal. C is incorrect—Insomnia does occur with opioid withdrawal but later in the cycle. Diarrhea is usually not seen as the client has a decrease in motility due to the opioid. D is incorrect—Nausea and vomiting occur late in the withdrawal process.

PSYCHOSOCIAL INTEGRITY

Grief and Loss

Assist client/family/significant others in coping with suffering grief, loss, dying, and bereavement

39. A client is nearing the end of his life. To assist the family to cope, the nurse should suggest that the family:
- tell the client good-bye.
 - leave the client to die in peace.
 - become visibly upset to expel all emotions.
 - contact a local psychiatrist to discuss what has occurred.

The answer is A. The family will gain closure through telling the client good-bye. Gaining closure will help the family through the grieving and bereavement process.

B is incorrect—When the family leaves the client, they carry the fact that their family member died alone and this can harm the grieving process. C is incorrect—A family should respond to death in their own way; therefore, encouraging the family to become visibly upset is inappropriate. D is incorrect—The family should be provided with a list of support services to assist with grieving but a family should not be instructed to contact a psychiatrist by the nurse.

PSYCHOSOCIAL INTEGRITY

Stress Management

Implement measures to reduce environmental stressors

40. A client is being weaned from a patient controlled analgesic pump (PCA pump). Which nursing intervention would be best to assist in the control of pain?
- Provide small chatter in the background.
 - Play classical music in the background.
 - Darken the room and close the door.
 - Teach the client to only call for pain meds when pain is a 10/10.

The answer is C. Dimming the lights and closing the client's door will lessen environmental stressors, which can precipitate pain.

A is incorrect—Chatter can be perceived as an added stress to the client. B is incorrect—While music in the back-

ground can assist in pain control, the client may find classical music annoying and not helpful. The client should be allowed his or her favorite music, if desired, during the period weaning. D is incorrect—The client should learn to call for pain medication before the pain is a 10/10 or pain management becomes more difficult.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Monitor client hydration status

41. Based on the postsurgical client's 24-hour intake and output documentation, which data should be reported to the physician?

| | Day 1 | | Day 2 | | Day 3 | | Day 4 | |
|---|--------|--------|--------|--------|--------|--------|--------|--------|
| | Intake | Output | Intake | Output | Intake | Output | Intake | Output |
| A | 2000 | 1000 | 1500 | 1250 | 1325 | 1300 | 1250 | 1300 |
| B | 2000 | 900 | 1800 | 1100 | 1750 | 1000 | 1500 | 1000 |
| C | 2000 | 1700 | 1700 | 1625 | 1575 | 1400 | 1300 | 1275 |
| D | 2000 | 1500 | 1500 | 1300 | 1400 | 1300 | 1425 | 1400 |

The answer is B. The client is not maintaining an appropriate fluid balance after surgery as expected and the chances of electrolyte imbalances and pulmonary edema are high. The physician should be notified so that pharmacological interventions can occur and a fluid restriction can be ordered.

A, C, and D represent a normal ratio of fluid intake to fluid lost and does not require notification of the physician.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and Blood Products

Check the client for appropriate venous access for red blood cell/blood product administration

42. Prior to administering a blood product, the nurse must ensure which of the following is present?
- A patent intravenous line
 - Y-Site tubing
 - An intravenous pump
 - A 20 gauge or large intravenous line

The answer is D. A client must have a 20 gauge or larger intravenous line before blood products can be administered. If this is not present, a new IV must be initiated.

A is incorrect—While a patent line is important, the size of the line is the most important item a nurse must ensure is present before blood is administered. A 22-gauge line may be patent, but it is not sufficient for blood administration and a

new site IV must be initiated. B is incorrect—Y-site tubing is important but not as important as the correct size intravenous line. C is incorrect—Blood should be administered on a pump, but it is not as important to ensure a pump is present as it is to ensure the proper size intravenous line is present.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Review pertinent data prior to medication administration

43. Prior to administration, a client starting an increased dose of clonidine (Catapres) should be assessed for which of the following
- Orthostatic hypotension
 - Tachycardia
 - Hyperglycemia
 - Oliguria

The answer is A. A client who starts an increased dose of Catapres will experience orthostatic hypotension and so assessment for preexisting orthostatic hypotension is important and the physician can be notified for further orders.

B is incorrect—An adverse effect of Catapres is bradycardia not tachycardia and is not a contraindication to administering the medication. C is incorrect—Hyperglycemia is not a side effect of Catapres and is not a contraindication to administering the drug. D is incorrect—There is no contraindication to administering Catapres if oliguria is present.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Monitor client for side/adverse effects of TPN

44. For a client that is receiving total parenteral nutrition (TPN), which assessment data would be most indicative of infection within 48 hours of initiation of therapy?
- Confusion
 - Diaphoresis
 - Heart rate 120
 - Temperature of 101°Fahrenheit.

The answer is D. Fever in an afebrile patient is indicative of sepsis in a client that is receiving TPN.

A is incorrect—Confusion is common in the first 24–48 hours of initiation of TPN. This is due to the shift of electrolytes from the plasma to the cell. B is incorrect—Diaphoresis is common with hypoglycemia associated with TPN. C is incorrect—While tachycardia accompanies a fever, it is not the most indicative sign of infection in the client.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Intervene to manage potential circulatory complications

45. Which finding in a client who has undergone repair of a radial fracture 12 hours ago would require immediate notification of the orthopedic surgeon?
- Pain at the incision site
 - Edema of the affected arm
 - Pain with passive movement of the fingers
 - Fever

The answer is C. The client has compartment syndrome and one of the indicative signs is pain with passive movement of the fingers. This requires the physician to be notified immediately so that intervention can occur.

A is incorrect—Pain is common after a surgical repair of a fractured arm. B is incorrect—Edema is common after surgical repair due to the body's response to the injury and the beginning of repair. D is incorrect—Fever is a sign of infection and should be reported but it does not require the nurse to notify the orthopedic surgeon immediately.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform a risk assessment

46. A home health nurse is performing an admission assessment on a client who has been discharged from the hospital. Which finding on the risk for falls assessment must be resolved prior to the nurse leaving the home?
- Carpet in the home
 - Throw rugs over hardwood floors
 - Shower/tub combo with shower curtain
 - Steps leading into the home

The answer is B. Throw rugs over hardwood floors are a common problem in homes of older clients and is an area where clients may fall. The nurse should remove the throw rugs prior to leaving the home and explain to the client her rationale.

A is incorrect—Carpet is not a falls risk. C is incorrect—While a tub/shower combo is not ideal and the client can fall getting into or out of the tub, the nurse cannot fix this before leaving and should request items that would assist the client to continue using the shower. D is incorrect—Although steps leading into the home present a fall risk, the nurse cannot modify these.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Evaluate achievement of client treatment goals

47. A client with a history of COPD complains of increased shortness of breath and has wheezing noted upon auscultation. The client is administered a nebulizer treatment of Albuterol and Atrovent. Which evaluation would indicate a therapeutic response to this treatment?
- Increase in wheezing upon auscultation
 - Pink frothy sputum
 - Decrease in shortness of breath
 - Decrease in heart rate

The answer is C. The client is complaining of shortness of breath, and therefore, a decrease would be considered a therapeutic response to the treatment.

A is incorrect—An increase in wheezing upon auscultation is not considered a therapeutic response to the breathing treatment. B is incorrect—Pink frothy sputum is indicative of pulmonary edema and is not a therapeutic response to the treatment. D is incorrect—A decrease in the heart rate is not a therapeutic response and indicates a complication since Albuterol and Atrovent are known to increase the client's heart rate.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Apply knowledge of pathophysiology when caring for a client experiencing a medical emergency

48. A client presents to the emergency department after being ejected from an all terrain vehicle. The client received an opioid analgesic in route for control of pain associated with a lower leg injury. Which assessment data is most indicative of early increased intracranial pressure?
- Irritability
 - Hypotension
 - Pupils 2 mm
 - Decreased respiratory rate

The answer is A. Irritability is the most indicative sign of increased intracranial pressure due to the changes the oxygen the brain receives due to compressed vessels. The absence of oxygen places the brain in a state of hypoxia, which causes irritability to occur.

B is incorrect—Hypertension is a sign of increased intracranial pressure due to the excited fibers, which control

vasoconstriction. C is incorrect—Pupil dilation occurs due to increased intracranial pressure but in this case the pupils are constricted due to the administration of an opioid analgesic in the field. D is incorrect—Initially, the respiratory rate will be increased due to the body's response to hypoxia, as a late sign it will decrease.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Radiation Therapy

Apply knowledge of pathophysiology when discussing radiation therapy with client/family/significant others

49. A nurse is teaching a client about care of a wound after surgery, which will also be the site of radiation treatments. Discharge instructions should include:
- How to care for the surgical site.
 - Signs and symptoms of delayed wound healing.
 - How often to report to outpatient for a treatment.
 - Signs and symptoms of anaphylactic reaction to radiation.
 - Signs of radiation toxicity.
 - Foods to avoid during therapy.

The discharge instructions should include how to care for the surgical site and the signs and symptoms of delayed wound healing since difficulties in wound healing are common in the client undergoing radiation therapy. Reporting to outpatient is important so that treatments stay on the scheduled path for the greatest benefits. Radiation toxicity is common and the signs and symptoms should be discussed with the client so that the individual can seek medical attention as needed. Foods to avoid are taught about due to the possibility of oral ulcerations and sores associated with radiation therapy.

Anaphylactic reactions are not a risk with radiation therapy.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and Blood Products

Administer blood products and evaluate the client response

50. A nurse has an order to administer packed red blood cells to a client. Prior to administration, the nurse should (check all that apply):
- obtain consent
 - gather IV tubing with a filter
 - gather D5 ½ NS
 - prime the line with fluid
 - check the blood with either an RN or LPN

- ___ warm the blood to 100°F
- ___ assess the site for patency

Before administering blood, the nurse should obtain consent for blood administration, gather IV tubing ensuring a filter for blood administration is present, prime the line with fluid, and assess the site for patency.

The nurse should not use D5 ½ NS for blood administration. Only NS can be used for blood administration and only an RN can check blood with another RN. The blood should not be warmed unless orders are present to warm the blood to a specific temperature for rapid infusion. Warming of the blood will cause it to clot and can promote bacterial growth.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Reporting of Incident/Event/Irregular Occurrence/Variance

Report error/event/occurrence per protocol

51. A nurse walks into a room after the bathroom call light is sounded and finds a client lying on the floor. The client states that he became dizzy and lost his balance after using the bathroom. Which documentation of the fall is most appropriate?
- “Client fell after standing-up from the toilet.”
 - “Client fell due to lowering in blood pressure upon standing.”
 - “Client found lying in floor, states ‘I became dizzy and lost my balance after using the bathroom.’”
 - “Client experienced a vagal response and fell after using the bathroom.”

The answer is C. The nurse should only document what she saw and what the client told her. Documentation other than what was stated and visualized is falsifying a document.

A is incorrect—This is a nursing assumption and is not legal. B is incorrect—This is not reporting what was seen or what the client told the nurse; therefore, it is inappropriate charting. D is incorrect—This is assuming the client experienced a vagal response and is not appropriate charting.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

Calculate expected delivery date

52. A client has her pregnancy confirmed by the nurse in a physician’s office. The client wishes to know her expected date of delivery and the first day of her last

menstrual period was July 4th. The nurse calculates the delivery date as:

- April 10th
- April 11th
- April 1st
- April 4th

The answer is B. The client’s expected date of delivery is April 11th. This is calculated by subtracting 3 months from the month the client had her last menstrual period and adding 7 days to the date of the last menstrual period.

A, C, and D are incorrect using this method.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

53. List in order from first to fourth the assessment technique used for a client who is complaining of abdominal pain.
- Inspection
 - Palpation
 - Auscultation
 - Percussion

Inspection is the first step for an assessment of the gastrointestinal system. The second step is auscultation so that sounds can be heard since manipulation of the abdominal wall may alter sounds. The third step is to percuss for tympani or dullness and the last step is to palpate the abdomen for pain, tenderness, or other abnormalities.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Values

Obtain specimens other than blood for diagnostic testing

54. A nurse has an order for a wound culture to be taken via aspiration; prior to aspirating the wound bed, the nurse should:
- massage the wound bed.
 - irrigate the wound bed with normal saline.
 - clean the wound bed edges with normal saline.
 - dry exudate from the wound bed with sterile gauze.

The answer is B. The wound bed should be irrigated first with normal saline to remove exudate, which allows for fresh exudate from the wound bed to surface.

A is incorrect—The wound is massaged after the old exudate and saline irrigant is removed from the wound bed.

C is incorrect—Wound edges are not required to be cleaned when aspirating for a culture. D is incorrect—Exudate is removed from the wound bed with sterile gauze after saline irrigant is placed in the wound.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Continuity of Care

Perform procedures necessary for admitting, transferring, or discharging a client

55. Prior to transferring a client from the medical surgical floor to the intensive care unit, the nurse should first:
- obtain a signed consent from the client for transfer.
 - notify the nurse manager.
 - obtain an accepting physician.
 - phone a report to the nurse in the ICU who will receive the client.

The answer is D. The nurse must transfer care of the client to another nurse and this is performed in a patient report.

A is incorrect—A client does not need to sign consent if a transfer is within the same facility. B is incorrect—A nurse manager is not needed in a transfer as long as there is a physician order and a bed is available in the receiving unit. C is incorrect—The client's primary physician is responsible for following the client within the facility, and if a transfer of care to another physician is required, it is the responsibility of the physician to obtain an accepting physician.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Staff Education

Assess purpose of staff education activities

56. A nurse understands that the primary rationale behind attending an in-service for newly acquired unit specific equipment is to:
- aid in medicaid reimbursement for the hospital.
 - gain continuing education credits for licensure.
 - meet JCAHO requirements for staff education of hospital equipment.
 - maintain patient safety by understanding the proper use of hospital equipment.

The answer is D. The nurse possesses the responsibility to remain current on all equipment that is used in a specific area of employment so he or she can assist in maintaining

patient safety. Being unfamiliar with equipment can lead to litigation if he or she is negligent and causes client harm.

A is incorrect—Medicaid does not require nurses to attend in-services before reimbursement for client care is awarded. B is incorrect—While gaining continuing education credits are possible with some in-services, those that deal specifically with equipment use are not governed by the licensure board therefore are not applicable for continuing education credits. C is incorrect—JCAHO requires that staff is educated regarding equipment used in the facility but the primary purpose of attending an in-service on equipment use is to maintain patient safety.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

Provide care that meets the special needs of the preschool client ages 1 month to 4 years

57. When performing a routine assessment on a 1-year-old client, which data should be collected first?
- Rectal temperature
 - Heart rate
 - Respirations
 - Blood pressure

The answer is C. Respirations should be counted first before the client becomes upset with the assessment process. Changes in respiratory rate will often occur before other signs and symptoms are present in a child.

A is incorrect—The rectal temperature should be performed last since it will upset the child. B is incorrect—The heart rate should be assessed after the respiratory rate since it requires a stethoscope and will alter the respiratory rate if the client becomes upset. D is incorrect—The blood pressure is not performed on the 1-year-old client unless there is a cause of concern such as altered level of consciousness, depressed or bulging fontanel, or signs and symptoms of dehydration. In this scenario, the assessment is routine.

HEALTH PROMOTION AND MAINTENANCE

Health and Wellness

Evaluate client/family/significant other understanding of health promotion behaviors/activities

58. A client in the doctor's office for a routine check-up demonstrates an understanding of health promotion behaviors and activities when he says that he will: (check all that apply)
- walk at least twice a week.
 - avoid excessive caffeine.

- cut down to one pack of cigarettes a day.
- eat a vegetable at every meal.
- take medication exactly as prescribed.
- have blood pressure checked regularly.

The client voicing that he will walk at least twice a week, avoid excessive caffeine, eat a vegetable at every meal, take medication as prescribed and have blood pressure monitored frequently demonstrates an understanding of health promotion behaviors and activities.

The client stating he will cut down to one pack of cigarettes a day shows he does not realize the necessity of quitting smoking to improve health and further education is needed.

PSYCHOSOCIAL INTEGRITY

Abuse/Neglect

Identify risk factors for domestic, child and/or elder abuse/neglect, and sexual abuse

59. Which clients are at a high risk for sexual abuse? (Select all that apply.)
- An 8-year-old boy who lives with both parents.
 - A 6-year-old girl living in foster care.
 - A 21-year-old female living in a college dorm.
 - An 88-year-old client living in a nursing home.
 - An 18-year-old male living in an apartment in a new town.

The answers are the 6-year-old girl living in foster care and the 21-year-old female living in a college dorm. Females are at a higher risk for sexual abuse than any other group. Sexual abuse for this group can consist of molestation of the 6-year-old girl or rape of either the 6- or 21-year-old.

Incorrect—The 8-year-old is at a low risk because he is male and lives with both parents making it a stable environment. The 88-year-old client living in a nursing home is at a low risk of being sexually abused due to age and facility. An 18-year-old male is at a low risk of being sexually abused even though he lives in a new town.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Identify signs and symptoms of impaired cognition

60. A client's family is concerned about recent changes in their family member's behavior and is afraid that he is developing Alzheimer's disease. Which signs and symptoms reported by the family is associated with Alzheimer's disease? (Check all that apply.)
- Memory loss
 - Seizures
 - Syncope
 - Personality changes

- Anorexia
- Poor judgment

The answers are memory loss, personality changes, anorexia, and poor judgment. All of these are signs and/or symptoms of Alzheimer's disease and require reporting to the physician for follow up.

Seizures is incorrect—they are not associated with the disease. Syncope is not associated with Alzheimer's unless a pre- or coexisting cardiac problem exists.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Complementary and Alternative Therapies

Evaluate client/family/significant other outcomes of alternative and/or complementary therapy practices

61. A cancer client has been attending yoga to aid in relaxation and mind healing. Which evaluation would indicate a therapeutic response to this alternative therapy?
- A. The client claims to be "cancer free."
 - B. The client has decided death will occur and is ready to "pass on."
 - C. The client states she has found inner strength and has accepted the diagnosis.
 - D. The client has decided to stop treatment and allow the body to heal itself.

The answer is C. The cancer patient will often turn to alternative therapies to assist in the treatment process. Yoga has proven to be a method of relaxation and allows for reflection and finding peace within one's self. The client who has a successful response to yoga will find the peace within and learn how to relax and channel thoughts until peace is achieved.

A is incorrect—The client has a false sense of being cancer free and this has proven to be a negative result of an alternative therapy. B is incorrect—The client has made the decision that the end will occur and this can leave the client with a negative outlook on the future and impede healing. D is incorrect—The client has a false assurance of the reality of yoga and the expectations of ones self. The client needs counseling on the benefits of yoga and the expected outcomes.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Assess client for actual or potential side effects and adverse effects of medications

62. A client is being discharged home with a prescription for warfarin (Coumadin). Discharge instructions include:
- A. avoid Tylenol while taking Coumadin.
 - B. avoid ginseng while taking Coumadin.

- C. avoid clopidogrel (Plavix) while taking Coumadin.
- D. avoid clonidine (Catapres) while taking Coumadin.

The answer is B. A client who takes Coumadin should avoid taking herbal supplements that contain ginseng due to the risk of increased risk of blood thinning beyond desired effects.

A is incorrect—Tylenol is acceptable to take while on Coumadin therapy unless hepatic function is impaired. C is incorrect—Plavix is a common drug used to prevent platelet aggregation and is compatible for use with Coumadin therapy. D is incorrect—Catapres is commonly used for hypertension and is compatible with Coumadin therapy.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Interactions

Provide client/family/significant others with information on known pharmacological interactions of medication prescriptions

63. A client is prescribed theophylline (Theo-24) for COPD. Discharge instructions should include the interaction of which of the following:
- A. Nicotine transdermal patches
 - B. fosinopril (Monopril)
 - C. Advair Diskus 250/50
 - D. clopidogrel (Plavix)

The answer is A. Nicotine is contraindicated with the use of theophylline because of the stimulant effects and may cause tachycardia.

B is incorrect—Monopril is an ACE inhibitor and does not carry any interactions with theophylline. C is incorrect—Advair is a nonsteroidal bronchodilator and is safe to be used concurrently with theophylline. D is incorrect—Plavix is a platelet aggregate and is safe to be used with theophylline.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Intervene when client vital signs are abnormal

64. The vital signs on a client are as follows:
- B/P 178/120
 - P 112
 - R 28
 - O₂Sat 98%
 - T 99.0

The client is complaining of a headache and blurred vision. Which medication from the client's MAR should the nurse administer?

- A. Metoprolol (Toprol XL) 100 mg p.o.
- B. Clonidine (Catapres) 0.3 mg p.o.

- C. Metoprolol (Lopressor) 5 mg IV
- D. Tylenol 650 mg p.o.

The answer is C. The client meets criteria for a hypertensive crisis. Lopressor is to be given intravenously. This is the best drug to give from the client's MAR. Lopressor will lower the blood pressure and heart rate.

A is incorrect—The Toprol XL will also lower blood pressure and heart rate, but it is taken by mouth and will take 30 minutes to act. In hypertensive emergency, intravenous antihypertensives are given followed by oral dosing. B is incorrect—The client has an increased heart rate as well as increased blood pressure, the drug of choice would be an antihypertensive agent that will work on both areas. The Catapres is used for hypertensive emergencies but it does not have a labeled use for lowering the heart rate and the oral dose will take longer to show results. D is incorrect—The client does have a low-grade fever and a headache, but the headache will resolve with a resolution in the blood pressure.

PSYCHOSOCIAL INTEGRITY

Abuse/Neglect

Assess client risk for abuse/neglect

65. Which client is at the highest risk for neglect?
- A. Infant of a 30-year-old woman who is single.
 - B. Infant of a 14-year-old girl who lives with her parents.
 - C. 95-year-old client living in an assisted living facility.
 - D. 79-year-old client living at home with her 41-year-old daughter.

The answer is B. Statistically, a child of a teenager is at the highest risk for neglect. The mother and father live with the teenager but in most situations, the teenager is still responsible for the care of the infant. A teenager generally does not have the coping skills and knowledge to care for an infant.

A is incorrect—The mother is an adult and the infant is less likely to be neglected. C is incorrect—A client in an assisted living facility is able to provide care with some assistance by other personnel lessening the chances of neglect. D is incorrect—The client living with her daughter is at a low risk with the daughter still young enough to provide adequate care.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Perform peritoneal dialysis

66. A nurse is performing peritoneal dialysis and instills 2 L of dialysate into the peritoneal cavity. After 30 minutes has elapsed, the client returns only 1 L of solution. The nurse should:

- A. have the client roll from side to side.
- B. gather a syringe and pull fluid from the peritoneal cavity.
- C. apply warm compresses to the abdomen.
- D. stop the process and call the physician.

The answer is A. The client should move from side to side in the bed so that drainage can occur.

B is incorrect—A syringe should not be used to pull dialysate from the cavity. C is incorrect—Warm compresses on the abdomen will not help removing the solution from the peritoneal cavity. D is incorrect—The physician should not be notified unless moving the client is unsuccessful in removing the fluid.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Review pertinent data prior to medication administration

67. A client has vancomycin (Vancocin) ordered every 12 hours. The client has one IV access and it currently has dopamine (Intropin) infusing to maintain blood pressure. Prior to the administration of the vancomycin (Vancocin) the nurse should:
- A. obtain another IV access.
 - B. check for patency of the existing IV site.
 - C. discontinue the Dopamine.
 - D. check for compatibility of Dopamine and Vancomycin.

The answer is D. Before obtaining another IV site, the nurse should check for compatibility of the Dopamine and the Vancomycin. If compatibility is not assured, then another IV site should be obtained.

A is incorrect—The nurse should check for compatibility first. B is incorrect—The patency of the IV line should be unquestionable if a medication is infusing in it currently. C is incorrect—Dopamine cannot be discontinued for the length of time it will take for Vancomycin to infuse.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

68. A client is being discharged after receiving the diagnosis of human immunodeficiency virus (HIV). Priority teaching at the time of discharge is:
- A. how to prevent the spread of infection to others.
 - B. when to take medications.
 - C. what foods to avoid.
 - D. when to follow up with physician.

The answer is A. Preventing the spread of the disease is the most important fact to teach the client prior to discharge from the hospital. This is most important with a new diagnosis of HIV.

B is incorrect—Although when to take medications is important, the nurse should first ensure that the client knows how to prevent the spread. C is incorrect—With a new diagnosis there are not any food restrictions. D is incorrect—When to follow up with the physician is important but not the most important fact to teach to the client before discharge.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Client Rights

Recognize the client's right to refuse treatment/procedures

69. A client who is scheduled to undergo chemotherapy today states, "I do not wish to undergo my treatment today." Which action by the nurse is most appropriate?
- A. Discuss with the client the need to follow the prescribed treatment regime.
 - B. Ask the client as to what has occurred to make him or her not want today's treatment.
 - C. Notify the physician that the client has refused a treatment.
 - D. Notify the chemotherapy nurse that the client has refused today's treatment.

The answer is B. The nurse needs to recognize that the client has the right to refuse treatment but he or she should also determine what has occurred to make the client refuse treatment so that an intervention can occur if needed.

A is incorrect—It discounts the client's feelings. C and D are incorrect—Although they recognize the client has refused treatment neither choice addresses the client and his or her current state of mind.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Information Technology

Use information technology to enhance the care provided to a client

70. A 14-year-old client has been diagnosed with diabetes and needs diabetes education at the time of discharge. Which method of instruction would be best for this client?
- A. A book that discusses diabetes, including how to administer medications.
 - B. Interactive computer software that discusses diabetes management.

- C. A diabetes educator discussing diabetes management in a group environment.
- D. A pamphlet that contains pictures on diabetes management.

The answer is B. A teenage would benefit most from computer software since teenagers are accustomed to a computer and learn best when they can interact with the information being given.

A is incorrect—A teenager is less likely to read a book discussing diabetes and thus leading to incomplete information. C is incorrect—Because of the nature of the illness and the psychological changes that a teenager goes through, a teenager often will not participate in a group discussion about diabetes management and therefore will not learn. D is incorrect—A pamphlet is not best for a teenager since they are active learners.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Home Safety

Educate client/family on home safety issues

71. Which of the following should be included in the discharge teaching for a family who is in the pediatrician's office for a 2-year-old well baby check-up?
- A. Cover all outlets in the home.
 - B. Place pots and pans on the front of the stove while cooking.
 - C. Avoid leaving the child for more than 1 minute while in the tub.
 - D. Remove all pets while the child is in the home.

The answer is A. A 2-year-old child is ambulatory and possess the motor skills to place objects in the electrical outlets which could potentially cause an electrical shock. The parents need to cover all outlets to prevent this from occurring.

B is incorrect—The parents should not place pots and pans on the front of the stove. They should be placed on the back. C is incorrect—A child should never be left alone in the tub. D is incorrect—Pets are not required to be removed from the home unless the child has an allergy to pets or other risks are associated.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Emergency Response Plan

Implement emergency response plans

72. A nurse would expect the internal disaster plan to be enacted if which event occurs?

- A. Plane crash
- B. Infant abduction
- C. Fire in a client's room
- D. Explosion at a local plant

The answer is C. A fire in a client's room is an internal disaster and the plan should be enacted by administrative staff.

A is incorrect—A plane crash is an external disaster and requires an external disaster plan to be enacted. B is incorrect—An infant abduction carries a separate plan of action by the hospital and is not considered an internal disaster. D is incorrect—An explosion at a local plant is an external disaster and requires the external disaster plan to be enacted.

HEALTH PROMOTION AND MAINTENANCE

Expected Body Image Changes

Assess occurrence of expected body image changes

73. A client is in the hospital after experiencing a burn to the face. Which statement made by the client demonstrates an acceptance of the change in her appearance?
- A. "I will make sure to avoid going outside during the day."
 - B. "I am ready to look into the mirror."
 - C. "I can put a scarf over my face so no one will notice."
 - D. "Going to a salon is worthless; a new hairstyle won't fix my deformity."

The answer is B. This statement made by the client demonstrates an acceptance of the changes that occurred as a result of the burn. The client is ready to see her face after the event, which is the first step to healing.

A is incorrect—This demonstrates that the client continues to have a disturbed body image. C is incorrect—Wearing a scarf is a sign that the client has not accepted the changes that have occurred. D is incorrect—The client continues with a disturbed body image and has yet to accept the changes that have occurred. The client needs continued support and counseling.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Reporting of Incident/Event/Irregular Occurrence/Variance

Identify need/situation where reporting of incident/event/irregular occurrence/variance is appropriate

74. The nurse should fill out an incident report for which occurrence?

- A. A client is found lying on the floor of his room.
- B. An “as needed” medication is given for a complaint of pain.
- C. Calling a physician for an illegible order.
- D. A medication is held due to a decreased blood pressure.

The answer is A. A client found lying in the floor is considered an unexpected event and requires an incident report to be completed.

B is incorrect—A medication given for the complaint of pain is an expected occurrence and an incident report is not needed. C is incorrect—Calling a physician for an illegible order is preventing an error and does not require an incident report. D is incorrect—Holding a medication due to a low blood pressure is a valid nursing judgment and does not require an incident report.

PSYCHOSOCIAL INTEGRITY

Crisis Intervention

Assess the need for, initiate, and maintain suicide precautions

75. A client presents to the emergency department and states that he wants to kill himself. Which action by the nurse is the priority?
- A. Removal of client’s clothing.
 - B. Placement of client in room with camera.
 - C. Search of client for weapons.
 - D. Pad the side rails of the bed.

The answer is B. The first action by the nurse is to place the client in a room with a camera. The client will need to be monitored at all times and this is the best method.

A is incorrect—The client will need to remove clothing that could be used to assist with a suicide but this needs to be done in a room with a camera so that the staff can make sure the client is not harming self while alone. C is incorrect—The client’s clothing will be searched for a weapon upon removal and the search of clothing is performed by security staff. D is incorrect—The side rails do not need to be padded for a suicidal client. The padding of side rails is reserved for the client experiencing seizures.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to client and/or family

76. A pediatric client is scheduled for a bone marrow biopsy. The mother begins to sob stating, “I am a horrible mother for letting this happen to my little girl.” The nurse’s best response is:

- A. to leave the mother alone to cry.
- B. to ask “Is there anyone I can call for you?”
- C. to call the physician and request a sedative for the mother.
- D. to state “You are not responsible for your child being ill; you have placed your child in the best environment for what she needs.”

The answer is D. The mother needs hope for the situation at hand and needs to be reminded that this is not her fault and that she is doing what is best for her child.

A is incorrect—Leaving the mom will only worsen the situation. B is incorrect—The mother needs support at the moment. Calling other family is helpful but does not address the current situation. C is incorrect—The physician will not be able to prescribe a sedative for the mother. The mother must be of sound mind to make decisions for her child if needed and a sedative would impair her mental state.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Personal Hygiene

Assist the client in the performance of activities of daily living

77. Which of the following should a nurse perform every day to ensure the client’s activities of daily living have been met?
- A. Set the client in a chair with the supplies needed to bathe.
 - B. Administer medications on time.
 - C. Place a consult for occupational therapy.
 - D. Perform wound care.

The answer is A. The client needs to bathe every day, and to assist the client the nurse should set him or her in a chair and allow time for bathing.

B is incorrect—Administering meds is not ensuring that activities of daily living have been met. C is incorrect—Placing the consult does not ensure that activities of daily living have been met. D is incorrect—Wound care is not part of the client’s activities of daily living.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Evaluate and document client response to medication

78. Which of the following is a sign that IV ondansetron (Zofran) was therapeutic?
- A. The client has a bowel movement within 6 hours.
 - B. The client no longer complains of a headache.

- C. The client's abdominal pain is relieved.
- D. The client no longer complains of nausea.

The answer is D. Zofran is an antiemetic and is used for nausea and vomiting associated with chemotherapy and surgery.

A is incorrect—Zofran, as with all antiemetics, has the tendency to cause constipation. B is incorrect—Zofran does not contain any pain-relieving properties. C is incorrect—Zofran does not contain any pain-relieving properties.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Evaluate the results of diagnostic testing and intervene as needed

79. The technician reports to the nurse that the client has 2 mm ST segment elevation in lead II and III on a 12-lead electrocardiogram. What is the priority nursing intervention?
- A. Assess the client
 - B. Repeat the test
 - C. Administer Oxygen 2L NC
 - D. Phone the physician

The answer is A. When a nurse is presented with a suspicious test result, the nurse must first assess the patient for signs and symptoms of distress, as in this case, a suspected myocardial infarction. This allows the nurse to intervene as needed.

B is incorrect—The test may be repeated after an assessment of the client. C is incorrect—The nurse must first assess the client before performing any nursing action. D is incorrect—The physician is phoned after the nurse assesses the client and any actions are taken that are deemed necessary.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Identify factors that result in delayed wound healing

80. A nurse is assessing four of her assigned clients. Which client is at the highest risk for delayed wound healing?
- A. 18-year-old admitted after right knee arthroscopy.
 - B. 34-year-old diabetic admitted for hernia repair.
 - C. 64-year-old with peripheral vascular disease that underwent a toe amputation.
 - D. 78-year-old with congestive heart failure admitted for a thoracentesis.

The answer is C. The 64-year-old client with peripheral vascular disease is at the highest risk for delayed wound healing.

The client has vascular deficiency already as evidenced by the toe amputation. The body's ability to transport oxygen-rich blood and nutrients to the area is compromised and the client is likely to have difficulty healing from the procedure due to the already compromised state.

A is incorrect—The 18-year-old is not likely to have difficulty healing from the procedure. B is incorrect—While 34-year-old diabetic client will have difficulty with wound healing, the 64-year-old client with peripheral vascular disease is at the highest risk due to evidence of an already compromised system. D is incorrect—The 78-year-old client with congestive heart failure has a cardiac pump problem and will have decreased blood supply; although, for this question, C is the best answer.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Educate client and family about home management of care

81. A client is being discharged with a CPAP machine for a diagnosis of sleep apnea. Which of the following should be included in the discharge instructions?
- A. Clean the face mask with bleach solution.
 - B. Stop using the machine if noise precipitates insomnia.
 - C. Place the mask securely on the face.
 - D. Redness to the face where the mask is placed is normal.

The answer is C. The mask should fit securely on the face to prevent air leaking around the mask and causing eye irritation and maintain desired outcome.

A is incorrect—The bleach solution will harm the client's skin; the mask should be cleaned with vinegar and water solution. B is incorrect—The CPAP should be worn as directed by the physician and if the noise is causing insomnia, the physician should be notified. D is incorrect—Redness to the face may indicate an allergic reaction to the mask and should be reported to the physician.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Perform or assist with dressing change

82. A nurse has an order to perform central line care. Which action by the nurse will be best in removing bacteria from the catheter insertion site?
- A. Allowing the chlora-prep to dry on the site.
 - B. Scrubbing the insertion site for 2 minutes with chlora-prep.

- C. Wearing a mask during the procedure.
- D. Placing a medicated disk (bio-patch) around the insertion site.

The answer is B. Scrubbing the site with chlora-prep will be best nursing action in removing bacteria from the site of the catheter and prevent infection.

A is incorrect—The chlora-prep can dry on the site after it is scrubbed. C is incorrect—Wearing a mask is beneficial in preventing the introduction of new bacteria, but is not the best action when removing bacteria from the catheter insertion site. D is incorrect—Placing a bio-patch on the site will prevent growth of bacteria but it is not the best action in removing bacteria from the site.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolytes

Implement interventions to restore client fluid and/or electrolyte balance

83. A client has a magnesium level of 1.4 mg/dL. The nurse administers magnesium oxide at 1300 and will plan on ordering a redraw of the magnesium level at:
- A. 1500
 - B. 1600
 - C. 1700
 - D. 2100

The answer is C. Magnesium has an onset of action in 3 hours of administration. The blood redraw is performed in 4 hours from administration to see if a desired response occurred.

A and B are incorrect—These time frames are not long enough from administration to onset for levels to increase. D is incorrect—This time frame is too long from the time of administration to know if desired outcomes occurred.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Apply knowledge of pathophysiology to interventions in response to the client's abnormal hemodynamics

84. Which client will not exhibit the expected assessment findings in response to septic shock?
- A. A client with a previous myocardial infarction.
 - B. A client who is taking a beta blocker for hypertension.
 - C. A client who performs peritoneal dialysis.
 - D. A client with diabetes.

The answer is B. A client taking a beta blocker will not exhibit the heart rate change associated with septic shock and the blood pressures will remain at a lower level.

A is incorrect—A client with a myocardial infarction will exhibit the anticipated response. C is incorrect—A client who performs peritoneal dialysis will have the findings expected with septic shock. D is incorrect—While the client with diabetes will have an alteration such as an increase in blood pressure, the individual will exhibit the findings associated with septic shock.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Provide emergency care for wound disruption

85. List in order the steps the nurse will take if faced with a wound dehiscence
- ___ Notify the physician
 - ___ Cover the wound with sterile saline soaked gauze
 - ___ Lay the client in low Fowlers and bend the client's knees
 - ___ Instruct the client to splint the abdomen if needing to cough

The client should first lie down initially to prevent further strain on the incision site. Next, the nurse applies saline soaked sterile gauze to the area to keep the area moist. The nurse should then instruct the client on splinting during coughing in the event he or she needs to cough while the physician is being notified.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Unexpected Response to Therapies

Assess client for unexpected adverse response to therapy

86. A client is on the ventilator due to a diagnosis of acute respiratory distress syndrome (ARDS). Which assessment finding is most indicative of a complication?
- A. Diminished breath sounds on auscultation
 - B. Deviation of the trachea
 - C. Weight gain
 - D. Decreased urine output

The answer is B. A deviated trachea is indicative of a tension pneumothorax associated with noncompliant lungs (as with ARDS) being ventilated at a higher pressure than the lung can tolerate. This requires immediate intervention by the physician.

A is incorrect—Diminished breath sounds are common in the client with ARDS due to decrease lung compliance

and collapsed alveoli. C is incorrect—While weight gain may occur in ARDS, it is not the most indicative sign of a complication. D is incorrect—Although decreased urinary output is a problem and needs to be addressed, it is not the most indicative sign of a complication.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of the client condition and/or procedure

87. A client with a history of congestive heart failure who has gained 3 pounds in 1 day should be placed on:
- 1800 calorie ADA diet
 - calorie count
 - fluid restriction
 - potassium restriction

The answer is C. The client who has gained more than 2 pounds in 1 day and has a history of congestive heart failure should be placed on a fluid restriction to keep the client from exacerbating his or her condition.

A is incorrect—The 1800 calorie ADA diet is for a diabetic and will not be beneficial in this situation of volume overload. B is incorrect—The client should not count calories but count liquid intake in volume. D is incorrect—A potassium restriction is not needed unless lab values indicate a high potassium level.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Administer oxygen therapy and evaluate response

88. A nurse is assessing the vital signs of a client and notices that the oxygen level is 91% on room air. The client complains of a headache and wheezing is noted upon auscultation. Which nursing intervention would be best?
- Ask the client to sit in high Fowlers.
 - Ask the client to cough and reassess.
 - Apply 2 L of oxygen per nasal cannula.
 - Offer a pain medication for the headache.

The answer is C. The client has a low oxygen saturation level, is wheezing, and has a headache. The headache could be attributed to the low oxygen saturation level and so the nurse should place oxygen on the client to see if symptoms improve. The wheezing should be addressed with a bronchodilator.

A is incorrect—Making the client sit in high Fowlers will not resolve the situation of a low oxygen level. B is incorrect—Asking the client to cough is used when rhonchi is auscultated; wheezing is due to a narrowing of the airway. D is incorrect—Pain medication will worsen the oxygen saturation level.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Medical Surgical Asepsis

Assess client environment area for sources of infection

89. In the room of a client who has sustained a burn, which of the following would be the greatest potential source of infection?
- Fresh flowers
 - Fresh fruit
 - Helium filled latex balloons
 - Staff

The answer is D. Staff is the greatest source of infection for clients with a burn. For this reason, isolation is ordered for most clients who have sustained a burn.

A is incorrect—Fresh flowers produce toxins as they die; they are also a source of infection and should be limited in the rooms of client's with a burn. B is incorrect—Fresh fruit that is to be eaten is safe in the room of a client as long as it has not begun to rot. C is incorrect—Helium filled latex balloons are safe as long as the client does not have a latex allergy.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Informed Consent

Ensure that client has given informed consent for treatment

90. A client is scheduled for a colonoscopy to be performed this morning. Prior to preparing the client for the procedure, the nurse must first:
- ensure that the client has an advance directive in the chart.
 - assess the client's level of understanding about the procedure.
 - verify that consent for the procedure has been signed by the client.
 - verify that the client has not eaten since midnight.

The answer is C. Prior to preparing the client for the procedure, the nurse must ensure a signed consent is on the chart. The signing of the consent is the responsibility of the physician who will be performing the surgical procedure.

A is incorrect—An advanced directive is desired but not essential in the chart of a client who is going for a colonoscopy. B is incorrect—The client's level of understanding regarding the procedure is required prior to consent being signed. The signed consent establishes that the client understands the procedure that the physician will perform. D is incorrect—Verification that the client has remained NPO is less of a priority than verification that consent is on the chart prior to prepping the client for the procedure.

HEALTH PROMOTION AND MAINTENANCE

Ante/Intra/Postpartum and Newborn Care

Assess client for symptoms of postpartum complications

91. Which assessment data would be most indicative of a uterine infection in the postpartum client who underwent a vaginal delivery?
- Dark brown discharge from the vagina.
 - Pain at the site of the episiotomy.
 - Cramping in the lower abdomen.
 - Foul smelling vaginal discharge.

The answer is D. Foul smelling discharge is indicative of an infection in the postpartum client and requires intervention.

A is incorrect—Dark brown discharge is old blood that is being expelled through the vagina and is normal. B is incorrect—Pain at the site of the episiotomy is normal until healed. C is incorrect—Cramping in the lower abdomen occurs as the uterus returns to its pre-pregnancy state.

HEALTH PROMOTION AND MAINTENANCE

Principles of Teaching/Learning

Assess readiness to learn, learning preferences, and barriers to learning

92. Which evaluation would be most indicative of readiness to begin self-wound care?
- The client does not wish to see the wound.
 - The client no longer needs pain medication before wound care.
 - The client watches the nurse perform care of the wound.
 - The client begins to ask questions about the care of the wound.

The answer is D. When the client begins to ask questions about the care of the wound he or she has taken an interest in the procedure, which demonstrates a readiness to learn.

A is incorrect—If the client is unwilling to visualize the wound then he or she is not ready to care for the wound. B is incorrect—The client may no longer require pain medication

before wound care but that does not show a readiness to learn how to care for the wound. C is incorrect—The client may begin to watch the care of the wound prior to being ready to take over the care. Watching the wound care is the first step but is not most indicative of a readiness to begin self-care.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/Immobility

Maintain client skin integrity

93. Which of the following is the best method for preventing skin breakdown in an immobile client?
- Use of an alternating mattress.
 - Turning every 2 hours.
 - Keeping wrinkles out of sheets.
 - Elevating heels off of the bed.

The answer is B. The best method of preventing skin breakdown is to turn the client every 2 hours.

A is incorrect—Even though a client uses an alternating mattress, a staff member must still turn the client every 2 hours. C is incorrect—The client will benefit from removal of wrinkles that may be in the sheets but it is not the best method of preventing skin breakdown. D is incorrect—While elevating the feet will prevent shearing, it is not the best method of preventing skin breakdown for an immobile client.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and Blood Products

Identify the client according to facility/agency policy prior to administration of red blood cells/blood products

94. Which of the following is the first action a nurse must take prior to initiating blood administration?
- Check the chart for the physician's order.
 - Ask the client to sign consent for blood.
 - Order a type and cross from the lab.
 - Check the chart for the hematocrit and hemoglobin level.

The answer is C. Prior to blood administration, the nurse must be sure an order is on the chart signed by the physician. Without an order, the nurse cannot proceed with the process.

B is incorrect—The client should not sign consent unless an order is present on the chart. For the options given, ensuring an order is on the chart is the best answer. C is incorrect—The physician must write an order for a type and cross to be performed on the client. D is incorrect—After a physician's order is received, the nurse is responsible for checking the client's level before having a consent signed by the client.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Pain Management

Evaluate and document client use and response to pain medications

95. The assessment of a client complaining of pain is documented as:
- RR 24
 - BP 140/90
 - HR 100
 - grimacing, guarding

Demerol 50 mg IM was administered 30 minutes prior to the pain reassessment. Which findings would best indicate a therapeutic response to the medication?

- A. RR 20
- B. HR 95
- C. BP 138/88
- D. Patient resting with eyes closed

The answer is D. The client is resting now, which shows a resolution from the grimacing and guarding the client was demonstrating before pharmacological intervention.

A is incorrect—The respiratory rate is not the best indicator of pain resolution. B is incorrect—The heart rate has only decreased by 5 bpm, which is not a significant indicator of pain relief. C is incorrect—The blood pressure has not decreased enough to demonstrate pain relief and is not the best indicator of pain relief.

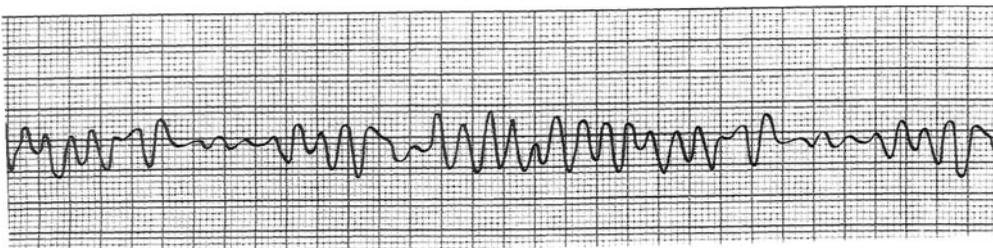

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Identify cardiac rhythm strip abnormalities

96. The nurse attaches an unresponsive client to the monitor. What is the rhythm the nurse sees on the monitor?
- A. Asystole
 - B. Ventricular fibrillation
 - C. Ventricular tachycardia
 - D. Torsades De Pointes

The answer is B. The rhythm is ventricular fibrillation. There are irregular ventricular contractions due to the absence of depolarization in the heart.

A is incorrect—With asystole, there is an absence of impulses to cause ventricular contractions. C is incorrect—Ventricular tachycardia exist with an increased and irregular ventricular rate. D is incorrect—Torsades De Pointes is due to prolonged repolarization and will progress to VF if left untreated.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Apply knowledge of pathophysiology when caring for a client experiencing a medical emergency

97. A client is brought to the emergency department after working outdoors. The temperature is 99°F with a heat index of 102. The nurses assess for which of the following knowing it is the most indicative sign of a heat stroke?
- A. Agitation, confusion
 - B. Nausea, headache
 - C. Shedding of clothes, unable to move
 - D. Syncope, neck stiffness

The answer is A. Agitation and confusion are the first signs of a heat stroke due to the body's response to the vasoconstriction and subsequent cerebral hypoxia associated with the body attempting to conserve fluid loss from sweating.

B is incorrect—Nausea and headache are common with heat exhaustion. C is incorrect—The shedding of clothes and inability to move is found with hypothermia. D is incorrect—Syncope and neck stiffness are not associated with heat stroke, but are associated with meningitis.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of client condition and/or procedure

98. A client is being admitted to the floor from the emergency department with possible seizures. Before the client arrives to the floor, the nurse should plan on:

- A. padding the rails of the bed.
- B. placing a bed alarm on the bed.
- C. placing restraints at the bed side.
- D. placing the crash cart at the bedside.

The answer is A. The rails of the bed should be padded to prevent injury if the client has a seizure while in the bed.

B is incorrect—Placing a bed alarm on the bed will not be beneficial in protecting the client if he or she has a seizure. C is incorrect—Restraints are not used on a client who might have a seizure. D is incorrect—There is no need for the crash cart to be at the bedside for a client with possible seizures.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Counsel/teach client, family, or significant others about managing client health problems

99. The nurse is teaching the client and the family regarding peritoneal dialysis, which will be performed at home. The priority discharge instruction is:
- A. signs and symptoms of peritoneal infection.
 - B. how to care for and clean the catheter.
 - C. how to take a blood pressure and heart rate.
 - D. how long the procedure should take.

The answer is B. How to care for and clean the catheter is priority teaching for the client. Prevention of infection is a high priority for clients who are performing peritoneal dialysis at home.

A is incorrect—Signs and symptoms of peritoneal infection are important and the client should be taught to report these to the physician. C is incorrect—How to take a blood pressure and heart rate is important but not necessary before every at-home treatment unless the client has complaints. D is incorrect—How long a procedure should take is important but it is better to teach the client about how to measure input to output to know that the treatment was successful.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assist client/family/significant others to integrate new members into family structure

100. A mother states that her 3-year-old potty trained child has begun to urinate in his pants after the new baby was brought home from the hospital. Which response by the nurse is best?
- A. “Children often regress when new members are introduced; continue to remind him to go to the rest room every hour.”
 - B. “Punish him before this becomes a pattern.”
 - C. “Children often regress at this age; it is normal and will improve with time.”

- D. “Talk to your child about what is occurring and then show him he is still important by spending an hour of one-on-one time with him every day while someone watches the baby.”

The answer is D. The most important thing is to let the parents know it is okay to talk about what is occurring with their child and assist the family with a plan to help the child feel loved and still an important member of the family.

A is incorrect—This does explain to the family what is occurring but reminding the child to go to the restroom does not show the child that he or she is still a valuable member of the family. B is incorrect—Regression is a normal response to a new family member and punishment does not validate normalcy. C is incorrect—This will not resolve without intervention by the parents. Waiting for change to occur without action by the parents will only lead to more problems.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Values

Provide client with information about the purpose and procedure of prescribed laboratory tests

101. A client presents to the ED with chest pain. The nurse draws blood during the initiation of an intravenous line for a triponin and CPK. The client asks what this test is for. The best response by the nurse is:
- A. “the triponin looks for a heart attack.”
 - B. “the triponin will verify what the EKG shows.”
 - C. “the triponin is the cardiac marker test that shows cardiac injury.”
 - D. “the triponin shows muscle damage.”

The answer is C. The triponin is the only test that is explicitly for cardiac muscle ischemia making this the correct option.

A is incorrect—Although the client can have muscle ischemia from lack of blood supply, it is not the only indicator of a heart attack. B is incorrect—While the EKG and the triponin are used as indicators of muscle ischemia, this test is not used to verify another test. D is incorrect—The triponin is specifically a cardiac marker test. The CPK is the test that shows muscle damage.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Dosage Calculation

Perform calculations needed for medication administration

102. A client has ordered Cardizem 250 mg in 250 mL to run at 10 mg/h. To deliver the ordered dose, the infusion pump should be set at:
- A. 8 mL/h
 - B. 10 mL/h

- C. 5 mL/h
- D. 1 mL/h

The answer is B. The concentration of drug is a 1:1 ratio. The infusion pump should be set to 10 mL/h.

A, C, and D are incorrect—These choices would be under dosing the client.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Assistive Devices

Assess client for actual/potential difficulty with communication and speech/vision/hearing problems

103. Which of the following drugs requires regular hearing exams with prolonged use?
- A. Streptomycin
 - B. Ciprofloxacin (Cipro)
 - C. Hydromorphone (Dilaudid)
 - D. Isoniazid (INH)

The answer is A. The client who receives an aminoglycoside such as streptomycin requires auditory exams routinely to assess for hearing loss due to the drugs ototoxic affects.

B is incorrect—Cipro does not require routine exams of any sensory functions. C is incorrect—Dilaudid causes CNS depression, which leads to changes in respiratory rate and blood pressure and does not require routine auditory exams. D is incorrect—INH requires routine liver enzyme studies due to the possibility of liver toxicity with use.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Resource Management

Plan safe, cost-effective care for the client

104. Which action by the nurse would be the safest and most cost-effective when administering daily medications?
- A. Administer all morning meds at the same time regardless of time scheduled.
 - B. Date and time all IV tubing on piggybacks and continuous infusions.
 - C. Use only one medicine cup per client when administering meds in a 24-hour period.
 - D. Use Betadine versus alcohol swabs when cleaning sites for injections.

The answer is B. Dating and timing all tubing for intravenous medications and fluids eliminates the need to change tubing each shift. Tubing is acceptable for continuous use 24 hours after being attached to a bag and the client.

A is incorrect—Medications are scheduled by the pharmacy and should be followed. Administering medications as scheduled can prevent poor absorption and alterations in the client's physiologic status. C is incorrect—Using one medicine cup per day is unsanitary and should be avoided. D is incorrect—Betadine can damage the cells of the skin; using Betadine is not recommended for routine injections.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Advance Directives

Provide client or family with information about advance directives

105. While admitting a client to the unit, the nurse asks the client if he or she has a living will. The client questions the nurse as to what a living will is. The nurse's best response is:
- A. "A living will lets the family know your wishes if you go into cardiac arrest."
 - B. "A living will is a legal document that explains your wishes for health care depending on the severity of your illness."
 - C. "A living will is a written order by the physician."
 - D. "A living will allows you to name someone to make decisions for you."

The answer is B. A living will is an advance directive that states the wishes of a client in the event he or she is critically or terminally ill.

A is incorrect—A living will states more than the wishes of a client if he or she is in cardiac arrest. A living will not only informs the family of the client's wishes but also the health care team. C is incorrect—"Do not resuscitate" is the order written by the physician and placed in the chart after the wishes are made known by the client in an advance directive. D is incorrect—A living will does not allow the client to name an individual to make decisions for him or her, a durable power of attorney allows an appointed individual to make decisions for the client anytime he or she is unable to do so.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Collaborate with Interdisciplinary Team

Identify significant information to report to other disciplines

106. A nurse enters a client's room to administer ferrous sulfate 324 mg. When the nurse checks the MAR against the medication, he or she notices that the dosage on

the package indicates ferrous sulfate 300 mg. Which action would be the most appropriate?

- Notify the pharmacist of the dosage error and request the correct dosage.
- Administer the medication since milligrams to be administered is lower than the ordered dose making it safe.
- Hold the medication until the physician can be notified.
- Ask the nurse who cared for the client yesterday what he or she administered to the client.

The answer is A. The nurse should phone the pharmacist first to request the correct dosage for the client before it is administered.

B is incorrect—Administering a medication that is under or over the ordered dose is a medication error unless an order is written for the dose being administered. C is incorrect—The pharmacy is responsible for dispensing medication and needs to be notified of the error. D is incorrect—The nurse should take responsibility for today and clarify the dosage with the pharmacy.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Legal Rights and Responsibilities

Report unsafe practice of health care personnel to internal/external entities

107. A nurse walks by the room of a client and sees a licensed practical nurse beginning the administration of blood. Which action by the nurse would be most appropriate?
- Confront the licensed practical nurse as to what is occurring.
 - Check the chart of the client to see if blood was ordered.
 - Report what was seen to the charge nurse.
 - Phone the board of nursing to report unsafe practice.

The answer is C. If a nurse suspects unsafe practice, it is imperative he or she follows the chain of command and report the nurse to the charge nurse. The charge nurse is responsible for confronting the nurse and continuing to report the nurse through the chain of command to the appropriate individuals.

A is incorrect—It is policy of most institutions to report unsafe practice to the nurse in charge of the unit. B is incorrect—Regardless of the order, it is not in the scope of practice of an LPN to administer blood. D is incorrect—The nursing administration is responsible for reporting a nurse for unsafe practice.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Supervision

Evaluate effectiveness of staff member's time management skills

108. Which assessment by the charge nurse is most indicative that a staff member is demonstrating difficulty with time management of daily assignments?
- Performing 3 minute assessments on all clients.
 - Being unable to leave the unit by the end of shift.
 - Administering medications as scheduled.
 - Not meeting the standards of client care during the shift.

The answer is D. Not meeting the standards of care is a sign that a nurse has difficulty with time management. Nurses are required to multitask to complete all assignments but meeting the standards of care is essential and should never be compromised.

A is incorrect—A 3-minute assessment is acceptable on a client that is not a new admission. It addresses the system-specific assessment and an overview of all other systems. B is incorrect—Being unable to leave the unit when the day is complete is not the highest indicator that a nurse has poor time management skills. Not meeting the standards of care ranks higher. C is incorrect—Administering medications on time demonstrates that a nurse does have the correct priorities for time management.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Security Plan

Participate in maintaining the institution's security plan

109. The hospital's policy regarding infant abductions is below:

Hospital Policy Regarding Infant Abductions: Code Pink

- If an infant is found to be missing or is reported missing by staff, phone the hospital operator immediately and a code pink will be called over the intercom system.
- All staff should stand by elevators, doors leading to the outside, and stairwells in their department.
- Anyone carrying a large bag, backpack, wearing a heavy coat or appears to be pregnant should be followed and a description of the person should be noted.
- Phone security and follow the person.
- Avoid confronting the individual, wait on security.

A nurse is working in a hospital and as she is exiting the elevator on the main floor a code pink is called over the intercom. Which action by the nurse is most appropriate?

- A. Stand outside the elevator until an all clear is called.
- B. Return to the assigned floor to stand outside the stairwell.
- C. Leave the elevator and go to a stairwell and stand.
- D. Begin stopping all staff and visitors and ask them to open bags and coats.

The answer is A. If a code pink is called, according to the policy the staff is to stand by any port of exit. In this case, the nurse should stand outside of the elevator so that it is attended during a possible abduction.

B is incorrect—Returning to the assigned floor does not follow the policy and leaves the elevator as a possible exit site for the abductor. C is incorrect—The elevator is a portal of exit as is the stairwell and so the one the staff member is at should be manned. D is incorrect—According to the policy, staff should not confront anyone suspected of being the abductor, but follow the possible abductor and phone security.

HEALTH PROMOTION AND MAINTENANCE

Health Promotion Programs

Instruct client on ways to promote health

110. A male should be instructed on using which method when performing a routine testicular self-examination?
- A. Perform before taking a shower.
 - B. Perform every 3 months.
 - C. Roll the testicle between the thumb and fingers.
 - D. Pinch the epididymis until sensation is lost in the penis and release.

The answer is C. The client should be instructed to roll the testicle between the thumb and fingers to monitor for abnormalities.

A is incorrect—The test should be performed after taking a shower so that the scrotum is relaxed. B is incorrect—Self-exams should be performed every month to monitor for changes so they can be caught early. D is incorrect—The epididymis should not be pinched due to the potential for damage to the structure.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Handling Hazardous and Infectious Materials

Identify biohazardous, flammable, and infectious materials

111. Which of the following should be placed in a biohazardous bag?
- A. Foley urine bag of a client with CHF

- B. Used intravenous medication bag of a client suffering from dehydration.
- C. Soiled diaper of a client with *Clostridium difficile*.
- D. Syringe used to flush a central line.

The answer is C. *Clostridium difficile* is highly contagious and the stool of this client should be placed in a biohazardous bag for proper disposal.

A is incorrect—A client's Foley bag should be emptied in the toilet prior to throwing the bag in the trash can which removes waste into the appropriate facility. B is incorrect—A used intravenous bag can be thrown into the trash can in a client's room as long as a name is not on the bag. If a name is on the bag, the label should be removed and the bag can be placed in the trash receptacle. D is incorrect—A syringe used to flush a central line should be placed in a sharps receptacle and not into a biohazardous bag.

PSYCHOSOCIAL INTEGRITY

Mental Health Concepts

Explore why the client is refusing/not following the treatment plan (e.g., nonadherence)

112. A client with end stage renal disease (ESRD) tells the transporter that he is not going down for his dialysis treatment today. The nurse should
- A. tell the client that it is okay and he can go tomorrow.
 - B. notify the physician.
 - C. ask the client if he is frustrated with the process of dialysis.
 - D. tell the client he will need to sign an "Against Medical Advice" form.

The answer is C. The most common reason for nonadherence to treatment regimens is a frustration with the procedure and the aspects of the disease process. Acknowledging that the client may be unhappy with the demands of the disease and the loss of control over life will help the nurse and client devise a plan to meet the treatment regimen that benefits both parties.

A is incorrect—The client needs to go to dialysis every scheduled day, telling him it is okay to miss a treatment will enable him to refuse every treatment and does not determine why he refused. B is incorrect—Notifying the physician does not explore why the client refused today's treatment. D is incorrect—Having the client to sign an AMA form does not explore why the client refused today's treatment.

PSYCHOSOCIAL INTEGRITY

Support Systems

Promote independence of client/family/significant others

113. Which of the following would promote independence in the client who recently underwent a below-the-knee amputation?

- A. Teach range of motion exercises.
- B. Provide the client with a wheelchair.
- C. Instruct the client on proper wound care.
- D. Provide analgesics for pain relief.

The answer is B. The client has the disability of limited mobility after an amputation. Providing the client with a wheelchair will enable him or her to move around in the environment and continue with independent activities.

A is incorrect—While a range of motion exercises prevent contractures and prepare the stump for prosthesis, it is not the best method of promoting independence initially. C is incorrect—Instructing the client on wound care promotes readiness to care for self, but does not promote independence overall. D is incorrect—Analgesics do not promote independence for the client.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Palliative/Comfort Care

Assess client's symptoms related to end of life

114. Which of the following would a nurse find in her assessment of a client that is nearing the end of life? (Check all that apply.)
- Decrease in time spent sleeping
 - Loss of appetite
 - Alteration in mental status
 - Generalized weakness
 - Periods of apnea
 - Seizures

The answers are loss of appetite, alteration in mental status, generalized weakness, and periods of apnea. These are consistent with the findings a nurse might see in his or her assessment of someone nearing the end of life. The loss of appetite is due to the decrease in metabolism that the body undergoes at death. Generalized weakness and an alteration in mental status is due to the changes in metabolism as well. Periods of apnea occur and are called Cheyne-Stokes; panting respirations will accompany the periods of apnea in some cases.

Incorrect answers are decrease in time spent sleeping and seizures. The client will often have an increase in time sleeping and seizures are uncommon.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Review pertinent data prior to medication administration

115. The morning assessment of a client reveals this data:
- BP 90/60
 - HR 110
 - RR 20

- Temp 98.9

The nurse should hold which of the following drugs:

- A. levothyroxine (Synthroid)
- B. carvedilol (Coreg)
- C. gabapentin (Neurontin)
- D. pioglitazone (Actos)

The answer is A. The nurse should hold the dose of Levothyroid if the client has a resting pulse of greater than 100 bpm. This is a sign of hyperthyroidism and a dose will only compound the problem.

B is incorrect—While the blood pressure is borderline, it is within normal limits. Coreg is a beta blocker and is needed to lower the heart rate. C is incorrect—Neurontin is a drug used for nerve pain and there are no contraindications to administration based on vital signs. D is incorrect—Actos is used to serum glucose levels and does not carry a contraindication based on vital signs.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Provide client/family/significant others with information on TPN

116. A family is taking a client home that will be receiving total parenteral nutrition (TPN). The family should be instructed on:
- A. how to perform glucose monitoring.
 - B. how to change the intravenous dressing every 24 hours.
 - C. how to dilute the TPN solution.
 - D. how to turn off the infusion pump.

The answer is A. The client receiving total parenteral nutrition requires frequent monitoring of glucose levels. The client's family will need to learn how to assess the client's glucose level and what action to take depending on the outcome.

B is incorrect—The dressing is changed every 48–72 hours unless contamination is suspected. Changing more often than needed is not cost-effective and opens the site to the possibility of contamination. C is incorrect—The TPN solution should not be diluted. The solution should be administered in its prepared form. D is incorrect—The infusion should never be stopped or changed abruptly to allow time for the body to change its metabolic needs.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Alterations in Body Systems

Identify client potential for aspiration

117. Which client is at the highest risk for aspiration pneumonia?

- A. A client who has a nasogastric tube to low suction and an endotracheal tube in place.
- B. A client who has a PEG tube feeding and is lying at 20 degrees
- C. A client who has recently undergone surgery and is eating clear liquid diet.
- D. A client who has returned from esophageal dilatation and is ready for discharge.

The answer is B. A client who has a PEG tube should not lie below 30 degrees to prevent aspiration of gastric contents.

A is incorrect—A client with an endotracheal tube has a protected airway and aspiration is not a worry. C is incorrect—A client on a clear liquid diet has an intact gag reflex and aspiration is a low risk. D is incorrect—A client who has undergone an esophageal dilatation and is ready for discharge is at a low risk for aspiration.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications from Surgical Procedures and Health Alterations

Apply knowledge of pathophysiology to monitoring for complications

118. A client has returned to the floor following a transverse loop colostomy. Which assessment finding would be indicative of a complication?
- A. Hypoactive bowel sounds
 - B. A dusky color to the stoma
 - C. Liquid stool measuring 900 mL
 - D. Scant bleeding at the stoma site

The answer is B. A dusky colored stoma reveals that necrosis is occurring to the bowel that has been brought to the surface. The physician needs to be notified of this finding.

A is incorrect—Hypoactive bowel sounds are expected following a colostomy and are no cause for concern postoperatively. C is incorrect—Liquid stool is a normal finding following a colostomy. The bowel will need time to begin reabsorbing water from the GI track before stool will be more formed. D is incorrect—Scant bleeding is normal following a colostomy and is due to a rich blood supply from the GI track.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Assess client for signs of hypoglycemia or hyperglycemia

119. A nurse is performing the morning assessment on a client that has a diagnosis of diabetes mellitus con-

trolled by diet. Which assessment finding requires notification of the physician?

- A. Urine output of 1000 cc in 2 hours
- B. BP 140/90
- C. Heart rate 100
- D. Temp 99.9°F

The answer is A. Polyuria is indicative of hyperglycemia and requires the physician to be notified so that orders can be written for fluid replacement and insulin administration if needed.

B is incorrect—This is borderline hypertension, but does not require notification of the physician. A reassessment of the blood pressure should occur. C is incorrect—Mild tachycardia is not a reason to consult the physician. The tachycardia may be secondary to the polyuria and may resolve when the condition improves. D is incorrect—This is a mildly elevated temperature and does not require notification of the physician.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Provide pre- and/or postoperative education

120. Prior to a client undergoing a pinning of the right hip, the client should be instructed on:
- A. how to use the client controlled analgesic pump.
 - B. when he can expect to eat a meal.
 - C. how soon after surgery discharge is possible.
 - D. how to care for the surgical wound.

The answer is A. The client should be instructed on how to use the client controlled analgesic pump prior to surgery to ensure understanding has occurred.

B is incorrect—When the client can eat is not something the nurse must prepare the client for prior to a surgical procedure. C is incorrect—Discharge is based on the individual's progress and the physician is responsible for writing the order and discussing a time frame for discharge with the client. D is incorrect—How to care for the wound occurs after the surgery when the client feels he or she is ready to take over the care.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assess parental techniques related to discipline

121. A school nurse is evaluating families during an open house at a school. Which assessment indicates

abnormal discipline techniques and requires intervention?

- A. A mother telling her child she will place her in “time out” once they are at home.
- B. A mother yelling at her child to “behave” during a walk down the hall.
- C. A mother stating “When we get home, I will beat you with a belt.”
- D. A mother stating “You need to learn to control your behavior or you will go straight to bed when we are home.”

The answer is C. The mother is threatening the child with physical harm, which is a sign of abuse and should be acted on by the school nurse. Not reporting abuse or suspected abuse places the child in danger.

A is incorrect. Placing a child in “time out” is an appropriate method of discipline. B is incorrect—Asking a child to “behave” is a normal form of parental discipline. D is incorrect—Threatening a child with going to bed does not place the child in physical harm and is an appropriate form of parental discipline.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Radiation Therapy

Implement interventions to address side/adverse effects of radiation therapy

122. A client has experienced mucositis while undergoing radiation therapy. Which nursing action will be best to assist the client’s nutritional intake?
- A. Offer the client foods with enhanced taste.
 - B. Offering a commercially prepared mouth rinse.
 - C. Offer the client bland, soft foods such as puddings, shake.
 - D. Administer oral antibiotics to the client to swish daily.

The answer is C. The client should avoid spicy or hard foods if mucositis occurs. By offering the client foods that are bland and soft, he or she will be more likely to continue eating and maintain a nutritional intake sufficient for the body’s needs.

A is incorrect—Offering foods with enhanced taste is equivalent to offering foods with spices. These foods may irritate or worsen the condition. B is incorrect—Most mouthwashes contain alcohol, which can worsen the mucositis. The client should rinse with water and hydrogen peroxide. D is incorrect—Oral antibiotics will not be beneficial in assisting the client with his or her nutritional intake when mucositis is present.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Connect and maintain pacing devices

123. Place an X where the nurse will place the pads for pacing on a client who is in a third-degree heart block with a rate of 38.

The pads should be placed on the anterior chest wall and the back for external, noninvasive transcutaneous pacing.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

124. A client is admitted for pneumonia. Which assessment finding is most indicative of a potential complication?
- A. Skin that appears dry
 - B. Clear sputum
 - C. Asymmetric fremitus
 - D. Bronchovesicular breath sounds

The answer is C. Asymmetric fremitus is a significant finding. Fremitus is the vibration felt upon palpation in pneumonia. If this is asymmetrical, it means that the side with fremitus may have a tumor or the side without fremitus may be indicative of a pneumothorax. Decreased fremitus occurs when there is excess air in the lung space.

A is incorrect—Skin can appear dry and still be considered normal. B is incorrect—Clear sputum is a normal finding. D is incorrect—Bronchovesicular breath sounds are the normal sounds heard upon auscultation of the lung fields.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

Identify precautions and contraindications to immunizations

125. The MMR (measles, mumps, rubella) vaccine should be held if the client has a history of

- A. anaphylactic reaction to eggs.
- B. HIV.
- C. rotavirus.
- D. tuberculosis.

The answer is A. A client with a history of an anaphylactic reaction to eggs should not receive the MMR vaccine.

B is incorrect—A history of HIV is not a contraindication to the MMR vaccine. C is incorrect—The rotavirus is not a contraindication to receiving the MMR vaccine. D is incorrect—A client with tuberculosis or a positive PPD skin test can still receive the MMR vaccine.

HEALTH PROMOTION AND MAINTENANCE

Disease Prevention

Inform client/family/significant others of actions to maintain health and prevent disease

126. While preparing a client for discharge, which of the following should be included in the discharge instructions for a client who received stents during a heart catheterization?
- A. Eat foods high in fat
 - B. Exercise daily
 - C. Limit fruits and vegetables
 - D. Increase intake of garlic

The answer is B. A client with new stents should exercise daily to maintain proper blood flow and improve overall health.

A is incorrect—Eating foods high in fat should be avoided after stent placement to prevent occlusion due to plaque accumulation. C is incorrect—A client who has undergone stents needs a diet of fruits and vegetables for heart health. D is incorrect—Garlic should be avoided and may interact with postprocedure prescription medications administered at home.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Case Management

Plan individualized care for client based on need

127. A client is being discharged from the hospital after experiencing a myocardial infarction. The client desires to have home health care scheduled to make biweekly visits. Which finding in the discharge

needs assessment indicates that home health care will not be beneficial?

- A. The client does not have a home telephone.
- B. The client does not have a wheelchair ramp to get into the home.
- C. The client is unable to drive.
- D. The client does not have family in town to check on him daily.

The answer is A. If the client does not have a home telephone, he or she will not have the ability to call 911 for an emergency or a method for the home health care agency to contact the client, which is a requirement for admission into home health care services.

B is incorrect—The question does not state that there is a need for a wheelchair ramp. C is incorrect—In order for a client to receive home health care, he or she is considered homebound and the inability to drive is irrelevant. D is incorrect—Not having family in town does not indicate that home health care will not be beneficial.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Consultation

Initiate consultations

128. Which of the following clients would benefit from the social services department consultation for help with prescription medications? (Check all that apply.)
- A disabled veteran who uses the veterans' hospital facilities.
 - A homeless client with HIV.
 - A elderly client who has Medicare.
 - A child who does not have health insurance.
 - A client who is employed but is without health insurance.
 - A teenager who is currently enrolled on his parents' health insurance.

The homeless client, the child, and the client who is employed all are without health insurance and would benefit from social services for assistance with payment for prescription medications. These clients are the best choice for the answer since they are without any governmental or private assistance.

The veterans' hospital will assist the client who is a veteran, Medicare has prescription cards that are dependent upon the need of the client, and the teenager who is on his parent's health insurance will have coverage for medications.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Ergonomic Principles

Review necessary modifications with client to reduce stress on specific muscle or skeletal groups

129. An elderly client is going home after hip replacement surgery. Which discharge instructions are most appropriate for this client?
- Turn kneecap toward body while standing still to maintain balance.
 - Avoid crossing legs while sitting in a chair.
 - Keep the operative leg behind you when bending.
 - Use a long handled grabber to reach.
 - Avoid using an elevated toilet seat.
 - Keep a pillow between legs while sleeping.

The answers are B, C, D, and F. These activities will allow the client to avoid flexion greater than 90 degrees, adduction of the hip and internal rotation of the hip, which can cause the prosthesis to become dislocated.

A and E are incorrect answers—The client should not cause adduction by placing the kneecap inward toward the operative side to maintain balance. If balance is in question, an alternative assistive device should be used. Avoiding an elevated toilet seat is incorrect since it is recommended that clients use an elevated toilet seat to ease with standing and help to avoid dislocation of the prosthesis while standing and sitting.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nonpharmacological Comfort Interventions

Provide therapies for comfort and treatment of inflammation and swelling

130. A client has undergone repair of a fractured femur. Which nonpharmacological therapy is best for reducing swelling?
- Application of heat.
 - Application of compression bandages.
 - Elevation of affected leg.
 - Acupuncture therapy.

The answer is C. Elevation of the leg will decrease swelling and subsequent pain in the leg.

A is incorrect—Heat is used to reduce muscle spasms and not for the reduction of swelling. Ice is used for the reduction of swelling. B is incorrect—Compression bandages are used to prevent deep vein thrombosis and do not provide relief from swelling. D is incorrect—Acupuncture

therapy is an alternative therapy for pain relief but does not aid in the reduction of swelling.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Identify symptoms/evidence of an allergic reaction

131. A client has an order for an intravenous injection of sodium ferric gluconate complex (Ferrlecit). Which nursing action would be best in monitoring for allergic reaction to the medication?
- Administer the dose in twice the recommended time frame.
 - Perform an iron reaction scan prior to administration.
 - Administer 10 gts/min for a 10 minute test dose.
 - Assess the client for allergy to eggs and wheat.

The answer is C. A test dose of 10 drops/minute for 10 minutes is best to monitor for allergic reaction to the iron-containing product.

A is incorrect—Administering a dose faster than the recommended time frame is not safe nursing practice and can lead to undesired effects. B is incorrect—There is no such scan as an iron reaction scan. D is incorrect—While a client taking iron supplements should avoid using eggs or whole grain breads an hour after the administration of iron-containing medications, there is no evidence of a correlation between these items and reactions to iron medications.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing Priorities

Assess/triage client(s) to prioritize the order of care delivery

132. Which client should be assessed first upon receiving report?
- A 70-year-old postop client with hip replacement who has a new onset of A-fib.
 - A 54-year-old client admitted 2 hours ago with chest pain, which is relieved by ketorlac (Toradol) while in the ED.
 - A 69-year-old client scheduled for discharge today after being treated for a pulmonary embolism.
 - A 75-year-old client admitted 2 days ago for a myocardial infarction who has been transferred from CCU during the night shift.

The answer is A. The client who has a rhythm change is a priority to assess for symptoms associated with atrial fibrillation,

such as shortness of breath and/or chest pain. This client is already at a high risk for thrombosis due to the nature of the surgical procedure.

B is incorrect—A client whose pain was relieved by an antiinflammatory is lower priority than option A. C is incorrect—A client who is scheduled to be discharged receives the last assessment of all four. This client is considered stable if discharge was ordered by the physician. D is incorrect—A client who is transferred from CCU is considered stable and requires assessment after the client described in option A.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Compare client psychosocial/behavioral/physical development to norm for age/developmental stage of client

133. Which of the following is an abnormal finding in the growth and development assessment of a 6-month-old client?
- Imitates sounds
 - Bears weight on hands while prone
 - Holds bottle
 - Pulls self to standing position

The answer is D. A child does not pull self to standing position until the ninth month. A 6-month-old child will bear most of weight if held in standing position by an adult.

A is incorrect—A 6-month-old child will babble sounds such as ma and hi. B is incorrect—A child of this age can bear weight on hands while prone and will lift chest and upper abdomen. C is incorrect—A child of this age can hold a bottle without assistance.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Orient client to reality

134. A client presents to the emergency department stating that he is an FBI agent and is there to secure the building. Which technique will be best in caring for this client?
- Following with the story and allow the client to continue with the delusion.
 - Medicate the client till sedation occurs.
 - Tell the client that he is in a hospital and he does not work for the FBI.
 - Ask the client if he has used drugs in the last 24 hours.

The answer is C. The client needs to be oriented to reality to begin the process of treating the delusion.

A is incorrect—The nurse should not follow with the story, this only feeds the delusion and does not allow for

interventions to begin. B is incorrect—The client does not need sedation until an assessment can be performed to see if the client is a danger to self or others and what other manifestations are associated with the current delusion. D is incorrect—The client is delusional and will not be able to tell the nurse what occurred in the last 24 hours.

Psychosocial Integrity

Situational Role Changes

Evaluate whether client/family/significant others have successfully adapted to situational role changes

135. Which statement made by a client's wife indicates that she has not accepted her husband's acute condition?
- "I will call a gardener to take over the yard until my husband recovers."
 - "I know my husband will recover faster than expected and be ready to go back to work."
 - "I will look into how we can modify our schedule so someone can always be by his side in the hospital."
 - "I have planned on having someone at home to help me when we are discharged."

The answer is B. The wife has not accepted her husband's illness and the change in her role in the family as the support person and the caregiver.

A is incorrect—The wife realizes her husband is ill and will not be able to continue strenuous labor at the home. C is incorrect—The wife understands her role change as the caregiver and is ready to change as needed. D is incorrect—The wife understands her husband's illness and the need to gather support personnel to assist where needed.

PSYCHOSOCIAL INTEGRITY

Therapeutic Environment

Make client room assignments that promote the therapeutic milieu

136. When planning to provide a therapeutic environment for a client, the appropriate room assignment for a client who has recently been diagnosed with breast cancer is
- a room with a client who has renal cell carcinoma.
 - a room with a client who has bone cancer.
 - a room with a client who recently underwent a mastectomy.
 - a room with a client who is scheduled for a lobectomy.

The answer is C. The client who has been diagnosed with breast cancer will be able to relate to the client who has undergone a mastectomy providing for a therapeutic environment.

A is incorrect—The client who has renal cell carcinoma is not a therapeutic choice for the client since the cancers

differ and the treatments will differ as well. B is incorrect—The client with bone cancer is in chronic pain; therefore, sharing a room with a client is not a therapeutic environment for either. D is incorrect—A client who is undergoing a lobectomy is not a therapeutic choice for the client who has breast cancer due to the difference in the type of cancer and the treatments.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administer and document medications given by common routes

137. Which of the following forms of insulin can be given intravenously?
- Novolin 70/30
 - Novalog
 - Lantus
 - Novolin-R

The answer is D. Regular insulin is a short-acting insulin and is the only insulin approved to be given intravenously.

A is incorrect—Novolin 70/30 is a combination of 70% NPH and 30% regular insulin and therefore contains a short and intermediate acting form of insulin and is only approved to be administered subcutaneously. B is incorrect—Novalog is a rapid-acting insulin and is only administered subcutaneously. C is incorrect—Lantus is a long-acting insulin and is not approved to be given intravenously, only subcutaneously.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Values

Know laboratory values for ABGs, BUN, cholesterol, glucose, hematocrit, hemoglobin, hemoglobin A1C, platelets, potassium, RBC, sodium, urine-specific gravity, and WBC

138. The respiratory therapist draws ABGs and shows them to the nurse. Which state is the client currently in based on the values:
- pH: 7.39
 - CO₂: 40
 - HCO₃: 23
 - PaO₂: 90
- Metabolic acidosis
 - Respiratory acidosis
 - Respiratory alkalosis
 - Homeostasis

The answer is D. The client's values are within normal limits and the client has compensated and is a state of homeostasis.

A is incorrect—For a client to be in a state of metabolic acidosis the pH less than 7.35 and the HCO₃ less than 22. B is incorrect—The client would need a pH less than 7.34 and a CO₂ greater than 45 to be in a state of respiratory acidosis. C is incorrect—The client would need a pH greater than 7.45 and CO₂ less than 45.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Intervene to manage potential circulatory complications

139. A client is found lying on the floor after a fall out of the bed. On assessment, the left foot appears shorter than the right and externally rotated. Palpation of the affected leg reveals a cold extremity with no palpable pulse at the dorsalis pedis or the posterior tibial. What is the priority nursing action?
- Palpate for a popliteal pulse
 - Call the physician
 - Try to realign the injured leg
 - Elevate the injured leg and reassess

The answer is B. When an injury has caused disruption of the neurovascular system to the point that pulses are lost, the physician must be notified immediately so that action can be taken to prevent the tissue in the affected extremity from becoming necrotic.

A is incorrect—Palpating for a popliteal pulse would show whether the injury was severe enough to cause vascular compromise. Regardless if a pulse is present or not at the popliteal site, the area distal is without adequate blood supply and the physician needs to be notified immediately. C is incorrect—An injured leg should not be realigned by the nurse to prevent further injury. D is incorrect—The leg should not be elevated to prevent further injury to the vascular system.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Monitor and maintain the client on a ventilator

140. A client is placed on the ventilator and has positive end-expiratory pressure (PEEP) added. Which assessment data will be most indicative of a potential complication?
- Tachycardia
 - Wheezes

- C. Hypotension
- D. Hypertension

The answer is C. Hypotension is a sign of a complication. Hypotension can be related to a decreased venous return or a pneumothorax. Assessments should follow that determine the cause of hypotension.

A is incorrect—Tachycardia is due to the body's response to the illness and is not necessarily indicative of a complication. B is incorrect—Wheezing is due to bronchial constriction and is common with intubation. D is incorrect—Hypertension is due to the physiological response to the stress the client is under.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolytes

Implement interventions to restore client fluid and/or electrolyte balance

141. A client has a sodium level of 153. The nurse consults the physician and is given orders for dietary restrictions. The nurse should instruct the client to avoid which foods?
- A. Cheese
 - B. Squash
 - C. Tomatoes
 - D. Apples

The answer is A. Cheese is considered to be high in sodium and should be restricted for the client who has a high sodium level.

B, C, and D are incorrect—These items are fresh foods and are not considered to be high in sodium.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Assess the client for decreased cardiac output

142. A client with congestive heart failure has been coughing up pink frothy sputum and exhibiting shortness of breath. The client's assessment 1 hour ago revealed:
- BP 80/40
 - HR 90
 - rhonchi upon auscultation
 - oxygen saturation 90%
 - normal sinus rhythm

Which assessment finding shows a worsening in the client's condition and a decrease in the client's cardiac output?

- A. Premature ventricular contractions
- B. HR 99
- C. Wheezing upon auscultation
- D. Oxygen saturation of 89%

The answer is A. Premature ventricular contractions are a direct result of cardiac muscle hypoxia, which is secondary to the pulmonary edema. PVCs do not allow for the diffusion of gasses to occur across the alveolar capillary membrane. All of this is directly proportional to the decrease in the cardiac output, which has caused blood to back up into the lungs.

B is incorrect—The heart rate change is due to the body trying to compensate for the state of hypoxia that exist by pumping faster in an attempt to supply dying cells with oxygen. C is incorrect—Wheezing does not indicate a worsening in the cardiac output. D is incorrect—The hypoxia is still present and is not the best indicator of a worsening in the client's condition.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Monitor and maintain a client on the ventilator

143. A client on the ventilator becomes agitated and restless. Which action by the nurse is best?
- A. Check the cuff pressure on the tube.
 - B. Remove the ventilator and bag the patient.
 - C. Assess for breath sounds.
 - D. Restrain the client to prevent tube dislodgement.

The answer is C. The client should be assessed for breath sounds to see if ventilation is occurring. Agitation is often due to hypoxia and lack of adequate ventilation would be seen with absent breath sounds.

A is incorrect—Checking the cuff pressure will not assist in determining the source of agitation. B is incorrect—Bagging the client will not be beneficial if the tube is not in the lungs. D is incorrect—Restraining the client will prevent tube dislodgement but it is not the best method to determine the cause of the agitation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Unexpected Response to Therapies

Assess the client for unexpected adverse response to therapy

144. Which of the following are preventable adverse outcomes to the placement of a urinary catheter?
- ___ Infection
 - ___ Urethral damage

- ___ Ureter damage
- ___ necrosis of the meatus
- ___ Vaginal tearing

A client who has an indwelling urinary catheter may develop infection from nonmaintenance of sterile technique, urethral damage if the balloon is placed in the urethra, and necrosis of the meatus due to shearing of the catheter on the meatus. All these are preventable by appropriate nursing actions such as maintenance of sterile technique and meticulous perineal care, ensuring the balloon is in the bladder before inflation, and applying a lubricant to the meatus to lessen shearing.

Ureter damage should not occur since the tube does go above the structure of the bladder. Vaginal tearing should not occur since the catheter is placed in the bladder and not the vaginal area.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Identify signs and symptoms of impaired cognition

145. An elderly client is brought to the emergency department after being found trying to enter a home. The paramedics state that the client says she is 25 years old and lives in the home. The client is barefoot and has feces- and urine-stained clothes. The first nursing action is to:
- A. provide the client with a change of clothes.
 - B. assess the client for bruising/injuries.
 - C. reassure the client that she is safe and in a hospital.
 - D. ask the client her name and date of birth.

The answer is C. The client should be assured that she is safe and of her location. Then the physical assessment can continue.

A is incorrect—The client can undergo a change of clothes after trust is formed. B is incorrect—The client's physical exam will show any bruising or injuries after the client is assured of her safety. D is incorrect—The client will not give the correct date of birth due to her current confused state.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Evaluate invasive monitoring data

146. A client has a ventriculostomy after suffering a traumatic brain injury. The monitor is measuring the intracranial pressure at 30 mmHg. Which nursing action is best for this client?

- A. Raise the head of bed to 30 degrees.
- B. Assess the client for peripheral edema.
- C. Dim the lights and place the bed at 15 degrees.
- D. Suction the client.

The answer is C. The client should have minimal stimuli and the bed should not be at a height that will cause increased pressure. This will help to lower the intracranial pressure and prevent it from rising.

A is incorrect—Raising the bed to semi Fowlers will cause the pressure to rise. B is incorrect—The client has increased pressure in the cranial vault. Assessment for peripheral is not a priority action for this situation. D is incorrect—Suctioning the client will increase the pressure, which can lead to ischemia of the brain.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Informed Consent

Identify appropriate person to provide informed consent for client

147. An unidentified client is brought to the emergency department after being found on the side of the road with multiple stab wounds and an obvious head injury. After a series of radiological test, it is found that the client has a lacerated liver, brain injury, and needs immediate surgery. Which of the following would be best in obtaining consent for the surgical procedure?
- A. The client should be placed in state custody and consent obtained from the appropriate personnel.
 - B. The physician should consider this implied consent and should follow the hospital policy for the situation.
 - C. The nurse should sign consent for the client as the client advocate.
 - D. The facility should wait to see if the client wakes up to give consent.

The answer is B. The hospital policy should be followed in this situation. In implied consent, the law recognizes that client in need of life saving measures will be provided with those measures unless documents can be provided that states otherwise. In this situation, the client is unidentified and needs surgery to save his life.

A is incorrect—To place a client in state custody, the state must go through a judge. In this case, there is not enough time for that to occur and this action would place the client's life in jeopardy. C is incorrect—The nurse cannot sign consent for a client. D is incorrect—The client may not

wake up to give consent and while waiting on this to occur, the client's condition could decline.

HEALTH PROMOTION AND MAINTENANCE

Health Screening

Perform health history/health and risk assessment

148. When performing the health history of a pediatric client in for a well baby visit, the nurse should determine if which of the following is present?

- Immunizations are up to date
- Smoking in the home
- History of cardiac disorders
- History of Asthma
- Eating habits
- Toileting concerns

The nurse should assess for immunizations, smoking in the home, eating habits, and any toileting concerns to understand if the client is receiving the care needed and if there are concerns that may not be verbalized by the mom without a direct question.

A history of cardiac disorders or asthma should be questioned on a routine visit only if assessment findings indicate a concern.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

149. A client is found in the room holding his hands to his throat and his lips are turning blue. Which action by the nurse is most appropriate?

- A. Lying the client on the floor and administering abdominal thrust.
- B. Ask the client to cough.
- C. Placing both fists around the abdomen above the umbilicus and administering abdominal thrust.
- D. Attempting a blind finger sweep.

The answer is C. The nurse should perform the Heimlich maneuver. The client is demonstrating the universal sign for choking and is obviously lacking oxygen.

A is incorrect—The client should not be lowered to the floor unless he or she is unconscious. B is incorrect—The client will not be able to cough at this point. D is incorrect—A blind finger sweep is not recommended since it can push the food further into the throat.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Notify primary health care provider of side effects, adverse effects, and contraindications of medications and parenteral therapy

150. A client is taking digoxin (Lanoxin) for atrial fibrillation and cardiomegally. Which assessment finding requires the nurse to notify the physician of a potential adverse effect?

- A. Abdominal pain and nausea
- B. Rhythm change to normal sinus rhythm
- C. Heart rate of 62
- D. Weight gain of 1/2 pound

The answer is A. Abdominal pain and nausea are the first signs of digoxin toxicity in the elderly and should be reported so that the physician can order a digoxin level desired.

B is incorrect—A rhythm change is not an adverse effect. The client continues to need the digoxin to treat the cardiomegally. C is incorrect—The heart rate is within normal limits for the drug to be administered. D is incorrect—A 1/2 pound weight gain is not an adverse effect. Monitoring of I&O should continue.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Interpret client data that needs to be reported immediately

151. Which of the following should be reported to the physician immediately?

- A. Monitor showing a sinus rhythm with a premature ventricular contractions (PVC) occurring every 10th beat.
- B. Sodium level 130 mEq/L.
- C. Potassium level of 5.9 mEq/L.
- D. Oxygen saturation level of 90% on room air.

The answer is C. The nurse should phone the physician to receive orders for treatment of the high potassium level, which can cause cardiac arrhythmias if untreated.

A is incorrect—This is considered sinus rhythm with occasional PVCs and is considered a normal finding. B is incorrect—This sodium level is lower than the normal range of 135–145 mEq/L, but is not low enough to bear reporting to the physician immediately. Lower than 127 mEq/L is considered critical. D is incorrect—The oxygen saturation level

should not be reported unless it remains low after oxygen is applied. This finding requires a nursing intervention before phoning the physician.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Assess the client for an abnormal response following a diagnostic test/procedure

152. A client has just undergone a computerized tomography (CT) of the abdomen with oral contrast. Which assessment finding is indicative of an abnormal response to the exam?
- Feeling of fullness in the abdomen
 - Redness of the face, generalized itching
 - Increase in urination
 - Nausea, diarrhea

The answer is B. The client who has undergone a CT of abdomen has been exposed to oral contrast. Those who are allergic to oral contrast will experience redness to the face, generalized itching, and other signs of a systemic reaction. This requires intervention by a physician order.

A is incorrect—Feeling of fullness is common after a CT where oral contrast was used. C is incorrect—The client will have an increase in urination following the ingestion of oral contrast for a CT. D is incorrect—The oral contrast contains a laxative and it is common for the client to become nauseated and experience diarrhea until the contrast has been passed through the system.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Unexpected Response to Therapies

Assess the client for unexpected adverse response to therapy

153. After placing a nasogastric tube into the right nare of a client, which assessment finding is indicative of an adverse response to this therapy?
- Epistaxis
 - Vomiting
 - Feeling of fullness in the throat
 - Sore throat

The answer is A. Epistaxis is an adverse response to the placement of a nasogastric tube and measures should be implemented to stop the bleeding.

B is incorrect—The nasogastric tube will cause the client to vomit due to the irritation of the gag reflex. C is incorrect—The client will feel fullness in the throat until the body becomes accustomed to the tube. D is incorrect—A sore throat is common after a nasogastric tube is placed due to the irritation during insertion.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Radiation Therapy

Assess the client for signs and symptoms of adverse effects of radiation therapy

154. Which assessment finding requires immediate nursing intervention in a client who is receiving radiation therapy for esophageal cancer?
- Alopecia
 - Skin ulceration
 - Hearing loss
 - Difficult swallowing

The answer is D. The nurse should take action regarding the client's difficulty swallowing. If there is damage to the esophagus then subsequent damage to the trachea could be occurring, which will compromise the client's airway.

A is incorrect—Alopecia is the loss of hair and is inevitable for the client undergoing radiation therapy. B is incorrect—Skin ulcerations are common with radiation therapy and require wound care to prevent infection. C is incorrect—Hearing loss is common with radiation to the neck and while precautions can be taken to lessen the effects, damage will likely occur.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious Disease

Evaluate client response to treatment for an infectious disease

155. Which evaluation would indicate a therapeutic response to treatment for tuberculosis?
- A negative sputum culture after 3 months of therapy.
 - Absence of symptoms.
 - Decrease in cavities on an x-ray.
 - Completion of medication therapy.

The answer is A. If cultures convert to negative within 3 months of therapy, the treatment is considered a success.

B is incorrect—Symptoms may disappear even if the bacteria are active. C is incorrect—Cavities on the x-ray are not a

determinant for a therapeutic response to treatment. D is incorrect—Completion of medicinal therapy is not a therapeutic response to the treatment since the bacteria can still be active.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Monitor and maintain arterial lines

156. A nurse is assessing the arterial line via an intra-arterial catheter in a client in the ICU. Which assessment finding is most indicative of a potential complication?
- Cool extremities bilaterally
 - Low blood pressure reading
 - Capillary refill <2 seconds on affected arm
 - Low mean arterial pressure

The answer is C. The capillary refill of less than 2 seconds is a sign that a thrombus may have formed and blood flow via the ulnar artery and the microcirculation is compromised.

A is incorrect—Cool extremities bilaterally are not the most indicative finding in a potential complication. B is incorrect—A low blood pressure reading is not a sign of a complication since the arterial line is used for monitoring the client's blood pressure. D is incorrect—A low mean arterial pressure is a direct reflection of the client's blood pressure and does not indicate a complication with the line itself.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Provide suctioning via endotracheal or tracheostomy tube

157. Prior to suctioning a client who has an endotracheal tube, the nurse must first:
- hyperoxygenate the client.
 - place saline in the endotracheal tube.
 - ask the client to cough.
 - deflate the cuff on the endotracheal tube.

The answer is A. Prior to suctioning a client with an artificial airway such as an endotracheal tube, the nurse must provide adequate oxygen to the client.

B is incorrect—While placing saline down the tube may loosen secretions, it is not what the nurse must first do prior to suctioning the client. C is incorrect—A client with an endotracheal tube should not cough to prevent tube dislodgement. D is incorrect—The endotracheal tube cuff is only deflated when moving of the tube is necessary.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Monitor effective functioning of therapeutic devices

158. When performing an assessment on a client with a chest tube and an attached drainage system, which assessment finding is indicative of a complication?
- Continuous bubbling in the suction chamber.
 - Yellow fluid accumulating in the drainage chamber.
 - Suction in the off position.
 - Vigorous bubbling in the water seal chamber.

The answer is D. Vigorous bubbling in the water seal chamber is indicative of a leak. The nurse must determine where the leak is and fix the problem before the lung is compromised.

A is incorrect—The suction chamber should have continuous bubbling if suction is connected. B is incorrect—Yellow fluid is serous and is normal with a chest tube drainage system. C is incorrect—Suction may or may not be connected to the drainage system depending on the client needs based on the physician's assessment.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Concepts of Management

Supervise care provided by others

159. A member of the nursing team approaches you to complain that an unlicensed assistive personnel is not performing accuchecks on patients as assigned. Which action is most appropriate?
- Confront the unlicensed assistive personnel about the neglect in her role.
 - Ask the nurse why he or she could not perform the accucheck on the patient.
 - Ask the unlicensed assistive personnel if there is something preventing her from completing her assignment.
 - Report the unlicensed assistive personnel to the nurse manager of the unit for a verbal reprimand.

The answer is C. Asking the unlicensed assistive personnel if there is something preventing her from completing her assignment gives the individual an opportunity to verbalize what is occurring that has delayed client care and follows the chain of conflict resolution.

A is incorrect—Confronting an individual will cause increased tension and does not resolve the conflict. B is incorrect—The licensed personnel is being asked to perform the duty of an unlicensed personnel therefore negating the

delegation of duty. D is incorrect—This response does not follow the chain of conflict resolution and does not provide the unlicensed assistive personnel the opportunity to explain her actions.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Delegation

Ensure appropriate education, skills, and experience of personnel performing delegated task

160. Match the appropriate personnel to the task that is within the scope of practice. (Choices may be used more than once.)
- ___ Insert a Foley catheter.
 - ___ Perform an admission assessment.
 - ___ Perform postprocedure vital signs.
 - ___ Administer one unit of packed red blood cells.
 - ___ Perform a morning assessment.
- A. Registered Nurse
B. Licensed Practical Nurse
C. Unlicensed Nursing Assistant

B *Insert a Foley catheter:* It is within the scope of practice for a LPN to insert an indwelling catheter.

A *Perform an admission assessment:* Only a registered nurse can perform an admission assessment.

C *Perform postprocedure vital signs:* It is within the scope of practice for unlicensed personnel to perform postprocedure vital signs as long as a licensed personnel is reviewing the data obtained and the unlicensed personnel has gone through the verification process in conjunction with the rules of the hospital.

A *Administer one unit of packed red blood cells:* Only a registered nurse can administer blood products.

B *Perform a morning assessment:* A LPN can perform a morning assessment on a client who has undergone an assessment by a RN upon admission to the area.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Performance Improvement (Quality Improvement)

Define performance improvement/assurance activities

161. Which of the following is an example of quality assurance that meets the standards of JCAHO?
- A. Gathering a second opinion before administering as needed pain medications.
- B. Use of clinical pathways by all health care team members.

- C. Avoid admitting clients that have chronic conditions.
- D. Performing tests that are covered by insurance and avoiding those that are not.

The answer is B. The use of clinical pathways has replaced nursing care plans. Clinical pathways enable the staff to monitor for a progression of prescribed client care among all health care disciplines, which is a component of quality assurance.

A is incorrect—A client should receive pain medication based on his or her rating on the pain scale. Gathering a second opinion before medication is administered delays care and is not cost-effective and does not meet the standards. C is incorrect—Clients with chronic conditions may need to be admitted making this not an effective method of quality assurance. D is incorrect—Avoiding tests that are not covered by insurance may lessen overall cost, but is not meeting the standards of care a client deserves.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Accident Prevention

Identify deficits that may impede client safety

162. Which finding in an admission assessment is most indicative of a potential falls risk?
- A. Hearing deficit
- B. Numbness in the left foot
- C. Confusion
- D. Unsteady gait

The answer is D. A client with an unsteady gait is at the highest risk for a fall due to an inability to correct a potential fall or brace during a fall.

A is incorrect—A loss of hearing is not the highest risk. A client who cannot hear can still maintain a steady gait while ambulating in a room. B is incorrect—Numbness in one foot does not place the client at the highest risk for falls risk, often a client will compensate with the normal extremity. C is incorrect—A confused client can possess a steady gait therefore not placing this client at the highest risk.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Injury Prevention

Question prescriptions for treatments that may contribute to an accident or injury

163. Which discharge prescription should be questioned for a client who has peripheral neuropathy due to diabetes?

- A. A prescription for shoes to be purchased at a health care supply store.
- B. A prescription to follow up with diabetic services for routine foot care.
- C. A prescription for a heating pad to be used on the lower extremities twice a day.
- D. A prescription for TED hose to be used on the lower extremities unless bathing.

The answer is C. An order for a heating pad should be questioned because a client with diabetic neuropathy should not use a heating pad since he or she will be unable to feel if burning to the skin is occurring. A is incorrect—A prescription for shoes at a health care supply store is appropriate for the diabetic client. B is incorrect—The client with peripheral neuropathy due to diabetes should follow up with diabetic services for routine foot care such as nail cutting and inspections for ulcerations. D is incorrect—TED hose are useful to prevent deep vein thrombosis and swelling that may occur with peripheral neuropathy and diabetes.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Use of Restraints/Safety Devices

Monitor client responses to restraints

164. Which assessment is priority for a client who is being placed in restraints due to confusion and agitation?
- A. Toiletry needs
 - B. Hydrations needs
 - C. Circulation in restrained extremities
 - D. Client's knowledge of restraint purpose

The answer is C. Monitoring the extremities for adequate circulation is most important to prevent damage to underlying structures. Assessments of the area where the restraint is placed should be performed every 2 hours or per hospital policy.

A is incorrect—Toiletry needs are important while a client is in restraints but this is not the priority assessment. B is incorrect—Hydration needs are assessed every 2 hours but this is not the priority. D is incorrect—A client who is confused and agitated will not understand why he or she is being restrained.

HEALTH PROMOTION AND MAINTENANCE

Family Planning

Assess client need/desire for contraception

165. Which statement made by a client indicates a need for counseling regarding contraceptive devices?

- A. "I plan on abstaining from sex until I am married."
- B. "My boyfriend and I use condoms for protection."
- C. "I have been having sex, but my boyfriend pulls out."
- D. "It is against my religion to use birth control."

The answer is C. The client is using the withdrawal method, which is has a high failure rate. The client needs information regarding contraceptive devices to prevent pregnancy.

A is incorrect—The client does not have a plan to participate in sexual activity. The client should be reminded to contact her health care provider if her intentions change. B is incorrect—The client currently has a form of contraception in use. D is incorrect—The client is citing a religious restriction on the use of birth control; therefore, counseling is not needed.

HEALTH PROMOTION AND MAINTENANCE

High-Risk Behaviors

Assist client/family/significant others to identify behaviors/risks that may impact health

166. A client is being discharged after an admission for a sodium of 127 and recent weight loss. The family voices a concern that the client may be suffering from anorexia. At the time of discharge, the family will be instructed to monitor the client for which sign of the disorder?
- A. Increase in menstrual cycles per month.
 - B. Pushing food around plate without taking bites.
 - C. Lack of desire to exercise.
 - D. Heat intolerance.

The answer is B. The client with anorexia nervosa will push food around on the plate and put bites of food to the face without eating the bite.

A is incorrect—A client with anorexia nervosa will experience amenorrhea due to loss of weight. C is incorrect—In anorexia nervosa, a client will exercise excessively and may not attend events/school to exercise. D is incorrect—With anorexia nervosa the client is intolerant of cold.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

167. Which equipment will be most important when performing the physical assessment of a client with a deep vein thrombosis (DVT) of the left leg?
- A. Tape measure
 - B. Doppler

- C. Tongue depressor
- D. Penlight

The answer is B. When a client has a DVT, a Doppler is needed to assess for pulses in the affected extremity to ensure blood flow is occurring in the extremity at one of two pedal pulse areas.

A is incorrect—A tape measure is used to document the size of the leg compared to the unaffected leg, but it is not as important as the Doppler, which will assess for adequate blood flow to the affected foot. C is incorrect—A tongue depressor is not needed when assessing the client who has a DVT. D is incorrect—A penlight is needed to assess papillary response when performing a physical assessment, but is not the most important piece of equipment for this client.

PSYCHOSOCIAL INTEGRITY

Cultural Diversity

Incorporate client cultural practice and beliefs when planning and providing care

168. A client of Asian descent has been admitted to the surgical floor. Which of the following should the nurse consider when building the client care map for pain management?
- A. Consult an acupuncturist.
 - B. Offer a narcotic every 4 hours.
 - C. Offer daily medications only in the morning.
 - D. Have a rabbi visit the client daily for prayer.

The answer is A. The Asian American culture uses acupuncture as a form of oriental medicine, which is based on an energy system that when used balances the yin and yang and promotes balance in the life and thus pain relief.

B is incorrect—This Asian American culture uses narcotics as a last form of pain relief, and the primary form of pain relief is acupuncture and herbs. C is incorrect—The Asian American culture does not have a preference on when medications are offered making this a nonjustified choice. D is incorrect—The Asian American culture uses a temple healer for religious needs and this is not a significant choice for care mapping of pain management.

PSYCHOSOCIAL INTEGRITY

Religious and Spiritual Influences on Health

Assess and plan interventions that meet client emotional and spiritual needs

169. A client who practises Catholicism will be undergoing a hip repair. Which nursing plan will be best to prevent tension between the patient and nurse and meet hospital policies and procedures?
- A. Allow the client to wear his medicine bundle into the operating room.

- B. Remove the client's traditional headpiece before leaving for the operating room.
- C. Inform the client that you will take his rosary and give it to his wife.
- D. Inform the client that all spiritual pieces need to be surrendered to security until after surgery.

The answer is C. The nurse should take the client's rosary and allow a trusted family member to hold it while he is in surgery. A rosary is sacred to the catholic religion and the nurse must treat it respectfully.

A is incorrect—Medicine bundles are worn by Native Americans. B is incorrect—Traditional headpieces are worn by Islamic Muslim women and they are not to be removed in public leaving the patient to remove it once in the holding room and giving it to a family member. D is incorrect—Spiritual pieces are not surrendered to security unless the client requests.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Elimination

Insert/remove nasogastric, urethral catheter, or other tubes

170. A nurse is inserting a nasogastric tube when resistance is met. The nurse should:
- A. continue to push the tube into the nose.
 - B. ask the client to swallow.
 - C. pull out the tube and try the other side.
 - D. check for correct placement with 30 cc of air.

The answer is C. If resistance is met during the insertion of a nasogastric tube, the nurse should remove the tube and try the other nostril to prevent damage to the nasal mucosa and internal structures.

A is incorrect—The nurse should avoid continuing to push the tube into the nose to prevent injury. B is incorrect—Asking the client to swallow will not prevent injury to the client. D is incorrect—The tube has met resistance and when it is inserted in the stomach, this does not occur; therefore, checking for placement is invalid.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Assess client's ability to eat

171. A client has returned from having a procedure that required conscious sedation. Prior to offering food the nurse should:
- A. assess for the return of the gag reflex.
 - B. administer morning medications missed due to NPO status.
 - C. order a warm tray for the client.

- D. view the chart to see the time the last dose of a medication was given for sedation.

The answer is A. Prior to offering food, the client should be evaluated to see if the gag reflex has returned. Without a gag reflex, the client should not eat due to the potential for aspiration.

B is incorrect—The client may need to eat before being offered meds. The client must also have an intact gag reflex before meds can be offered. C is incorrect—The client will need a warm tray but only after the client has been assessed to see if eating can occur without the risk of aspiration. D is incorrect—Regardless of the last dose of medication, the nurse is responsible for assessing to see if the gag reflex is intact before offering food.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Rest and Sleep

Schedule client care activities to promote adequate rest

172. A burn client is recovering and needs periods of rest to aid in healing. Which plan would be best to promote rest periods for the client?
- Group activities such as physical assessment, bath, linen change, and morning meds together.
 - Administer a sleeping aid every night from the “as needed” medication list.
 - Schedule the client to go to occupational therapy and physical therapy consecutively.
 - Place a sign on the door to limit visitors.

The answer is A. The best method for promoting rest is to group client care so that there are periods of time for the client to rest without interruption.

B is incorrect—The client may not need a sleeping aid at night when activities can be altered to assist with rest during the day. C is incorrect—Sending the client to both areas for therapy consecutively will place the client at a disadvantage. A client who has experienced a burn will need to rest between sessions due to an increased use of energy for healing. The client will not benefit from therapy sessions if he or she is too tired to participate. D is incorrect—Placing a sign on the door will help to warn visitors that the client is resting but it is not the best method of promoting rest.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and Blood Products

Administer blood products and evaluate client responses

173. A client who is experiencing an acute hemolytic transfusion reaction will exhibit what symptom?
- Hypertension
 - Back pain

- Bradycardia
- Hyperglycemia

The answer is B. The symptoms of an acute hemolytic transfusion reaction are due to the breakdown of the red cell antibodies and cell destruction, which manifest as pain and an increase in body temperature.

A is incorrect—Hypotension occurs with an acute hemolytic transfusion reaction. C is incorrect—Tachycardia is common with an acute hemolytic transfusion reaction due to the body's response to the stress, increase in temperature, and hypotension. D is incorrect—Hyperglycemia does not occur in a hemolytic reaction.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents/Actions

Identify a contraindication to the administration of a prescribed or over-the-counter medication to a client

174. During an admission assessment a client states an allergy to Motrin. Which drug order should be questioned?
- ketorlac (Toradol) 60 mg IM every 8 hours × 2 doses for pain.
 - Tylenol 650 mg p.o. every 4 hours as need for pain.
 - Morphine 2–4 mg IV every 4 hours as needed for pain.
 - orphenadrine (Norflex) 100 mg p.o. BID prn pain.

The answer is A. Toradol is an antiinflammatory and is in the same classification as Motrin. A cross sensitivity may exist so it is best to avoid using Toradol for client's with an allergy.

B is incorrect—Tylenol is a non-opioid analgesic and Motrin is a nonsteroidal antiinflammatory. There is no evidence of cross sensitivity leaving this to be a safe drug for mild pain relief. C is incorrect—Morpine is an opioid analgesic and does not fall into the same category as Motrin. D is incorrect—Norflex is a muscle relaxant and is not contraindicated in the client with an allergy to Motrin.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Provide wound care

175. A nurse caring for a client with a burn has an order to apply a silver sulfadiazine (Silvadene) dressing to the area. Which plan would be best to prevent infection of the wound during cleaning?
- Avoid applying Silvadene to areas that are not burned.
 - Cleaning the area with Betadine.
 - Using an irrigation system for cleaning.
 - Wearing a mask, gown, and sterile gloves during care.

The answer is D. The nurse's goal for wound care is to prevent infection and promote revitalization of the tissue. The nurse should place a barrier between her and the client to prevent infection.

A is incorrect—Applying Silvadene to areas that are not burned will cause redness to the surrounding skin. B is incorrect—Betadine is avoided in burns since it can cause damage to the cells and will dry out the tissue. C is incorrect—While an irrigation system is best for removal of debris found in the wound bed, it is not the best plan for preventing infection.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Use clinical decision making/critical thinking when addressing expected effects/outcomes of medications

176. A client is complaining of tightness in her throat and arm pain. The nurse assesses the client and administers nitroglycerine 0.4 mg sublingual. After 4 minutes, the client claims no relief was felt. The nurse should:
- administer another dose and reassess in 5 minutes.
 - check the client's blood pressure.
 - administer Maalox from the "as needed" order list.
 - notify the physician.

The answer is B. The client has no relief from the initial dose of nitroglycerine but with its potent vasodilatation, the nurse should assess the client's blood pressure before administering the second dose. If hypotension exist, the next dose should be held and other actions taken.

A is incorrect—The client's blood pressure should be assessed after every dose of nitroglycerine to assess for hypotension. C is incorrect—The nurse could attempt the use of Maalox to see if relief occurs but the blood pressure should be assessed prior to the administration of any other medications. D is incorrect—The physician should be notified after the nurse exhausts the protocol.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Evaluate and document client response to emergency interventions

177. A client in respiratory distress is intubated by the physician. Which evaluation by the nurse best indicates the intubation was successful?
- Decrease in anxiety
 - Lowering of blood pressure

- Increase in heart rate
- Bilateral breath sounds

The answer is D. Bilateral breath sounds are the best indicator of a successful intubation.

A is incorrect—While anxiety is an indicator of hypoxia, the resolution of anxiety is not the best indicator of a successful intubation. B is incorrect—Lowering of a client's blood pressure is not an indicator of a successful intubation. C is incorrect—An increase in the heart rate is not an indicator of a successful intubation.

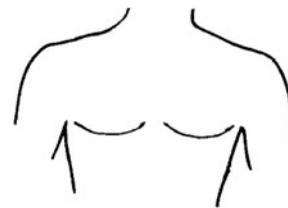

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Perform an electrocardiogram test

178. Place a client in lead II using a 5-lead monitor.
An "X" should be placed at:

RA (white lead) is placed below the right clavicle where the arm and torso meet. The LA is placed below the left clavicle where the arm and torso meet. The LL is red and is placed on lower abdomen where the leg and torso meet. The RL is placed at the lower right abdomen and the C lead is placed at the fourth intercostal space, right sternal border.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Monitor client for signs of bleeding

179. A client has recently undergone a cardiac catheterization. Which assessment is the best to monitor for post-procedure bleeding?
- Assessing the insertion site.
 - Assessing the area directly posterior to the insertion site.
 - Assessment of vital signs.
 - Assessment of neurological status.

The answer is A. Assessment of the insertion site is best when monitoring for postoperative bleeding. This site will be the first source of clot dislodgement and hemorrhage.

B is incorrect—The area posterior to the insertion site is secondary on the areas to assess for bleeding. This is usually noted if vital signs change. C is incorrect—Although vital signs are an appropriate assessment for the procedure that was performed, the first area to be assessed is the insertion site. D is incorrect—The neurological status will not be the best assessment for postprocedure bleeding.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Apply knowledge needed to perform related nursing procedures and psychomotor skills when assessing vital signs

180. A nurse takes the blood pressure with an electronic blood pressure machine and receives a reading of 80/54. A review of the chart indicates this is uncharacteristic of the client's usual reading. The nurse should perform which action next?
- Retake the blood pressure using the electronic machine.
 - Auscultate the blood pressure using a manual cuff.
 - Phone the physician for orders.
 - Leave the client and reassess in 30 minutes.

The answer is B. The nurse should assess the blood pressure using a manual cuff and stethoscope prior to taking any further action.

A is incorrect—The machine could be reading inappropriately. The nurse should perform option B. C is incorrect—The physician should not be notified until a manual pressure is taken. D is incorrect—The client should not be left for 30 minutes.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolytes

Apply knowledge of pathophysiology when caring for client with fluid and electrolyte imbalances

181. A nurse is assigned to four clients. Which client is at an increased risk for developing fluid volume deficit?
- A client who is in renal failure.
 - A client receiving normal saline at 125 mL/h.
 - A client who has an NG tube to low continuous suction.
 - A client who has diarrhea related to *Clostridium difficile*.

The answer is D. The client with *Clostridium difficile* is at an increased risk for fluid volume deficit due to the loss of fluid via the GI tract.

A is incorrect—The client in renal failure is at an increased risk of fluid volume excess. B is incorrect—The client receiving normal saline is at a risk for fluid volume excess. C is incorrect—A client with an NG tube to low suction is not at as high a risk as the client with diarrhea.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Perform gastric lavage

182. A nurse has an order to perform a gastric lavage on a client who has overdosed on Tylenol. After the lavage tube is inserted in the nose, the nurse should:
- place tap water in the stomach and begin pulling out gastric contents.
 - verify placement of the tube in the stomach using 60 cc of air.
 - tape to tube in place.
 - verify placement of the tube in the stomach using 30 cc of normal saline.

The answer is B. Prior to instilling anything in the stomach of a client who is undergoing gastric lavage, the nurse must make sure the tube is in the correct place by auscultation for air.

A is incorrect—While tap water can be used for lavage where the tap water will be pulled from the stomach, the nurse must assure the tube is in the stomach prior to performing the lavage. C is incorrect—The tube should not be taped in place until placement is verified. D is incorrect—Verification of the placement should be performed using air and not normal saline.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Apply knowledge of pathophysiology when caring for client with fluid and electrolyte imbalances

183. A client is in a state of respiratory acidosis. The nurse understands that which of the following is a potential cause of the current acidotic state?
- Morphine (M.S. Contin)
 - Vomiting
 - Diarrhea
 - Over the counter antacids

The answer is A. Morphine will place a client in a state of respiratory acidosis by lowering the respiratory drive, which causes the client to retain carbon dioxide.

B is incorrect—Vomiting will place a client in a state of metabolic alkalosis due to the loss of acid through the GI track. C is incorrect—Diarrhea will place the client in a state of metabolic acidosis by removing the bicarbonate from the GI track. D is incorrect—Antacids cause a build up on bicarbonate and will place the client in a state of alkalosis.

HEALTH PROMOTION AND MAINTENANCE

Ante/Intra/Postpartum and Newborn Care

Provide newborn care

184. An 8-pound infant is delivered via vaginal delivery. After the cord is cut and handed to the nurse, the nurse should first assess the baby's:
- respiratory effort
 - Apgar score
 - vital signs
 - blood sugar

The answer is A. The respiratory effort should be assessed and assisted as needed.

B is incorrect—The Apgar score is second in the assessment. C is incorrect—Vital signs are assessed after the respiratory effort and Apgar score. D is incorrect—Unless mom was a diabetic, the baby does not require a blood sugar check.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Concepts of Management

Apply principles of conflict resolution as needed when working with health care staff

185. Two staff nurses on the nursing unit disagree on how to involve a client's family in the client's care. Nurse A feels that only the husband needs to be included in the planning of the client's care as he will be the primary care giver when she is discharged home. Nurse B feels that both her husband and her son need to be involved as they are both very close to the client and both will have a role in her care once she is discharged. As the nurse leader you must decide how you will manage the conflict.
- Ignore the situation: if it isn't acknowledged it will go away.
 - Do nothing and allow the two staff nurses to work out a mutually agreed upon decision.
 - Make a decision for the staff nurses, as it is not appropriate for the client to be in the middle of the conflict.

- Sit down with the two staff nurses and allow them to express their points of view, encouraging both to consider the positive and negative aspects of their views.

The answer is D. By sitting with both nurses, each has a chance to consider the other's opinion. This will help the nurses to settle conflicts in the future.

Ignoring the situation and doing nothing will not resolve the problem. Decisions made by the authority will not resolve future problems and may lead to resentment on the nurses' part.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Provide postoperative care

186. A client has been brought to the floor by the PACU nurse after having a cholecystectomy. When performing the postop assessment, which finding would be most indicative of a complication?
- Nausea, vomiting
 - Abdominal pain
 - Shoulder pain
 - Rigid abdomen

The answer is D. A rigid abdomen is a sign of internal bleeding and requires immediate intervention.

A is incorrect—Nausea and vomiting are common after abdominal surgery and are not a complication. B is incorrect—Pain is common after surgery and is not a complication unless other symptoms of hemorrhage are present. C is incorrect—Shoulder pain is due to the gas that is placed in the abdomen for the surgeon to see the organs inside the abdominal cavity.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Position client to prevent complication following tests/treatments/procedures

187. A client who has undergone a spinal tap should be placed in what position after the procedure?
- Prone
 - Supine
 - Semi-Fowlers
 - Side lying

The answer is B. A client who has undergone a spinal tap should be placed in the supine position for 2 hours after the procedure.

A is incorrect—The client should not be placed prone after the procedure to prevent airway compromise. C is incorrect—The client should remain supine. Semi-Fowlers would likely place pressure on the insertion site and cause bleeding. D is incorrect—While the client may be placed in the side-lying position during the procedure, after the procedure the client should be supine. Side-lying carries the possibility of placing pressure onto the insertion site.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolytes

Identify signs and symptoms of client fluid and/or electrolyte imbalance

188. A nurse will expect which assessment findings when caring for a client with a potassium level of 2.9?
- Irregular pulse
 - Orthostatic hypertension
 - Seizures
 - Deep tendon hyperreflexia

The answer is A. An irregular pulse is found in the client with a low potassium level due to the effects on cardiac muscle activity.

B is incorrect—Hypokalemia will cause orthostatic hypotension not hypertension. C is incorrect—There are alterations in neuromuscular excitability leading to muscle weakness and flaccidness. D is incorrect—Hyporeflexia is common in hypokalemia due to alterations in neuromuscular excitability.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Monitor wounds for signs and symptoms of infection

189. A nurse is caring for a surgical wound which is 3 days old. Which assessment data is most indicative of a wound infection?
- Increased white blood cell count
 - Separated wound edges
 - Purulent drainage
 - Edema at the site

The answer is C. Purulent drainage is an indication of a wound infection due to the body's response to the bacteria that has invaded the wound.

A is incorrect—While an elevated white blood cell count is indicative of the activation of the body's immune response system, it does not mean the source of infection is the wound

itself. B is incorrect—Wound edges may separate without infection being present. A client can strain and dislodge sutures or sutures can be dislodged if enough stress is placed on the operative area. D is incorrect—Edema is expected initially due to the body's response to invasion of skin integrity.

PSYCHOSOCIAL INTEGRITY

Abuse/Neglect

Provide a safe environment for an abused/neglected client

190. A client presents to the emergency department after her husband physically assaulted her during a fight. She states she feels as though he will come to the hospital to find her and she does not want to see him. Which nursing intervention will be best to protect this client from her husband?
- Notify security
 - Place the client as "confidential"
 - Notify the police department of the assault
 - Place the client in a room separate from the emergency department

The answer is B. Placing the client as confidential places a restriction on employees of the hospital so they cannot tell any visitors that the client is at the hospital. This is best since the husband may try to search for his spouse and/or lie to security about who he is.

A is incorrect—Notifying security is not the best intervention for this client as evidenced by the rationale provided for answer A. C is incorrect—While the police should be notified on all assaults, it is not the best choice for protecting the client at the hospital. D is incorrect—Placing the client away from the emergency department is not an appropriate choice. If the client is away from the department, she is too far for the nurse to monitor and the husband may be able to find her.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Remove sutures or staples

191. An order has been written to remove the staples, which were placed in a client's left hip during surgery. Prior to removing the staples, the nurse should first:
- assess the site for infection.
 - determine the number of staples from the operative note.
 - soak the site with normal saline.
 - clean the site with hydrogen peroxide.

The answer is B. Prior to removing sutures from a wound, the nurse needs to determine how many staples were placed

during surgery to make sure the same number of staples is removed as were placed.

A is incorrect—Assessing the site is part of the process but not the first step. C is incorrect—The site is soaked if excess dry blood is around the area or the staples are embedded into the wound bed but this is not the first step. D is incorrect—Hydrogen peroxide can be used as needed if the wound has dried exudate or the staples are embedded in the skin, but this is not the first step.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious Disease

Recognize signs and symptoms of infectious diseases

192. A client presents to the emergency department complaining of cough, fever, and night sweats. Which nursing intervention would have the highest priority?
- Provide the client with a sputum cup.
 - Place a mask on the client.
 - Move the client to a private room in the treatment bay.
 - Provide the client with a tissue to cover the mouth when he or she coughs.

The answer is B. The client exhibits signs of tuberculosis and should be placed on isolation via a mask until he or she can be placed in a room in the treatment bay to prevent spread to those in the surrounding area.

A is incorrect—The client can be given a sputum cup after isolation measures are taken to protect those in the area. C is incorrect—The client does need to be moved after begin given a mask to wear. D is incorrect—The client should wear a mask or airway coverage at all times versus only when coughing.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

193. A nurse is assisting a physician with the intubation of a client. Which assessment is the priority after the intubation is complete?

- Oxygen saturation level
- Heart rate
- Breath sounds bilaterally
- Rise and fall of the chest

The answer is C. The breath sounds are the priority for a client who has just been intubated. If breath sounds are present, then the intubation was successful and the lungs are being ventilated.

A is incorrect—The oxygen saturation level is not the best indicator of successful intubation immediately after the procedure is complete. The oxygen level will improve as the lungs are ventilated and diffusion of gases occurs. B is incorrect—While the heart rate is important, the first assessment after intubation should be breath sounds in both lungs. The heart rate will respond to the physiological status of the body. Initially, the heart rate will be high while the heart is trying to pump blood to meet the oxygen needs of the body. It will return to a more normal state as oxygen rich blood is available. D is incorrect—The rise and fall of the chest is important, but the nurse must hear breath sounds bilaterally to ensure the intubation was successful and the lungs are being ventilated.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Identify cardiac rhythm strip abnormalities

194. A client on the unit was complaining of chest pain when he became unresponsive. The nurse attaches the monitor and sees the following rhythm. Which action by the nurse is most important?
- Begin chest compressions
 - Palpate for a pulse
 - Check to see if the leads are attached properly
 - Assess for breathing

The answer is D. The first step in CPR is to assess for breathlessness and begin rescue breathing for the client. If breathing is present, assess for lead placement; if the client is not breathing, begin CPR.

A is incorrect—Chest compressions begin after airway, breathing, and pulses are assessed. B is incorrect—Palpation

for pulses occurs after airway and breathing are assessed. C is incorrect—Lead placement is assessed after airway and breathing is assessed.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

195. A client with a diagnosis of chronic obstructive pulmonary disease (COPD) is being discharged from the hospital. Which of the following is appropriate patient teaching before discharge?
- “Make sure to use a humidifier in your room while you sleep.”
 - “Apply powder to all crevices to prevent yeast while taking oral steroids.”
 - “Turn the oxygen up to no more than 6 L if you are short of breath.”
 - “Use your inhalers every day as directed even if symptoms are not present.”

The answer is D. The client needs to use the inhalers every day regardless of symptoms to keep condition controlled and lessen the frequency of exacerbations.

A is incorrect—A humidifier is not necessary in the room of a client with COPD and can be a source of infection. B is incorrect—Powder can be an irritant to the client with COPD and cause an exacerbation of the disease. C is incorrect—The client with COPD should not use oxygen at greater than 2 L per nasal cannula.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

Monitor and maintain arterial lines

196. A nurse is working with a client who has an arterial line for direct blood pressure monitoring. What is the first action the nurse should take when performing an assessment of the system?
- Ensure the transducer is at the phlebostatic axis.
 - Zero out the system.
 - Flush the system with normal saline.
 - Administer a bolus of normal saline into the line.

The answer is A. The transducer should be placed at the phlebostatic axis, which is at the junction of the fourth intercostal space and the midchest area. If the transducer is

placed above the axis, the monitor will give a low reading; if it is too low, the reading will be high.

B is incorrect—The transducer must be at the phlebostatic axis before zeroing occurs. C is incorrect—The system allows for blood draws but does not allow for fluid infusion. D is incorrect—The system has a Heparin solution which is used to keep the area from clotting; with that known other fluids such as normal saline are not to be instilled into the line as a flush or bolus.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Use clinical decision making/critical thinking when addressing expected effects/outcomes of medications

197. A nurse is reviewing a client's chart and notices the potassium level is 6.0; the nurse plans on administering which drug from protocol?
- Sodium polystyrene sulfonate (Kayexalate) 30 grams retention enema \times 1 dose.
 - 1 L normal saline with 20 mEq potassium chloride IV over 2 hours.
 - Normal saline 1 L IV over 10 hours.
 - phosphate/biphosphate (Phospho-Soda) 48 grams by mouth \times 1 dose.

The answer is A. Kayexalate binds with the potassium and removes it from the body via the GI track. This drug carries less of a risk of hypovolemia than other preparations.

B is incorrect—This is adding potassium to the client, which will potentiate the problem. C is incorrect—Normal saline will not remove the potassium. Attempting to flush the system with normal saline places the client at risk for fluid overload. D is incorrect—Phospho-Soda inhibits absorption of fluids and electrolytes in the small intestine through an increase in peristalsis. This drug can potentially place a client in a state of hypovolemia and is not preferred for potassium reduction.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Evaluate invasive monitoring data

198. A nurse is caring for a client who has a pulmonary artery catheter. Which assessment finding should be reported to the physician immediately?

- A. Increase in capillary wedge pressure to 15 mm Hg.
- B. Central venous pressure of 2 mm Hg.
- C. Right ventricular pressure of 20 mm Hg systolic.
- D. Cardiac output of 4 L/min.

The answer is A. The normal wedge pressure is from 8 to 12 mm Hg and anything above that indicates increased pressures in the left side of the heart, which are indicative of left sided heart failure and should be reported to the physician immediately.

B is incorrect—The normal central venous pressure is 2–6 mm Hg and indicates the volume status of the client. This reading will rise with volume overload. C is incorrect—The normal right ventricular pressure is 20–30 mm Hg and indicates the right ventricular function and volume. D is incorrect—The normal cardiac output is 4–8 L/min and is found by multiplying the stroke volume by the heart rate. This value is a direct reflection of the adequacy of cardiac function.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

Identify client status based on pathophysiology

199. The nurse has received report on a client who has just been admitted for an acute myocardial infarction. The nurse's assessment findings are:
- BP 90/66
 - HR 100
 - RR 16
 - skin cool to touch
 - A&O \times 3 with mild anxiety
 - Urine output 40 mL/h

The nurse understands that this assessment data is indicative of:

- A. class I cardiogenic shock
- B. class I hypovolemic shock
- C. class II septic shock
- D. class II neurogenic shock

The answer is A. In mild cardiogenic shock, the body responds to hypoperfusion by the heart through the activation of the Renin-Angiotensin system, which causes vasoconstriction. The heart rate increases to meet the demand of the body and the blood pressure is within normal limits during compensation. The antidiuretic hormone is secreted in response and urine output is decreased due to an increased resistance in the vascular system. Respirations will increase to provide oxygen to the critical organs. The cool skin is the

response of the body shunting blood to the critical organs and the anxiety is due to the body's response to the shock and developing metabolic acidosis.

PHYSIOLOGICAL INTEGRITY

Elimination

Insert/remove nasogastric, urethral catheter, or other tubes

200. List in order the steps a nurse would follow prior to inserting a nasogastric tube:
- ___ Identify the client
 - ___ Explain the procedure to the client
 - ___ Wash hands
 - ___ Gather supplies
 - ___ Measure for tube placement
 - ___ Assess the client
 - ___ Turn suction to desired level
 - ___ Sit client in high Fowlers

The nurse should first identify the client and then explain the procedure to gather a verbal acceptance. At that point, a system-specific assessment should be performed to ensure the client has no underlying complications that need immediate attention. Next the nurse gathers his or her supplies, washes hands, and then measures for tube placement. The suction is then set for the ordered level and finally the client is placed in high Fowlers.

MANAGEMENT OF CARE

Safety and Infection Control

Error Prevention

Verify appropriateness and/or accuracy of a treatment order

201. A client who has been in a car wreck resulting in head trauma and chest contusion is complaining of headache, chest pain radiating down his left arm, and difficulty breathing. The nurse receives the following orders from the physician. Which of the orders would the nurse question?
- A. Start an IV at a keep open rate.
 - B. Raise the head of the bed 45 degrees.
 - C. Start oxygen at 4 L per minute as ordered.
 - D. Medicate with Nitrostat (Nitroglycerine) sublingual every 5 minutes \times 3 for chest pain

The answer is D. Nitroglycerine is a vasodilator and may increase intracranial pressure.

The other actions would all be inappropriate.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

202. Which cranial nerve is being tested when the nurse asks the client to shrug his/her shoulders and resist pressure to put them down?
- One (olfactory)
 - Eleven (spinal accessory)
 - Five (trigeminal)
 - Seven (facial)

The answer is B. Cranial nerve eleven (spinal accessory) is tested by asking the client to shrug the shoulders and resist pressure to put them down because this cranial nerve controls muscular strength of the trapezius and sternocleidomastoid muscles.

A is incorrect—Cranial nerve one (olfactory nerve) is responsible for the sense of smell. It is tested by occluding each of the client's nostrils one at a time, holding a substance such as coffee or vanilla with a familiar aroma under the other nostril, and asking the client to identify the smell. The test is repeated with a different aromatic substance to determine if the client can differentiate smells.

C is incorrect—Cranial nerve five (trigeminal nerve) has both motor and sensory components. It is responsible for sensation in the face, scalp, oral and nasal mucous membranes, and the cornea and allows chewing movements of the jaw. Its three-part sensory division is tested by touching the forehead, cheek, and chin on each side with a wisp of cotton and asking the client whose eyes are closed to identify the type of touch and its location. Next the cornea of each eye is lightly touched with a wisp of cotton brought in from the side and the eye observed for the normal blink response. The motor function of cranial nerve five is tested by asking the client to clench the teeth and keep them clenched while the examiner pushes down on the chin to try and separate the jaws.

D is incorrect—Cranial nerve seven (facial nerve) is responsible for taste on the front two thirds of the tongue and for movement of the face including the ability to close the eyes and move the lips for speech. To test taste, an applicator dipped in a sugar, salt, or lemon solution is placed on the tongue and the client is asked what is tasted. Motor function of cranial nerve seven is tested by asking the client to smile, frown, grimace, show the upper and lower teeth, keep the eyes closed while the examiner tries to open them and puff out the cheeks. The examiner observes for symmetry and movement and presses the puffed out cheeks in to check if air is expelled equally from both sides.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Evaluate appropriateness/accuracy of medication order for client

203. A client is admitted with a diagnosis of cholecystitis. One of the admitting orders is for morphine PRN for pain. Why would the nurse question this order?
- Morphine is constipating.
 - Morphine can cause nausea and vomiting.
 - Morphine promotes biliary stone formation.
 - Morphine causes spasm of the bile ducts.

The answer is D. Morphine is contraindicated for clients with cholecystitis because of the risk of precipitating duct spasm.

A, B, and C are incorrect—Morphine, which is an opioid, does cause constipation and also can cause nausea and vomiting but these are not the reason it is not used for clients with cholecystitis. Morphine is not documented as a factor in the formation of biliary stones.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

204. Which would be a normal finding when percussing the left 10th intercostal space at the anterior axillary line?
- Tympany over the gastric air bubble
 - Dullness over the spleen
 - Resonance over the lungs
 - Flatness over bone

The answer is B. Dullness over the spleen.

A, C, and D are incorrect. At the tenth intercostal space one is percussing over the spleen not over the gastric air bubble, lungs, or bone.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Obtain specimens other than blood for diagnostic testing

205. A diabetic client is admitted with a foul smelling, draining leg wound and a wound culture is ordered. When should the nurse plan to obtain the culture?
- Before any antiinfectives are administered.

- B. When the blood sugar is within normal range.
- C. Within 12 hours of a dose of a broad spectrum antibiotic.
- D. After 48 hours of antimicrobial therapy

The answer is A. The culture needs to be obtained before any antiinfectives are given because antiinfectives will alter the microbial population. Blood sugar is unrelated to the timing of the culture.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Elimination

206. The nurse is planning care for a client who requires a Sarita lift or the assistance of two people for transfer or ambulation. Which likely would be the best time to schedule having the client taken to the bathroom?
- A. On awakening in the morning.
 - B. After breakfast.
 - C. Following mid-morning medications.
 - D. At bedtime after a warm drink.

The answer is B. The gastrocolic reflex is most active after breakfast so this is the time that the client is most likely to have a bowel movement. It is important to utilize the reflex because the client is somewhat immobilized and therefore prone to constipation. Warm fluids can stimulate the reflex but it is still most active in the morning.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

207. Which is an appropriate nursing intervention for a newly admitted client diagnosed with schizophrenia?
- A. Avoid offering choices to the client.
 - B. Use touch to calm and reassure the client.
 - C. Keep explanations of care and activities to a minimum.
 - D. Spend time with the client even if there is no response.

The answer is D. The nurse should spend time with the client even if the client cannot respond. Being with the client is an indication of caring and is a form of human interaction. Initially, the client should not be offered choices; with treatment the client is gradually assisted in making decisions. Maintenance of ego boundaries is important when caring for

the schizophrenic client and touching the client should be avoided. Explanations are an important part of the care of the schizophrenic client and everything that is being done should be explained to help create trust.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

208. Which instruction would the nurse give when teaching a client pursed lip breathing?
- A. Take a slow breath in through your mouth.
 - B. Breathe out through your mouth puffing out your cheeks.
 - C. Use your abdominal muscles to help exhale as deeply as possible.
 - D. Use this breathing technique before any strenuous activity.

The answer is C. Abdominal muscles should be used to help force as much air out as possible during each exhalation. All other instructions are incorrect. When teaching pursed lip breathing the client is instructed to breathe in through the nose with the mouth closed and then to purse the lips as if to whistle and exhale slowly (exhalation should be double the time of inspiration) through the mouth without puffing the cheeks using the abdominal muscles to maximize exhalation of air. Pursed lip breathing should be used during not before physical activity.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

209. Which statement made by a client with cirrhosis indicates the need for further clarification on self-care?
- A. "I will not get any injections unless my doctor specifically approves."
 - B. "I will use an electric razor."
 - C. "I will take two acetaminophen tabs every 4 hours if I have pain."
 - D. "I will avoid exposure to people with colds or other infections."

The answer is C. Acetaminophen is hepatotoxic and contraindicated in cirrhosis so if the client says that he or she is going to take acetaminophen then further instruction is self-care is required.

A, B, and D are incorrect—Avoiding unnecessary injections and using an electric razor are appropriate because of the

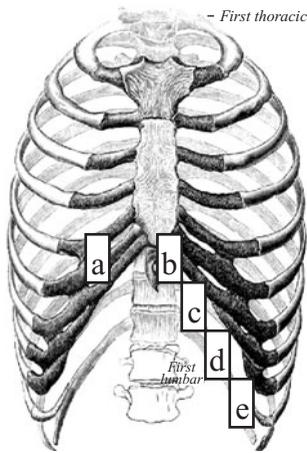

risk of bleeding due to impaired clotting. Avoiding exposure to infection is appropriate because of decreased immune function.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

210. When assessing the heart, the nurse palpates for heaves over the tricuspid area which would be an abnormal finding. Which lettered block on the accompanying diagram marks the location where the nurse would place the ball of the hand to palpate over the tricuspid area. Write the letter of the block on the line provided.

The answer is D.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Use the six “rights” when administering client medications

211. A client’s order for pain medication reads “Codeine 15 sc q4h PRN for pain.” Which aspect of this order should the nurse question?

- Frequency
- Route
- Dose
- None

The answer is C. The dose is incomplete and therefore needs to be questioned. No unit of dosage is specified and the nurse cannot assume mg or any other unit was intended. Route and frequency are specified. This is an as needed order and the reason for the need is also specified as required.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

212. When assessing the knee, which types of motion must be present to a normal degree for the nurse to document full range of motion? (Mark all that apply.)

- A. Supination
- B. Flexion
- C. Pronation
- D. Hyperextension
- E. Internal rotation
- F. External rotation
- G. Abduction
- H. Adduction

The answers are B, D, E, and F. Normal range of motion in the knee is flexion, hyperextension, and internal and external rotation. Normal flexion is the ability to fully bend the knee so the calf touches the thigh. Hyperextension is the ability to extend the knee beyond the normal point of extension. Internal rotation is the ability to rotate the knee and lower leg toward the midline. External rotation is the ability to rotate the knee and lower leg laterally.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Evaluate the client response to interventions to correct fluid and electrolyte imbalance

213. Which assessment finding indicates that a young adult client admitted with dehydration has been successfully rehydrated?

- Urine output of 40 mL/h.
- Skin “tents” when pinched.
- Urine-specific gravity of 1.031.
- Apical pulse of 120 and blood pressure of 90/40.

The answer is A. Urinary output of 40 mL/h or more indicates adequate hydration and glomerular filtration rate.

B is incorrect—Tenting of the skin is indicative of dehydration, although care must be taken particularly with the elderly to check for tenting in areas such as around the top of the sternum because tenting can occur when the skin of the forearm or hand is pinched due to normal age changes and therefore does not always indicate dehydration. C is incorrect—Urine-specific gravity of 1.031 is indicative of concentrated urine, which would be seen when hydration is inadequate. D is incorrect—An

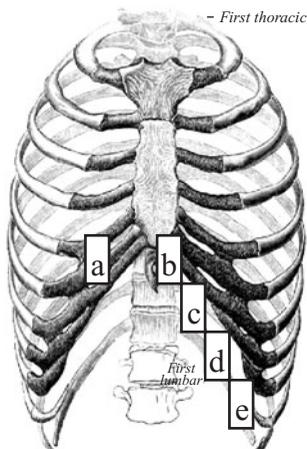

apical pulse of 120 is abnormally rapid and a blood pressure of 90/40 is low. These findings are consistent with dehydration.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

214. When assessing the heart, the nurse auscultates for abnormal heart sounds over the mitral area. Which lettered block on the accompanying diagram marks the location where the nurse would place the diaphragm of the stethoscope to auscultate the mitral area? Write the Letter of the block on the line provided.

The answer is E.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of client pathophysiology to illness management

215. When assessing a client with cholecystitis, a report of which type of pain would the nurse interpret as consistent with the diagnosis?
- Dull, aching upper right abdominal pain.
 - Sharp, crampy periumbilical pain.
 - Sharp pain in the back under the shoulder blade.
 - Dull upper abdominal and right shoulder pain.

The answer is C. Cholecystitis causes right upper quadrant pain referred to the back under the shoulder blade.

A is incorrect—Liver cancer causes dull, aching pain in the right abdomen. B is incorrect—Crampy, sharp perium-

bilical pain is characteristic of a variety of intestinal disorders including food poisoning. D is incorrect—An enlarged spleen can press on the diaphragm and stimulate the phrenic nerve resulting in referred shoulder pain but this is pain on the left side not the right.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

216. When assessing a client's hands, the nurse notes clubbing of the fingers. The nurse recognizes that clubbing is a sign of:
- respiratory disease
 - cardiomegaly
 - diabetes
 - rheumatoid arthritis

The answer is A. Clubbing of the fingers occurs secondary to low oxygen tension leading to an increased hemoglobin and hematocrit. The other answers are incorrect.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Use clinical decision making/critical thinking when addressing expected effects/outcomes of medications

217. Which is the priority assessment when caring for a client taking a calcium channel blocker medication?
- Weight
 - Breathing
 - Blood pressure
 - Urinary output

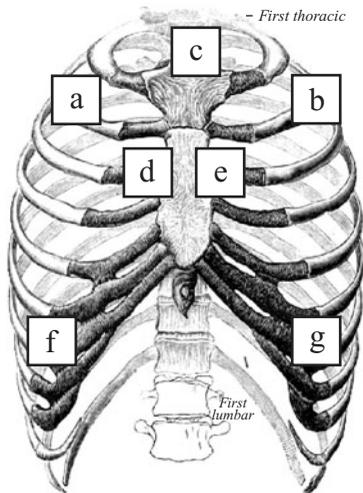

The answer is C. Calcium channel blockers cause coronary and peripheral vasodilation, which can lead to drop in blood pressure. There are no effects on weight, breathing, or urinary output requiring priority assessment.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

218. Which lung sound if auscultated over point E in the diagram would be evaluated by the nurse as a normal assessment finding?

- A. Bronchovesicular
- B. Crackle
- C. Gurgle
- D. Sibilant
- E. Tracheal
- F. Vesicular
- G. Wheeze

The answer is A. Bronchovesicular sounds are normally heard over the areas where the right and left bronchi branch. Anteriorly this is at the first and second intercostal spaces and posteriorly between the scapulae so this includes point B. Bronchovesicular sounds are of medium intensity and pitch with the inspiratory and expiratory phases equal.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Implement interventions to manage the client recovering from an illness

219. Which intervention would be inappropriate in the emergent care of a client with a dislocation?
- A. Putting joint through passive range of motion
 - B. Splinting the joint in the dislocated position
 - C. Applying ice to the joint
 - D. Providing tactile stimulation distal to the affected joint

Option A is the inappropriate intervention. The joint is not moved through a ROM; so this option is incorrect.

Other interventions are correct actions—The joint would be splinted in the dislocated position until controlled reduction is possible. Cold is applied initially to reduce swelling. Tactile stimulation distal to the affected joint serves no purpose.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing Priorities

Assess/triage the client to prioritize the order of care delivery

220. The nurse is planning care for a client newly admitted for rectal bleeding. What is the priority order in which the nurse should plan to carry out the following nursing care activities? (Arrange the options in priority order. All options must be used.)
- A. Start an intravenous.
 - B. Observe the client's level of anxiety.
 - C. Continue to monitor the client for rectal bleeding.
 - D. Teach the client self-care in preparation for the discharge.
 - E. Assess the client's skin, blood pressure, heart rate, and urine output.
 - F. Teach the client about the upcoming diagnostic tests that the doctor has ordered over the next couple of days.

Correct order of priorities: E, A, B, C, F, and D. Physical needs precede psychological needs. Client teaching would be the last priority in this situation.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of client condition and/or procedure

221. When caring for a client with a long intestinal tube attached to suction, the nurse would ensure that the suction does not exceed how many mmHg? (Record your answer using a whole number.)

The answer is 25. Suction higher than 25 mmHg can damage the intestinal mucosa.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

222. The nurse asks a client what the client would do if she/he found a stamped and addressed envelope on the street.

The client says she/he would put it in a mailbox. What conclusion should the nurse draw from this exchange?

- A. Judgment is intact
- B. Short-term memory is intact
- C. Mathematical abilities are intact
- D. Abstract thinking is intact

The answer is A. Judgment is intact. This scenario requires the patient to exercise judgment before reacting.

B, C, and D are incorrect—The question and answer exchange does not address short-term memory, mathematical ability, or abstract thinking.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate the client/family about medications

223. A 19-year-old college student is diagnosed with a strep throat and penicillin is prescribed. Which question should the nurse ask the girl when giving her the prescription?
- A. Do you drink milk?
 - B. Are you allergic to shellfish?
 - C. Do you take birth control pills?
 - D. Have you ever had vaginitis?

The answer is C. Penicillin can interfere with the action of oral contraceptives so if they are being used for birth control, the client needs to be advised to use an additional method while taking the medication. The other questions are not relevant to taking penicillin.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

224. When monitoring abdominal girth, which guideline should the nurse follow?
- A. Measure at the same time each day.
 - B. Measure before breakfast each morning.
 - C. Have the client empty the bladder before measuring.
 - D. Measure at the same location each time.

The answer is D. In order for the measurements to be comparable and therefore provide accurate information on the development of ascites, the girth of the abdomen must be measured at the same location each time. Usually the umbili-

cus is the location of choice but records of the measurements need to specify the location.

A, B, and C are incorrect—Time of day, breakfast, or a full bladder do not have the same potential for affecting the measurement as does location of the measurement on the abdomen.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Assess the client for actual or potential side effects and adverse effects of medications

225. A client comes to the clinic complaining of unexplained black and blue areas and red tinged urine. Which type of medication is it most important to find out if the client is taking?
- A. Urinary antiseptic
 - B. Systemic glucocorticoid
 - C. Antianemic
 - D. Anticoagulant

The answer is D. Unexplained black and blue areas and hematuria are signs of bleeding associated with excessive doses of anticoagulants. Because of the potential harmful effects of abnormal bleeding, checking for use of anticoagulants is the most important.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

226. When assessing the hip, which types of motion must be present to a normal degree for the nurse to document full range of motion? (Mark all that apply.)
- A. Supination
 - B. Flexion
 - C. Pronation
 - D. Extension
 - E. Internal rotation
 - F. External rotation
 - G. Abduction
 - H. Adduction

The answers are B, D, E, F, G, and H. The hip is a ball and socket joint as is the shoulder and this type of joint provides for the most movement. Types of movement possible are flexion, extension, adduction (movement toward the mid-

line of the body), abduction (movement away from the midline of the body), and internal and external rotation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

227. Which are risk factors for cancer of the liver? Mark all that apply.
- A. ___ Hepatitis A
 - B. ___ Cirrhosis
 - C. ___ History of gastric cancer
 - D. ___ Alcohol abuse
 - E. ___ Portal hypertension
 - F. ___ Exposure to environmental toxins
 - G. ___ Smoking
 - H. ___ Hepatitis C

The answers are B, D, F, G and H. Cirrhosis, alcohol abuse, exposure to chemicals and toxins, smoking, and hepatitis C are identified as risk factors for liver cancer. Liver cancer occurs more often among males and heredity seems to play a role in its occurrence.

A, C, and E are incorrect—Hepatitis A and a history of gastric cancer are unrelated to the development of liver cancer. Portal hypertension occurs with cirrhosis and can accompany liver cancer and other diseases. It is a result of rather than a cause of liver cancer.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Evaluate the results of diagnostic testing and intervene as needed

228. Which results of a CBC (complete blood count) with differential should the nurse interpret as indicating the client has a viral infection?
- A. WBC 8,500; lymphocytes 45%
 - B. WBC 25,000; band neutrophils 20%
 - C. WBC 15,000; segmented neutrophils 50%
 - D. WBC 20,000; segmented neutrophils 58%

The answer is A. With a viral infection the WBC is normal with elevated lymphocytes.

B is incorrect—This indicates a severe bacterial infection because the total white blood cell count is above normal and the band neutrophils are elevated because the body is trying to fight the infection so quickly that the neutrophils are being released into the circulation before they

are mature cells. C is incorrect—This indicates a bacterial infection, but not a severe one because the WBC count is above normal but the segs are normal. D is incorrect—This again indicates a bacterial infection, but not a severe one because although the WBC count is elevated, the segs are still within normal limits.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

Assess the client/family/significant other knowledge of immunization schedules

229. Which statement made by a client at an immunization clinic indicates an understanding about the hepatitis B vaccine?
- A. “I have to come back in six months to a year for the booster dose.”
 - B. “I won’t have maximum protection until after the third dose of the vaccine.”
 - C. “I’ll be able to eat shellfish without worry once I get all these injections.”
 - D. “I regret I won’t be able to give blood anymore after I get these injections.”

The answer is B. Three doses of vaccine are needed for maximum protection.

A is incorrect—It is hepatitis A vaccine that requires a booster dose in 6–12 months after the initial dose is given. C is incorrect—Hepatitis A, not hepatitis B, can be contracted from eating contaminated shellfish. D is incorrect—Receiving hepatitis B vaccine does not prevent blood donation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of pathophysiology to illness management

230. Which would be an expected finding when assessing a client with gout?
- A. Rash over the nose and cheeks.
 - B. Joint stiffness for 1–2 hours on arising.
 - C. Reddened edematous joints.
 - D. Intolerance of vegetable protein.

The answer is C. Reddened erythematous joints are signs of gout.

A is incorrect—Rash over the nose and cheeks is a symptom of SLE. B is incorrect—Joint stiffness for more than 1 hour on arising in the morning is characteristic of rheumatoid

arthritis. D is incorrect—Intolerance to vegetable program is unrelated to a musculoskeletal disorder.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Review pertinent data prior to medication administration

231. Because of the risk of a toxic drug reaction, monitoring laboratory reports for hypokalemia would be a part of the plan of care for a client receiving which medication?
- Hydrodiuril
 - Motrin
 - Lovastatin
 - Digoxin

The answer is D. Hypokalemia can precipitate a toxic reaction to digoxin.

A, B, and C are incorrect—Hypokalemia does not precipitate a toxic reaction to Hydrodiuril, Motrin, or Lovastatin.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

232. In which group of clients would the nurse expect to find a positive plantar reflex with an up going first toe and the others fanning out?
- The elderly
 - Adolescents
 - Infants
 - School aged children

The answer is C. Infants. The plantar or Babinski reflex in infants is positive, i.e., first toe goes up and toes fan.

A, B, and D are incorrect—In all other age groups, the first toe curls and the rest of the toes move downward.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate the client/families about medication

233. Which instruction should the nurse give to an elderly patient about the proper storage of medications?
- Keep medications in their original containers.
 - Store in a bathroom cabinet out of the reach of children

- Keep in a brightly lit area to better read labels.
- Avoid storing in dry, cool locations.

The answer is A. Medications should always be kept in their original, properly labeled containers to decrease the risk of taking the wrong drug, or of taking the right drug but in the wrong amount, by the wrong route, or at the wrong time.

B is incorrect—Medications should be stored out of the reach of children but not in the bathroom cabinet where exposure to moisture can occur. C is incorrect—Drugs should be stored out of the light and away from heat and so a dark, cool location is needed. D is incorrect—It is important to pour pills from their containers in good lighting so that labels can be read accurately but bottles of medication should not be stored in bright light.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

234. Which is a priority goal for a client with borderline personality disorder?
- Acceptance of group therapy.
 - Elimination of bizarre fantasies.
 - Development of social relationships
 - Decrease of actual and intended self-destructive behavior

The answer is D. Clients with borderline personality disorder make recurrent threats or gestures of self mutilation or suicide or actually attempt to mutilate or kill themselves. As a result a priority nursing intervention is to support efforts to decrease the actual behaviors as well as the client's intent to perform them. Group therapy can assist the client with borderline personality disorder in developing awareness of how one's behavior affects others.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of the client condition and/or procedure

235. When caring for a client with pancreatitis, the nurse monitors the nasogastric tube attached to suction for proper functioning. It is important that proper functioning be maintained:

- A. To prevent backup of secretions to the liver.
- B. To protect the intestine from gastric secretions.
- C. To allow for monitoring of gastric pH.
- D. To protect the gastric lining from pancreatic enzymes.

The answer is B. The N/G tube serves to remove acidic gastric contents so these do not enter and damage the intestine. This is a risk because alkaline pancreatic secretions are not available to neutralize them.

A, C, and D are incorrect—Gastric secretions do not back up to the liver, gastric pH is not measured as part of the management of pancreatitis, and pancreatic enzymes back flowing to the stomach is not a problem.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

236. When assessing the elbow, which types of motion must be present to a normal degree for the nurse to document full range of motion? (Mark all that apply.)
- A. Supination
 - B. Flexion
 - C. Pronation
 - D. Extension
 - E. Rotation
 - F. Tilting

The answers are A, B, C, and D. As a hinge joint the basic movement possible in the elbow is flexion and extension. In addition checking ROM of the elbow joint includes pronation and supination. To assess pronation the nurse asks the client to hold each arm straight out and turn the palm upward toward the ceiling. To assess supination, the arms are held out straight and the palms turned downward toward the floor.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administer and document medications given by common routes

237. What instruction would be most effective in helping a client relax the rectal sphincter in preparation for administration of a rectal suppository?
- A. “Turn on your left side and flex your knees.”
 - B. “Bear down as though for a bowel movement.”
 - C. “Take a deep breath exhaling through the mouth.”
 - D. “Think of something that you find soothing.”

The answer is C. Taking a deep breath and exhaling through the mouth helps relax the rectal sphincter. Turning on the left side and flexing the knees is a desirable position for inserting the suppository. Bearing down as though for a bowel movement would act to eject the suppository. Thinking of something soothing may help the client relax but is not specific to the rectal sphincter.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Evaluate the results of diagnostic testing and intervene as needed

238. A nurse is reading a PPD test that he or she administered to a healthy 50-year-old grade school teacher. Which of the following measurements would the nurse interpret as a “positive” reading for this individual?
- A. 10 mm of erythema
 - B. 5 mm of induration
 - C. 10 mm of induration
 - D. 15 mm of induration

The answer is C. With the exception of the immunocompromised, clients with risk factors such as teachers, health care workers, and people living in crowded areas, 10 mm and above of induration is considered positive.

A is incorrect—Erythema is not considered as positive. B is incorrect—5 mm of induration is positive if the person is immunocompromised. D is incorrect—15 mm of induration is positive for persons with no known risk factors.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of pathophysiology to illness management

239. Which would be an expected finding when assessing a client with lupus erythematosus?
- A. Rash over the nose and cheeks.
 - B. Joint stiffness for 1–2 hours on arising.
 - C. Reddened edematous joints.
 - D. Intolerance to milk sugar.

The answer is A. Rash over the nose and cheeks is a symptom of SLE, which is an autoimmune disease.

B is incorrect—Joint stiffness for more than 1 hour on arising in the morning is characteristic of rheumatoid arthritis. C is incorrect—Reddened erythematous joints are a sign of gout. Intolerance to milk sugar or lactose intolerance is unrelated to lupus erythematosus.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

240. When assessing the ankle, which types of motion must be present to a normal degree for the nurse to document full range of motion? (Mark all that apply.)
- A. Supination
 - B. Dorsiflexion
 - C. Pronation
 - D. Hyperextension
 - E. Eversion
 - F. Plantar flexion
 - G. Abduction
 - H. Adduction
 - I. Inversion

The answers are B, E, F, G, H, and I. Movements that are part of the normal range of motion for the ankles are dorsiflexion (foot bent upward with toes pointing at head), plantar flexion (foot pointed downward, abduction, adduction, and eversion (movement of the sole of the foot outward), and inversion (movement of the sole of the foot inward). Supination and pronation are movements of the elbow. Hyperextension is a movement of the shoulder, elbow, and knee.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Vital Signs

Apply knowledge needed to perform related nursing procedures and psychomotor skills when assessing vital signs

241. When delegating blood pressure measurement to an unlicensed assistant, the nurse cautions that correct technique must be used to avoid obtaining false low pressures. Which is one of the directions the nurse would give to prevent a false low pressure reading?
- A. Take the blood pressure on an extremity positioned below heart level.
 - B. Use a cuff whose width is 40% of the diameter of the extremity.
 - C. Wrap the cuff loosely around the extremity.
 - D. Apply the cuff unevenly to the extremity.

The answer is B. The width of the cuff should be 40% of the diameter of the arm; use of a cuff that is too wide can cause false low blood pressure readings and use of a cuff that is too narrow can result in false high readings.

A is incorrect—Taking the blood pressure on an extremity positioned below heart level can result in a false low read-

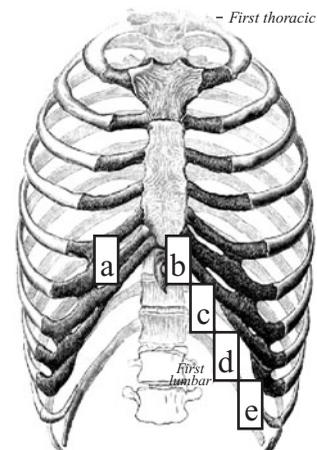

ing; it does not prevent it. The extremity needs to be supported and at heart level. C is incorrect—Wrapping the cuff too loosely on the extremity results in a false high reading not a false low reading. D is incorrect—If the cuff is wrapped unevenly around the extremity, the result can be a false high, not a false low, pressure reading.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

242. When assessing the heart, the nurse auscultates for both aortic and pulmonic murmurs over Erb's point. Which lettered block on the accompanying diagram marks the location where the nurse would place the diaphragm of the stethoscope to auscultate over Erb's point? Write the letter of the block on the line provided.

The answer is C.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Perform diagnostic testing

243. When instructing a client on obtaining a stool specimen for an FOBT, the nurse tells the client not to take aspirin or NSAIDs for how many days prior to collecting the specimen?
- Record your answer using a whole number.

The answer is 2 days. FOBT is a screening test for colon cancer, a sign of which is occult blood in the stool. Aspirin and NSAIDs can cause GI irritation and bleeding and thus can result in a positive FOBT.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administer and document medications given by par-
enteral routes

244. In which situation would the nurse need to administer an injection using Z-track technique?
- The client is malnourished with muscle wasting.
 - The medication is thick and requires a large gauge needle.
 - The medication is very irritating.
 - The client's platelet count is 200,000 or more.

The answer is C. The Z-track method is designed to prevent backflow of medication through the needle track and into the surrounding tissues. It is used when medications are very irritating and can cause tissue damage.

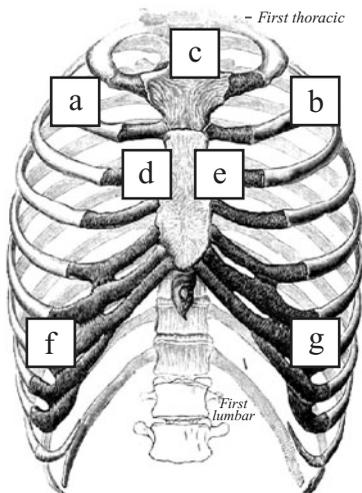

A, B, and D are incorrect—Administration using a Z-track technique is not determined by the size of the client, the thickness of the medication, or the client's platelet count.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

245. Which lung sound if auscultated over point F in the diagram would be evaluated by the nurse as a normal assessment finding?

- Bronchovesicular
- Crackle
- Gurgle
- Sibilant

- Tracheal
- Vesicular
- Wheeze

The answer is E. Vesicular sounds are normally heard over alveolar lung tissue, which is the majority of both lungs including point B. Vesicular sounds are soft in intensity and low in pitch. The inspiratory phase is longer than the expiratory phase.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Values

Provide the client with information about the purpose and procedure of prescribed laboratory tests

246. A client receives a report that his PSA level is 9 ng/mL and asks the nurse what this means. The nurse will base the response on the knowledge that:
- This result is within normal range and no follow up is required.
 - This result is below the normal range and repeat testing is needed.
 - This result is slightly elevated and may reflect problems such as urinary tract infection and benign prostatic hypertrophy as well as prostate cancer; follow up is needed.
 - This result is above normal and indicative of prostate cancer; treatment is needed.

The answer is C. The normal PSA is less than 4 ng/mL but can be elevated into the hundreds with metastatic prostate cancer. Elevations can occur as a result of BPH, cirrhosis, prostatitis, urinary tract infection, and urinary retention. False elevated levels can occur after urinary catheterization, cystoscopy, transrectal ultrasound, or prostate biopsy.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Laboratory Values

Recognizes deviations from normal

247. A pregnant woman is seen in the prenatal clinic. The following lab values are received during this visit. Which lab value requires further investigation?
- Positive HCG
 - High alpha fetoprotein
 - Low hemoglobin and hematocrit
 - Urine negative for protein and glucose

The answer is B. High alpha fetoprotein is seen in conjunction with fetal abnormalities, such as spina bifida and Down's syndrome and should be investigated further.

A is incorrect—Positive HCG means she is pregnant. C is incorrect—During pregnancy, the volume portion of blood increases at a faster rate than the cellular portion producing a pseudoanemia. D is incorrect—Negative urine protein and glucose is normal.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Evaluate the results of diagnostic testing and intervene as needed

248. Because of the risk of spontaneous bleeding, the nurse would institute bleeding precautions for a client whose laboratory report documents a platelet count below ___ /mm³. Record your answer using a whole number.

The answer is 20,000. Spontaneous bleeding can occur with a platelet count of less than 20,000/mm³. Therefore bleeding precautions are required:

- Test all urine and stool for blood.
- No rectal treatments (temperatures, suppositories, enemas, etc.).
- No IM injections.
- Put firm pressure on all venipuncture sites for 5 minutes and on arterial puncture sites for 10 minutes.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach the client about managing illness

249. Which topic would be included in the teaching plan for a client with gout?

- Need to decrease dietary intake of foods high in purine.
- Importance of restricting caffeine in the daily diet.
- Necessity of limiting fluid intake.
- Benefits of decreasing intake of dairy products.

The answer is A. Clients with gout need to limit intake of high purine foods such as scallops, sardines, gravies, and cream sauces.

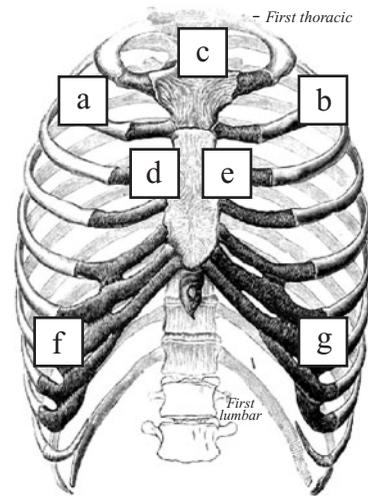

B is incorrect—Caffeine does not need to be restricted. C is incorrect—Fluid intake should be increased to aid renal filtration of uric acid from the blood; it should not be restricted. D is incorrect—Dairy products do not have to be decreased.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

250. Which lung sound if auscultated over point D in the diagram would be evaluated by the nurse as a normal assessment finding?

- Bronchovesicular
- Crackle
- Gurgle
- Sibilant
- Tracheal
- Vesicular
- Wheeze

The answer is A. Bronchovesicular sounds are normally heard over the areas where the right and left bronchi branch. Anteriorly this is at the first and second intercostal spaces and posteriorly between the scapulae so this includes point B. Bronchovesicular sounds are of medium intensity and pitch with the inspiratory and expiratory phases equal.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Assess the client for actual or potential side effects and adverse effects of medications

251. When caring for a client on antibiotic therapy, monitoring for which type of common complication is an important component of the plan of care?

- Electrolyte imbalance
- Suprainfection

- C. Liver failure
- D. Abnormal bleeding

The answer is B. Suprainfection is a common complication of antibiotic therapy because as organisms susceptible to the prescribed antibiotic are eliminated, other nonsusceptible organisms can overgrow. This results in a second infection caused by an organism different from the one causing the infection for which the antibiotic was prescribed. Common examples of suprainfection are monilial vaginal infections and diarrhea.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Delegation

Utilize five “rights” of delegations (right task, right circumstances, right person, right direction or communication, and right supervision or feedback)

252. When delegating blood pressure measurement to an unlicensed assistant, the nurse cautions that correct technique must be used to avoid obtaining false high blood pressures. Which errors in technique should be identified as the potential causes of false high blood pressures? Mark all that apply.
- A. Use of an unsupported limb to take the blood pressure
 - B. Use of a cuff that is too wide.
 - C. Immediate reinflation of the cuff
 - D. Too rapid deflation of the cuff
 - E. Uneven application of the cuff

The answers are A, C, and E. Taking the blood pressure on an unsupported extremity, reinflation of the cuff without waiting 1–2 minutes, and applying the cuff unevenly to the arm all can cause a false high blood pressure.

B and D are incorrect—Use of a cuff that is too wide or deflating the cuff too rapidly can cause false low blood pressures.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Educate client/family about medications

253. Which statement made by a client who has been given instructions on taking NSAIDs for joint pain indicates the need for further teaching?
- A. “I have to take these pills with food and a full glass of liquid.”
 - B. “I can’t have beer or other alcoholic drinks while taking these pills.”

- C. “I need to be on the alert for any signs of abnormal bleeding.”
- D. “I can take other over the counter drugs with these as long as I don’t take more than the prescribed dose.”

The answer is D. NSAIDs cannot be mixed with any over the counter drugs; safe use of other drugs varies with what they are and how they work. NSAIDs should not be mixed with any other NSAIDs. This statement indicates that the client has not understood all the information necessary for safe use of the prescribed NSAID. Therefore the client is in need of further teaching. Other responses are correct. NSAIDs should be taken with food and a full glass of fluid because of their irritating effects on the gastric mucosa; alcoholic beverages also should be avoided. Because aspirin and ibuprofen, which are classic examples of the two types of NSAIDs (a salicylate and a prostaglandin synthetase inhibitor respectively) affect platelet function and can cause GI bleeding, a client needs to observe for and report any signs of bleeding.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Laboratory Values

Recognizes deviations from normal

254. A child is admitted to the hospital with a diagnosis of “rule out meningitis.” A spinal tap is performed in the emergency room. It will take 24–48 hours before a culture is grown. Which finding in the spinal fluid indicates a probable bacterial meningitis?
- A. Elevated protein
 - B. Decreased glucose
 - C. Elevated WBC count
 - D. Cloudy in appearance

The answer is B. The bacteria feed on the glucose lowering that level.

A, C, and D are incorrect—Elevated protein is usually indicative of a slowing or obstruction of the CSF, and elevated WBCs and cloudy appearance are seen in both types of meningitis.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

255. When assessing deep tendon reflexes, when does the nurse use the pointed end of the reflex hammer? Mark all that apply. The nurse uses the pointed end of the reflex hammer to check

- A. ___ brachioradialis reflex
- B. ___ biceps reflex
- C. ___ triceps reflex
- D. ___ patellar reflex
- E. ___ Achilles reflex
- F. ___ cremasteric reflex

The answers are A, B, and C. The brachioradialis reflex located in the forearm above the radial styloid process of the wrist, the biceps reflex located in front of the elbow, and the triceps reflex located just above the elbow on the back of the arm are all checked using the pointed end of the reflex hammer.

D, E, and F are incorrect—The patellar and Achilles reflexes located at the front of the knee and the back of the heel respectively are tested using the broad end of the reflex hammer. The cremasteric reflex is a superficial reflex, which causes elevation of one side of the testicle in response to stroking the thigh on that side. The handle of the reflex hammer is used to stroke the thigh.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Values

Provide the client with information about the purpose and procedure of prescribed laboratory tests

256. Which instruction should the nurse give to a client who is to be scheduled for blood work, which includes measures of cholesterol?
- A. Do not drink alcohol for at least 24 hours before the test.
 - B. Fast for 8 hours before the test.
 - C. Drink at least 4 large glasses of water the evening before the test.
 - D. Avoid fatty foods for 2 days before the test.

The answer is A. Alcohol should be avoided before the test.

B, C, and D are incorrect—Fasting is necessary for 9–12 hours before the test. There is no requirement regarding fluid intake or avoidance of fatty foods.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Apply knowledge of nursing procedures and psychomotor skills when caring for a client with potential for complications

257. A 72-year-old client is scheduled for a CT scan with contrast media. Prior to the test, the nurse checks to

ascertain that which laboratory tests have been done?

Mark all that apply.

- A. ___ Urinalysis
- B. ___ Fasting blood sugar
- C. ___ BUN
- D. ___ Aspartate aminotransferase (AST)
- E. ___ Alanine aminotransferase (ALT)
- F. ___ Creatinine

The answers are C and F. BUN and creatinine are tests of kidney function. Because contrast media is excreted through the kidneys, clients undergoing CT scans using contrast media need adequate kidney function. Because older clients are at risk for decreased renal function, those over age 60 have BUN and creatinine assessed prior to a test using contrast media.

Abnormal urinalysis, blood sugar (FBS), or liver function tests (AST, ALT) do not typically prevent a patient from having a CT scan.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

258. Which instructions should be given to the client with gout? (Mark all that apply.)
- A. “Do not drink red wine or other alcohol.”
 - B. “Drink a lot of nonalcoholic fluids.”
 - C. “Decrease intake of foods high in purine.”
 - D. “Increase intake of foods high in calcium.”
 - E. “Reduce intake of salt.”

The answers are A, B, and C. Clients with gout need to limit intake of high purine foods such as scallops, sardines, gravies, and cream sauces. Alcohol especially red wine should be avoided. Fluid intake should be increased to aid renal filtration of uric acid from the blood.

D and E are incorrect—Calcium does not need to be increased and salt does not need to be restricted.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Provide client and family with information about acute and chronic mental illness

259. The nurse is speaking to a group of family members of clients with Alzheimer’s disease. Which behaviors would the nurse identify as characteristic of Stage 2 Alzheimer’s disease?

- A. Progressive impairment primarily of short term memory
- B. Difficulties with house keeping and cooking
- C. Agitated movements and speech
- D. Confabulation
- E. Expressions of concern over loss of mental capacity

The answers are A, B, and D. Stage 2 of Alzheimer's disease is the stage of confusion. In this stage there is a progressive loss of memory with short term memory being most impaired. There is difficulty with the Instrumental Activities of Daily Living including house cleaning and cooking. Confabulation and stereotyped speech word usage occurs to cover up for memory loss. Agitation is a characteristic of stage 3 Alzheimer's disease which is ambulatory dementia. Expressions or awareness of the problem and concerns over mental abilities occur in Stage 1 which is the Stage of forgetfulness.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of client condition and/or procedure

260. When preparing to care for a client returning from surgery after a left lower extremity amputation, which piece of equipment is most critical to obtain for the bedside?
- A. Traction set up
 - B. Alternating pressure mattress
 - C. Tourniquet
 - D. Wire cutters

The answer is C. If hemorrhage occurs, a tourniquet must be immediately applied and therefore is kept at the bedside.

A is incorrect—Traction is used for a variety of orthopedic conditions including fractures and low back pain. B is incorrect—An alternating pressure mattress is used to prevent or manage skin breakdown. D is incorrect—Wire cutters are needed at the bedside of clients who have wired jaws.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

Provide newborn care

261. A newborn is admitted to the newborn nursery. Initial assessment findings are axillary, temperature 97°F, pulse 128, and respirations 33. Based on these findings, the nurse would delay which normal admission activity?

- A. Bath newborn and shampoo hair.
- B. Complete a head to toe assessment.
- C. Feed the infant 1 ounce or less of glucose water.
- D. Place in an overbed warmer for easy observation.

The answer is A. Bathing a newborn with a low temperature will further lower the infant's temperature and put the infant in cold stress. All other responses are correct.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Evaluate and monitor client height and weight

262. A 2-month-old infant was admitted for poor weight gain and frequent vomiting. The child is diagnosed with gastroesophageal reflux. Nursing interventions are implemented to reduce the vomiting. The nurse will know the interventions have been successful when:
- A. urine output increases.
 - B. the infant is discharged home.
 - C. the child shows daily weight gain.
 - D. the mother says she is comfortable feeding her infant.

The answer is C. Weight gain is the best indication that sufficient food is being retained.

A is incorrect—Urine output may or may not increase. B is incorrect—Discharge home does not indicate the problem is totally solved. D is incorrect—This is a physical problem for the child, not the mother.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Promote client wound healing

263. A client has been admitted to the hospital unit for stasis venous ulcers. Nursing care for this client would include:
- A. doing Burger-Allen exercises.
 - B. providing bedrest with legs in a dependent position.
 - C. placing a foot board on the bed.
 - D. placing the client in a high fowlers position.

The answer is C. This keeps pressure off of the ulcer.

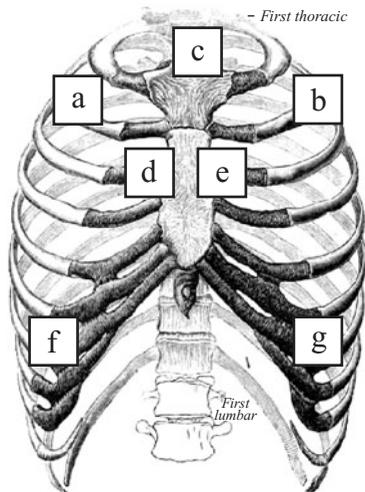

A is incorrect—Burger-Allen Exercises are done for Buerger's disease. B is incorrect—Keeping legs in a dependent position increases edema. D is incorrect—High Fowlers position increases pressure and kinking on the vascular system.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

264. Which lung sound if auscultated over point G in the diagram would be evaluated by the nurse as a normal assessment finding?

- A. Bronchovesicular
- B. Crackle
- C. Gurgle
- D. Sibilant
- E. Tracheal
- F. Vesicular
- G. Wheeze

The answer is F. Vesicular sounds are normally heard over alveolar lung tissue, which is the majority of both lungs including point B. Vesicular sounds are soft in intensity and low in pitch. The inspiratory phase is longer than the expiratory phase.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected effects/outcomes

265. Which class of drug is given to prevent heart failure in the first 24 hours after a myocardial infarction (MI)?

- A. Calcium channel blocker
- B. ACE inhibitor
- C. Beta blocker
- D. Digitalis derivative

The answer is B. Ace inhibitors prevent conversion of angiotensin I to angiotensin II.

A is incorrect—Calcium channel blockers cause coronary and peripheral vasoconstriction. C is incorrect—Beta blockers reduce heart rate and contractility. D is incorrect—Digitalis slows the heart and increases the force of contraction.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Implement procedures to counteract adverse effects of medications and parenteral therapy

266. A client who is in the cardiac care unit complains of mediastinal chest pain, dyspnea, and anxiety. The nurse gives the client a nitroglycerine tablet sublingual. The client now complains of being dizzy. Which of the following nursing interventions should the nurse do first?

- A. Get a 12 lead ECG.
- B. Raise the side rails on the bed.
- C. Open the D5W IV to 100 cc per hour.
- D. Take the client's vital sign including pulse oximetry.

The answer is B. Safety is the priority.

Option C would not be correct because it is not an isotonic solution and would not help to maintain circulating volume. Option A would be done but would not be the priority. Option D is not indicated as a priority.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents/Actions

Use clinical decision making/critical thinking when addressing actions of prescribed pharmacological agents on clients

267. A client with atrial fibrillation is receiving warfarin (Coumadin) 5 mg each day. His INR today is 1.8. What is the expected decision regarding change in medication dosage?

- A. His INR is too low. His warfarin dose needs to be increased.
- B. His INR is too high. His warfarin dose needs to be decreased.
- C. His INR is too high. His warfarin dose needs to be increased.
- D. His INR is within desired range. No change in warfarin dose is needed.

The answer is A. Target INR for clients with afib is 2.0–3.0. This client's INR is below this range so it would be expected that the dose of warfarin would be increased.

B and C are incorrect—The client's INR is not too low or high. D is incorrect—The INR is not within desired range.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

268. While assisting a client to perform activities of daily living, how can the nurse best enhance his/her balance?
- By spreading his/her feet a comfortable distance.
 - By stretching the thoracic cavity by taking deep breaths.
 - By performing the activity(ies) to the level the client can tolerate without experiencing adverse effects.
 - By exerting pressure against a solid object.

The answer is A. By spreading his/her feet a comfortable distance. Balance is achieved when there is a low center of gravity over a wide stable base of support.

B, C, and D are incorrect—Stretching the thorax will have no effect on balance; maintaining equilibrium responds to various head movements. Activity tolerance is performed to the level the individual can tolerate the activity, but this does not impact the nurse's balance. Isometric exercises involves exerting pressure against a solid object.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Plan nursing care based on assessment findings

269. A 4-year-old child was diagnosed with hydrocephaly shortly after birth and had a ventricular-peritoneal shunt inserted. The child has started vomiting and complaining of headaches in the morning but is well the rest of the day. Which problem would the nurse suspect?
- Meningitis
 - Gastroenteritis
 - Malfunctioning shunt
 - The development of a brain tumor

The answer is C. The symptoms are those of increased intracranial pressure. Early morning vomiting and headaches are common. While the child is asleep at night, blood increases the intracranial contents causing symptoms. The other responses would not be early morning only symptoms.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Potential for Complications from Surgical Procedures and Health Alterations

Apply knowledge of pathophysiology to monitoring for complications

270. Your patient is an 80-year-old female who is 4 hours postoperative from a right total hip replacement and is experiencing urinary retention. What is the most likely cause of this problem?
- Decreased renal blood flow
 - Decreased bladder muscle tone
 - Urethral edema
 - Benign prostatic hypertrophy.

The answer is B. Decreased bladder tone will result in urinary retention.

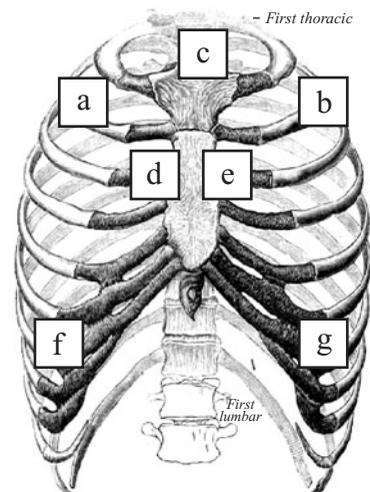

A is incorrect—Decreased renal blood flow is incorrect because this would result in decreased production of urine (anuria or oliguria) not urinary retention, which refers to the inability to empty urine from the bladder. C is incorrect—Urethral edema is unlikely because the surgery does not involve manipulation of the urethra or any adjacent tissues. D is incorrect—Benign prostatic hypertrophy is incorrect because the patient is female.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

271. Which lung sound if auscultated over point C in the diagram would be evaluated by the nurse as a normal assessment finding?

- A. Bronchovesicular
- B. Crackle
- C. Gurgle
- D. Sibilant
- E. Tracheal
- F. Vesicular
- G. Wheeze

The answer is E. Tracheal sounds are normally heard over the trachea, which lies below point B. Tracheal sounds are very loud and high pitched rather like the sound made by blowing through the cardboard tube found at the center of a roll of paper towels. The expiratory phase is longer than the inspiratory phase.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Implement interventions to manage the client recovering from an illness

272. Which interventions would appropriately be included in the care plan of a client experiencing an acute episode of rheumatoid arthritis? (Mark all that apply.)
- A. ___ Keep affected joints splinted for rest.
 - B. ___ Apply ice packs to affected joints.
 - C. ___ Maintain affected joints in a neutral, functional position.
 - D. ___ Assist the client to weight bear on affected joints for at least 15 minutes tid.
 - E. ___ Use heat to relieve pain.

The answers are A, B, and C. Ice helps reduce inflammation and relieve pain during acute episodes; heat is used to relax muscles and relieve pain at other times. During acute episodes affected joints are splinted for rest, are not exercised, are used to bear weight nor placed in a hyperextended position.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

273. A client is receiving vancomycin intravenously when the nurse notices the client's neck and face becoming red. The immediate response by the nurse should be to:
- A. notify the physician
 - B. stop the infusion
 - C. administer benadryl
 - D. do nothing since this is a common reaction to vancomycin

The answer is B. The nurse would stop the infusion, then notify the physician who would order Benadryl. Once Benadryl has been administered and the flushing disappears, the antibiotic can be restarted, but at a slower rate. This reaction is called Red Man's syndrome and can be fatal if appropriate interventions do not occur.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Identify Pharmacological Interactions

Educate the client/family about medications

274. Instructions given to a client taking which medication would include the need to keep the amount of green leafy vegetables eaten steady from day to day?
- A. Heparin
 - B. Warfarin sodium
 - C. Lovastatin
 - D. Digoxin

The answer is B. Warfarin sodium exerts its anticoagulant effect through interference with the use of vitamin K for clotting. Green leafy vegetables are a major dietary source of vitamin K. If a person varies the amounts of green leafy vegetables in the diet significantly, the dosage of warfarin will be incorrect—either too much or too little depending on whether the client has increased or decreased intake of the green leafy vegetables. For correct dosage of warfarin amounts of vitamin K need to be stable and so dietary intake needs to be stable.

A, C, and D are incorrect—Green leafy vegetables do not impact the effect of heparin, lovastatin, or digoxin.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior.

275. Which is a priority nursing intervention for a client with borderline personality disorder?
- A. Encourage acceptance of intensive therapy.
 - B. Eliminate bizarre fantasies.
 - C. Facilitate social relationships
 - D. Promote verbalization of feelings about self.

The answer is D. Promoting verbalization of feelings about self is important in an attempt to gain insight for clients with borderline personality disorder. These clients have a poor and unstable self image and sense of self. They have overwhelming feelings of aloneness, emptiness and rage which is often manifested as self abusive behavior such as head banging, skin scratching, substance abuse, and sui-

cide gestures and attempts. Relationships are typically unstable.

Clients with borderline personality disorder are dependent and needy and tend to seek help readily. Bizarre fantasies are not a prominent component of this disorder and facilitation of social relationships is not a priority need.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents/Actions

Identify a contradiction to the administration of a prescribed or over-the-counter preparation to the client

276. You are reviewing the medications taken by a client who is going to be scheduled for surgery. You note that one baby aspirin is taken each day. When asked if the medications listed are all that he takes, the client says “Oh, I also take two garlic pills because I heard garlic was good for me.” What should the nurse instruct the patient to do?
- Continue to take all of your medication including the garlic pill.
 - Discontinue taking the garlic pill and continue all other medication.
 - Discontinue taking the baby aspirin and continue all other medication.
 - Discontinue taking both the baby aspirin and garlic pill now

The answer is D. Both the garlic pill and aspirin inhibit platelet aggregation and prolong bleeding.

A, B, and C are incorrect because the client is only told to stop either taking the garlic or aspirin.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Assist client/family to identify/participate in activities fitting his/her age, preference, physical capacity, and psychosocial/behavior/physical development

277. The parents bring their 2-month-old to the clinic for a well baby check-up. The mother asks how they should start the baby on solid foods. Which information should be included in the nurse’s response?
- It is too early to start solid foods.
 - Rice cereal will be the first food added to the diet.
 - Start with baby desserts as the baby will not spit that out.
 - The solids can be put in the bottle with the milk in the beginning.

The answer is B.

A is incorrect—The parents did not ask when to start solids but how to start solids. C is incorrect—Desserts are not necessary and promote a “sweet tooth.” D is incorrect—If the infant should need to take medication, it will be from a spoon and this new skill will not be learned if the solids are put in the bottle.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct the client on medication self-administration procedures

278. Which client statement indicates understanding of the correct use of nitroglycerine paste?
- “I will decide on a convenient site for the medicine and use it consistently.”
 - “I will make sure I have medicine on 24 hours per day.”
 - “I will wipe the skin with alcohol before I put the paste on.”
 - “I will make sure to keep enough paste on hand because it is dangerous to just stop it.”

The answer is D. Use of nitroglycerine paste is tapered off at the direction of the prescriber; it is not abruptly stopped.

A is incorrect—Sites need to be rotated to avoid skin irritation. B is incorrect—The medication is not used 24 hours per day; there needs to be a period each day when the medication is not used. This is typically 8 hours out of every 24. C is incorrect—Skin should not be shaved nor should alcohol be applied prior to application of the paste because of irritation and possible breaks in the skin, which allows for increased absorption of medication.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

279. Which cranial nerve is being tested when the nurse asks the client to smile, frown, grimace, show the upper and lower teeth, keep the eyes closed while the examiner tries to open them and puff out the cheeks?
- One (olfactory)
 - Five (trigeminal)
 - Seven (facial)
 - Eleven (spinal accessory)

The answer is C. Cranial nerve seven (facial nerve) is responsible for taste on the front two thirds of the tongue and for movement of the face including the ability to close the eyes and move the lips for speech. Motor function of cranial

nerve seven is tested by asking the client to smile, frown, grimace, show the upper and lower teeth, keep the eyes closed, while the examiner tries to open them and puff out the cheeks. The examiner observes for symmetry and movement and presses the puffed out cheeks in to check if air is expelled equally from both sides. To test taste, an applicator dipped in a sugar, salt, or lemon solution is placed on the tongue and the client is asked what is tasted.

A is incorrect—Cranial nerve one (olfactory nerve) is responsible for the sense of smell. It is tested by occluding each of the client's nostrils one at a time, holding a substance such as coffee or vanilla with a familiar aroma under the other nostril, and asking the client to identify the smell. The test is repeated with a different aromatic substance to determine if the client can differentiate smells.

B is incorrect—Cranial nerve five (trigeminal nerve) has both motor and sensory components. It is responsible for sensation in the face, scalp, oral and nasal mucous membranes, and the cornea and allows chewing movements of the jaw. Its three-part sensory division is tested by touching the forehead, cheek, and chin on each side with a wisp of cotton and asking the client whose eyes are closed to identify the type of touch and its location. Next the cornea of each is lightly touched with a wisp of cotton brought in from the side and the eye observed for the normal blink response. The motor function of cranial nerve five is tested by asking the client to clench the teeth and keep them clenched while the examiner pushes down on the chin to try and separate the jaws.

D is incorrect—Cranial nerve eleven (spinal accessory) is tested by asking the client to shrug the shoulders and resist pressure to put them down because this cranial nerve controls muscular strength of the trapezius and sternocleidomastoid muscles.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious Disease

Recognize signs and symptoms of infectious diseases

280. The nurse is assessing an infant in the newborn nursery. Which finding requires intervention?
- Milia on the nose
 - Breasts are heavily engorged.
 - Erythema toxicum on the trunk
 - White adherent patches on the tongue

The answer is D. White patches are a sign of a candida infection called thrush. This must be reported to the physician so that a fungicide can be ordered.

A, B, and C are normal findings. Milia are white epidermal cysts that disappear on their own. Breast engorgement is normal and due to maternal hormones. Erythema toxicum or newborn rash is common and requires no intervention.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Laboratory Values

Recognize deviations from normal for values of WBC

281. How should the nurse interpret a laboratory report of "WBC 15,000; segmented neutrophils 50%"?
- Severe bacterial infection
 - Low- to moderate-grade bacterial infection
 - Viral infection
 - No infection

The answer is B. WBC count is elevated but segs are normal. This indicates nonsevere bacterial infection. Severe infection is indicated by an elevated WBC with elevated band neutrophils. Viral infection is indicated by a normal WBC and elevated lymphocytes. No infection is indicated by a normal WBC with normal segs.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

282. The nurse checks radial deviation as a part of the range of motion assessment of which joint (s) ?
- Cervical spine
 - Elbow
 - Wrist
 - Ankle

The answer is C. Radial deviation occurs at the wrist and allows the hand to be pointed toward the side with the thumb and the radial artery. Other movements of the wrist are ulnar deviation in which the hand is pointed toward the side with the fifth or little finger and the ulnar artery.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious Diseases

Apply knowledge of client pathophysiology when managing infectious disease

283. Which assessment findings would the nurse expect when caring for a client in the preicteric phase of hepatitis? Mark all that apply.
- Anorexia
 - Scleral jaundice

- C. ___ Fatigue
- D. ___ Liver tenderness
- E. ___ Headache
- F. ___ Weight loss
- G. ___ Vomiting

The answers are A, C, and E. Anorexia, headache, and fatigue are symptoms of the preicteric phase of hepatitis. Any jaundice, liver tenderness and weight loss are characteristic of the icteric phase. In the posticteric phase, the client begins to improve and anorexia lessens and jaundice begins to disappear.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Evaluate the results of diagnostic testing and intervene as needed

284. The nurse would interpret a PaO₂ value of less than how many mmHg as indicating hypoxemia? Record your answer using a whole number.

The answer is 70.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach the client about managing illness

285. Which statement made by a client who has a fractured hip indicates the need for additional teaching about required activity restrictions?
- A. "I can't fully extend my leg at the hip for one month."
 - B. "I won't be able to cross my knees for up to 8 weeks."
 - C. "I can't put weight on the affected leg until my doctor says to."
 - D. "I can flex my hip but not more than 90 degrees for up to 2 months."

The answer is A. There is no restriction on extending the leg so if the client says she is not allowed to fully extend her leg for a month it means that she has misunderstood her self-care instructions.

B is incorrect—Adduction past the midline must be avoided for up to 2 months so the knees cannot be crossed for 2 months. C is incorrect—Weight bearing is restricted and doctor's orders regarding extent of restriction need to be followed. D is incorrect—Hip flexion of more than 90 degrees must be avoided for up to 2 months.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Identify and report deviations from expected growth and development

286. When assessing the anterior fontanel, the nurse would interpret it as an abnormal finding requiring follow up if it was not closed in a child of which age?
- A. Six months
 - B. Nine months
 - C. One year
 - D. Two years

The answer is D. It would be an abnormal finding if the anterior fontanel was not closed by age 2 years. The posterior fontanel is smaller and closes earlier.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Use the six "rights" when administering client medications

287. A 0.7-mL oral dose of liquid medication is ordered for an infant. In which device should the nurse measure the dose for administration?
- A. 2 mL syringe
 - B. Tuberculin syringe
 - C. Infant teaspoon
 - D. Medicine cup

The answer is B. A tuberculin syringe allows accurate measurement of tenths of millimeters and so a dose of seven tenths of a milliliter can be obtained.

A, C, and D are incorrect—A 2-mL syringe is marked off in two tenths of a milliliter increments and so seven tenths cannot be accurately measured and for an infant very small extra amounts of drug have the potential to cause serious effects. Neither an infant teaspoon nor a medicine cup allow accurate measurement of tenths of millimeters.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of client condition and/or procedure

288. Which postoperative exercise is best used to prevent deep vein thrombosis in postoperative clients?

- A. Deep knee bends
- B. Straight leg lifts
- C. Side leg lifts
- D. Forward lunges

The answer is B. Straight leg lifts exercise the muscle similar to walking to maintain normal blood flow to and from the lower extremity.

A, C, and D are incorrect. These exercises cannot normally be performed immediately following surgical procedures and require movement that may not be appropriate for all clients.

SAFE AND EFFECTIVE ENVIRONMENT

Management of Care

Establishing Priorities

Assess/triage the client to prioritize the order of care delivery

289. The nurse obtains the following vital signs on a client who has just been admitted to the unit. BP 162/84, pulse 100 and irregular, respirations 16, and pulse oximetry 88%. Which would be the immediate nursing intervention?
- A. Place the client on cardiac telemetry.
 - B. Call the physician to report the vital signs.
 - C. Start a saline lock for IV medication access.
 - D. Start oxygen at 2–4 L per minute per nasal cannula per protocol.

The answer is D. The client's oxygen level is very low. All other interventions would be done later.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach the client about managing illness

290. Which statement made by the mother of a child with muscular dystrophy indicates a need for further teaching about the disease?
- A. "I cannot believe that my son inherited this terrible disease."
 - B. "I'm going to try to see that my son has the best life possible even though it will be short."
 - C. "If intellectual impairment was not always a part of the disease, it would be easier to deal with."
 - D. "It will be very hard watching as the muscle wasting and loss of function occur."

Option C indicates a misunderstanding. Intellectual impairment occurs with a few forms of MD but not with all so the mother believing that intellectual impairment is always a

part of the disease indicates a misunderstanding and therefore further teaching is needed.

The other statements are correct—Muscular dystrophy is an inherited disorder, with a shortened life expectancy. Muscle wasting, weakness, and loss of function are characteristic of muscular dystrophy.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

291. When assessing the temporomandibular joint, where does the nurse palpate as the client is asked to clench the teeth and move the jaw?
- A. In front of the ear
 - B. Behind the mastoid process
 - C. Just beneath the occipital lymph nodes
 - D. Over the insertion of the sternocleidomastoid muscle

The answer is A. The nurse palpates in front of the ear as the client clenches his/her teeth and moves the jaw. The temporomandibular joint is the junction of the temporal and mandibular bones in front of each ear and allows movement of the jaw.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Illness Management

Interpret client data that needs to be reported immediately

292. Which symptom reported in the health history of a 45-year-old man should be interpreted by the nurse as requiring immediate follow-up evaluation for possible upper GI bleeding?
- A. Black, tarry stools
 - B. Loose, frothy stool
 - C. Flat, ribbon-shaped stool
 - D. Mahogany colored, formed stool

The answer is A. Black, tarry stools are indicative of blood from the upper GI tract, which has been in the GI tract long enough to be completely digested.

B is incorrect—Loose, frothy stool is indicative of high fat content and is associated with malabsorptive disorders. C is incorrect—Flat, ribbon shaped stool is consistent with a tumor, which alters the shape of the left colon and prevents formation and passage of normally formed stool. D is incorrect—Mahogany colored stool is a symptom of right-sided cancer of the colon. It results from the mixing of blood from the tumor with the stool and its exposure to digestive tract secretions as it progresses through the remaining colon.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Vital Signs

Assess vital signs

293. A client is assessed for orthostatic hypotension with blood pressure and pulse taken lying and standing after 3 minutes in the supine position and then after standing for 1 minute. Which sets of blood pressure measurements is indicative of orthostatic hypotension? Mark all that apply.

- A. Supine 188/92; standing 164/78
- B. Supine 148/84; standing 116/52
- C. Supine 132/84; standing 102/50
- D. Supine 114/72; standing 90/56

The answers are B and C. A drop of 30 mm Hg or more is indicative of orthostatic hypotension.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of client condition and/or procedure

294. Which direction given to a postoperative client will best promote comfort during coughing and deep breathing?

- A. Listen to music
- B. Practice imagery
- C. Watch TV during the exercise
- D. Splint the incision with a pillow

The answer is D. Splinting the incisional area prevents stress on the injured area and thereby reduces pain associated with coughing and deep breathing.

A, B, and C are incorrect—Listening to music, practicing imagery, and watching TV are good distractors but do not address the actual prevention/limitation of pain that occurs with deep breathing and a forceful cough.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

295. What is being assessed when the client is approached from the back and the nurse puts his or her hands on either side of the trachea pushing one side medially while asking the patient to swallow?

- A. Patency of the trachea
- B. Size and regularity of the thyroid gland
- C. Size and movement of the pineal body
- D. Elasticity of the cricoid cartilage

The answer is B. The size and regularity of the thyroid gland.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administer and document medications given by common routes

296. When using an oral syringe to administer medications, where should the tip of the syringe be placed?

- A. Between the cheek and the gums half way back in the mouth.
- B. In the hollow of the mouth under the tongue.
- C. One third of the way back on top of the tongue.
- D. In the lower back corner of the mouth.

The answer is A. Placing the medication between the cheek and the gums half way back in the mouth helps prevent choking, medication running out of the mouth, or medication being spit out of the mouth. In the other locations these problems are more likely.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach the client about managing illness

297. Which statement made by a client indicates a need for further teaching about systemic lupus erythematosus?

- A. Exposure to sunlight can exacerbate the disease.
- B. Exacerbations are most likely to occur in the spring and summer.
- C. Pulmonary function tests are needed annually because of frequent lung involvement.
- D. Blood pressure needs monitoring because of the risk of hypertension.

Option C indicates a need for further teaching. Pleuritis can be a symptom of the disease, but monitoring with annual pulmonary function tests is not part of the medical routine. The client stating that pulmonary function tests are needed annually is incorrect and therefore indicates that self-care instructions have been misunderstood and more teaching is needed.

The other statements regarding the disease are correct—Sunlight can exacerbate the disease and exacerbations occur

most often in the spring or summer. Clients with systemic lupus erythematosus are at risk for hypertension and therefore blood pressure monitoring is needed.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Implement measures to manage/prevent/lessen possible complications of the client condition and/or procedure

298. The charge nurse is observing another nurse who is inserting a nasogastric tube in a preterm infant. The charge nurse observes the following activities. Which action would the charge nurse correct?

The nurse

- A. checks placement by aspirating stomach contents.
- B. lubricates the tip of the tube with a water-soluble lubricant.
- C. measures the length to be inserted from the tip of the nose to the ear to the sternum.
- D. checks placement by inserting 5 mL air while listening over the stomach for the gurgle.

The answer is D. 5 mL of air would be an extremely large amount for the size of the infant. This volume is not necessary to check placement; 1 mL or less will provide adequate air for testing. All other activities are correct.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Laboratory Values

Recognize deviations from normal for values of WBC

299. Which results of a CBC (complete blood count) with differential should the nurse interpret as indicating the client has a severe bacterial infection?

- A. WBC 8,500; lymphocytes 45%
- B. WBC 15,000; segmented neutrophils 50%
- C. WBC 25,000; band neutrophils 20%
- D. WBC 20,000; segmented neutrophils 58%

The answer is C. With a severe bacterial infection, the total white blood cell count would be above normal. Band neutrophils would be elevated because the body is trying to quickly fight the infection; in fact, so quickly that the neutrophils are being released into the circulation before they are mature cells.

A is incorrect—The WBC count is normal with elevated lymphocytes, indicating viral infection. B is incorrect—WBC

count is above normal but segs are normal, thus indicating the infection is not severe. D is incorrect—Although the WBC count is elevated, the segs are still within normal limits, again indicating the infection is not severe.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

300. The nurse checks inversion as a part of the range of motion assessment of which joint(s)?

- A. Lumbar spine
- B. Knee
- C. wrist
- D. ankle

The answer is D. Movements that are part of the normal range of motion for the ankles are dorsiflexion (foot bent upward with toes pointing at head), plantar flexion (foot pointed downward, abduction, adduction, and eversion (movement of the sole of the foot outward) and inversion (movement of the sole of the foot inward)). Flexion, hyperextension, abduction, and adduction are movements of the knee. Movements at the wrist are flexion, extension, radial deviation, and ulnar deviation.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Evaluate impact of disease/illness on nutritional status of the client

301. What symptom reported in the health history of a underweight teenager indicates the need for careful assessment of nutritional status?

- A. Black, tarry stools
- B. Loose, frothy stool
- C. Flat, ribbon-shaped stool
- D. Mahogany colored, formed stool

The answer is B. Loose, frothy stool is indicative of steatorrhea or fat in the stool. Large amounts of fat are expelled in the stool as a result of a variety of malabsorption syndromes. Therefore a report of this symptom would cause the nurse to carefully assess for other signs of malnutrition.

A is incorrect—Black, tarry stools are indicative of blood from the upper GI tract, which has been in the GI tract long enough to be completely digested. C is incorrect—Flat, ribbon shaped stool is consistent with a tumor, which alters the shape of the left colon and prevents formation and pas-

sage of normally formed stool. D is incorrect—Mahogany colored stool is a symptom of right-sided cancer of the colon. It results from the mixing of blood from the tumor with the stool and its exposure to digestive tract secretions as it progresses through the remaining colon.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assess parental techniques related to discipline

302. The mother of a preschool child tells the child, “If you don’t behave, I’ll have the nurse give you a shot.” The best nurse’s response would be to:
- ignore the comment as it is obviously not true.
 - reply, “Oh yes, you better be good while you are here.”
 - wait until the mother leaves the room and then tell the child that this was incorrect.
 - reply, “Oh, no, I only give shots when the doctor thinks it will make you better.”

The answer is D. This response provides the child with information about the nursing function and will reduce fear of the nurses.

A is incorrect—Ignoring the comment does not resolve any problem. B is incorrect—provides incorrect information. C is incorrect—would not help the mother to understand that her comment will make the child afraid of nurses.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct the client on medication self-administration procedures

303. Which instruction should the nurse give a client for whom a vaginal cream has been prescribed?
- Lie on your left side for about 5 minutes.
 - Remain supine with hips elevated for 5–10 minutes.
 - Remove excess medication with soap and water in 15 minutes.
 - Urinate and wipe front to back in 15–30 minutes.

The answer is B. Remaining supine with hips elevated for 5–10 minutes keeps the medication in place in the vagina where it is needed to exert its effect. If the client stands up immediately, the medication can slide down and out of the vagina.

A, C, and D are incorrect—Clients should lie on the left side following a rectal treatment such as an enema.

Instructions regarding washing or urinating are not critical to the self-administration of the medication.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected effects/outcomes

304. Which medication is given preoperatively to decrease gastric and pharyngeal secretions?
- Glycopyrrolate (Robinul)
 - Pentobarbital sodium
 - Hydroxyzine hydrochloride (Vistaril)
 - Lorazepam (Ativan)

The answer is A.

B, C, and D are incorrect—Pentobarbital sodium is used as an induction agent for anesthesia, hydroxyzine hydrochloride is used to decrease anxiety, and lorazepam is used to provide sedation and impair memory of the perioperative events.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Provide education on age-specific growth and development to clients and family

305. An 11-year-old girl is upset. She states her friends are buying bras and their breasts are much larger than hers. She is worried because only one of her breasts is developing and asks the school nurse what is wrong with her. How should the nurse respond? (Mark all that apply.)
- Suggest an appointment with an endocrinologist
 - Explain that development is unique to each individual
 - Suggest she watch her progress by looking at the Tanner stages of development
 - Reassure that asymmetrical development is not unusual
 - E. Ask her to return weekly so her progress can be monitored

The answers are B, C, and D. Explaining that development is unique to each individual, suggesting she use the Tanner stages of development to watch her progress, and reassuring that asymmetrical development is not unusual are all appropriate responses.

A and E are incorrect—There is no information given to suggest an endocrine consult is needed and asking her to return for weekly monitoring is unnecessary and communicates the idea of a problem.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Review pertinent data prior to medication administration

306. For which of the following medications should a patient undergo therapeutic drug monitoring?
- Penicillin (antibiotic)
 - Propranolol (beta-blocker)
 - Furosemide (diuretic)
 - Lithium (mood stabilizer)

The answer is D. There is a narrow margin of safety between therapeutic drug effect and drug toxicity with lithium.

A, B, and C are incorrect—There is a wide margin of safety with penicillin, propranolol, and furosemide and so therapeutic drug monitoring is not needed.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Implement interventions to manage the client recovering from an illness

307. Which intervention is inappropriate as part of the emergent treatment of a simple long bone fracture?
- Application of cold
 - Elevating the limb
 - Splinting above and below the fracture
 - Application of a pressure bandage

Option D is the inappropriate intervention. A pressure bandage would not be used for a simple fracture.

Other interventions are correct actions—Cold is applied immediately and the limb is elevated not lowered to limit edema. Above and below the fracture is stabilized to prevent movement of the bone segments and further damage.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

308. The nurse checks adduction as a part of the range of motion assessment of which joints? Mark all that apply.
- ___ Lumbar spine
 - ___ Knee
 - ___ Wrist
 - ___ Ankle
 - ___ Finger
 - ___ Toe

G. ___ Shoulder

H. ___ Elbow

The answers are D, E, F, and G. The ankle, fingers, toes, and shoulders can all be adducted and abducted. Adduction is movement toward the midline of the body and abduction is away from the midline. When the ankle is adducted, the foot is turned inward toward the other foot; when the ankle is abducted, the foot is turned out to the side away from the other foot. When fingers and toes are adducted they are brought close together; when they are abducted, they are spread apart. When the shoulder is adducted the arm is brought across the body to the opposite side; when abducted the arm is extended out to the side away from the body. Remember ad means to or toward; you send a letter to an address. Ab means away from as when a student is absent or away from class.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct the client on medication self-administration procedures

309. Which client statement indicates understanding of the procedure for using a steroid inhaler?
- “I will rinse my mouth out with water after using the inhaler.”
 - “I will take 5 to 6 slow deep breaths after each puff on the inhaler.”
 - “I will use my bronchodilator immediately after my steroid inhaler.”
 - “I will blow my nose forcefully after I finish with the inhaler.”

The answer is A. Steroid residual in the mouth can lead to Candida overgrowth and infection. Rinsing the mouth out with water after using the inhaler removes residual steroid and can prevent this problem.

B is incorrect—Deep breaths do not have to be taken after using the inhaler. C is incorrect—Bronchodilator inhalers are always used first to open the lung passages so that other medications such as the steroids can get deep into the lung for maximum effect. D is incorrect—Blowing the nose forcefully has no role in the use of a steroid inhaler.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Medical and Surgical Asepsis

Use appropriate supplies to maintain asepsis

310. When getting a drainage set for an indwelling catheter, the nurse notices that the bag containing the set is not

entirely sealed at one end. Which is the appropriate action for the nurse to take?

- A. Use it but notify purchasing about the condition of the bag.
- B. Dispose of it and get another.
- C. Use it only if the drainage system appears untouched.
- D. Check with the nurse manager on agency policy.

The answer is B. If the protective packaging is not sealed then the equipment is not sterile and it cannot be used. This applies regardless of its appearance. Notifying purchasing or whomever is responsible for equipment can help with quality control. It is not necessary to check on agency policy regarding its use because use of contaminated sterile items places the client at risk for infection and so the decision to not use falls within the scope of ethical, professional decision making of the individual nurse.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

311. Which is an appropriate nursing intervention for a client diagnosed with schizophrenia?
- A. Maintain a slightly higher level of environmental stimuli than usual.
 - B. Prevent the client from lapsing into periods of silence of longer than 5 minutes.
 - C. Tell the client if you do not understand what is being communicated.
 - D. Be warm with a show of positive emotion when interacting with the client.

The answer is C. The nurse should tell the client in a simple, direct manner that he or she is not being understood. Excessive environmental stimuli should be avoided; stimuli should not be increased. Clients may be silent and the nurse should accept this and sit with the client even during periods of silence if necessary. The client should be approached in a neutral manner as it is less threatening to the client than an overly warm approach.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Illness Management

Interpret client data that needs to be reported immediately

312. What symptom reported in the health history of a 64-year-old man should be interpreted by the nurse as requiring immediate follow-up evaluation for possible left colon cancer?
- A. Black, tarry stools
 - B. Loose, frothy stool

- C. Flat, ribbon-shaped stool
- D. Mahogany colored, formed stool

The answer is C. Flat, ribbon shaped stool is consistent with a tumor, which alters the shape of the left colon and prevents formation and passage of normally formed stool.

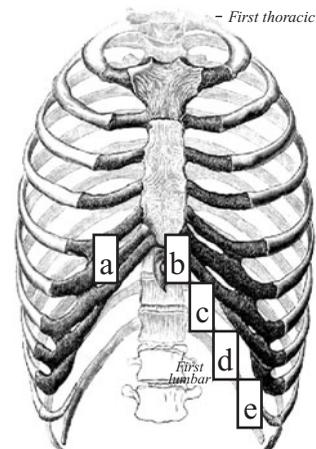

A is incorrect—Black, tarry stools are indicative of blood from the upper GI tract, which has been in the GI tract long enough to be completely digested. B is incorrect—Loose, frothy stool is indicative of steatorrhea or fat in the stool. Large amounts of fat are expelled in the stool as a result of a variety of malabsorption syndromes. D is incorrect—Mahogany colored stool is a symptom of right-sided cancer of the colon. It results from the mixing of blood from the tumor with the stool and its exposure to digestive tract secretions as it progresses through the remaining colon.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

313. When assessing the heart, the nurse palpates for pulsation over the aortic area which would be an abnormal finding. Which lettered block on the accompanying diagram marks the location where the nurse would place his or her finger tips to palpate over the aortic area. Write the letter of the block on the line provided.

The answer is A.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Assess client response to recovery from local, regional, or general anesthesia

314. An elderly postoperative client has a history of chronic obstructive pulmonary disease. Based on this history,

the nurse is especially concerned with monitoring the client for which problem?

- A. Aspiration
- B. Delirium
- C. Decreased gas exchange
- D. Positioning difficulty

The answer is C. Decreased gas exchange is a particular risk with a history of COPD.

A is incorrect—Aspiration would be associated with the age-related changes of the gastrointestinal system. B is incorrect—Delirium is associated with the age-related changes of the neurological system. D is incorrect—Positioning difficulty is associated with age-related changes of the musculoskeletal system.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

315. Which criterion should the nurse use when selecting the proper size cuff to use when assessing the blood pressure of an 8-month-old infant?
The cuff will
- A. say infant on the cuff
 - B. wrap around the arm twice
 - C. cover $\frac{1}{4}$ of the upper extremity.
 - D. cover 80% of the length of the extremity section

The answer is D. The cuff should cover 80% of the extremity section, if the upper arm is the site, the cuff should cover 80% of the distance from the elbow to the acromian process. Another way to determine size is the bladder should cover 40% of the circumference of the extremity. All other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of client pathophysiology to illness management

316. When assessing a client in the emergency room, which finding should be interpreted as a major indicator of acute pancreatitis?
- A. Positive Cullen's sign.
 - B. Postprandial elevated serum amylase.
 - C. Decreased pancreatic secretion with secretin stimulation.
 - D. Mid-epigastric pain worsened by fasting.

The answer is A. A positive Cullen's sign (cyanosis of the periumbilical skin due to subcutaneous intraperitoneal hemorrhage) is symptomatic of acute disease. Reduced volume

of pancreatic secretions on a secretin stimulation test is the most diagnostic measure of chronic disease. Elevated serum amylase is found with both acute and chronic disease. LUQ pain radiating to the back, not mid-epigastric pain, is characteristic of acute disease.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and Oral Hydration

Provide/maintain special diets based on the client diagnosis/nutritional needs and cultural considerations

317. Which is the basic type of diet that the nurse would obtain for a client with celiac disease?
- A. Fat free
 - B. Gluten free
 - C. Lactose free
 - D. Low sodium

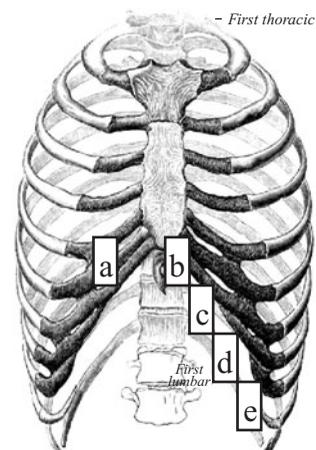

The answer is B. Clients with celiac disease are unable to break down gluten, which is a protein. These clients are treated with a gluten-free diet. This diet excludes products containing wheat, rye, oats and barley since these grains contain gluten.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

318. When assessing the heart, the nurse palpates for thrills over the pulmonic area which would be an abnormal finding. Which lettered block on the accompanying diagram marks the location where the nurse would place the ball of the hand to palpate over the pulmonic area. Write the Letter of the block on the line provided.

The answer is B.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents and Actions

Apply knowledge of pathophysiology when addressing the pharmacological agents/actions of client prescriptions

319. During discharge teaching, a client asks the nurse how the prescribed antacids relieve heart burn. The nurse's response should be based on the knowledge that antacids work by
- decreasing the secretion of gastric acid.
 - coating the stomach lining.
 - thickening the mucus secreted by the stomach wall.
 - neutralizing the acid present in the stomach.

The answer is D. Antacids are alkaline and they relieve heart-burn by neutralizing the acid in the stomach.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents/Actions

Identify a contraindication to the administration of a prescribed or over-the-counter medication to the client

320. On admission to the emergency room, a client with a traumatic lower extremity amputation is given an opioid for pain. Which herbal medication if taken by the client prior to the accident will prolong the sedative effects of the opioid?
- Echinacea augustifolia*
 - Hypericum perforatum* (St. John's Wort)
 - Piper methysticum* (Kava-kava)
 - Valeriana officinalis* (Valerian)

The answer is B. *Hypericum perforatum* (St. John's Wort) prolongs the sedative effects of opioids. It also prolongs the sedative effects of anesthesia.

A, C, and D are incorrect—*Echinacea augustifolia* increases the effectiveness of corticosteroids. *Piper methysticum* (Kava-kava) potentiates central nervous system depressants, anesthetics, and corticosteroids. Valerian only prolongs the sedative effects of anesthesia.

PHYSIOLOGICAL INTEGRITY

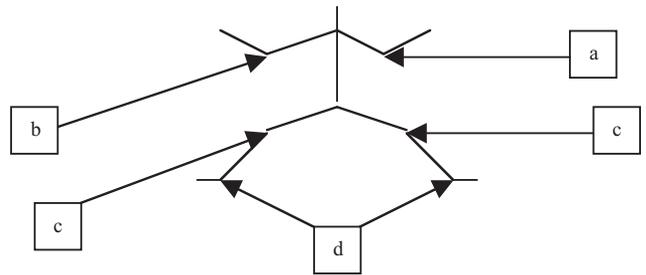

Reduction of Risk Potential

System-Specific Assessment

Assess client for abnormal neurological status

321. The nurse is assessing for diminished deep tendon reflexes in a client with increasing intracranial pres-

sure. Which location on the accompanying diagram would the nurse strike with the reflex hammer to check the biceps reflex?

- ___ A ___
 ___ B ___
 ___ C ___
 ___ D ___

The answer is A. To check the biceps reflex, the examiner's thumb is placed over the biceps tendon located in the antecubital space. The thumb is struck with the pointed end of the reflex hammer. The forearm should flex in response.

Location B denotes the triceps reflex; location C denotes the patellar or knee jerk reflex; location D denotes the Achilles reflex.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

322. Which cranial nerve is the nurse assessing when the client's gag reflex is checked?
- Five (trigeminal)
 - Six (abducens)
 - Nine (glossopharyngeal)
 - Twelve (hypoglossal)

The answer is C. The glossopharyngeal nerve is responsible for the pharyngeal gag reflex as well as for movement of the phonation muscles of the pharynx. It is also responsible for taste on the posterior third of the tongue and sensation from the ear drum and ear canal. The gag reflex is tested by touching the posterior pharyngeal wall with a tongue blade and observing for gagging.

A is incorrect—Cranial nerve five (trigeminal nerve) has both motor and sensory components. It is responsible for sensation in the face, scalp, oral and nasal mucous membranes, and the cornea and allows chewing movements of the jaw. Its three-part sensory division is tested by touching the forehead, cheek, and chin on each side with a wisp of cotton and asking the client whose eyes are closed to identify the type of touch

and its location. Next the cornea of each is lightly touched with a wisp of cotton brought in from the side and the eye observed for the normal blink response. The motor function of cranial nerve five is tested by asking the client to clench the teeth and keep them clenched while the examiner pushes down on the chin to try and separate the jaws.

B is incorrect—Cranial nerve six (abducens nerve) is responsible for lateral eye movement.

D is incorrect—Cranial nerve twelve (hypoglossal nerve) is responsible for tongue movement. It is tested by asking the client to stick out the tongue and later having the client say “late date night.”

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications from Surgical Procedures and Health Alterations

Apply knowledge of pathophysiology to monitoring for complications

323. After a difficult delivery, a newborn develops a large cephalohematoma. The nurse will monitor this infant for:
- A. infection
 - B. brain damage
 - C. hyperbilirubinemia
 - D. congestive heart failure

The answer is C. Cephalohematoma is bleeding into the periosteum of the bone. When blood escapes the vascular system, it is broken down. When red blood cells are broken down, bilirubin is released. The immature liver is unable to handle large amounts of bilirubin and jaundice is the result. The nurse will need to monitor the child so early interventions can be instituted to prevent complications from high levels of bilirubin in the blood.

A, B, and D are incorrect—The hematoma is on the outside of the skull and will cause no brain damage. There is no risk of infection or congestive heart failure from this condition.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-specific assessments

324. Which assessment finding should the nurse interpret as abnormal when admitting an infant to the newborn nursery?
- A. Pulse 142
 - B. Respirations 38
 - C. Head circumference: 29 cm
 - D. Chest circumference: 34 cm

The answer is C. Head circumference should exceed the chest circumference and could indicate microcephaly. The other assessment findings are normal.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

325. When assessing the scrotum of a 64-year-old client, what would be a normal difference as compared to the scrotum of a 24-year-old client?
- The scrotum of the 64-year-old would be
- A. longer
 - B. more pendulous
 - C. less flexible
 - D. more firm

The answer is B. The scrotum becomes more pendulous with age. It does not become longer, less flexible, or more firm.

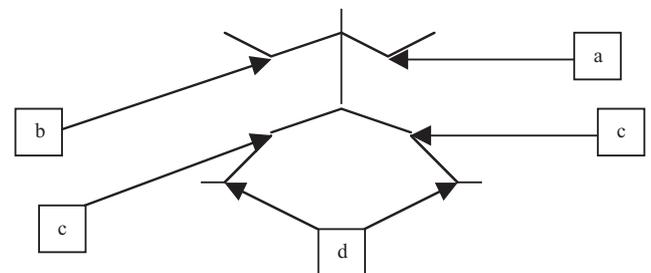

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Assess client for abnormal neurological status

326. The nurse is assessing for diminished deep tendon reflexes in a client with hypothyroidism. Which location on the accompanying diagram would the nurse strike with the reflex hammer to check the triceps reflex?

- ___ A ___
- ___ B ___
- ___ C ___
- ___ D ___

The answer is B. To check the triceps reflex, the client’s arm is positioned with the elbow bent and the arm and the forearm and hand relaxed and down. The triceps tendon located just above the elbow on the back of the arm is struck with the

pointed end of the reflex hammer. The forearm should extend in response.

Location A denotes the biceps reflex; location C denotes the patellar or knee jerk reflex; location D denotes the Achilles reflex.

PHYSIOLOGIC INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Assess client response to recovery from local, regional, or general anesthesia

327. Which of the following is a common postoperative cause of airway obstruction?
- Difficult intubation
 - Facial edema
 - PO₂ greater than 60 mmHg
 - Tongue blocking the airway

The answer is D. The tongue blocking the airway is a risk in the postoperative client who has had general anesthesia.

A is incorrect—Difficult intubation is not a common cause of airway obstruction in postoperative clients; it is most often associated with age-related respiratory system changes in the elderly. B is incorrect—Facial edema does not necessarily cause a blocked airway. C is incorrect—A PO₂ greater than 60 mmHg is not associated with respiratory difficulty.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Educate the client and family about treatments and procedures

328. A client having surgery for glaucoma asks the nurse how the doctor will know if the surgery is successful. Which would be an appropriate response for the nurse to make?
- IOP will decrease.
 - Ability to read small print will improve.
 - Pupil will remain permanently dilated.
 - Peripheral vision will increase.

The answer is A. The reason surgery is done for glaucoma is to lower intraocular pressure because increased IOP causes progressive loss of vision. Surgery is done when medication is ineffective.

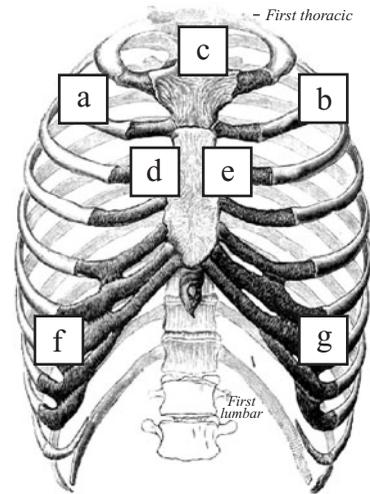

B is incorrect—Damage done by increased IOP is permanent therefore ability to read will not improve. C is incorrect—The pupil is not affected by the surgery so contraction and dilation occur normally. D is incorrect—Glaucoma causes loss of peripheral vision before loss of central vision and this loss is irreversible.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

329. Which lung sound is auscultated over point A in the diagram would be evaluated by the nurse as a normal assessment finding?

- Bronchovesicular
- Crackle
- Gurgle
- Sibilant
- Tracheal
- Vesicular
- Wheeze

The answer is F. Vesicular sounds are normally heard over alveolar lung tissue, which is the majority of both lungs including point A. Vesicular sounds are soft in intensity and low in pitch. The inspiratory phase is longer than the expiratory phase.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

330. Six hours after birth, an infant is found to have an axillary temperature of 97°F. The child is placed in an overbed warmer. When the nurse tells the mother that the infant will not be able to leave the nursery at the next feeding, the mother asks why this low temperature is a concern. The nurse explains that low body temperature in the newborn can cause which effects? (Select all that apply.)

- A. Hypoglycemia
- B. Metabolic acidosis
- C. Respiratory distress
- D. Hyperbilirubinemia
- E. Caput Succedaneum

The answers are A, B, C, and D. Heat loss causes the body to try to produce heat which causes the respiratory rate to rise and can lead to respiratory distress. Metabolic acidosis occurs from the anaerobic burning of fats for energy. Hypoglycemia occurs because the body has burned the glucose to produce heat. All of the stress taxes the liver which is unable to convert the indirect bilirubin to direct bilirubin causing hyperbilirubinemia.

Caput is a swelling of the presenting part and not related to cold stress.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

331. Which is a priority nursing intervention for a client with narcissistic personality disorder?
- A. Encourage acceptance of intensive therapy.
 - B. Eliminate bizarre fantasies.
 - C. Minimize potential for self harm.
 - D. Promote verbalization of feelings about self.

The answer is D. Clients with narcissistic personality disorder are self-centered, independent, not easily intimidated, quite aggressive individuals who lack the ability to be empathetic and hence have difficulties with establishing and maintaining interpersonal relationships. They put forth a sense of grandiosity but underneath have low self esteem, and feel insecure and inadequate. These clients need to be helped to view themselves differently and verbalization of feelings about self is a first step toward this goal. Other responses do not apply to the client with a narcissistic personality disorder.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

332. A child is being discharged 18 hours after a tonsillectomy and adenoidectomy. Discharge instructions for the parents would include:
- A. Give the child aspirin for pain
 - B. Use a straw to encourage drinking

- C. Offer a soft diet without spicy or acidic foods.
- D. Encourage the child to clear throat and cough frequently to remove secretions

The answer is C. A soft diet is maintained to prevent injury to the surgical area.

A, B, and D are incorrect—Aspirin would increase bleeding and would not be desirable. Drinking through a straw and throat clearing increases pressure and could dislodge a forming clot and cause hemorrhage.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

333. Which direction would the nurse give to a client when assessing function of cranial nerve twelve (hypoglossal)?
- A. “Holding your head straight, move only your eyes to look first to the right and then to the left.”
 - B. “Clench your jaw as tightly shut as you can.”
 - C. “Stick out your tongue.”
 - D. “Raise your eyebrows.”

The answer is C. Cranial nerve twelve (hypoglossal nerve) is responsible for tongue movement. It is tested by asking the client to stick out the tongue and later having the client say “late date night.”

A, B, and D are incorrect—Cranial nerve six (abducens) is responsible for lateral eye movement. Clenching the teeth and keeping the jaw shut while the examiner pushes down on the chin to try and separate the jaws is a test of cranial nerve five (trigeminal nerve). Raising eyebrows along with smiling, frowning, and showing the upper and lower teeth are tests of the motor division of cranial nerve seven (facial nerve).

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

334. The nurse would assess a client’s short-term memory by asking the client:
- A. his/her birth date
 - B. to count backwards from 100 to 7
 - C. to repeat the phrase “no ifs ands or buts”
 - D. about current events

The answer is D. Asking about current events assesses short-term memory.

A is incorrect—Asking about birth date assesses long-term memory. B is incorrect—asking the client to count backwards from 100 by 7s assesses mathematical calculation. C is incorrect—Asking the client to repeat the phrase “no ifs ands or buts” assesses speech.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

335. When teaching a type II diabetic client about preventing hypoglycemic episodes, which information is appropriate for the nurse to include?
- A. Delaying a meal for as little as 15 minutes can significantly increase the risk of hypoglycemia.
 - B. With the onset of menses, insulin requirement may decrease.
 - C. Prolonged exercise can precipitate a hypoglycemic episode.
 - D. Five grams of CHO raise blood sugar about 30 mg/dL.

The answer is B. With the onset of menses progesterone drops and this may cause a decrease in the need for insulin and so the risk of hypoglycemia is increased.

A, C, and D are incorrect—Delaying a meal for more than a half hour increases the risk of hypoglycemia. Exercise is associated with a drop in blood glucose levels in clients with type I diabetes. Prolonged exercise in these clients can cause increased rate of glucose uptake and use by cells for several hours after the exercise is complete. Thus blood glucose needs to be monitored and CHO supplements taken during exercise. Five grams of CHO raise blood sugar about 20 mg/dL not 30 mg/dL.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

336. The nurse considers which of the following aspects when performing a client’s activity and exercise assessment. Select all that apply:
- A. body alignment and posture
 - B. routine exercised patterns
 - C. the body’s response to activity and exercise
 - D. impact of activity and exercise on overall health

The answers are A, B, C, and D. All four aspects are components that necessary to consider to determine a correct nursing diag-

nosis. Assessment of activity tolerance, physical fitness, body alignment, and mobility are defining characteristics necessary to make a nursing diagnosis.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Dosage Calculations

Perform calculations needed for medication administration

337. The drug book states that a therapeutic dose for a medication is 50–75 mg per kg of body weight per day. The child weighs 33 pounds and is to receive the medication 4 times a day. What would be the maximum amount of drug the child should receive per dose? Record your answer is a whole number carried out to two decimal places. _____ mg per dose

Answer: 281.25 mg per dose; 33 pounds divided by 2.2 pounds per kilogram = 15 (the child’s weight in kilograms); 15 times 75 = 1125 mg per day divided by 4 doses equals 281.25 mg.

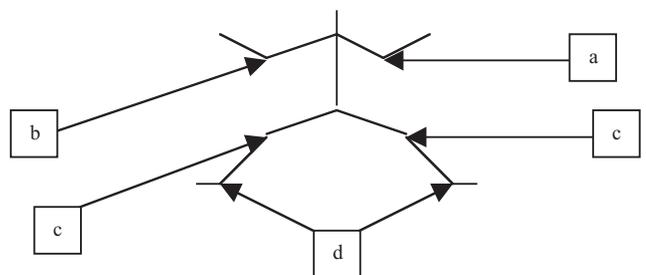

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Assess client for abnormal neurological status

338. The nurse is assessing for hyperreflexia in a client with preeclampsia. Which location on the accompanying diagram would the nurse strike with the reflex hammer to check the patellar reflex?

- A _____
- B _____
- C _____
- D _____

The answer is C. To check the patellar reflex, the client sits with legs dangling. The patellar tendon located just below the patella on the front of the knee is struck

with the wide end of the reflex hammer. The lower leg should extend in response. If the client cannot dangle, the knee may be supported by the examiner's nondominant hand in a flexed position while the reflex is checked.

Location A denotes the biceps reflex; location B denotes the triceps reflex; location D denotes the Achilles reflex.

HEALTH PROMOTION AND MAINTENANCE

Health Promotion Programs

Plan and/or, Participate in the Education of Individuals in the Community

Provide the client information about health screening tests

339. A 24-year-old unmarried woman has never had a mammogram. The client states that she has heard that the exam is painful and she is afraid to have one. The nurse's response should be:

- A. "Why don't you have the test once and if it is too painful don't do it again?"
- B. "No, the mammogram is not painful. Whoever told you this was lying to you."
- C. "Yes, it is uncomfortable but it only lasts a few seconds. And the test is so important."
- D. "Since you are not married, it is okay to delay the test until you become sexually active."

The answer is C. Honesty is important when responding to the client. This response will assist the client in seeking health promotion activities.

A is incorrect as if she decides it was too uncomfortable, the nurse has given permission to not follow national guidelines. B and D are incorrect information.

MANAGEMENT OF CARE

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply knowledge of the client pathophysiology to interventions related to standard/transmission based/other precautions

340. A child is being treated for bacterial meningitis. Nursing interventions would include:

- A. forcing fluids.
- B. positioning in Trendelenburg position.
- C. maintaining a brightly lit room to observe for seizures.
- D. maintaining respiratory isolation for 24–48 hours after antibiotics are started.

The answer is D. Although the organism may be a common one (*H. influenzae* or *pneumococci*), other children on the

unit must be protected from the infection. Isolation is maintained for at least 24 hours after antibiotics are started.

A is incorrect—Forcing fluids would not be advisable as cerebral edema is a concern. B is incorrect—The child should be positioned in semi-Fowler's position for comfort. C is incorrect—The child has photophobia; so a brightly lit room would not be appropriate.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

341. Which is a step in the assessment of jugular venous pressure?

- A. Assist the client to a right side lying position.
- B. Raise the head of the bed 10–15 degrees.
- C. Shine a light across the client's neck.
- D. Measure the horizontal distance from the sternal angle to the meniscus of the internal jugular vein.

The answer is C. A light is shone tangentially across the client's neck to highlight the pulsations of the jugular vein. All other steps listed are incorrect. The client is placed in a supine position. The head of the bed is raised 30–45 degrees. The meniscus which is the highest point at which the pulsation of the internal jugular vein can be seen is identified. The sternal angle is located and a centimeter ruler is used to measure the vertical distance from the sternal angle to the meniscus. The number of centimeters, normally not more than 4, equals the jugular venous pressure.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Parenteral/intravenous therapies

342. A client's parenteral antibiotic therapy has been completed. The physician writes orders to discontinue to IV line and discharge the client home. Which is a step the nurse will take when discontinuing the intravenous line?

- A. Leave the IV site open to the air.
- B. Use sterile gloves for catheter removal.
- C. Remove the catheter and apply an occlusive dressing.
- D. Use alcohol to prevent infection of the site during removal.

The answer is C. An occlusive dressing is recommended following catheter removal. The site should not be left open to the air. Clean gloves, not sterile gloves, are necessary for

nurse protection. Alcohol will increase the bleeding at the site. A dry sterile dressing will be applied to the site.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Vital Signs

Assess vital signs

343. A client is assessed for orthostatic hypotension with blood pressure and pulse taken lying and standing after 3 minutes in the supine position and then after standing for 1 minute. Which sets of pulse rates is indicative of orthostatic hypotension? Mark all that apply.
- A. Supine 96 beats per minute; standing 54 beats per minute
 - B. Supine 88 beats per minute; standing 62 beats per minute
 - C. Supine 84 beats per minute; standing 70 beats per minute
 - D. Supine 80 beats per minute; standing 50 beats per minute

The answer is A. A drop of 40 beats per minute or more in pulse rate is indicative of orthostatic hypotension.

HEALTH PROMOTION AND MAINTENANCE

Health Promotion Programs

Instruct the client on ways to promote health

344. A female client is being taught self-breast exam. Which information should the nurse include in the instructions?
- A. The nipple area should be avoided in palpating the breast.
 - B. Breast exams are best performed immediately prior to menses.
 - C. Self-breast exams are performed in the upright and supine positions.
 - D. Should a lump be found, make an appointment for a professional examination if it hasn't disappeared in a month.

The answer is C. Supine and upright positions are used while palpating the breast.

A is incorrect—The entire breast including the nipple region should be palpated. B is incorrect—The best time for self-breast exam is immediately after their menstrual period as the hormonal influence will be at the minimal. D is incorrect—If a lump is found, a medical appointment should be made immediately.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Applies knowledge of intravenous therapy to the care of client

345. A child is admitted to the hospital with gastroenteritis. The physician orders D₅1/4 NS with 20 mEq KCL per 1000 ml to be administered at a rate of 50 ml per hour. The appropriate nursing action for this order would be to
- A. delay adding the KCL until the child has voided.
 - B. ask why the physician didn't include other electrolytes.
 - C. question the physician why a hypertonic solution was ordered.
 - D. monitor the child for fluid volume overload because of the fast rate.

The answer is A. Potassium would not be added until the child has voided. Hyperkalemia would occur if kidney function was impaired resulting in cardiac dysfunction.

The other responses are incorrect. Fluid replacement is the main concern in gastroenteritis, the fluid is hypotonic and the rate is not excessive.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/Immobility

Apply knowledge of nursing procedures and psychomotor skills when providing care to clients with immobility

346. Mr. Clark, a 77-year-old, was admitted with a CVA 3 days ago. This is the first time you have been assigned to care for the gentleman. You carry out an assessment of Mr. Clark's mobility level and ability to participate in activities of daily living. You identify a nursing diagnosis of *Impaired Mobility related to Hemiplegia and Weakness*. Select all the nursing interventions that would be appropriate for the nursing diagnosis.
- A. ___ Change Mr. Clark's position every 2 hours, maintaining sound body alignment.
 - B. ___ Use appropriate supportive devices to assist in maintaining correct positioning.
 - C. ___ Teach client and his family correct positioning.
 - D. ___ Prepare Mr. Clark for bed based on his usual bedtime patterns prior to the stroke.

The answers are A, B, and C. Correct positioning prevents contractures and maintains proper body alignment; support devices aid in maintaining correct body alignment; teaching involves the family in Mr. Clark's care from the beginning.

D is incorrect—Bedtime patterns are not related to nursing diagnosis of impaired mobility.

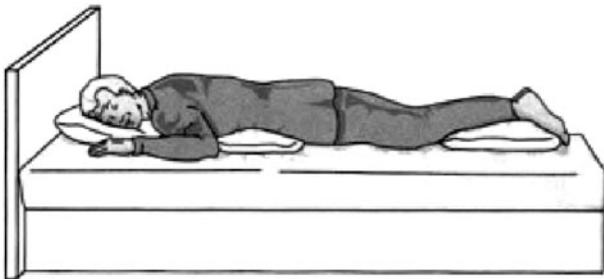

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

347. Identify the position depicted in the picture.

- A. Sims' position
- B. Supine position
- C. Prone position
- D. Fowlers position

The answer is C. In the prone position, the client has her/his head turned to the side when lying on the abdomen. The shoulders, head, and neck are in an erect position, the arms are in alignment with the shoulder girdle, the hips are extended.

A is incorrect—Sims' position is a position halfway between the lateral and prone positions where the lower arm is placed behind the client and the upper arm is flexed; both legs are flexed in front of the client. B is incorrect—Supine position is a position in which the client lies on his/her back with head and shoulders slightly elevated on a pillow. D is incorrect—Fowlers position is a semisitting position with the head of the bed elevated 45–60°.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

348. When teaching a client with type I diabetes, which factors would the nurse identify as increasing the risk of hypoglycemic episodes? Mark all that apply.
- A. End of menses
 - B. Change in injection site
 - C. Use of a new bottle of insulin
 - D. Delaying a meal for 30 minutes

The answers are B, C, and D. Some individuals experience hypoglycemia as a result of an increased rate of absorption of insulin when the site of injection is changed. Hypoglycemia can occur when a new bottle of insulin is used if the old bottle had lost some of its potency. Delaying a meal for more than 30 minutes can also result in hypoglycemia because of deficient food intake.

Onset of menses with the associated drop in progesterone can increase the risk of hypoglycemia; the end of menses does not.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

Uses assessment findings to plan nursing care

349. A nurse is working in the labor and delivery unit. The nurse assesses all the laboring clients and notes that one has a small baby in breech position, one has a large baby who is engaged, one has an average sized infant in a transverse lie, and the last has an average sized infant with a floating head. Which client will the nurse definitely have to prepare for a cesarean delivery? The client with the
- A. small baby in breech position
 - B. large baby who is engaged
 - C. average sized infant in transverse lie
 - D. average sized infant with a floating head

The answer is C. A transverse lie is a shoulder presentation and cannot be delivered in this position. All of the other infants could be delivered vaginally.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

350. Which parameters would the nurse assess as part of a complete neurological assessment? (Mark all that apply.)
- A. Deep tendon reflexes
 - B. Shape of the head
 - C. Cranial nerves
 - D. Sensory perception
 - E. Coordination
 - F. Skin
 - G. Heart

The answers are A, C, D, and E. The other areas are not part of the neurological examination.

PHYSIOLOGICAL INTEGRITY

Reduction risk potential

Provide Pre- or Postoperative Education

351. A 4-year-old child has just returned from surgery for a tonsillectomy. Instructions that the nurse should give the parents would include:
- A. encourage the child to cough frequently.
 - B. have the child drink through a straw to promote hydration.
 - C. avoid red liquids in the postoperative period.
 - D. aspirin is available for pain relief.

The answer is C. Red liquids are avoided to prevent confusion over bleeding in vomitus or stool.

A is incorrect—Coughing can cause the loss of a clot, leading to hemorrhage. B is incorrect—Drinking through a straw may cause the loss of the clot and lead to hemorrhage. D is incorrect—Aspirin inhibits clotting.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

352. A postpartum woman comes to the lactation clinic 2 weeks after birth. The woman states that she doesn't seem to produce enough milk for her infant. Which statement by the woman indicates a possible source of the lactation problem?
- A. "My breasts are not the least bit sore."
 - B. "I am always hungry and just eat and eat."
 - C. "I make sure I drink 500 ml of fluid every day."
 - D. "The baby latches on and nurses for 20 minutes on each breast every 2 to 3 hours."

The answer is C. A minimal fluid intake is 1000 ml a day. Most breast feeding moms exceed this fluid intake as thirst is common.

A, B, and D are incorrect—The fact that the breasts are not sore is a positive finding. A breast feeding mother needs to increase her caloric intake by about 500 calories per day, which this woman seems to be doing. The infant is nursing for sufficient time.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

353. A woman has delivered an infant by cesarean section. Which factors place this woman at risk for thromboembolic disease? (Select all that apply.)

- A. Due to the surgical procedure, the client will be less active.
- B. The platelet count is elevated as the body prepared for delivery.
- C. The pregnant woman's blood volume decreases in later pregnancy.
- D. Venous stasis in the lower extremities is common in late pregnancy.
- E. The fetus produces platelets which cross the placenta into the maternal circulation.

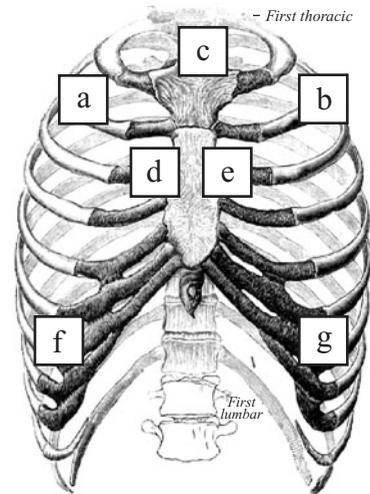

The answers are A, B, and D. Stasis of blood due to pressure of the term uterus and elevated platelet count in late pregnancy places all postpartum women at risk for thrombus. The cesarean client has the added burden of decreased mobility. The pregnant woman's blood volume increases not decreases. The fetal blood components do not readily cross the placenta.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

354. Which lung sound if auscultated over point B in the diagram would be evaluated by the nurse as a normal assessment finding?

- A. Bronchovesicular
- B. Crackle
- C. Gurgle
- D. Sibilant
- E. Tracheal
- F. Vesicular
- G. Wheeze

The answer is F. Vesicular sounds are normally heard over alveolar lung tissue, which is the majority of both lungs including point B. Vesicular sounds are soft in intensity and low in pitch. The inspiratory phase is longer than the expiratory phase.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical emergencies

355. While being fed, a newly admitted infant with tetralogy of Fallot suddenly becomes very cyanotic and shows severe cardiac distress. Physician orders have not been written. Which action should the nurse take?
- Administer oxygen
 - Administer morphine sulfate
 - Place the child in knee chest position
 - Place the child in high fowler's position

The answer is C. The child is displaying a “Tet” or hypercyanotic spell. Placing the child in knee chest reduces the blood return from the lower extremities and allows better recovery of the heart. High Fowler's position does not as effectively trap blood in the lower extremities and decrease venous return to the heart. The other responses are not appropriate as independent nursing actions.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

356. When assessing deep tendon reflexes, when does the nurse use the wide end of the reflex hammer? Mark all that apply.
- The nurse uses the wide end of the reflex hammer to check
- ___ brachioradialis reflex
 - ___ biceps reflex
 - ___ triceps reflex
 - ___ patellar reflex
 - ___ Achilles reflex
 - ___ cremasteric reflex

The answers are D and E. The patellar and Achilles reflexes located at the front of the knee and the back of the heel respectively are tested using the broad end of the reflex hammer.

A, B, C, and F are incorrect—The brachioradialis reflex located in the forearm above the radial styloid process of the wrist, the biceps reflex located in front of the elbow, and the

triceps reflex located just above the elbow on the back of the arm are all checked using the pointed end of the reflex hammer. The cremasteric reflex is a superficial reflex, which causes elevation of one side of the testicle in response to stroking the thigh on that side. The handle of the reflex hammer is used to stroke the thigh.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

357. Which type of precautions would be used when caring for a client with hepatitis A?
- Standard precautions
 - Airborne precautions
 - Droplet precautions
 - Contact precautions

The answer is A. Standard precautions are used to decrease the risk of transmission from bloodborne pathogens and moist body substances. Moist body substances include blood, urine, feces, sputum, saliva, wound drainage, and all aspirated fluids. Because hepatitis A is spread by the fecal oral route, standard precautions are appropriate.

B is incorrect—Airborne precautions are used when the mode of spread of an organism is by small particle droplets borne on air currents. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn. C is incorrect—Droplet precautions are used when the mechanism of transmission is by large droplets spread by coughing, sneezing, or talking. Droplet precautions require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room. D is incorrect—Contact precautions are used when organisms causing serious disease are easily transmitted through direct contact. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

358. A young female adult client is admitted for anorexia nervosa. The client's weight has reached a precarious level and hospitalization was deemed necessary for the

client's physical well being. Which is the priority nursing intervention?

- A. Obtaining daily weights
- B. Referring for psychological counseling
- C. Administering total parenteral nutrition
- D. Reinforcing a positive body image

The answer is C. Because the client's weight loss has reached a critical level, it is important that nutritional support be begun immediately. The other interventions are not the priority interventions.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Provide client and family with information about acute and chronic mental illness

359. The daughter of a woman who has just been admitted to an Alzheimer's care unit because of stage 3 symptoms of ambulatory dementia, asks the nurse what changes she should expect in her mother as the disease continues to progress. The nurse explains that stage 4 is endstage disease and identifies which symptoms that the client will likely manifest?
- A. Does not recognize family members
 - B. Does not walk
 - C. Engages in minimal purposeful activity
 - D. May yell or scream spontaneously
 - E. Is incontinent
 - F. Does not recognize self in the mirror

The answers are A, B, C, D, E, and F. Endstage Alzheimer's Disease is characterized by inability to recognize family members, inability to recognize self in a mirror, incontinence and possibly seizures, inability to walk, little purposeful activity, spontaneous yelling or screaming often interspersed in periods of muteness, forgetting how to eat, swallow or chew, weight loss, and problems associated with immobility such as pressure ulcers, contractures, UTIs, and pneumonia.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

360. A child is admitted to the pediatric unit with acute glomerulonephritis. The unit secretary receives a phoned lab report from the laboratory. Which result should the nurse question?
- A. Urine protein 3+
 - B. Urine RBCs 4+
 - C. Urine color: Smokey gray
 - D. Urine-specific gravity 1.003

The answer is D. Protein and RBCs are expected findings in the urine. The urine will be very concentrated. All of these facts will cause the urine-specific gravity to be high, not low. The color is smoky gray or "cola" colored.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate the client/family about medications

361. A pregnant woman has been found to be very anemic. Because she can't take pills, liquid iron supplements have been ordered. Which direction would the nurse give the client about taking the liquid iron preparation?
- A. Take the iron with milk
 - B. Drink the iron through a straw
 - C. Take the iron on an empty stomach
 - D. Take the iron at the same time every day

The answer is B. Iron stains the teeth so should be taken in a manner to bypass the teeth.

A is incorrect—Milk will prevent iron absorption—iron should be taken with juice for the best absorption. C is incorrect—Iron can be irritating to the stomach. D is incorrect—It doesn't matter what time of day the iron is taken.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform a comprehensive health assessment

362. What is the nurse assessing when, with the client's eyes closed, the nurse traces the number 3 on the palm of the client's hand with a capped pen and asks the client to identify what was traced?
- A. Two-point discrimination
 - B. Stereognosis
 - C. Graphesthesia
 - D. Light touch

The answer is C. This is the procedure for assessing graphesthesia.

Two-point discrimination involves touching the skin simultaneously with two sterile needles at closer and closer distances to each other until the client perceives only one touch. Stereognosis is asking the client to identify a familiar object such as a key when it is placed in the client's hand with the client's eyes closed. Light touch is tested by stroking an area of the client's skin with a wisp of cotton.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

363. An infant's crib is placed next to the window allowing the infant to lose heat to a cooler solid surface not in contact with the infant's skin. This type of heat loss is termed
- radiation
 - convection
 - conduction
 - evaporation

The answer is A. This type of heat loss occurs by radiation. Convection is the loss of heat into the cooler room temperature. Conduction is the loss of body heat to a solid surface in direct contact with the body. Evaporation is the loss of heat when moisture on the skin is converted to a vapor.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

364. Which activity requires an individual carrying out the activity to use the most energy:
- Rolling
 - Pivoting
 - Lifting
 - Turning

The answer is C. Lifting a person or object requires going against the force of gravity.

A, B, and D are incorrect—Rolling, pivoting, and turning a client use a limited amount of energy compared to lifting a client. Moving an object along a level surface requires less energy than moving an object against the force of gravity.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alterations in body systems

365. The client has pulse oximetry ordered to monitor oxygen saturation. The nurse applies the monitoring probe to the right index finger and receives a reading of 91%. The nurse should
- notify the physician.
 - encourage the client to take a deep breath.
 - check the oxygen level on each of the other fingers.
 - check the monitor site for skin breakdown from the probe.

The answer is A. The test is used to titrate levels of oxygen. This value is low. Taking a single deep breath will not resolve the problem. There is no reason to check the oxygen level of the other fingers, this is not a test of circulation to the hands. Although the probe uses heat to read the oxygen level, skin breakdown is not common in adults.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

366. Which equipment does the nurse need to perform a Rinne test on a client?
- Reflex hammer
 - Pneumatic otoscope
 - Tuning fork
 - Snellen chart

The answer is C. The Rinne test utilizes a tuning fork to compare bone conduction and air conduction of sound. The base of a lightly vibrating tuning fork is placed on the mastoid process and the client is directed to state when the tone is no longer heard. When the client reports no longer hearing the tone the tuning fork is moved so the tines are in front of the opening to the auditory canal. The client is asked if sound is heard and if so to report when it stops. Normally, the client hears the sound for as long as the sound was heard with the base of the tuning fork on the mastoid bone. This means that air conduction is normally twice as long as bone conduction. If air conduction is found to be equal to or shorter than bone conduction, the client has a conductive hearing loss. If air conduction is longer, but not twice as long as bone conduction, sensorineural hearing loss is indicated.

A is incorrect—A reflex hammer is used to check reflexes. B is incorrect—A pneumatic otoscope is used to check for motion of the tympanic membrane. D is incorrect—A Snellen chart is used to test distance vision.

PHYSIOLOGICAL INTEGRITY

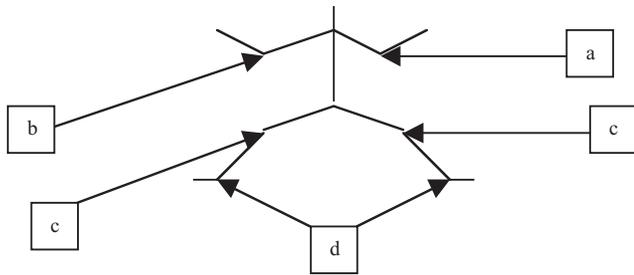

Reduction of Risk Potential

System-Specific Assessment

Assess the client for abnormal neurological status

367. The nurse is assessing for diminished deep tendon reflexes in a client with increasing intracranial pressure. Which location on the accompanying diagram

would the nurse strike with the reflex hammer to check the achilles reflex?

- ___ A ___
 ___ B ___
 ___ C ___
 ___ D ___

The answer is D. To check the Achilles reflex, the knee is flexed, the foot is dorsiflexed and held by the examiner, and the leg is externally rotated to allow easy access to the back of the heel. The Achilles tendon is struck with the wide end of the reflex hammer. The examiner should feel plantar flexion in the foot in response.

Location A denotes the biceps reflex; location B denotes the triceps reflex; location C denotes the patellar reflex.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological interactions

368. A client with known heart disease is being treated with digoxin and lasix. The client is admitted to the hospital for lethargy and shortness of breath. The admission labs show a potassium level of 2.9. The nurse would suspect
- renal failure
 - digoxin toxicity
 - a respiratory infection.
 - decreased chloride levels

The answer is B. Low potassium levels can result from Lasix administration but would increase the action of the digoxin causing digoxin toxicity. The other responses are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Identify and report deviations from expected growth and development

369. When assessing a 5-month-old child, which finding would the nurse interpret as representing normal growth and development?

- Presence of the tonic neck reflex
- Presence of the crawling reflex
- Presence of the dance reflex
- Presence of the rooting reflex

The answer is A. The tonic neck reflex disappears between 4 and 6 months of age and so if it was still present at 5 months it would not be interpreted as an abnormal finding.

B, C, and D are incorrect—The crawling and dance reflexes disappear between 1 and 2 months of age. The rooting and sucking reflexes disappear at 3–4 months of age.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

370. An adult client with SIADH is on restricted fluids to return serum sodium to normal. A serum sodium level within which range would indicate that this client management goal was achieved?
- 105–115 mEq/L
 - 118–125 mEq/L
 - 135–145 mEq/L
 - 148–158 mEq/L

The answer is C. The normal range of serum sodium is 135–145 mEq/L. Below 135 mEq/L is hyponatremia and above 145 mEq/L is hypernatremia. With SIADH serum sodium level is low as a result of dilution by retained fluid because of the inappropriate secretion of antidiuretic hormone which prevents diuresis.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

371. When moving a client from the bed to a stretcher the nurse needs to consider utilizing a:
- draw or pull sheet
 - pillow
 - footboard
 - trapeze bar

The answer is A. A draw or pull sheet will provide friction which will lead to less force needed to move the client.

Pillows are used in positioning clients. Footboards are used to prevent foot drop. Trapeze bar is used when the client can assist in pulling him/herself up in bed.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

372. A newborn is being admitted to the newborn nursery. The father has accompanied the infant to the nursery. During the admission process, the nurse prepares to administer vitamin K intramuscularly. The father asks why his baby needs the vitamin K. Which response by the nurse would be most appropriate?
- “We give this to all babies born by cesarean section.”
 - “Babies can’t take fruits and juices which are the main source of vitamin K in the diet.”
 - “Your baby will not have anything by mouth for the next 12 hours so he will be unable to get any vitamin K from his diet.”
 - “Newborns have sterile intestines. You and I get vitamin K from bacteria that live in our intestines.”

The answer is D. The main source of vitamin K is from the intestinal flora and from the ingestion of fats.

A is incorrect because it is also given to infants born by vaginal delivery. Vitamin K is found in fats, not fruits. The infant will not be NPO.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

373. A premature male infant is admitted to the high risk nursery. On the admission assessment, the nurse notes there are no testes in the scrotum. In relation to this finding, the nurse would
- document the finding.
 - monitor urine output.
 - prepare the parents for immediate orchiopexy.
 - evaluate the child for low set ears.

The answer is A. Undescended testes are a common finding in the preterm infant and do not warrant further investigation at this time. Orchiopexy may be scheduled prior to the child starting school, but the testes may descend on their own. Low set ears are associated with renal abnormalities. Undescended testes are a sign of immaturity not renal abnormalities.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Develop and maintain therapeutic relationships with client/family/significant others

374. Upon return from a group meeting a client is visibly upset. When the nurse notes this fact and asks if the client would

like to talk about it, the client replies “I’ll tell you what happened but you can’t tell anyone I told you.” Which is the most appropriate response for the nurse to make?

- “I will respect your confidentiality.”
- “I cannot make that promise.”
- “As long as it doesn’t involve another client, I won’t say anything.”
- “I won’t write it in your record but I may need to tell someone.”

The answer is B. “I cannot make that promise.” This is the appropriate response because promising to keep information secret may be appropriate in a social relationship but is inappropriate in a therapeutic relationship. It is also an honest, direct answer to the client.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications from Surgical Procedures and Health Alterations

Applies knowledge of pathophysiology to selected assessment findings

375. A client is known to have hyperthyroidism with symptoms including recent weight loss, diarrhea and mild exophthalmos. The client is seen in the emergency room with a high temperature, tachycardia and hypertension. Tremors are noted in the hands. Which problem should the nurse suspect based on these assessment findings?
- Goiter
 - Urinary tract infection
 - Thyrotoxic Crisis (thyroid storm)
 - Overdose of Synthroid (Levothyroxine sodium)

The answer is C. Thyroid storm is the sudden oversecretion of thyroid hormone and can be life threatening. Goiter is an enlargement of the thyroid gland secondary to decreased thyroid production. A urinary tract infection would cause hyperthermia but not the other symptoms. The client with hyperthyroidism would not be on medication for hypothyroidism (Synthroid).

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected effects/outcomes

376. A newly diagnosed asthma client calls the clinic nurse to ask which medication is taken routinely to prevent an asthma attack. Which medication is the one that would be taken prophylactically?
- Cromolyn sodium (Intal)
 - Inhalant glucocorticoids such as flunisolide (Aerobid)

- C. Short-acting bronchodilator such as albuterol (Preventil)
- D. Long-acting bronchodilator such as salmeterol (Serevent)

The answer is A. Cromolyn sodium is a mast cell stabilizer and is used to prevent an asthmatic attack.

Glucocorticoids are anti-inflammatories used to reduce inflammation and airway constriction. Oral glucocorticoids may be administered for severe asthmatics as a prophylactic, the accumulated side effects are very problematic. Short-acting bronchodilators would be used prn for exercise induced asthma. Long-acting bronchodilators are used to obtain control of asthmatic attacks.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform a comprehensive health assessment

377. What would you ask the client to do as you assess respiratory excursion?
- A. "Take two or three rapid breaths."
 - B. "Say 99."
 - C. "Take a deep breath."
 - D. "Cough."

The answer is C. Respiratory excursion refers to the symmetry and degree of chest expansion upon taking a deep breath. Posteriorly excursion is measured by placing the palms of the hands with fingers spread wide and thumbs facing each other on either side of the spinal column with a skinfold pushed up between them. The client is then asked to exhale and then to take a deep breath and hold it. The examiner notes the amount of increased distance between his or her thumbs when the deep breath is taken. This increase in distance represents the amount of chest expansion or excursion. Normally the thumbs will separate by 1 ¼ to 2 inches.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

378. A 59-year-old male was admitted to your unit following removal of a tumor on the sigmoid colon with a diverting colostomy. On the third postoperative day, the client's wife asks that you look at the dressing because it is all wet. Upon removal of the dressing you observe bowel protruding out of the abdomen through a dehiscence. What is the priority nursing action?

- A. Notify the surgeon
- B. Reassure the client that he will be fine
- C. Apply sterile, normal saline soaked gauze to the bowel and cover with a second sterile dressing
- D. Gently push the bowel back into the abdominal cavity and apply an abdominal binder

The answer is C. Sterile gauze soaked with normal saline should be applied to the bowel to prevent drying and then covered with a secondary sterile dressing to prevent contamination.

A is incorrect—The nurse's priority action is to preserve the bowel; then the surgeon is notified. B is incorrect—Although the nurse does want to assure the client that this problem will be corrected immediately, it is not the priority action. D is incorrect—Pushing loops of bowel back into the abdominal cavity could result in injury to the bowel.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

379. A known drug addict arrived in the labor unit at 8 cm dilated. The client managed the contractions and the infant was delivered within 1 hour of the mother's admission. For which conditions would the infant be monitored? (Select all that apply.)
- A. Hyperbilirubinemia
 - B. Congenital anomalies
 - C. Narcotic depression immediately after birth
 - D. Narcotic withdrawal within a few hours of delivery

The answers are B, C, and D. Many drug abusers will wait to the last minute to arrive at the labor unit and will have used recreational drugs immediately before admission. Therefore, the infant could be depressed at birth but then will develop withdrawal within a short period of time. Congenital anomalies are associated with some recreational drugs. The infant will probably not have problems with hyperbilirubinemia as the narcotic exposure in utero seems to mature the liver and infants born to substance abusers seem to have fewer problems with bilirubin than other infants.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

380. A client needs help in transferring from his bed to a chair. He is 6 feet 2 inches tall, weighs approximately 250 lbs,

has weakness on his left side, and has been on prolonged bed rest. Which factors should the nurse consider prior to implementing the transfer? Select all that apply.

- A. ___ Determine the need for assistance from other personnel
- B. ___ Determine the client's activity tolerance
- C. ___ Assess muscle strength in the client's legs and upper arms
- D. ___ Assess the amount of instruction the nurse will need to provide the client's

The answers are A, B, C, and D. Clients require various levels of assistance; the nurse needs to recognize her/his strengths and limitations; a safe transfer is the first priority. Determining a client's activity tolerance will aid in determining the client's ability to assist in the transfer. Clients that have been immobile for a period of time may have decreased muscle strength, tone, and mass. This will effect his/her ability to bear weight and raise the body. By explaining the transfer procedure the client will be involved and maybe able to help in the transfer.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Identify and report deviations from expected growth and development

381. When assessing a 6-month-old child, which finding should the nurse interpret as a sign of possible developmental delay?
The child
- A. is not attempting to pull up to a standing position.
 - B. does not turn toward a person who is speaking.
 - C. does not imitate speech.
 - D. does not respond to infant games like peek-a-boo.

The answer is B. At 6 months of age an infant should turn toward a person who is speaking. If the infant does not do this, the possibility of developmental delay or other disability exists.

A, C, and D are incorrect—At 1 year a child should have begun to pull up to a standing position; begun to imitate a variety of speech sounds; and begun to respond to games like peek-a-boo and pat-a-cake.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body system

382. A pregnant woman at 39 weeks gestation tells the nurse “I started feeling like I can breathe better two

days ago, but now I noticed I have to void a lot.” How should the nurse would suspect interpret this information?

- A. Lightening has most likely occurred.
- B. Quickening has occurred.
- C. Labor has begun.
- D. A urinary tract infection has developed.

The answers is A. As the uterus descends into the pelvis in preparation for labor, the client will be able to breathe easier but will now have pressure on the bladder causing urinary frequency.

Quickening is feeling fetal movement. The client gives no indication of contractions although the body is preparing for labor. A urinary tract infection would cause frequent urination but not easier breathing.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications and side effects

383. An 80-year-old man comes to the clinic complaining of erectile dysfunction. Which question is most important for the nurse to ask?
- A. How often do you usually have intercourse?
 - B. What medications do you take?
 - C. When was the last time you had your prostate examined?
 - D. Do you have any problems urinating?

The answer is B. As clients age, the likelihood that they take medications increases. Many of the medications taken by the older population have erectile dysfunction as a side effect, including antihypertensives. In many cases the problem can be eliminated by changing the medication. The other questions, although they might be asked, do not most directly impact the problem.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assist client with achieving and maintaining self-control of behavior

384. Which statement accurately describes a “no suicide” contract?
- A. The contract provides a boundary.
 - B. The contract takes the responsibility for control away from the client.
 - C. The contract serves to reinforce to the client that life is valuable.
 - D. The contract must be written to be effective.

The answer is A. A “no suicide” contract is a way of providing boundaries. Contracts help place control in the domain of the client; they don’t remove control. Contracts assure the client that someone is concerned enough about them to provide boundaries but do not directly reinforce that life is valuable. Verbal “no suicide” contracts have been proven effective.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

385. The husband of an elderly client tells the clinic nurse that the doctor has diagnosed his wife who has been increasingly confused, with anemia caused by a vitamin deficiency. The husband asks which vitamin could be causing the problem. Which vitamin deficiency would the nurse suspect is the cause of the problem?
- A
 - B₁₂
 - C
 - D

The answer is B. Vitamin B₁₂ deficiency is associated with anemia and mental confusion. This vitamin deficiency is common in the elderly. The other vitamins are not associated with these symptoms.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

386. A client was diagnosed with a hiatal hernia. Discharge teaching was provided and the client was discharged home. The client returns to clinic a week later to complain that the symptoms have not improved. The nurse questions the client on activities and notes that the client eats small frequent feedings; eats at least one hour before going to bed; has switched from coffee to tea to reduce caffeine ingestion; and has begun a smoking cessation program with moderate success. Which activity should the nurse counsel the client to change?
- Eats small frequent feedings.
 - Eats at least one hour before going to bed.
 - Has switched from coffee to tea to reduce caffeine ingestion.
 - Has begun a smoking cessation program with moderate success.

The answer is C. Both coffee and tea are to be avoided as they increase stomach acidity. All the other activities are appropriate for a client with a hiatal hernia.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

387. Prior to discharge, a client still experiencing some weakness on his left side has axillary crutches ordered for him. Which is the correct crutch gait for the nurse to teach this client?
- four-point gait
 - three-point gait
 - two-point gait
 - swing through gait

The answer is B. The three-point gait requires the weight to be borne on both crutches and then on the uninvolved leg or side. Since this client still has some left sided weakness this would be the gait of choice.

The four-point gait requires weight bearing on both legs. The two-point gait requires at least partial weight bearing on each foot. The swing through gait is used by an individual wearing braces which assist in supporting the person’s weight.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

388. An obese 34-year-old black man with a high stress job is seen for primary hypertension. His diet is high in fried foods and sodium. The client asks why he developed this problem. Which are the risk factors for hypertension that this man has? (Select all that apply.)
- ___ Age
 - ___ Race
 - ___ Obesity
 - ___ Fat Intake
 - ___ High Stress
 - ___ Sodium Intake

The answers are B, C, E, and F. Hypertension is more common in blacks. Obesity and high sodium intake have been associated with high blood pressure. Stress is associated with hypertension. This gentleman is young, the risk of hypertension increases with age. Although fat intake is related to obesity, fat intake alone has not been associated with hypertension.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Alteration in Body Systems

Compare current client data with baseline client data

389. A 63-year-old female, with a history of lymphoma treated with chemotherapy, is admitted for repair of a fractured right tibia. Postoperatively her white blood cell count is 4 mm^3 and temperature is 98.6°F . She is complaining of not feeling well and being chilled. Which is the priority nursing action?
- Compare the postoperative lab value and temperature to the preoperative data.
 - Ask the client what her WBC and temperature has been in the past.
 - Notify the physician of the change.
 - Do nothing, these are normal values.

The answer is A. With a known history of cancer treated with chemotherapy the client has a low white blood cell count and a value close to normal is indicative of an infection.

B is incorrect—The client may not know what their lab values or temperatures typically have been. C is incorrect—The answer does not provide information that should be shared with the physician. D is incorrect—Doing nothing may result in a negative event for the patient.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Identify expected physical, cognitive, psychosocial and moral stages of development

390. The nurse is observing a 9-month-old infant to see how the child is developing cognitively. Which behavior indicates object permanence has developed?
- The infant
- has found his hands
 - reaches for a toy out of his reach
 - cries when mother leaves the room
 - puts a block into his mouth while playing

The answer is C. A child who cries when mother leaves the room is aware that mother exists outside his vision so object permanence has developed. None of the other activities indicate the child is aware of objects when not in his or her vision.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological agents/actions

391. The nurse caring for a client on digoxin checks the client's electrolyte reports because of the risk of toxic-

ity precipitated by hypokalemia. To avoid this risk, the client's serum potassium level should be equal to or above how many milliequivalents per liter?

Write your answer as a whole number carried to one decimal place. _____ mEq/L.

The answer is 3.5 mEq/L. The normal range of serum potassium is 3.5-5.0 mEq/L.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

392. Which is a priority goal for a client with obsessive compulsive personality disorder?
- Acceptance of group therapy.
 - Elimination of bizarre fantasies.
 - Development of social relationships
 - Decrease of maladaptive behaviors

The answer is D. Clients with obsessive compulsive personality disorder are rigid and preoccupied with issues of control and power. They fear losing control and utilize different maladaptive behaviors in an effort to control anxiety. Primary goals of therapy are to reduce anxiety, improve self esteem and understand and decrease maladaptive behaviors.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

393. The physician instructs a client to eat a low residue diet. Which foods would the nurse instruct the client to reduce or avoid? (Select all that apply.)
- ___ Eggs
 - ___ Bananas
 - ___ Strong cheeses
 - ___ Lean tender meats
 - ___ Whole grain cereals
 - ___ Dried beans and beans

The answers are C, E, and F. These foods contain significant residue. The other foods are considered low residue.

HEALTH PROMOTION AND MAINTENANCE

Health Screening

Apply knowledge of pathophysiology to health screening

394. A 68-year-old client participating in a community skin screening tells the nurse about a raised "spot" on

his upper, outer arm, which has enlarged and changed color. Inspection discloses an irregular border and variegated color. What is the priority nursing response?

- A. Caution the client to avoid sun exposure.
- B. Advise the client to see a dermatologist as soon as possible.
- C. Suggest use of a topical OTC antibiotic ointment to prevent infection.
- D. Instruct to wash with a mild soap and avoid irritation.

The answer is B. See a dermatologist as soon as possible. A skin lesion that has an irregular border, inconsistent color, and is enlarging may be a serious condition such as melanoma. It is wise for the patient to see a specialist soon.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication administration

395. A 10-year-old child is diagnosed in the pediatric clinic with conjunctivitis (pink eye) and an antibiotic eye ointment is ordered. Which instruction is appropriate for the nurse to give the mother in regard to the administration of the eye ointment?
- A. Place the ointment directly on the pupil
 - B. Have the child apply the ointment by himself
 - C. Ask the child to close his eyes and spread the ointment on the lids
 - D. Pull the lower lid down and place the ointment into this “sack”

The answer is D. The lower lid is pulled down to form a sack and the ointment is spread into the sack from the inner corner to the outer corner.

The ointment should not be placed directly on the pupil. The child will be unable to instill the ointment by himself. The ointment should be placed into the subconjunctival sac not on the outer lids.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Identify and report deviations from expected growth and development

396. When assessing a 12-month-old child, observation of which behavior is indicative of normal developmental progression?
- A. Feeds self with a spoon
 - B. Smiles and babbles

- C. Says two or three words such as mama, dada, and bye bye.
- D. Arches the back and raises the head when lying on abdomen.

The answer is C. Saying two or three words is a developmental milestone that should be achieved by 1 year of age.

A is incorrect—Feeding self with a spoon is not expected until 18 months. B is incorrect—Smiling and babbling should be present by 6 months of age and so is not an indicator of normal development at the 1-year level. D is incorrect—Arching the back and raising the head when lying prone also is expected by the age of 6 months.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and blood products

397. A client is to receive a transfusion of packed cells. Prior to administering the unit, which steps will the nurse take? (Select all that apply.)
- A. Take vital signs
 - B. Start an IV of D₅W
 - C. Check that the blood types match
 - D. Check the client's arm band for match to the unit of blood
 - E. Double check the client's name and packed cells unit for match

The answers are A, C, D, and E. All are correct except B. The IV should be started with normal saline. Dextrose in the line will cause the cells to clot.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

398. Which type of precautions would be used when caring for a client with hepatitis B?
- A. Standard precautions
 - B. Airborne precautions
 - C. Droplet precautions
 - D. Contact precautions

The answer is A. Standard precautions are used to decrease the risk of transmission from bloodborne pathogens and moist body substances. Moist body substances include blood, urine, feces, sputum, saliva, wound drainage, and all aspirated fluids. Because hepatitis B is spread by blood and blood products, standard precautions are appropriate.

B is incorrect—Airborne precautions are used when the mode of spread of an organism is by small particle droplets borne on air currents. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn. C is incorrect—Droplet precautions are used when the mechanism of transmission is by large droplets spread by coughing, sneezing, or talking. Droplet precautions require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room. D is incorrect—Contact precautions are used when organisms causing serious disease are easily transmitted through direct contact. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administers parenteral medication in a safe and effective manner

399. The physician has ordered a medication to be given by IV push method. Which is an appropriate nursing action?
- Refuse to push the medication.
 - Push the medication over 1 full minute.
 - Push the medication over 5 full minutes.
 - Determine the rate of infusion for this particular medication.

The answer is D. Each medication has an individual rate of infusion allowed for IV bolusing (pushing).

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

400. During the third trimester of her pregnancy, a client develops mild PIH (pregnancy induced hypertension). Which instruction would be included in the teaching planned for this client?
- Avoid all sodium containing foods.
 - Rest in bed during the mid-afternoon.
 - When recumbent, always lay in the supine position.
 - Notify the physician at the next prenatal visit if headaches or visual disturbances occur.

The answer is B. Rest is beneficial to reduce hypertension. Rest should be in the lateral position to prevent vena cava syndrome.

Sodium is a necessary nutrient so eliminating all sodium would be incorrect. If headaches or visual disturbances occur, the physician should be notified immediately as they may indicate worsening of the client's condition.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

Identify and report deviations from expected growth and development

401. When assessing a 3-month-old infant, which finding indicates the need for further evaluation?
- Infant reacts to sudden noise.
 - Infant does not vocalize sounds.
 - Infant does not reach for toys.
 - Infant raises head without arching the back when in a prone position.

The answer is B. By 3 months of age, an infant should be vocalizing sounds and so the absence of this behavior indicates possible developmental delay or other disability and requires further evaluation.

A, C, and D are incorrect—It is normal for a 3-month-old infant to react to sudden noises and so no further investigation is required. Infants are not expected to reach for toys as a developmental marker until 6 months of age. It is normal for a 3-month-old to raise the head without arching the back when in a prone position; arching of the back is not expected until 6 months of age.

PHYSIOLOGICAL INTEGRITY

System Specific Assessment

Perform Focused Assessment or Reassessment (Respiratory)

Identify alterations

402. A client has COPD and a barrel chest. Which finding would the nurse expect when assessing the chest?
- Paradoxical chest movement
 - Presence of a friction rub
 - Decreased respiratory excursion
 - Absent breath sounds

The answer is C. Respiratory excursion is decreased in the client with emphysema because a barrel chest develops as a result of air trapping in the alveoli and the accompanying lung hyperinflation and flattening of the diaphragm.

A, B, and D are incorrect—Paradoxical chest movement exists when an unaffected area of the chest wall rises on inspiration and the affected area falls and the reverse occurs during expiration. This is seen with flail chest not with emphysema. Friction rubs are associated with pleural inflammation secondary to problems such as pleuritis, tuberculosis, and pneumonia.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

403. A client has blood drawn for an electrolyte profile. The venipuncture was difficult and the blood aspiration was slow. The findings included the following: sodium 150 mEq/L, potassium 6.1 mEq/L, chloride 101 mEq/L, and CO₂ 25 mEq/L. Which conclusion could the nurse draw from this information?
- The client is doing well as all values are normal.
 - The sodium is low so the client may have heat stroke.
 - The CO₂ is elevated so there may be a respiratory problem.
 - The potassium is high, the specimen may have been hemolyzed.

The answer is D. The potassium is very high but all other values are normal. Because of the problems with the blood draw, the specimen could have been hemolyzed. Hemolysis results in the release of intracellular potassium and hence can cause hyperkalemia in the specimen. All other values are within normal limits.

HEALTH PROMOTION AND MAINTENANCE

Provide education on age specific growth and development to the client and families

404. A toddler is shopping with mother. The toddler grabs a toy off the shelf. When mother replaces the toy on the shelf, the toddler cries and falls on the floor. Which is the best response by the mother?
- Buy him the toy
 - Spank his hands and tell him no
 - Explain to the child why he can't have the toy.
 - Remove the child from the area and divert attention to something else

The answer is D. The child is expressing his frustration. The goal of the parent is to allow the child to regain control without a loss of self-esteem. Removing and distracting him will allow him to regain self control.

Buying him the toy will not help him learn to deal with frustrations. Spanking his hand does not help with self-

esteem. The child doesn't have the vocabulary for long explanations and frustration will continue as long as the desired object is in sight.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Ergonomic Principles

Use ergonomic principles when providing care

405. The nurse is reinforcing the correct way for a client to descend stairs using crutches. In which order would the nurse instruct the client to proceed with the listed steps?
- Places crutches on the next stair, transfers weight to the crutches, moves affected side (leg) forward
 - Moves unaffected side (leg) forward
 - Transfers body weight to the unaffected side (leg)

The answer is C, then A, and then B. The client transfers body weight to the unaffected side (leg) then places the crutches on the next stair. Next the client transfers weight to the crutches and moves the affected side (leg) forward. Finally the client moves unaffected side (leg) forward.

This order enables balance to be maintained and allows the client to more safely go down the stairs.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications and side effects

406. A client is receiving a chemotherapy agent that is known to be irritating to the bladder wall. Which nursing action would best reduce irritation?
- Encourage the client to drink milk
 - Restrict fluids to decrease urine volume
 - Administer the once daily drug at bedtime
 - Have the client void every two hours while awake

The answer is D. Having the client void frequently reduces the time the medication sits in the bladder. The nurse would also force fluids to dilute the medication and on once daily meds, give it early in the morning so the client can void frequently. Milk would have no effect on bladder irritation.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of impaired cognition

407. A client with schizophrenia says "raining turkeys" to himself and to others as he walks around the unit and

performs various activities. Which would be a correct label for the nurse to use when documenting this behavior?

- A. word salad
- B. clang association
- C. neologism
- D. verbigeration

The answer is D. Verbigeration is the purposeless repetition of words or phrases. Word salad refers to the meaningless connection of words and phrases. Clang association refers to repeating words and phrases which sound alike but are otherwise unconnected. A neologism is a new word coined by the client and with meaning only to the client.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total parenteral nutrition

408. A client has an order for total parenteral nutrition to run at 95 ml/hour. The TPN is infusing into a central line. While transferring the client to a stretcher to go to x-ray, the central line is accidentally pulled out. Which is the immediate nursing action?
- A. Give the client sugar laced orange juice by mouth.
 - B. Start a peripheral line with D5W running at 95 ml/hour.
 - C. Start a peripheral line and administer the TPN at 95 ml/hour.
 - D. Notify the physician and wait for the central line to be restarted.

The answer is B. The client's body is accustomed to receiving a strong sugar solution at that rate so sudden stopping would cause hypoglycemia. TPN cannot be given by peripheral line. Sugar laced orange juice would not meet the need for continuous glucose infusion until the central line could be replaced.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

409. A client has been severely burned in a house fire and admitted to the burn unit. After emergency stabilization, one of the primary nursing goals is to prevent contractures. Which nursing intervention supports achievement of this goal?
- A. Administration of albumin
 - B. Promoting the intake of protein foods.

- C. Application of splints to immobilize body parts
- D. Treating the burns with the open method and not wrapping the burned injury.

The answer is C. Whereas all of the interventions may be used in the treatment of burns, the one intervention associated with prevention of contractions is the application of splints. In addition to splinting, ROM exercises are important in maintaining joint function.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

410. An infant received her first immunization on schedule but is now past due for both the second and third immunization of the series. The nurse should
- A. give the infant the second and third immunization during this visit.
 - B. start the immunizations over, giving the infant the first of the series.
 - C. give the second immunization and schedule the infant for a return visit for the third immunization.
 - D. give a double dose of the second immunization and then give the third immunization one month later.

The answer is C. Although there is an abnormal space between the first and second immunization, the nurse will give the second and schedule the third immunization for later. There is no need to restart the immunization. Two immunizations should not be given at the same time.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

411. A teenager is admitted to the hospital with a diagnosis of osteomyelitis. An IV is started for administration of parenteral antibiotics. The teenager complains about hospitalization and asks the nurse: "Why can't I just be given some pills to take like my friend that had the abscess?" The nurse's response would be based on the knowledge that osteomyelitis:
- A. Lacks an effective oral antibiotic.
 - B. Can cause pathologic fractures so the child must be hospitalized.
 - C. Is caused by a different organism than the one that causes abscesses.
 - D. Requires parenteral antibiotics to reach bone levels of the drug high enough to be effective.

The answer is D. Blood supply to the bones is less than to the skin. Parenteral antibiotics provide the best blood levels. The organism may or may not be the same as the other child had. Although pathologic fractures can occur from osteomyelitis, bedrest prevents the fracture not hospitalization.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

412. A child has a tonsillectomy. On return to the floor, the child is positioned prone until fully awake. Instructions given to the parents should include: (Select all that apply.)
- A. Avoid red liquids
 - B. Use a straw to make drinking easier
 - C. Cold liquids like popsicles will feel good.
 - D. Give milk and non-acidic liquids to soothe the throat
 - E. As soon as the child wakes up, start the child drinking

The answers are A, C, and E. Red liquids could be confused with blood in vomitus or stool. Cold liquids will reduce pain and promote blood clotting. Pushing oral fluids will keep the throat moist and reduce discomfort. A straw requires suction which could dislodge the clot that has formed in the throat. Milk thickens secretions requiring more throat clearing which is discouraged.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

413. A client with polycystic kidney disease needs a kidney transplant. Which action will the physician take prior to another family member being considered as a suitable donor?
- A. Discuss with the client feelings about the donor.
 - B. Instruct the client to take over the counter drugs for pain
 - C. Screen the family member for evidence of polycystic kidney disease
 - D. Stop dialysis treatment so that the client's kidney function can be adequately evaluated

The answer is C. Polycystic kidney disease is inherited as an autosomal dominant disorder. Any family member should be screened for kidney disease before consideration as a donor. Until a donor is found, there is no need to discuss the client's feelings about the donor. Medications are avoided because of the injury to the kidneys. If the client was on dialysis, the kidney function is known so stopping would be unnecessary and unhealthy.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Safe Use of Equipment

Ensure appropriate and safe use of equipment in performing client care procedures and treatments

414. Which are safety measures that the nurse needs to keep in mind when transporting a client in a wheelchair? Select all that apply.
- A. Lock the wheels before the client transfers from bed to wheelchair
 - B. Push the wheelchair in a forward direction when getting on an elevator
 - C. Be sure the footplates are in the down/lower position as the client gets into the wheelchair
 - D. Position the client well back in the seat

The answers are A and D. The wheelchair's wheels always need to be locked before transferring a client into the wheelchair to prevent the wheelchair from moving and the client falling. Ensuring the client is sitting fully in the wheelchair will prevent the wheelchair from being off balance and possibly tipping forward.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological agents/actions

415. Due to an allergy to cats, a client has had several allergy attacks after visiting a family member. The physician has prescribed an antihistamine to reduce the symptoms. The client asks the nurse when would be the best time to take the antihistamine. The nurse's response is based on the knowledge that antihistamines
- A. transfer the allergic response to a mast cell.
 - B. destroy the allergen that caused the symptoms
 - C. block histamine from attaching to receptor sites.
 - D. destroy histamine, the cause of allergic symptoms.

The answer is C. Antihistamines compete with histamine for the receptor sites. Once histamine is attached to the receptor site, an anti-histamine will not work. The best time to take the anti-histamine would be before going to the house with cats.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

416. Due to injuries in a car accident, a client has a tracheostomy. Which is a step in providing tracheostomy care?

- A. Put on clean gloves in preparation for the procedure.
- B. Advance the suction catheter while applying suction.
- C. Insert the suction catheter as deep into the airway as possible and begin suctioning.
- D. Rotate the suction catheter while applying intermittent suction during withdrawal.

The answer is D. Rotating the catheter cleans all surfaces of the trach. Intermittent suction prevents the client from becoming hypoxic. The procedure is sterile so sterile gloves are worn. Suction is never applied while inserting the catheter. The suction catheter is inserted fully and then withdrawn slightly before suctioning begins.

HEALTH PROMOTION AND MAINTENANCE

Human Sexuality

417. A woman is talking to her best friend who is a nurse. The woman knows that she does not carry the gene for sickle cell anemia. She tells the nurse she is going to marry a man who has the disease. She asks whether her future children will be affected with sickle cell anemia. The nurse's best response would be
- A. no, but they will all be carriers for the disease.
 - B. one in four of your children will have the disease
 - C. none of your children will have the disease but 50% will be carriers.
 - D. there is no way to determine the possible outcome for your future children.

The answer is A. Sickle cell anemia is an autosomal recessive disorder, which means the child must receive an affected gene from each parent. Since she does not carry the affected gene, none of the children will be affected. However, since the both of the husband's genes are affected, the children will all receive one copy of the affected gene meaning they will be carriers. The other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Potential for complications of diagnostic tests/treatments/procedures

418. An infant was diagnosed with hydrocephalus shortly after birth and a ventriculo-peritoneal shunt was inserted. Three years later, the child is readmitted to the hospital with a malfunctioning shunt. Which assessment findings would the nurse interpret as expected based on the problem?
- A. Vomiting and headache

- B. Temperature and bradycardia
- C. Abdominal pain and electrolyte imbalance
- D. Bulging fontanels and increasing head circumference

The answer is A. Early symptoms of a malfunctioning shunt (and of hydrocephalus) are vomiting and headache, especially in the early morning. A younger child might have bulging fontanels and increasing head circumferences but this child is over 3 and fontanels should have closed.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alteration in body systems

419. There are several clients currently in the burn unit with extensive burns. Which client would be at greatest risk for infection in the burn?
- The client who:
- A. has skin grafts completely covering all burn surfaces.
 - B. is being discharged home with follow-up physical therapy.
 - C. is being treated with the open method (no dressings) of burn treatment.
 - D. is being treated with the closed method (dressings covering) of burn treatment.

The answer is C. The client whose burns are open to the air would be most likely to develop an infection. Dressed burns and grafted burns have coverings which will reduce the likelihood of infection. The client who is being discharged for follow-up physical therapy has burns that are well on the way to healing.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform a comprehensive health assessment

420. Which question should the nurse ask the parent of a 7-month-old infant to obtain the most meaningful information about the child's development?
- A. Can she sit up by herself?
 - B. Does she make cooing sounds?
 - C. Does she turn over?
 - D. Can she transfer a spoon hand to hand?

The answer is A. By seven months, the infant should be able to sit without support. The other options are appropriate for younger children.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication administration

421. A 10-month-old infant needs an immunization. Which is the best site for the intramuscular injection?
- Deltoid
 - Gluteal
 - Dorsogluteal
 - Vastus lateralis

The answer is D. This muscle is the best choice until the child is walking well.

The deltoid is never used on young children. The gluteal and dorsagluteal both refer to the same site and should not be used in children under 2.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Injury Prevention

Protect the client from injury

422. After admission to the hospital unit, a 5-year-old child is diagnosed with a brain tumor involving the cerebellum. While providing care in the preoperative period, which would be the primary nursing intervention?
- Protect the child from falls
 - Monitor the child for seizures
 - Measure the head circumference daily
 - Maintain the child's temperature within the normal range

The answer is A. Pathology in the cerebellum leads to ataxia which places the child at risk for falls.

B, C, and D are incorrect—Seizures are a late symptom in brain tumors so would not be expected here. The child's sutures have closed at 5 years of age so head circumference will not change. The temperature is not likely to be affected.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

423. An elderly client is going to have a feeding tube permanently placed. The physician is debating placing a PEG gastrostomy tube or a jejunostomy tube. Which fact about the client suggests that a jejunostomy tube is the best option?
- The client's caloric needs are high.
 - The client has a tendency to vomit.

- The client's family will be caring for the feeding tube.
- The client is mentally confused and may pull on a tube.

The answer is B. Vomiting would decrease with a jejunostomy tube as the feeding will be placed in the duodenum rather than in the stomach. The other statements would have no bearing on the decision.

HEALTH PROMOTION AND MAINTENANCE

Self-Care

424. A client has recently been diagnosed with a mild case of emphysema and has been instructed in self care at home. On a return visit to the clinic, the client makes the following statements. Which statement indicates the need for further client education?
- "I quit the gym since I shouldn't exercise."
 - "I told my family they could no longer smoke in my house."
 - "I have increased the water I drink by two extra glasses per day."
 - "I had a room air conditioner put into my home so that I can stay indoors when the pollution level is high."

The answer is A. Moderate exercise can be beneficial to help keep the airways open and clean. All other statements were correct information and do not indicate need for further intervention.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

425. A nurse is working with several pediatric renal clients. The nurse notes similarities between the labs of the pediatric clients with nephrotic syndrome and those with acute glomerulonephritis. Which lab findings would be similar?
- Urine positive for protein
 - Serum albumin decreased
 - Elevated serum triglyceride levels
 - Urine positive for red blood cells.

The answer is A. In nephrotic syndrome, albumin is lost while in acute glomerulonephritis, red blood cells are lost in the urine. Both are proteins and would give a positive proteinuria level. In nephrotic syndrome, the serum albumin is

decreased and serum triglyceride levels are elevated. RBCs are in the urine for acute glomerulonephritis.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

426. A child is found to be allergic to milk. To ensure adequate calcium intake, which foods would the nurse recommend be included in the child's diet?
- Coffee and tea
 - Pork and ground beef
 - Fruits such as apples and pears
 - Green leafy vegetables such as collard greens and spinach

The answer is D. Greens and spinach are good sources of calcium. The other foods are not sources of calcium.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

427. Many high schools organize programs to discourage teenagers from driving drunk, e.g., a fatal car accident involving popular students is staged in a place where students will see it. On which developmental fact is the effectiveness of these programs postulated?
- Teenagers
- view death as a result of an accident.
 - view death as a temporary separation.
 - think death only occurs to the elderly and the sick.
 - recognize that death is universal but usually do not see themselves as susceptible.

The answer is D. Teenagers can conceptionally view death as an adult does, but often do not think it can happen to them or their friends. These programs help them to understand the reality that driving and drinking can be fatal to everyone. The other views of death are those of younger children.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication administration

428. Which is a step in the procedure for applying a transdermal patch for medication administration?
- Wear sterile gloves when handling the patch.
 - Apply the patch to clean, dry, and un-inflamed skin.

- Wipe the skin with alcohol and Betadine before applying the patch.
- Rub the patch firmly after application to insure solid contact with skin.

The answer is B. Applying to clean dry and un-inflamed skin provides the best medication absorption.

Clean gloves should be worn, not sterile. The alcohol and Betadine are not used because they could affect medication absorption. Always follow manufacturer recommendations for application including rubbing the patch after application.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Diagnostic tests

429. A client admitted for a workup to rule out multiple sclerosis has an evoked response test. The client asks what this test will evaluate. Which is the correct reply? The test will evaluate:
- radiation uptake by the brain.
 - the size of the brain for atrophy.
 - the amount of protein in the cerebrospinal fluid.
 - the length of time it takes for the nerve cell to conduct an impulse.

The answer is D. The evoked response test stimulates one nerve and evaluates how long it takes that message to travel to the brain. The stimuli can be visual, auditory or somatosensory. Radiation uptake would be a scan, a CT will evaluate atrophy of the brain. The amount of protein in the CSF is evaluated by a lumbar puncture.

PSYCHOSOCIAL INTEGRITY

Grief and Loss

430. A terminally ill client tells the nurse "If I can only live to see my grandchild born." The nurse recognizes this is an example of
- disbelief
 - bargaining
 - depression
 - acceptance

The answer is B. Bargaining is the "If this, then that" response.

The disbelief response is "No, not me" and doctor shopping looking for a more acceptable diagnosis. In depression, the client accepts that death is inevitable and is saddened about all that they are losing. Acceptance is when the client is at peace with the terminal illness.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications of diagnostic test/treatments/procedures

431. A client with a history of severe allergic reactions, is to be allergy tested. Which type of allergy test requires the most careful monitoring for a severe reaction?
- A RAST test
 - Skin patch testing
 - An eosinophil count
 - Intracutaneous skin testing

The answer is D. This test provides the risk of the greatest exposure to potential allergens. Skin patch testing also involves exposure to potential allergens, but since the allergen is not injected, there is less risk of a systemic reaction. RAST test and eosinophil counts involve no risk of an allergic reaction.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

432. A client develops Bell's Palsy affecting the right side of their face. Which would be an important nursing intervention?
- Instill artificial tears into the right eye.
 - Reinforce that appearance doesn't matter.
 - Provide a clear liquid diet to prevent choking.
 - Apply skin care products to the right side of the face from scalp to jaw line.

The answer is A. Because of the palsy, the client will be unable to blink on the right side. This will cause the right eye to dry out so artificial tears will keep the eye moist and promote comfort. Telling someone appearance doesn't matter doesn't affect how the client feels about appearance. Chewing and swallowing are only minimally affected so clear liquids are not appropriate. The skin on the affected side remains intact so skin care products are not required.

HEALTH PROMOTION AND MAINTENANCE

Self-Care

433. A diabetic client is being taught foot care. Which information will the nurse include in the teaching? (Select all that apply.)
- Do not wear sandals or open toed shoes
 - Rubber/plastic shoes are best for your feet.

- Use a mirror to inspect the soles and back of the foot daily
- Buy your shoes in the late afternoon when your feet are their largest.
- Cut your toenails first thing in the morning when they are the softest.

The answers are A, C, and D. Sandals and open toed shoes increase the risk of injury to the feet. A mirror will allow the inspection of hard to see areas. Your feet are their largest in late afternoon, so that is the best time to shop for shoes.

Natural fibers such as leather and canvas allow perspiration to escape and are better than rubber and plastic. Toenails should be cut after a bath when they are the softest.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

434. A client is seen in the emergency room for severe pain secondary to renal calculi. Following the administration of pain medication, the client is sent home and instructed to filter all urine for stones. Which other instructions will the nurse give the client? (Select all that apply.)
- Limit milk intake
 - Rest in the lateral Sims position
 - Void every two hours while awake
 - Increase intake of meat, eggs and cranberries
 - Increase fluid intake to 2 to 3 liters of fluid per day.

The answers are A, D, and E. In some clients, milk intake increases the calcium levels which are a component of some renal calculi. In addition, milk increases the alkalinity of the urine which can be a factor contributing to renal calculi. Meat, eggs, and cranberries produce acidic urine which reduces renal calculi. Fluid intake will help to reduce calculi. Resting in the lateral Sim's position and voiding every two hours will not reduce renal calculi.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Therapeutic procedures

435. A client with nutritional deficiencies has a jejunostomy tube placed for enteral feedings. The physician orders the client to receive 2400 ml of feeding per day. Which is an appropriate nursing action?
- Divide the feeding into 3 parts and feed at meal times.
 - Feed the client an equal amount every two hours around the clock.

- C. Place the feeding on a pump and feed continuously around the clock.
- D. Divide the feeding into 6 feedings and feed every 4 hours around the clock.

The answer is C. Jejunostomy feedings should be continuous. Gastrostomy feedings can be bolused.

PSYCHOSOCIAL INTEGRITY

Mental Health Concepts

436. A client has been ordered by the court into a facility which specializes in the treatment of substance abuse. Group meetings are an integral part of the program. On the third day of treatment, the client says “I am not going to group this morning.” In responding to the client, which fact must the nurse consider?
- A. The client may be required to be in the facility but he has the right to informed consent in regard to participation in treatment.
 - B. The client can be physically escorted to the meeting room but cannot be made to enter.
 - C. The client can be coerced into attending the meeting as long as no physical force is used.
 - D. The client can elect not to attend 20% of treatment activities without any repercussions.

The answer is A. Because a client is involuntarily admitted to a facility does not mean that his right to informed choice is forfeited.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications/side effects

437. The client has been on antibiotics for 10 days. When talking to the clinic nurse, the client mentions that diarrhea has become bothersome. Which would be an appropriate action for the nurse to suggest?
- A. Decrease water intake
 - B. Add yogurt to the diet.
 - C. Increase milk in the diet.
 - D. Inform the physician at the next clinic visit

The answer is B. Antibiotics eliminate the normal flora of the intestines. Decreasing water intake will worsen the problem with dehydration. Adding yogurt to the diet will help replace the normal flora. Milk would not benefit the client. Putting off intervening until the next clinic visit is not appropriate.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Parenteral/intravenous therapies

438. A client is receiving erythromycin by peripheral IV. On the third dose, the client complains of pain at the IV insertion site. The nurse checks the insertion site but the site is benign. Which action is appropriate for the nurse take to decrease the risk of phlebitis?
- A. Give the infusion faster to reduce vein exposure.
 - B. Give the medication orally instead of intravenously.
 - C. Give the client the pain medication that has been ordered prn.
 - D. Call the pharmacist and ask for the medication to be diluted.

The answer is D. Diluting the concentration of the drug will reduce the irritation to the vein. The other responses will not improve the developing phlebitis.

HEALTH PROMOTION AND MAINTENANCE

Family Planning

439. A woman has just delivered her fourth baby in 5 years. She states she doesn't want to become pregnant again immediately. Which is the birth control option that would offer the best protection for this client in the first 6 weeks post partum?
- A. Diaphragm
 - B. Breast feeding
 - C. Intrauterine device (IUD)
 - D. Natural family planning (Rhythm)

The answer is C. An IUD may be inserted soon after child-birth as it does not affect involution. A diaphragm needs to be fitted to the cervix. During involution, the cervical shape could change thus altering the fit of the diaphragm so it no longer provides protection. Breast feeding is not a method of contraception. Natural family planning can be used, but since many women ovulate before menstruation returns, it may not be successful in the immediate postpartal period.

PSYCHOSOCIAL INTEGRITY

Coping Mechanisms

440. A toddler has been hospitalized for several days. The mother visits irregularly. Although the toddler cried a lot at first, the child now seems to have settled in and is happy and playful. Which type of reaction is the child displaying?

- A. Despair
- B. Denial
- C. Protest
- D. Bargaining

The answer is B. Protest, despair, and denial are the three stages of toddler hospitalization reaction. Denial is a symptom of a severe psychological reaction. In despair, the child mourns the loss of the mother. In protest, the toddler is angry, and screams and kicks. Bargaining is not a component of toddler hospitalization reaction.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

441. A child is admitted with marked edema and frothy urine. Lab tests showed proteinuria and decreased serum albumin and globulin. Which is an appropriate diet for this child?
- A. Low protein, high calorie
 - B. High protein, no added salt
 - C. High calorie, low sodium
 - D. High protein, low calorie

The answer is B. Nephrotic syndrome is the idiopathic loss of protein in the urine. With the loss of protein, there is a loss of osmotic pressure and fluid escapes from the vessels into the tissues. Replacement of protein is key to reducing edema. Sodium promotes fluid retention, however low sodium diets are not tasty. In children, low sodium diets are avoided if possible so no added salt would be the right choice.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

442. The mother tells the nurse that her older children have been trading money with her 3-year-old. The older children offer the toddler their pennies for her dimes. The nurse recognizes that the toddler has not developed:
- A. Egocentrism
 - B. Conservation
 - C. Object permanence
 - D. Cognitive dysfunction

The answer is B. Conservation is the ability to deal with a number of different aspects at the same time. At this time, the toddler can only see that the penny is bigger than the dime and cannot understand that the dime has more value. This is a skill learned in the school-age period. Egocentrism is the inability to put themselves in others' place. Object

permanence is the realization that objects exist even when the child cannot see the object.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory Test

Calculates an absolute neutrophil count

443. A client has a white blood cell count of $6000/\text{mm}^3$. The differential reports 47% of these are neutrophils (segs) and 5% are bands. What is the absolute neutrophil count?
- A. 2520
 - B. 2820
 - C. 3120
 - D. 3420

The answer is C. $\text{ANC} = \text{segs} + \text{bands} \times \text{white blood cell count}$. $.47 + .05 = .52 \times 6000 = 3120$.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic tests

444. A pregnant woman at term comes to the labor unit saying her membranes have ruptured. Which characteristic of the client's vaginal secretions would confirm that the membranes had ruptured? The vaginal secretions:
- A. Are positive for glucose
 - B. Contain red blood cells
 - C. Turn nitrazine paper a reddish orange
 - D. Appear fern like under the microscope when dried on a slide.

The answer is D. Amniotic fluid present in the vagina indicates the membranes have ruptured. When dried amniotic fluid is examined under a microscope, a crystalline fern pattern may be observed.

When vaginal secretions are tested with nitrazine paper, the color change would be blue green if the membranes have ruptured as amniotic fluid is alkaline. The presence of glucose gives no indication of the status of the membranes. Red blood cells would be positive even before the membranes ruptures.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to the client and/or family

445. A client is scheduled for a surgical procedure under local anesthesia. Which is an appropriate nursing

intervention when preparing the client for the surgery?

- A. Reassure the client that a nurse will stay with him.
- B. Explain to the client what will be felt, seen, and heard.
- C. Tell the client not to worry as the physician has done it many times before.
- D. Explain what the nurse and the surgeon will be doing during the procedure.

The answer is B. Preparations for any procedure should be in terms of what the client will feel, see and hear.

Choice A does not prepare the patient for what will happen. C is not a reassurance. D explains the procedures in terms of what happens to the nurse and doctor, not the client.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

446. A client is suspected of having renal calculi. Which is the classic assessment finding indicative of this problem?
- A. Oliguria
 - B. RBCs in the urine
 - C. Frothy appearing urine
 - D. Acute severe flank pain on one side

The answer is D. Pain is the chief symptom although blood may be noted especially in bladder calculi. The volume of urine does not change so oliguria is not a symptom. Frothy appearing urine is seen in the individual with albumin in the urine.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

447. An elderly client returned from surgery this am. Since surgery, the client has become increasingly confused. The nurse reviews the client chart and notes the following:
- The biopsy from surgery was positive for cancer.
 - The wound dressing had a small amount of serosanguineous drainage.
 - An NG tube to suction was in place during the first 6 hours post surgery.
 - Meperidine HCL (Demerol) has been given every 4 hours for pain.

Which of these findings could account for the increasing mental confusion?

- A. The biopsy from surgery was positive for cancer.
- B. The wound dressing had a small amount of serosanguinous drainage.

- C. An NG tube to suction was in place during the first 6 hours postsurgery.
- D. Meperidine HCL (Demerol) has been given every 4 hours for pain.

The answer is D. Meperidine is broken down in the body and releases by-products that are difficult for the elderly client to excrete. These by-products build up in the body with repeated doses causing mental confusion. None of the other findings would be associated with mental confusion.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

448. When admitted for labor, the client had been excited and talkative. Now, two hours later, the client appears serious and does not participate in “chit-chat.” How should the nurse interpret this behavior?
- The client is:
- A. worn out from laboring.
 - B. in the active phase of labor.
 - C. dissatisfied with the nursing care.
 - D. displaying concern for the fetus’ well-being.

The answer is B. Clients in early (latent) labor are excited and talkative. As they proceed into active labor, their demeanor becomes serious and they are less talkative. There is no evidence that any other of the statements are true.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Instructs the client on measures to promote health

449. A client is admitted for pneumonia. The nurse instructs the client to change positions every two hours. The client asks the nurse why this is important. The nurse explains that turning:
- A. prevents Atelectasis of the lungs.
 - B. promotes drainage from the lung lobes by gravity.
 - C. changes the portion of the lung that is splinted by the bed.
 - D. keeps uninvolved portions of the lungs from becoming infected.

The answer is C. The bed splints the chest and limits the ability of the lung to expand. Turning changes the portion of the lung that is splinted promoting better oxygenation. The other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

450. A child has just been diagnosed with asthma. The nurse has taught the mother how to “allergy proof” the home. Which statement by the parent indicates a need for additional teaching?
- “I will remove all stuffed toys from my child’s bedroom.”
 - “Out of season clothes will be stored away from my child’s room.”
 - “I will enclose my child’s mattress and box springs with plastic coverings.”
 - “I will put wall-to-wall carpeting in my child’s room to reduce exposure to chemicals.”

The answer is D. Wall to wall carpeting will hold dust and increase allergy exposure. A better option is hard wood floors which can be mopped on a daily basis. The other options are correct.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious disease

451. The client has been diagnosed with syphilis and begins treatment with intramuscular penicillin G. Within 24 hours of this first injection, the client returns to the clinic complaining of joint pain and fever. On assessment, the nurse notes tachycardia and hypotension. How should the nurse interpret these signs and symptoms?
- A worsening of the syphilis
 - An allergic reaction to the penicillin
 - Cellular debris from the destruction of the spirochetes.
 - Anxiety due to the diagnosis of a sexually transmitted disease

The answer is C. The symptoms describe Jarisch-Herxheimer reaction, indication that a large amount of spirochetes have been killed by the penicillin. The client would be treated symptomatically; the penicillin would not be stopped. Symptoms will abate in another 12 hours.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

452. During a well child visit, a mother tells the nurse she will be bringing her toddler to a play group for the first

time and asks what the child’s reaction is likely to be. As part of her response, which type of play does the nurse describe as characteristic of toddlers?

- Solitary
- Cooperatively with several toddlers
- Interactively in groups of no more than 3
- Beside another toddler but not with the other toddler

The answer is C. Parallel play in which a toddler plays beside but not with another toddler is the type of play characteristic of the age group. Infants play alone, called solitary play. Cooperative play is organized and seen in older children. Toddlers do not interact with other children well because of their egocentricity.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

453. A child is admitted to the hospital for Kwashiorkor, protein malnourishment. Which physical finding would be expected on the admission assessment?
- Eczema
 - Edematous
 - Height below normal range
 - Weight below normal range

The answer is B. Protein provides the osmotic property of the blood and without protein, liquid escapes into the tissues. The child may be overweight if there were adequate carbohydrates in the diet.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

454. An adult client is scheduled for a tonsillectomy. Several labs are ordered pre-operatively. Which lab test is most significant prior to this surgery?
- CBC
 - PTT
 - Urinalysis
 - WBC with differential

The answer is B. The surgery includes a significant risk for hemorrhage; so the client’s ability to clot should be carefully evaluated prior to the surgical procedure. CBC is important but not the most important. Urinalysis is usually not significant. WBC with differential probably would be ordered as tonsillectomies are not done when there is infection present.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Infectious diseases

455. Several members of a family have been diagnosed with pinworms. In addition to treating the family with medications, which is an important instruction for the nurse to give the family?
- Cook all meats well.
 - Never go barefoot outside
 - Wash all vegetables before eating
 - Wash all clothes and bed linens in hot soapy water.

The answer is D. Pinworms are spread from person to person and have no dirt cycle. The primary source of contamination is the clothing. Cooking meats reduces the risk tapeworms. Walking barefoot can lead to hookworm. Washing all vegetables reduces the risk of roundworms.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

456. What is the nurse assessing when with the client's eyes closed, the nurse moves the client's toes up or down one by one and asks the client to say in which direction each was moved?
- Two-point discrimination
 - Stereognosis
 - Position sense
 - Light touch

The answer is C. This procedure is a test of position sense.

A, B, and D are incorrect—Two-point discrimination involves touching the skin simultaneously with two sterile needles at closer and closer distances to each other until the client perceives only one touch. Stereognosis is asking the client to identify a familiar object such as a key when it is placed in the client's hand with the client's eyes closed. Light touch is tested by stroking an area of the client's skin with a wisp of cotton.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Administer and document medications given by common routes

457. A 2-year-old client with otitis media is to receive ear drops. To properly administer the ear drops, the nurse pulls the pinna:

- Up and back
- Up and forward
- Down and back
- Down and forward

The answer is C. The pinna of the ear is pulled down and back for children under three and up and back for children over three.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

458. A 1-week-old infant has surgery to repair a cleft lip. Which is the priority concern when the child returns from the recovery room?
- Feeding method
 - Maintaining airway
 - Preventing scarring of the lip
 - Preventing incisional infection

The answer is B. Immediately after surgery, the concern is airway. Because of surgery to the nares and the fact that newborns are obligant nasal breathers, swelling could occlude the nares. Feeding method will be a concern because sucking will interfere with the integrity of the suture line. Preventing scarring and infection are also concerns but not immediately on return to the floor.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/transmission-based/other precautions

459. A client with cancer is being treated with chemotherapy. The client becomes neutropenic. To prevent infection, the nurse implements the following: (select all that apply)
- Place the client in contact isolation
 - Eliminate fresh flowers from the client's room
 - Serve the client only cooked fruits and vegetables
 - Use a soft toothbrush to prevent the gums from bleeding
 - Allow only close family members (spouses and children) to visit

The answers are B and C. Fresh flowers may spread mold. Only cooked vegetables and fruits are allowed to be sure all organisms have been destroyed.

A, D, and E are incorrect—The client will be in protective isolation, not contact. Bleeding gums is thrombocytopenia. Visitors are acceptable as long as they are not

sick. The client will avoid crowds and children who might be infected.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

460. Following an automobile accident, the client is admitted to the hospital unit with a fractured femur. The client is placed in skeletal traction. Which is an appropriate nursing action?
- Restrict fluid
 - Turn side to side every two hours
 - Perform Range of Motion exercises on the affected hip
 - Give sterile pin care using Betadine and sterile dressing

The answer is D. Skeletal traction involves a pin being inserted through the bone as a component of the traction. Since there is a loss of skin integrity at the site of the bone pinning, this site is at risk for infection. Therefore, pin care is an important part of the nursing care.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Parenteral/intravenous therapies

461. The nurse is attempting to start a peripheral intravenous infusion line on a client with small veins. The nurse has made one attempt without success. The nurse states the veins aren't palpable with gloves on. Which action should the nurse take?
- Start the IV line without gloves.
 - Wear a glove on the dominant hand only.
 - Wear two gloves that the pointer finger of one glove has been removed for palpation
 - Locate the vein without gloves and mark the site then put on gloves

The answer is D. For all procedures where blood exposure could occur, gloves are required. Removal of one finger has the same consequence as removing the whole glove and is not acceptable.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

462. The nurse is doing a complete physical assessment on a young child. Which is the most appropriate order of assessment for the nurse to use?
- Heart and lungs sounds first
 - Percussion before auscultation

- Organized in a head to toe manner
- Invasive procedures first to get them over.

The answer is A. Listen to heart and lungs sounds first. Once an infant starts crying, it will be more difficult to hear these.

Auscultation is before percussion. Organized is appropriate but because of the child's developmental stage, it is not head to toe. Invasive should be performed last as children tend to be less cooperative after invasive procedures.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

463. A baby has been diagnosed with developmental dysplasia of the hips and a Pavlik harness is applied. The Pavlik harness is a type of splint that abducts and flexes the hips while still allowing leg movement. The harness can be removed and reapplied by the parents. Instructions to include for the family caring for an infant in this type of harness would include:
- increase fluid intake to promote urine output.
 - keep the harness on the child at least 23 hours a day.
 - take the harness off at night if the baby is uncomfortable.
 - the baby will need a high protein diet to allow hip repair.

The answer is B. When harnesses and splints can be applied and removed by the parents, there is a tendency for parents to remove them if the child complains.

C will result in insufficient treatment. A is not appropriate as this condition is not related to urinary function. D is incorrect as this is not a protein deficiency.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs of acute and chronic mental illness

464. A man brings his mother to the clinic and says she has been diagnosed with Alzheimer's disease but her behavior has changed drastically and he is concerned about what has happened. On obtaining the history, the nurse learns the client had been disoriented in terms of time and place, had loss of memory, and had difficulty with banking, housecleaning and other activities of daily living but has now become agitated and combative; doesn't bathe or groom; and rarely speaks. Which conclusion does the nurse draw from this information?
- The client has entered stage 2 of Alzheimer's disease.
 - The client has passed from stage 2 to stage 3 of Alzheimer's disease.

- C. The client has endstage disease.
- D. The client has a secondary disease process going on.

The answer is B. The client's past symptoms of disorientation, memory loss and difficulty with instrumental activities of daily living are all characteristic of stage 2 Alzheimer's disease. The client's new symptoms of agitation, combativeness, lack of bathing and grooming, and rarely speaking are all symptoms of stage 3 Alzheimer's disease.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

465. During the initial assessment process, a client tells the nurse that he is lactose intolerant. When the nurse questions the client about the lactose intolerance, the nurse would expect the client to describe symptoms including (select all that apply).
- A. ___ Rashes
 - B. ___ Flatus
 - C. ___ Constipation
 - D. ___ Black furry tongue
 - E. ___ Abdominal cramping

The answers are B and E. In addition to these symptoms, the other major symptom is diarrhea which can be explosive. Rashes are associated with allergic responses, not lactose intolerance. Black furry tongue is usually do to the overgrowth of organisms not susceptible to antibiotics and not associated with lactose intolerance.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications

Implement procedures to counteract adverse effects of medications and parenteral therapy

466. A cancer client is receiving chemotherapy known to cause stomatitis. Which nursing action would be appropriate in an effort to reduce or prevent the development of stomatitis?
- A. Ask the physician for a prophylactic antibiotic
 - B. Provide a firm toothbrush to enhance oral cleaning
 - C. Encourage the use of mouthwash containing alcohol
 - D. Instruct the client to rinse their mouth with water every two hours

The answer is D. Research has shown that simply rinsing the mouth with water on a frequent basis can reduce stomatitis in chemotherapy clients. A firm toothbrush could damage the oral mucous membranes. Alcohol is drying and would damage the mucous membranes. Antibiotics would be inappropriate.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

467. Which type of precautions would be used when caring for a client with *C. difficile*?
- A. Standard precautions
 - B. Airborne precautions
 - C. Droplet precautions
 - D. Contact precautions

The answer is D. Contact precautions are used when organisms causing serious disease are easily transmitted through direct contact. This includes all multidrug resistant strains of organisms such as *C. difficile*, shigella, and impetigo. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required.

A is incorrect—Standard precautions are used to decrease the risk of transmission from bloodborne pathogens and moist body substances. Moist body substances include blood, urine, feces, sputum, saliva, wound drainage, and all aspirated fluids. B is incorrect—Airborne precautions are used when the mode of spread of an organism is by small particle droplets borne on air currents. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn. C is incorrect—Droplet precautions are used when the mechanism of transmission is by large droplets spread by coughing, sneezing, or talking. Droplet precautions require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of client pathophysiology to illness management

468. A client presents to the emergency room in sickle cell crisis. The priority nursing intervention for this client to break the sickling cycle would be to:
- A. administer oxygen as ordered.
 - B. teach sources of iron and folic acid in the diet.
 - C. draw blood for a hemoglobin and hematocrit value.
 - D. explain to the client the need to seek treatment as soon as a crisis begins.

The answer is A. The crisis is caused by a decrease in oxygen in the blood. Activities designed to reduce sickling would include administration of oxygen, fluids including intravenous fluids, promoting rest and providing pain relief.

All other activities would be inappropriate to break the sickling cycle.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

469. A pregnant woman is in early labor. After performing Leopold's maneuvers, the nurse determines that the infant is probably a right occiput posterior presentation. Where would the nurse check fetal heart tones?
- Through the mother's back.
 - At the umbilicus on the left side.
 - Below the umbilicus on the right side.
 - Above the umbilicus on the right side.

The answer is C. The infant would be a vertex presentation on the right side making the fetal heart tones heard best below the umbilicus on the right. FHTs are never assessed through the maternal back. FHTs heard at the umbilicus are due to a transverse lie. Breech presentations put the FHTs above the umbilicus.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk potential

Diagnostic tests

470. The client's history indicates several allergic diseases including eczema and asthma as a child and hay fever as an adult. Which laboratory findings support this history?
- Moderate anemia
 - Elevated eosinophil count
 - Elevated C reactive protein
 - Alkaline Phosphatase decreased

The answer is B. Eosinophils are a type of WBC and are elevated in persons with allergies and worm infestations. The other responses are not related to allergic reactions.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapy

Medication Administration

Educate client/family about medications

471. A client was admitted to the burn unit after suffering extensive partial and full thickness burns in a house

fire. At 24 hours postadmission, the physician orders albumin for the client. The family asks why the client is receiving albumin. The nurse's response would be based on the knowledge that albumin is a:

- blood product that will help restore circulating RBCs.
- hypertonic solution that will help restore plasma volume.
- source of clotting factors that will control wound bleeding.
- source of antibodies to help the client fight infection secondary to the loss of skin.

The answer is B. Following a burn injury, the blood vessels become permeable and fluid and protein is lost into the tissues. Administering a hypertonic solution will cause the fluid to return from the tissues and maintain circulating volume. Although albumin is a blood product, it does not contain red blood cells. Wound bleeding is not a problem this late in the injury. Albumin is not given to fight infection.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

472. Which is a priority nursing intervention for a client with paranoid personality disorder?
- Encourage acceptance of intensive therapy.
 - Eliminate bizarre fantasies.
 - Promote social relationships
 - Minimize potential for aggression

The answer is D. Clients with a paranoid personality disorder is suspicious and hypervigilant with irritable, agitated moods. They can interpret all behavior as threatening and react in an aggressive manner. Therefore minimizing the potential for aggressive behavior is a priority nursing intervention. Clients with paranoid personality disorders are not good candidates for intensive therapy, especially group therapy, because it can heighten their suspiciousness and escalate the risk of aggressive response. Promotion of social relationships is a priority intervention for clients with schizoid personality disorder. Bizarre fantasies are characteristic of schizotypal personality disorder.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk potential

Laboratory values

473. A preterm infant has significant respiratory distress due to the immaturity of the lungs. When arterial blood gases results are received, the nurse would expect to see which abnormality?
- Respiratory alkalosis

- B. The pH is lower than normal
- C. The oxygen saturation is 94%
- D. The carbon dioxide pressure (PCO₂) is normal.

The answer is B. A lower pH is acidosis and an infant breathing poorly would have respiratory acidosis. An oxygen saturation of 94% is normal. The carbon dioxide pressure would not be normal.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

474. A client had polio as a child and now wears a leg brace. A pressure sore has formed under the leg brace. Instructions for this client should include:
- A. wear the brace only 6 hours per day.
 - B. do not wear the brace until the skin has healed.
 - C. apply a dressing over the sore to protect it from the brace.
 - D. cover the wound with petroleum prior to putting on the brace.

The answer is B. The brace should not be worn until the sore is healed as the brace is the most likely cause of the injury.

Wearing the brace 6 hours a day will further damage the skin. A dressing under a brace that is already rubbing on the skin will only make the pressure sore worse. Petroleum will not protect this wound if the brace is worn.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Uses therapeutic communications skills in providing care to the client

475. A 36-year-old woman has had a hysterectomy for fibroid disease. Prior to surgery, the woman stated her family was complete and she would be glad to not have to deal with her periods anymore. Two days after surgery, the nurse finds the woman crying. Which would be an appropriate response by the nurse?
- A. "I know what you are going through, I was upset after my hysterectomy too."
 - B. "You shouldn't cry. Just think, no more periods, no more cramps, no more birth control."
 - C. "I know that you thought you wouldn't be sad about the hysterectomy but it still bothers you, doesn't it?"
 - D. "Other clients have told me that they were surprised about their feelings of loss even though they didn't want more children. Is that what you are feeling?"

The answer is D. This statement allows the client to recognize her feelings are common and seeks verification on the cause of the sadness.

A is incorrect—Usually it is best to avoid personal experiences when talking to clients about their feelings. Option B denies the validity of the client's sadness. Option C seeks clarification but does not let the client know that her feelings are common.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Provide client/family/significant others with information on TPN

476. When the family notices that the Total Parenteral Nutrition the surgical client is receiving contains insulin, they question the nurse about why insulin has been added to the bag. The nurse explains that the client:
- A. is a diabetic and needs the exogenous insulin.
 - B. is underweight and the insulin will help with weight gain.
 - C. is a pseudodiabetic due to the sugar content of the solution.
 - D. needs the insulin because of ileus secondary to the surgical procedure.

The answer is C. TPN has a very high sugar content which stresses the client's pancreas. There is no evidence the client is diabetic or is underweight. Ileus does not affect the pancreas.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform comprehensive health assessment

477. Which cranial nerve is the nurse assessing when the nurse the client's blink reflex is checked?
- A. One (olfactory)
 - B. Five (trigeminal)
 - C. Seven (facial)
 - D. Eleven (spinal accessory)

The answer is B. The motor component of cranial nerve five (trigeminal nerve) controls the blink reflex, which is tested by bringing a wisp of cotton in from the side to touch the cornea of each eye.

A is incorrect—Cranial nerve one (olfactory nerve) is responsible for the sense of smell. It is tested by occluding

each of the client's nostrils one at a time, holding a substance such as coffee or vanilla with a familiar aroma under the other nostril, and asking the client to identify the smell. The test is repeated with a different aromatic substance to determine if the client can differentiate smells.

C is incorrect—Cranial nerve seven (facial nerve) is responsible for taste on the front two thirds of the tongue and for movement of the face including the ability to close the eyes and move the lips for speech. Motor function of cranial nerve seven is tested by asking the client to smile, frown, grimace, show the upper and lower teeth, keep the eyes closed, while the examiner tries to open them and puff out the cheeks. The examiner observes for symmetry and movement and presses the puffed out cheeks in to check if air is expelled equally from both sides. To test taste, an applicator dipped in a sugar, salt, or lemon solution is placed on the tongue and the client is asked what is tasted.

D is incorrect—Cranial nerve eleven (spinal accessory) is tested by asking the client to shrug the shoulders and resist pressure to put them down because this cranial nerve controls muscular strength of the trapezius and sternocleidomastoid muscles.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

478. A client has been admitted with a possible bowel obstruction. The nurse completes a head to toe assessment. Which finding should the nurse interpret as inconsistent with a bowel obstruction?
- Vital signs normal
 - Vomitus has a fecal odor
 - Complains of colicky pain
 - Loud rumbling bowel sounds

The answer is D. Bowel sounds in early obstruction are often high pitched and tinkling above the obstruction. Bowel sounds will be absent in late obstruction. Vital signs may remain within the normal range in early obstruction and progress to shock as the obstruction continues. The pain is often colicky and the vomitus may have a fecal odor.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

479. A client's care giver is performing tracheostomy care. Which action by the care giver would the nurse correct? The care giver

- Used half strength hydrogen peroxide to clean the inner cannula.
- Held the tracheostomy tube in place while changing the ties.
- Rinsed the inner cannula with sterile normal saline after cleaning.
- Used commercial tracheostomy dressing material to eliminate the need for cutting gauze

The answer is C. To prevent accidental decannulation, the soiled ties are not removed until the new ties have been put in place. Half strength hydrogen peroxide is used to clean the inner cannula and sterile saline is used to rinse it. Commercial tracheostomy dressings may be used for ease of application if desired.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/transmission-based/other precautions

480. A pregnant woman at term has an outbreak of genital herpes. She asks the nurse how this will affect her labor and delivery. Which response would be correct?
- "You will probably have a cesarean delivery."
 - "The baby will require antibiotics after delivery."
 - "You will be placed on antibiotics when you go into labor."
 - "You will need antibiotics in the postpartum period to prevent a uterine infection."

The answer is A. With an outbreak of genital herpes, the baby is usually delivered by cesarean section to decrease the infant exposure. Herpes is a virus; so antibiotics will not be effective against this organism.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alteration in body systems

481. A child has been diagnosed with Wilms Tumor. Prior to surgery, a sign is placed over the child's bed that states: "Do Not Palpate Abdomen." The mother asks why that sign was placed over the bed. The nurse's response will be based on the knowledge that palpating the abdomen:
- would be painful for the child.
 - can increase the child's anxiety.
 - may affect the blood supply to the kidney.
 - could release cancer cells that will migrate to other areas.

The answer is D. Wilms Tumor is encapsulated until relatively late in the disease. Palpating the abdomen may cause a seeding of tumor cells to other tissues by way of the blood and should be avoided except as absolutely necessary for diagnosis. Palpating the abdomen is not usually painful and should not cause anxiety. The blood supply to the kidney will not be affected except through cancer cell seeding.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Identify signs and symptoms of client fluid and/or electrolyte balance

482. A child is admitted to the hospital unit for gastroenteritis and dehydration. Which laboratory values does the nurse interpret as indicative of dehydration? Select all that apply.
- A. ___ Elevated WBC
 - B. ___ Elevated Hemoglobin
 - C. ___ Elevated Hematocrit
 - D. ___ Decreased urine-specific gravity.
 - E. ___ Elevated lymphocytes in the WBC differential

The answers are B and C. Both hemoglobin and hematocrit are comparisons of solids to liquids. If the amount of solids stays constant but the volume decreases, the Hgb and Hct would be elevated. Elevated WBC indicates infection, while the elevated lymphocytes indicate a viral infection. A decreased urine-specific gravity would be a more dilute urine and not associated with dehydration.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

483. A client is 12 weeks pregnant. During her regular prenatal visit, the following findings are noted:
- Leukorrhea is present
 - Complains of urinary frequency
 - Uterus is lower in the pelvis than 12 weeks gestation
 - Has symptoms of PIH (pregnancy induce hypertension)
- Which finding is suggestive of a hydatiform mole?
- A. Leukorrhea is present
 - B. Complains of urinary frequency
 - C. Uterus is lower in the pelvis than 12 weeks gestation
 - D. Has symptoms of PIH (pregnancy induced hypertension)

The answer is D. PIH is rare in the first trimester except in the case of a hydatiform mole. Urinary frequency and leucorrhoea are normal in pregnancy. In molar pregnancies, the uterus is larger than anticipated.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

484. A client has been diagnosed with pre-invasive cervical cancer. When assessing the client, what type of symptomatology would the nurse expect?
- A. Pain
 - B. Anorexia
 - C. Bleeding
 - D. None

The answer is D. There are usually no symptoms of preinvasive cervical cancer.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications and side effects implementation procedures to counteract adverse effects of medications and parenteral therapy

485. A toddler is seen in the emergency room after taking a number of codeine tablets belonging to a grandparent. Which antidote does the nurse expect the child to receive?
- A. Glucagon
 - B. Naloxone
 - C. Vitamin K
 - D. Sodium Bicarbonate

The answer is B. Naloxone (narcan) is an antidote for narcotics such as codeine.

The other answers are incorrect.

SAFE AND EFFECTIVE ENVIRONMENT

Management of Care

Establishing Priorities

Apply knowledge of pathophysiology when establishing priorities for interventions with multiple clients

486. A nurse on the postpartum unit receives report on his or her assigned clients. Which client should the nurse assess first?
- A. Primipara with problems breastfeeding.
 - B. Fresh delivery complaining of severe perineal pain.

- C. Multipara, 48 hours postpartum, with elevated blood pressure.
- D. Client who received spinal anesthesia for delivery and is complaining of a headache.

The answer is B. The severe perineal pain could be a labial hematoma. The other clients present no immediate concern.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Applies knowledge of bloodborne pathogens to the care of the client

487. A nurse has been diagnosed with hepatitis C. The source of the hepatitis C is not known. Which factor may have contributed to the nurse becoming infected?
- A. Having a tattoo
 - B. Used oral street drugs during the teen years.
 - C. Failure to complete the Hepatitis Vaccine Series
 - D. Frequently eats vegetables straight from the garden

The answer is A. There is a major concern that tattoos may be a source of the hepatitis C if the tattoo artist does not use new or properly sterilized needles.

Oral drugs would not be a source of hepatitis C, injectibles would be. The hepatitis vaccine series protects against hepatitis B. It offers no protection for hepatitis C. Hepatitis C is a bloodborne pathogen. Hepatitis A comes from contaminated food and water.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total parenteral nutrition

488. A client is receiving total parenteral nutrition. In recognition of a common complication of TPN, the nurse will monitor the client for:
- A. Dehydration
 - B. Renal failure
 - C. Cerebral edema
 - D. Pulmonary hypertension

The answer is A. TPN is a hypertonic solution which can lead to diuresis. The other complications are not associated with TPN.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

489. Which behaviors exhibited by a client alert the nurse to the need to take measures to protect self and others against an aggressive outburst? Mark all that apply.

- A. ___ fist clenching
- B. ___ finger snapping
- C. ___ foot tapping
- D. ___ pacing
- E. ___ shouting
- F. ___ glaring

The answers are A, D, E, and F. Fist clenching, pacing, shouting, glaring along with jaw clenching are all common signs of markedly increased agitation and indicate that the risk of aggressive behavior is real and immediate. Foot tapping and finger snapping often occur unrelated to risk of aggression and if related generally indicate a lower level of agitation.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Palliative/Comfort Care

Assess, intervene, and educate client/family/significant others about pain management

490. A client had a vulvectomy yesterday. On initial assessment, the nurse notes the client is dosing while sitting up in bed in Fowler's position. When she awakens, the client states she is uncomfortable. Which is the priority nursing action?
- A. Call the physician
 - B. Change the client's position to Semi-Fowler's.
 - C. Give more pain medication
 - D. Explain it is normal to be uncomfortable after a surgical procedure

The answer is B. Lowering the head of the bed will reduce the pressure and tension on the incision and reduce the client's pain.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptability

Illness Management

Apply knowledge of client pathology to illness management

491. A newborn has been transferred to the pediatric hospital from the birth hospital with a large myelomeningocele. On admission to the pediatric hospital, in which position will the nurse place the infant?
- A. Prone
 - B. Supine
 - C. In semi-Fowler's
 - D. In trendelenburg

The answer is A. The myelomeningocele is extremely fragile prior to surgical removal. The infant is positioned prone to

prevent pressure on the sac. The other responses are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

492. The home economics class in a high school has a class on pregnancy as part of the family life curriculum. A nurse has been asked to present information about pregnancy to the class. The nurse tells the students that smoking during pregnancy can have a negative effect on the fetus. The nurse explains that mothers who smoke often give birth to:
- diabetic infants.
 - low birth weight infants.
 - large for gestational age babies.
 - infants who grow up to be smokers.

The answer is B. Miscarriages, preterm birth, and low birth rate babies are associated with smoking during pregnancy. It is not associated with diabetic infants or large for gestational age babies. Seeing a parent smoke can be an influencing factor in the children smoking but the mother smoking during pregnancy does not encourage smoking by the infant when he or she grows up.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

493. An 18-month-old child has returned from cleft palate repair. The postoperative physician's orders include full liquid diet. Which would be the best feeding method for this child?
- Cup
 - Straw
 - Spoon
 - Baby bottle

The answer is C. Anything that can be made into a liquid could be fed to the child. Drinking from a cup will prevent injury to the palate. Nothing rigid should be allowed in the mouth that could damage the palate repair. Sucking on a bottle or straw would also be inappropriate.

PSYCHOSOCIAL INTEGRITY

Coping Mechanisms

494. When the new baby comes home from the hospital, the older sibling, a toddler, begins wetting himself.

The mother calls the clinic nurse to ask what is happening as the toddler was toilet trained over a year ago. Which is the most likely explanation for this problem? The client:

- May need more oral fluids.
- Has a urinary tract infection.
- Has regressed due to the stress of the new baby.
- Is mad at the mother for bringing home a new baby.

The answer is C. Regression is common when a child is psychologically stressed. There is no evidence of a need for increased fluids or a urinary tract infection. Even a toddler that is excited about a new sibling will feel stress when the family dynamics change.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

495. Which statement made by a client with COPD after being taught about the use of pursed lip breathing indicates the need for additional instruction?
- "I will make sure to puff my cheeks out when I breathe out through my mouth."
 - "I will set my lips for breathing out like I am going to whistle."
 - "Breathing out should take me twice as long as breathing in."
 - "I will never hold my breath when trying to lift something heavy."

The answer is A. Exhalation should be slow through pursed lips taking care not to let the cheeks puff out. All other statements accurately reflect instructions related to pursed lip breathing. Lips are set as if to whistle. Exhalation should be twice as long as inhalation. Pursed lip breathing should be used during any strenuous physical activity and the client should inhale before exerting and exhale during the activity. The breath should never be held.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

496. The nurse has completed client teaching on activities to reduce the recurrence of kidney stones. Which statement by a client indicates the need for additional teaching?
- "I need to increase my intake of dried fruits and milk products."

- B. "I should increase my intake of liquids to at least 2–3 liters per day."
- C. "It is important that I drink extra water at bedtime to keep my urine dilute during the night."
- D. "Cranberries, eggs and meats may help acidify my urine to reduce my kidney stones."

The answer is A. Dried fruits and milk products are high in calcium which is often associated with renal calculi so should be avoided. This statement indicates the need for additional teaching. Fluid intake, especially at night and acidifying the urine are all associated with reduced episodes of renal calculi.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

497. Four days postoperatively, a client is noted to have thick yellow drainage on the operative dressing. The nurse would document this drainage as:
- A. serous
 - B. purulent
 - C. sanguineous
 - D. serosanguineous

The answer is B. This drainage is purulent containing dead organisms and white blood cells. Serous is clear and watery; sanguineous is bloody; serosanguineous is pale, more watery but blood streaked.

HEALTH PROMOTION AND MAINTENANCE

Self-Care

498. Following a automobile accident, a client is treated for a head injury in the emergency room. After 12 hours of observation, the client is discharged. Which information should be given to the client/family in preparation for discharge?
- A. Narcotic analgesics may be taken for headache
 - B. Memory of the car accident should return within the next 12 hours.
 - C. Vomiting may be a symptom of worsening neurologic status
 - D. The physician should be notified if the client is sleepy but easily aroused.

The answer is C. Vomiting could be a symptom of increased intracranial pressure. Narcotics would be avoided as they may mask increasing neurologic symptoms. Amnesia is com-

mon for the events surrounding the head injury. As long as the client is easily aroused, sleepiness is not a concern.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Vital signs

499. When delegating blood pressure measurement to an unlicensed assistant, the nurse cautions that correct technique must be used to avoid obtaining falsely high pressures. Which is one of the directions the nurse would give to prevent a falsely high pressure reading?
- A. Take the blood pressure on an extremity positioned below heart level.
 - B. Use a cuff whose width is at least 60% of the diameter of the extremity.
 - C. If you have to inflate the cuff a second time, be sure to wait 1–2 minutes.
 - D. Apply the cuff loosely to the extremity.

The answer is C. Reinflating the cuff without a 1–2 minutes interval between inflations can result in a falsely high blood pressure reading. Therefore waiting the 1–2 minutes between inflations helps prevent a falsely high reading. Taking the blood pressure on an extremity positioned below heart level can result in a falsely low reading; the extremity needs to be supported and at heart level. The width of the cuff should be 40% of the diameter of the arm so a cuff that is at least 60% the diameter is too wide. Use of a cuff that is too wide can cause a falsely low blood pressure reading not a falsely high one. If the cuff is wrapped too loosely around the extremity the result can be a falsely high pressure reading so loose wrapping does not prevent a falsely high reading.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total parenteral nutrition

500. A client is receiving TPN. The bag of TPN arrives on the hospital unit with an ampule of multi-vitamins for the nurse to add. A new staff nurse asks why the pharmacy didn't add the vitamins before sending the bag to the floor. The experienced nurse will explain that:
- A. The client may be allergic to the vitamins.
 - B. The vitamins are infused in the first 100 ml of the TPN bag.
 - C. The physician may change the order and leave out the vitamins.
 - D. Vitamins must be infused within 24 hours of being added to the bag.

The answer is D. The vitamins are stable only for 24 hours after being added to the TPN bag. The other responses are incorrect.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

501. Which type of precautions would be used when caring for a client with tuberculosis?
- Standard precautions
 - Airborne precautions
 - Droplet precautions
 - Contact precautions

The answer is B. Airborne precautions are used when the mode of spread of an organism is by small particle droplets borne on air currents and tuberculosis is spread by this route. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn.

A is incorrect—Standard precautions are used to decrease the risk of transmission from bloodborne pathogens and moist body substances. Moist body substances include blood, urine, feces, sputum, saliva, wound drainage, and all aspirated fluids. C is incorrect—Droplet precautions are used when the mechanism of transmission is by large droplets spread by coughing, sneezing, or talking. Droplet precautions require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room. D is incorrect—Contact precautions are used when organisms causing serious disease are easily transmitted through direct contact. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required.

PHYSIOLOGICAL INTEGRITY

Reduction in Risk Potential

Vital signs

502. A decrease in blood pressure of ____ mm Hg or more between the pressure taken after the client has been supine for 3 minutes and the pressure taken after the client arises and stands for a minute is indicative of orthostatic hypotension.

Answer is 30 mm Hg.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

503. A wet to dry dressing has been ordered for an ulcer on the leg. Which is a step in the correct procedure for changing the dressing?
- Remove the soiled dressing dry.
 - Apply the new dressing that has been wet with tap water.
 - Moisten the soiled dressing with sterile water prior to removal.
 - Moisten the soiled dressing with normal saline prior to removal.

The answer is A. A wet to dry dressing starts with sterile dressing wet with sterile water, sterile saline, or other prescribed liquid, placed over the wound and allowed to dry. Once dry, the soiled dressing is removed, taking with the dressing the adherent debris.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

504. A newborn is admitted to the nursery with a history of maternal diabetes that was poorly controlled during the pregnancy. The newborn's admission weight is over 9 pounds. The initial blood glucose level is within normal limits. Which is the priority nursing intervention for this infant?
- Initiate formula feedings.
 - Encourage parental bonding.
 - Avoid blood draws which could contribute to anemia.
 - Monitor the temperature because the infant is macrosomic.

The answer is A. Although the infant's blood glucose is normal now, the levels are expected to drop in the next two to three hours. Feeding protein foods (formula) will maintain blood glucose better than glucose water.

B, C, and D are incorrect—Parenteral bonding is not the priority intervention. Blood draws will be necessary to monitor glucose levels. The infant's temperature will need to be monitored but it is not the priority.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

505. The evening nurse is assessing a client who had a modified mastectomy earlier that morning. Which is a

fact that must be considered when planning nursing care?

- A. The client will be depressed and asking for medication frequently
- B. Blood pressures should not be performed on the arm of the operative side
- C. The client will need to hold off doing arm exercises for 10 days
- D. The client should not elevate involved extremity

The answer is B. Blood pressures should not be performed on the arm on the operative side to prevent venous congestion in the affected extremity. The other responses are incorrect.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of impaired cognition

506. A client with schizophrenia says “cat tree swim house sick jump pretty” when the nurse asks how he is feeling this morning. Which would be a correct label for the nurse to use when documenting this communication?
- A. word salad
 - B. clang association
 - C. neologism
 - D. verbigeration

The answer is A. Word salad refers to the meaningless connection of words and phrases. Clang association refers to repeating words and phrases which sound alike but are otherwise unconnected. A neologism is a new word coined by the client and with meaning only to the client. Verbigeration is the purposeless repetition of words or phrases.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Evaluate and document client response to medication

507. A client on the burn unit is receiving IV albumin. Which parameter will the nurse monitor to determine the effectiveness of this treatment?
- A. Weight
 - B. Pain
 - C. Wound healing
 - D. Hematocrit

The answer is A. With a burn injury, the integrity of the vessels is lost and fluid escapes into the tissues. Albumin is a

hypertonic solution which draws fluids from the tissues to the plasma from where the kidneys can excrete it. Weight loss indicates fluid loss in this manner.

Albumin will not affect pain sensation. Albumin contains antibodies but does not promote wound healing directly and is not the reason for administering it. Albumin contains no red blood cells.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Teach client about managing illness

508. The nurse is working with the parents of a child newly diagnosed with hemophilia. Which topics should be included in teaching about home care of the child?
- A. Providing extra iron in the child's diet
 - B. Oral administration of the missing factor
 - C. Avoiding sports activities as the child grows
 - D. Avoiding the use of aspirin for temperature elevations

The answer is D. Use of aspirin would decrease the clotting ability of the child's blood. The child does not need extra iron as the child is able to produce ample red blood cells. Factor is administered intravenously. The child would not avoid all sports. The nurse would provide guidance about sporting activities that would not put the child at risk for injury.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

509. A child is in for a routine immunization. The child has recently received the following medications:
- insulin
 - antibiotic
 - antihistamine
 - immunoglobulins (IVIG)
- Which would interfere with the effectiveness of the vaccination?
- A. insulin
 - B. antibiotic
 - C. antihistamine
 - D. immunoglobulins (IVIG)

The answer is D. Immunoglobulins are antibodies. An immunization is an antigen designed to stimulate immunoglobulin production. If the immunoglobulins are already present, the antigen will be destroyed before antibodies are produced. The other responses would not have a significant effect on vaccination.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/immobility

Maintain client skin integrity

510. At what interval should an elderly client be instructed to change position when up in her wheelchair during the day?
- Two (2) hours
 - One (1) hour
 - Thirty (30) minutes
 - Fifteen (15) minutes

The answer is A. Frequent shifts of body weight are needed to maintain circulation and decrease the risk of a pressure ulcer. Repositioning is required every 2 hours.

A, B, and C are incorrect because more frequent body shifts while in a chair have been shown to be ineffective.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

511. A client has had a cesarean section. The client complains of postoperative discomfort due to abdominal distention. Which suggestion would reduce the client's discomfort?
- Walk to promote peristalsis
 - Chew ice to facilitate peristalsis
 - Lay flat in bed as much as possible
 - Drink through a straw instead of sipping from a cup.

The answer is A. Walking promotes peristalsis. Drinking through a straw and chewing ice increases the amount of air the client swallows increasing the abdominal distention. Laying flat is not an appropriate intervention for abdominal distention.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and blood products

512. A hospitalized client receives a transfusion of whole blood. The client suddenly develops chest pain, fever and chills. The nurse suspects a hemolytic transfusion reaction. Which is the priority nursing intervention?
- Notify the physician.
 - Flush the line with D₅NS.
 - Stop the infusion and maintain the IV line with normal saline.
 - Give the client the Benadryl (diphenhydramine) available as a prn order.

The answer is C. Hemolytic transfusion reactions are caused by a reaction from antibodies in the recipient blood reacting to the donor's blood protein. This can lead to serious consequences and may be fatal. Stopping the infusion is critical to reduce the source of the reaction. It is essential that the IV line be kept open for emergency access. The physician needs to be notified but it is not the priority action. Flushing the line with dextrose will cause the blood to clot. This is not an allergic reaction so Benadryl will not resolve the problem.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

513. A pregnant woman, whom the nurse notes has lordosis, asks why she has had bad back pain. Which factor explains the development of the lordosis and back pain and should serve as the basis of the nurse's response to the client's question?
- Maternal hormones
 - The shifting center of gravity
 - The loosening of the pelvic structure.
 - Stasis of blood in the lower extremities

The answer is B. With the weight of the fetus shifting the center of gravity, the pregnant woman will develop lordosis and back pain.

Maternal hormones are present but not the cause of the back pain. The loosening pelvic structures affect the pregnant woman's balance and walk, not back pain. The pressure of the uterus will cause stasis of blood in the lower extremities but not back pain.

PHYSIOLOGICAL INTEGRITY

Physiologic Adaptation

Illness Management

Teach client about managing illness

514. Which actions might the nurse discuss with a client with multiple sclerosis who has recently had a number of exacerbations of the disease? (Select all that apply.)
- Joining a support group
 - Avoiding the use of hot tubs.
 - Preventing pregnancy
 - Limiting fluid intake to 1250 ml per day
 - Requesting a job transfer to a less stressful situation

The answers are A, B, and E. Support groups help support emotional coping mechanisms. The MS client is encouraged to avoid heat and cold situations as they have been implicated in exacerbations. A job transfer may allow the client to

continue working. Pregnancy in general does not seem to affect the overall outcome of MS. Fluid intake is important to maintain body function and should not be limited.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

515. A client with thrombocytopenia, secondary to leukemia, has developed epistaxis. Which instruction should the nurse give the client?
- Lie supine with the neck extended
 - Sit upright, leaning slightly forward and apply heat.
 - Blow the nose and then put lateral pressure on the nose
 - Hold the nose while bending forward at the waist

The answer is D. This response provides pressure to halt the bleeding while preventing the blood from draining into the lungs. The other answers are incorrect. A would promote blood entering the respiratory system. Heat would increase bleeding. Blowing the nose will remove any clots which have formed and should be discouraged.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of acute and chronic mental illness

516. Which type of personality disorder does the nurse suspect when the client's history indicates an apparent lack of concern with others' opinions, a "loner", unfocused lifestyle without close friends, and a cold, aloof persona?
- paranoid
 - schizoid
 - antisocial
 - borderline

The answer is B. Clients with schizoid personality disorder are detached from social relationships and demonstrate little emotional expression with other people. There appears to be no pleasure derived from interaction with other people. These individuals prefer solitary activities and can perform well when left alone.

Clients with paranoid personality disorder are suspicious of others believing that others are trying to exploit, deceive or harm them. They question the loyalty and trustworthiness of others; read hidden meanings into events; and bear grudges.

Clients with antisocial personality disorder are impulsive, risk takers who do not learn from experience, exploit others and ignore their rights; and lack guilt, honesty, fidelity and loyalty.

Clients with borderline personality disorder have a poor and unstable self image; are unable to maintain stable relationships; fear abandonment; engage in impulsive activities that are damaging to self such as substance abuse, binge eating and reckless sexual activity; repeatedly threaten or engage in self mutilating or suicidal behavior; experience a chronic sense of emptiness; and manifest inappropriate, intense, uncontrolled anger.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Monitor client for side/adverse effects of TPN

517. A client is receiving Total Parenteral Nutrition (TPN). Which is a common complication of TPN for which the nurse must monitor?
- Phlebitis
 - Hypoglycemia
 - Electrolyte Imbalance
 - Fluid Volume Deficiency

The answer is D. The hypertonic fluid draws water from the tissues and can lead to fluid volume deficit. Hyperglycemia may be a problem, not hypoglycemia. The physician writes TPN orders based on the client's electrolyte balance TPN is always administered by central line so phlebitis would be a minimal risk.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Intervene to prevent potential neurological complications

518. A client has been casted for a fractured radius. The cast extends from the hand to above the elbow. The client complains of constant pain under the cast. The nurse completes a neurovascular check and notes swelling of the hand and loss of sensation to the little finger. Which is the priority nursing intervention?
- Elevate the arm
 - Notify the physician
 - Administer pain medication
 - Reassure the client that these are common findings.

The answer is B. The client is demonstrating diminished circulation secondary to the cast which can lead to compartment syndrome. The cast may need bivalving. Elevating the arm is appropriate to reduce swelling but it is not the priority action at this time. Pain management may be appropriate but not the priority. These sensations are not normal but symptoms of compartment syndrome from a cast that is too tight.

PSYCHOSOCIAL INTEGRITY

Cultural Diversity

519. An ultra-orthodox Jewish client is 1 day postpartum. It is the Sabbath for this client. The client calls to the nurse and asks help in changing her peripad. The client asks the nurse to open the pad's packaging for her as this is considered work in her culture and not allowed on the Sabbath. Which is an appropriate nursing response?
- Ask the client if a family member couldn't open the package for her.
 - Open several pads and leave them covered so that the client can use them as needed.
 - Assign a male nurse to the client as she wouldn't ask him to open her peri packages.
 - Tell the client that opening a peri pad package is not work and encourage her to do it for herself.

The answer is B. By opening several packages and leaving them within her reach, she will be able to perform self care without deviating from her religious beliefs.

The client's family would probably be of the same culture and therefore would not be willing to perform this task. A male nurse would make the ultraorthodox Jewish woman uncomfortable and not be culturally sensitive. Telling the client that this is not work does not consider her beliefs and feelings at all.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

520. The clinic is running short of RSV Immune Globulin (the immunization for respiratory syncytival virus). Which child should have priority in receiving the vaccine?
- The 8-year-old with cystic fibrosis.
 - The teenager who is sexually active.
 - The 5-year-old with failure to thrive.
 - The 6-month-old premie with a history of bronchial pulmonary dysplasia.

The answer is D. RSV is primarily a disease of infancy so preference would be given to children under 2 years of age.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Implement procedures to counteract adverse effects of medications

521. A client with leukemia is scheduled to get chemotherapy which includes vincristine. Which nursing action is appropriate?
- Insert the intravenous line in a vein in a joint area.
 - Ensure that the intravenous is administered per pump.
 - Administer the medication in a free flowing intravenous line.
 - Always use an intravenous line that has been in place for several days.

The answer is C. Because it is so irritating to tissues, it is critical that extravasation of vincristine into tissue be prevented. A free flowing line means that the line is most likely in the vein. A pump will continue to pump IV fluids even after the line has extravasated. A fresh line is best to ensure its integrity and the joint areas should be avoided.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Rest and sleep

522. A client informs the nurse that he is "unable to fall asleep at night and tends to walk around until he gets sleepy." Which suggestion can the nurse make to help the client to develop better sleep habits?
- Have an alcoholic drink prior to bedtime
 - Exercise when unable to sleep
 - Increase fluid intake prior to bedtime to maintain hydration
 - Avoid stressful situations prior to bedtime
 - Wear loose clothing to bed
 - Avoid caffeinated beverages before bedtime

The answers are D, E, and F. Stress will deter the client from falling asleep so avoiding stressful situations prior to bedtime will promote sleep. Wearing loose clothing to bed and avoiding caffeinated beverages before bedtime will also facilitate sleep.

Alcohol, exercise, and increasing fluid intake before bed all interfere with sleep.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

523. Which comment made by a teenager who is attending a health class on pregnancy indicates the need for clarification of information?

- A. “I didn’t realize that smoking during pregnancy could cause a miscarriage.”
- B. “I didn’t realize that smoking during pregnancy could cause the baby to have high blood pressure as an adult.”
- C. “I didn’t realize that smoking during pregnancy could result in a large baby and a difficult birth.”
- D. “I didn’t realize that smoking during pregnancy is associated with asthma as the child grows older.”

The answer is A. Miscarriages, preterm birth and low birth weight babies are associated with smoking during pregnancy. It is not known to be associated with adult hypertension nor with childhood asthma.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

524. Following a long history of vomiting, a child is diagnosed with GERD, Gastric esophageal reflux disease. Instructions are given to the parents for conservative management to reduce the reflux. Following the parent teaching, the nurse will recognize the need for additional information when the parent states:
- A. “I will keep my child’s weight at the recommended levels.”
 - B. “My child should avoid caffeine, and spicy foods to reduce reflux.”
 - C. “I will lay my child down in bed after meals to allow time for digestion.”
 - D. “I will see that my child receives the antacid that his physician prescribed for him.”

The answer is C. The child should not be placed flat in bed following feedings but should be maintained in a semi to high fowler’s position to promote formula retention. Overweight children are more prone to GERD. Caffeine, chocolate and spicy foods seems to weaken the esophageal pressure and increase the reflux. The physician may order an H2 antagonist, a proton pump inhibitor or other drugs to promote stomach emptying.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Assistive Devices

Evaluate correct use of assistive devices by staff/client/family

525. A client is recovering from a broken tibia and is walking on wooden crutches. Which observed client behavior requires nursing intervention?

- A. The client props his foot up while sitting.
- B. The cast is visibly dirty.
- C. While standing, the client rests his body weight on the top of the crutches.
- D. The client uses a swing through motion when walking with the crutches.

The answer is C. Resting the arm pits on the top of the crutches could damage nerves and circulation. A visibly dirty cast can be covered with adhesive tape for better appearances but this is not the priority intervention. It is appropriate to elevate the foot while sitting. A swing through motion is often used to prevent weight bearing on the casted leg.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

Provides safe nursing care to the pregnant client

526. A pregnant woman has developed diabetes during the pregnancy. After several attempts to control the diabetes with diet alone, the physician plans to place the woman on insulin. The woman asks the nurse why she can’t take the “oral” insulins like her grandpa. The nurse’s response is based on the knowledge that oral hypoglycemics:
- A. May cross the placenta and be teratogenic
 - B. Contain too little insulin and would require multiple pills.
 - C. Will affect the fetal pancreas leading to infantile diabetes.
 - D. Contain too much insulin and would be dangerous to the fetus.

The answer is A. The full effect of the oral hypoglycemics on the fetus is not yet known. The oral hypoglycemics are not insulin but stimulate insulin production.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment or reassessment

527. A newborn is suspected of having hydrocephalus. For which symptoms would the nursery nurse monitor the child? (Select all that apply.)
- A. Sunset eyes
 - B. Depressed fontanels
 - C. Thin scalp and sparse hair
 - D. Increasing head circumference
 - E. Head circumference equal to chest circumference

The answers are A, C, and D. The fontanelles would be bulging, not depressed. The head circumference is larger than the chest circumference at birth in normal children. In this child, the difference would be even greater.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of acute and chronic mental illness

528. When assessing a client newly admitted with a diagnosis of active phase schizophrenia, which are negative symptoms of schizophrenia which the nurse might find?

Mark all that apply.

- A. ___ disorganized speech
- B. ___ flat affect
- C. ___ alogia
- D. ___ impaired attention
- E. ___ bizarre behavior
- F. ___ avolition

The answers are B, C, D, and F. Flat affect, alogia, attention impairment, avolition along with anhedonia are all negative symptoms of schizophrenia.

Disorganized speech and bizarre or disorganized behavior are positive symptoms of schizophrenia.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Implement procedures to counteract adverse effects of medications and parenteral therapy

529. A client is receiving Vancomycin HCL for an infection. Shortly after the nurse starts the intravenous infusion, the client appears flushed and complains of feeling hot. The nurse should:

- A. slow the infusion.
- B. stop the infusion and call the physician.
- C. speed up the infusion as it seems to be making the client nervous.
- D. recognize the client is having a drug interaction.

The answer is B. The client is showing symptoms of red man syndrome. The flushing is caused by a release of histamine causing vasodilatation. If untreated, the problem could be fatal. The physician will usually order Benadryl and order the vancomycin to be restarted at a slower rate.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

Understand general principles of pathophysiology

530. The nurse is reviewing the laboratory report of a client who underwent a bone marrow biopsy. The finding that would most strongly support a diagnosis of acute leukemia is the existence of a large number of immature:

- A. nucleated red blood cells
- B. thrombocytes
- C. reticulocytes
- D. leukocytes

The answer is D. Leukocytes are immature WBCs. Thrombocytes are immature platelets and reticulocytes and nucleated red blood cells are immature red blood cells.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission Based/Other Precautions

Provides care to the child with an infectious disease

531. A child has been diagnosed with tubercule (tuberculosis) meningitis and is admitted to the hospital. The child should be placed on:

- A. contact isolation.
- B. droplet isolation.
- C. respiratory isolation.
- D. standard precautions.

The answer is D. These children are not considered contagious. Active, untreated respiratory tuberculosis is spread by droplets. The CDC recommends these individuals be placed in a negative flow (airflow) room with caregivers wearing masks and gowns.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

532. The nurse is performing a physical examination of a client's abdomen. In what order should the assessment be performed?

- A. Inspection, palpation, auscultation
- B. Palpation, auscultation, inspection
- C. Inspection, auscultation, palpation
- D. Auscultation, inspection, palpation

The answer is C. Inspection is always the first step. Palpation is always performed last because palpation of the abdomen may interfere with bowel sounds and could cause pain.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Provide nursing care that identifies potential complications

533. A client has been admitted to the hospital for a gastrointestinal procedure. The physician orders the following:
- NPO at midnight
 - Clear liquids except those that are red
 - Multiple tap water enemas until clear
 - One dose of an oral antibiotic the morning of the procedure.

Which order should the nurse question?

- A. NPO at midnight
- B. Clear liquids except those that are red
- C. Multiple tap water enemas until clear
- D. One dose of an oral antibiotic the morning of the procedure.

The answer is C. Multiple tap water enemas can lead to water intoxication. NPO at midnight is a common order preceding a treatment. Prophylactic antibiotics may be ordered. Clear liquids will maintain the cleanliness of the bowel—reds are avoided as it cannot be differentiated from blood in stool or vomitus.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

534. Two clients are comparing symptoms while waiting in the endocrine clinic. One client has been diagnosed with diabetes insipidus while the other client has diabetes mellitus. The clients note that they have many similar symptoms. Which symptom would differentiate the two disorders?
- A. Polyuria
 - B. Polydipsia
 - C. Polyphagia
 - D. Nocturnal voidings

The answer is C. Both clients will have excessive urination and thirst. Nighttime voiding would be common. Polyphagia, excessive hunger, would only be seen in the client with diabetes mellitus.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Injury prevention

535. An elderly client is admitted to the hospital unit. On admission, the family tells the nurse that the client has fallen several times recently. The nurse evaluates the client and finds the client alert and without symptoms of ataxia. Which is an appropriate nursing action?
- A. Place the client on fall precautions
 - B. Ask physical therapy to evaluate the client.
 - C. Not place the client of fall precautions
 - D. Question the family about what they did for the falls.

The answer is A. The nurse has been warned and therefore has a heightened legal liability to protect this client. The other responses are inappropriate.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

536. A client has been diagnosed with fibrocystic breast disease. Which information should be included in the self care teaching for this client?
- A. Occasional nipple discharge is normal.
 - B. If breast pain is not relieved after menses begins, the client should see her primary care provider.
 - C. Breast pain due to inflammation and root stimulation begins before the luteal phase of the menstrual cycle.
 - D. Diuretics are never used to relieve symptoms of fibrocystic breast disease.

The answer is B. If breast pain is not relieved after menses begins, the client should see her primary health care provider as inflammation and nerve root stimulation begin at 4–7 days into the luteal phase of the menstrual cycle and end with the beginning of menses.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Vital Signs

Apply knowledge needed to perform related nursing procedures and psychomotor skills when assessing vital signs

537. A nursing assistant reports to a staff nurse that the neonate assigned to her care is crying and has axillary

temperature of 90°F. Which is the appropriate action on the part of the staff nurse?

- A. Call a code
- B. Notify the physician
- C. Retake the temperature
- D. Place the infant in a warming unit

The answer is C. A temperature of 90 axillary is not compatible with life. When infants cry they also tend to wave their arms around which can interfere with obtaining an accurate axillary temperature. The temperature should be retaken.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

Assess client for drug/alcohol related dependencies, withdrawal, or toxicities

538. A client comes to the clinic saying he is withdrawing from heroin and needs help. Which assessment findings would support the client's statement?
- A. Vomiting and decreased respirations
 - B. confusion and ataxia
 - C. muscle twitching and dilated pupils
 - D. impaired memory and seizure activity

The answer is C. Symptoms of withdrawal from heroin include muscle twitching and dilated pupils along with yawning, rhinorrhea, lacrimation, abdominal cramps, diaphoresis, irritability, restlessness, anxiety, agitation, sleep disturbance, body aches, muscle cramps, "goose flesh" sensations of hot or cold, nausea, diarrhea, anorexia, fever, hypertension, tachycardia, tachypnea, dysphoria, and craving.

Confusion, impaired memory and seizure activity occurs with withdrawal from alcohol, sedatives/hypnotics, and anxiolytic drugs. Vomiting and ataxia are associated with withdrawal from alcohol, sedatives/hypnotics, and anxiolytic drugs. Respirations are increased with withdrawal from alcohol, opiates, and sedatives/hypnotics, and anxiolytics.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and Blood Products

Administer blood products and evaluate client response

539. A client is to receive a blood transfusion. When will the nurse plan to take vital signs? (Select all that apply.)
- A. Prior to starting the transfusion.
 - B. Every 15 minutes during the first hour of the transfusion.
 - C. Fifteen minutes after the transfusion is completed
 - D. At least twice during the transfusion.

The answers are A, B, and C. Changes in vital signs are early indications of reactions to the blood. Therefore baseline vital signs should be taken prior to starting the transfusion. Subsequently vital signs should be taken every 15 minutes during the first hour, periodically during the rest of the transfusion and then upon completion of the transfusion.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Use the six "rights" when administering client medications

540. The nurse is administering Cyanocobalamin (vitamin B₁₂) to a client with pernicious anemia, secondary to a gastrectomy. Which route should the nurse use to most effectively administer the vitamin?
- A. topical route
 - B. enteral route
 - C. parenteral route
 - D. transdermal route

The answer is C. Cyanocobalamin is administered IM or SC. The other routes are incorrect.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Delegation

Assure appropriate education, skills, and experience of personnel performing delegated task

541. There are three clients on the unit who are receiving chemotherapy. Which type of assignment of care is appropriate?
- A. Care divided among two newly hired and one experienced registered nurses
 - B. Care divided among three experienced registered nurses
 - C. Care assigned to an experienced Licensed Practice Nurse
 - D. Care assigned to a chemotherapy certified pregnant nurse

The answer is B. Chemotherapy administration should be divided among a number of nurses rather than assigning all chemotherapy to one nurse to decrease the cytotoxic chemical exposure. Chemotherapy certified nurse would be the best option, but because the nurse is pregnant, she

should protect her fetus by avoiding all exposure possible. The nurse administering chemotherapy does not have to be certified.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Elimination

Assess and intervene with a client who has an alteration in elimination

542. Which intervention would be included in the plan of care for a client who is post operative from pelvic surgery?
- Administer stool softeners to prevent constipation
 - Teach a low fat diet.
 - Limit fluid intake to reduce bladder filling.
 - Encourage pelvic tilt exercises.

The answer is A. Constipation will cause straining which will cause discomfort and pressure on the suture lines. There is no rationale for a low fat diet. Fluid intake is important to reduce urinary stasis. Pelvic tilt exercises are not appropriate at this time.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assist the family in crisis and under stress to adapt and change

543. An elderly woman was diagnosed with Alzheimer's disease several years ago. Her confusion is increasing. During AM care, the woman tells the nurse about something that happened to her years ago. The husband, who overheard, immediately corrects the woman and explains the correct information to the nurse. The nurse would talk to the husband in private to encourage him to:
- continue to correct her stories to help her stay in touch with reality.
 - discourage his wife from talking so that listeners will not be confused.
 - allow her to tell stories as she remembers them to reduce risk of agitation.
 - ignore all of the woman's rantings as everyone is aware of her confusion.

The answer is C. Clients with Alzheimer's are aware of their confusion and try to mask their loss of memory. That is why they spend so much time talking about the past. Eventually the past memories also become confused. Repeated corrections will increase the woman's agitation and may affect her self-esteem. In addition, it will not keep the woman in touch

with reality. Discouraging the woman from talking will further isolate the woman from the world as will ignoring her.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

544. During the later part of her pregnancy, a woman was treated for pregnancy-induced hypertension. The woman delivered a healthy infant 6 hours ago. Why is close monitoring of this client during the first two postpartum days an important nursing action?
- The client
- will have problems bonding to her infant.
 - could have heart damage from the hypertension.
 - is at high risk for renal failure in the postpartal period.
 - may become eclamptic for up to 48 hours after delivery.

The answer is D. Eclampsia or seizures could occur for up to 48 hours after delivery. The other responses are not correct.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications/side effects

545. A woman is getting married and asks for birth control pills. Which assessment finding suggests that "the pill" may not be the best choice of birth control for this client because of the associated risk of heart disease?
- The client
- is a heavy smoker.
 - is 22 years old.
 - had an abortion as a teenager.
 - has a sexually transmitted disease.

The answer is A. Smokers on oral contraceptives are significantly more at risk for the development of heart disease. This risk increases with age. The other findings are not significant risk factors.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

546. A client receives a dose of penicillin and has an anaphylactic reaction. Which is the priority nursing intervention for this client?

- A. Monitoring vital signs
- B. Maintaining a patent airway
- C. Assessing for adequate circulating blood volume
- D. Treating symptoms of vascular overload

The answer is B. Maintaining a patent airway is essential for the maintenance of tissue oxygenation. Monitoring vital signs and assessing for adequate circulating blood volume are both assessments and will not provide any relief to the client. The client will have circulatory collapse.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Error Prevention

Verify appropriateness and/or accuracy of a treatment order

547. A newborn with a diaphragmatic hernia and respiratory distress is admitted to the pediatric unit. The admitting physician writes the following orders:

- Position in semi- to high Fowlers
- Position on affected side.
- Diet for age.
- NG tube to suction

Which order should the nurse question in the pre-operative period?

- A. Position in semi- to high Fowlers
- B. Position on affected side.
- C. Diet for age.
- D. NG tube to suction

The answer is C. Feeding the infant would increase the contents in the GI tract. Since bowel material is in the chest, this would increase the contents of the chest further compressing the unaffected lung. Semi to high Fowlers would use gravity to decrease the contents of the chest which would help respirations. Position on the affected side so the unaffected lung has full expansion ability. NG tube to suction is used to decompress the gastric contents and is appropriate.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Evaluate and document client response to medication

548. A client is admitted with third degree burns. On the second day post burn, the physician orders the client to receive albumin. The nurse will know that the treatment was successful when the client:

- A. loses weight
- B. feels less pain
- C. doesn't develop a burn infection
- D. has an increased hemoglobin and hematocrit

The answer is A. With a burn injury, the integrity of the vessels is lost and fluid escapes into the tissues. Albumin is a hypertonic solution which draws fluids from the tissues to the plasma from where it can be excreted by the kidneys. Weight loss indicates fluid loss in this manner. Albumin will not affect pain sensation. Although albumin does contain antibodies, this is not the reason for administering it. Albumin contains no red blood cells.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic Tests

Apply knowledge of related nursing procedures and psychomotor skills when caring for clients undergoing diagnostic testing

549. A woman 9 months pregnant is admitted for a Non-Stress Test. How will the nurse position the woman?

- A. Prone
- B. Supine
- C. With legs elevated
- D. With right hip tilted with a pad.

The answer is D. The client is positioned with a pad used to slightly elevate the right hip. This position will prevent vena cava syndrome, a side effect of lying supine. When in the supine position, the pregnant uterus lies on the inferior vena cava reducing blood flow to the heart. The other options are incorrect.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected Effects/Outcomes

Use clinical decision making/critical thinking when addressing expected Effects/Outcomes of medications

550. A client is receiving levothyroxine (Synthroid) for hypothyroidism. Occurrence of which symptom would cause the nurse to suspect the dosage is too high?

- A. Weight gain
- B. Hypotension
- C. Diarrhea
- D. Round the clock sleepiness.

The answer is C. Symptoms of overdose would be those of hyperthyroidism. All the listed symptoms are those of hypothyroidism except for diarrhea.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

551. Which type of precautions would be used when caring for a client with *H. influenzae*?
- Standard precautions
 - Airborne precautions
 - Droplet precautions
 - Contact precautions

The answer is C. Droplet precautions are used when the mechanism of transmission is by large droplets spread by coughing, sneezing, or talking. This is the mechanism of spread of *H. influenzae*.

A is incorrect—Standard precautions are used to decrease the risk of transmission from bloodborne pathogens and moist body substances. Moist body substances include blood, urine, feces, sputum, saliva, wound drainage, and all aspirated fluids. B is incorrect—Airborne precautions are used when the mode of spread of an organism is by small particle droplets borne on air currents. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn. D is incorrect—Droplet precautions require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room. Contact precautions are used when organisms causing serious disease are easily transmitted through direct contact. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Assess client for alterations in mood, judgment, cognition, and reasoning as evidence of psychopathology

552. Which type of personality disorder presents a challenge to treatment because it is characterized by a charming manner often used to manipulate staff into agreeing with or granting client demands?
- dependent
 - histrionic
 - antisocial
 - narcissistic

The answer is C. Clients with antisocial personality disorder are typically intelligent, charming, manipulative and with outstanding verbal and nonverbal communication skills. As a result, staff must be on guard against being inadvertently manipulated by these clients and must consistently set firm limits to avoid reinforcing the clients maladaptive behaviors.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological interactions

553. Which assessment findings would the home care nurse interpret as increasing a new client's risk for problems related to polypharmacy? (Select all that apply.)
- Uses several practitioners
 - Currently being treated for several chronic conditions
 - Has switched health care providers frequently
 - Has a history of cataracts
 - Currently is on an antibiotic for an acute UTI

The answers are A, B, and C. Using several physicians, and switching physicians both can lead to multiple conflicting prescriptions. Multiple chronic conditions will be treated with numerous medications. History of cataracts is not a significant factor in polypharmacy. Short term use of antibiotic for UTI is not a problem.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Error prevention

554. A client is admitted with a draining wound. MRSA is suspected as the causative agent. The physician writes the following orders. Which order should the nurse question?
- Diet as tolerated
 - Contact isolation
 - D₅ 1/4 NS at keep vein open
 - Procaine Penicillin G 150,000 units every 4 hours IV

The answer is D. Procaine is an additive that is to slow the absorption of the medication from the muscle. Procaine is never administered intravenously. The intravenous form of penicillin is Aqueous penicillin.

PHYSIOLOGICAL INTEGRITY

Physiologic Adaptation

Pathophysiology

Identify client status based on pathophysiology

555. An infant in the newborn nursery has been cyanotic since birth. Which type of congenital problem could account for the cyanosis?

- A. A left to right shunt
- B. A right to left shunt
- C. Congestive heart failure
- D. Red blood cell deficiency

The answer is B. A right to left shunt is a cyanotic heart defect. A left to right shunt is acyanotic. The presence of cyanosis does not provide any information about congestive heart failure. A child with inadequate red blood cells would be hypoxic but not cyanotic as cyanosis is unoxygenated hemoglobin.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Perform a comprehensive health assessment

556. What is the nurse assessing when, with the client's eyes closed, the nurse places a key in the client's hand and asks the client to identify what it is?
- A. Two-point discrimination
 - B. Stereognosis
 - C. Position sense
 - D. Light touch

The answer is B. Stereognosis is asking the client to identify a familiar object such as a key when it is placed in the client's hand with the client's eyes closed.

A, C, and D are incorrect—Two-point discrimination involves touching the skin simultaneously with two sterile needles at closer and closer distances to each other until the client perceives only one touch. Position sense is tested by moving the client's toes up or down one by one and asking the client, whose eyes are closed, to say in which direction each was moved. Light touch is tested by stroking an area of the client's skin with a wisp of cotton.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Educate client and family about home management of care

557. The nurse is preparing a client with a full leg cast for discharge. Discharge instructions on cast care have been provided. Which statement by the client indicates the need for more information?
- A. "I will not get my cast wet."
 - B. "I will contact my physician immediately if the cast breaks."

- C. "Keeping my toes still will reduce my pain."
- D. "I should put nothing into the cast."

The answer is C. The client would be encouraged to wiggle his toes. All other responses would be correct responses by the client.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Central Venous Access Devices

Provide care for a client with a central venous access device

558. A client is admitted to the hospital unit with a PICC that was placed at another facility. Although the client has documentation indicating the PICC has been x-ray verified, there is no information about whether the catheter is valved or non-valved. Which is an appropriate nursing action?
- A. Flush the line with normal saline only.
 - B. Do not flush the line.
 - C. Ask the client what other nurses have done with the line.
 - D. Flush the line with heparin flush solution per hospital protocol.

The answer is D. Flushing the line with heparin flush solution will not harm a valved catheter but failure to flush with heparin in a non-valved line will result in occlusion of the line.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

559. A client with known cardiac disease becomes pregnant. The nurses monitor the woman throughout her pregnancy. At what point during her pregnancy is the client at greatest risk of developing congestive heart failure?
- A. First trimester
 - B. 20 weeks gestation
 - C. As the woman approaches 30–32 weeks gestation
 - D. As she goes into labor

The answer is C. The blood volume and workload for the heart reaches its maximum at 30–32 weeks. If the pregnant cardiac client makes it beyond this point, she will probably complete the pregnancy.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing Priorities

Assess/triage clients to prioritize the order of care delivery

560. The nurse is working in the emergency room. On what basis should the nurse determine the order that clients in the reception room should be seen?
- Triage
 - Time of arrival
 - Comprehensive assessment
 - Age

The answer is A. Triage identifies the clients who need medical attention first. Order of arrival is not appropriate because it does not address immediacy of need for care. Comprehensive assessment takes substantial time and slows the organization of client interventions. Age is not appropriate because by itself it does not determine the severity of a problem or the immediacy of the need for care.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate client/family about medications

561. A client with sickle cell anemia has been treated with several blood transfusions. Now deferoxamine (Desferal) has been ordered and the client asks the nurse the purpose of this medication. Which is the correct answer for the nurse to give?
- The medication will:
- prevent the RBCs from sickling
 - remove excessive iron from the body
 - improve the longevity of the red blood cells.
 - increase the oxygen carrying capacity of the blood.

The answer is B. When repeated blood transfusions are given, the RBCs will eventually be broken down. The body retains the iron from these donated cells leading to iron toxicity. All other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

562. A nurse stops at the scene of a car accident and provides first aid to the victim who has a neck injury. Which is the most appropriate way to open the airway of this victim?

- jaw-thrust
- head lift
- neck thrust
- neck tilt.

The answer is A. A jaw thrust will prevent damage to the spinal cord that could occur with other methods of opening the airway.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

563. A 3-year-old child is scheduled for surgery. The nurse is explaining the procedure to the child. Which is the most appropriate statement for the nurse to make about the anesthesia?
- “The doctor will give you some special medicine that:
- “Will help you take a nap.”
 - “Will put you to sleep.”
 - “Make you unconscious.”
 - “Mommy wants you to have.”

The answer is A. Children may be familiar with animals which have been “put to sleep” and never returned. Unconscious is a word that would not be in their vocabulary. Telling the child that mommy wants them to take the medicine does not explain what will happen.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

564. Which statement made by a client with Multiple Sclerosis indicates that the nurse needs to clarify self care instructions with the client?
- “When I am tired, I lay down and rest.”
 - “When I feel stressed, I get in the hot tub.”
 - “I try to avoid conflicts with my husband.”
 - “I’m thinking of changing jobs to reduce stress.”

The answer is B. Heat increases the risk of exacerbations in Multiple Sclerosis so hot tubs should be avoided. All the other statements will promote wellness in the client.

HEALTH PROMOTION AND MAINTENANCE

Immunizations

565. While administering the hepatitis vaccine to a group of medical students, the nurse is asked: “Is this going to

produce active or passive immunity?” Which is the correct response?

- A. This is passive immunity because I am giving you the vaccine.
- B. This is passive immunity because this shot contains the antibodies.
- C. This is active immunity because you did not get it from your mother.
- D. This is active immunity because your body must respond to the vaccine.

The answer is D. Most vaccinations contain toxins or attenuated organisms. Your body views the vaccine as an antigen and produces antibodies against it. That is what makes it active.

A, B, and C are incorrect—Vaccination produces active immunity. Antibodies received from the mother provides passive immunity.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Implement interventions to manage client recovering from an illness

566. A client is experiencing severe respiratory distress. The nurse would perform which of the following activities to promote gas exchange? Select all that apply
- A. Sit the client up in bed
 - B. Support both arms on a pillow
 - C. Encourage the client to drink clear liquids
 - D. Keep the room temperature somewhat warmer than usual

The answers are A and B. Sitting the client up in bed with both arms supported on pillows allows for better lung expansion by reducing pressure from abdominal contents and removing the weight of the arms from the chest. The client would not be encouraged to drink because the severe respiratory distress could cause aspiration. Keeping the room warm would raise the client's basal metabolism rate increasing the body's requirement for oxygen and should be avoided. The room should be kept cool.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Blood and blood products

567. An immunocompromised client is to receive a blood transfusion for anemia. Which type of blood product would the nurse expect the physician to order?
- A. Platelets
 - B. Whole blood

- C. Filtered packed cells
- D. Irradiated packed cells

The answer is C. An immunocompromised client is at risk for graft versus host disease. Irradiated packed blood cells will reduce this risk. Whole blood is rarely administered as packed cells provide the needed cells without the volume.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Understand communicable diseases and the modes of organism transmission

568. A college student has been admitted to the hospital unit with a diagnosis of meningococcal meningitis. The client should be placed in:
- A. droplet isolation
 - B. airborne isolation
 - C. protective isolation
 - D. no isolation as universal precautions is sufficient

The answer is A. Meningococcal meningitis is spread by droplets and is the only meningitis form that is readily transmitted to others. Droplet transmission involves contact with a large particle in the conjunctivae or mucous membranes of the nose or mouth. Transmission by large particle requires close contact whereas airborne can be transmitted through the air. Protective isolation protects the client from others and is not appropriate.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Palliative/comfort Care

Assess client for nonverbal signs of pain/discomfort

569. A client is seen in the emergency room following a fall at home. The client is known to have late stage Alzheimer's disease. A fractured hip is diagnosed and surgery is scheduled for the next morning. When asked, the client denies pain. Which symptoms would cause the nurse to suspect the client is in pain?
- A. Client yells for her long deceased husband
 - B. Client's hands finger the sheets continuously.
 - C. Blood pressure is elevated from admission findings
 - D. Client reaches for the nurse's hand when the nurse approaches the client.

The answer is C. Elevation in blood pressure may indicate an increase in pain.

Clients with Alzheimer's disease often call for individuals from their past, finger sheets, and other material and want physical contact.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

570. A newborn has been diagnosed with osteogenesis imperfecta. Which assessment findings would the nurse expect? Select all that apply.
- A. Blue sclera
 - B. Simian crease
 - C. Hyperbilirubinemia
 - D. Multiple fractures apparent at birth
 - E. Cephalohematoma developed within hours of birth

The answers are A and D. Blue sclerae and multiple fractures at birth are signs of osteogenesis imperfecta. Simian crease is a soft neurologic sign associated with Down's syndrome. Hyperbilirubinemia is not a symptom of osteogenesis imperfecta although it could result from bleeding injuries secondary to the broken bones. Cephalohematoma is not a symptom of osteogenesis imperfecta.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic tests

571. Which is the most important question to ask a 36-year-old woman prior to having a bone scan?
- A. Do you have an allergy to seafood?
 - B. Did you have anything to eat or drink after midnight?
 - C. Are you claustrophobic?
 - D. Are you pregnant?

The answer is D. With a bone scan, there is a risk of radiation exposure to the fetus.

A is incorrect—this question is asked of any client receiving an isotope. B is incorrect—the client does not have to be NPO for this diagnostic test. C is incorrect—not all CT or MRI machines are full enclosures.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

572. A 68-year-old female is admitted with a chief complaint of low back pain. Spinal x-ray indicates that the client has intervertebral disc disease. When asked by the client's family, the nurse would explain the etiology of this disease as:
- A. caused by weakening of the bone due to loss of calcium from the bone.

- B. the degeneration of the spine due to dehydration of the intervertebral discs.
- C. caused by inflammation of the joints and surrounding tissues.
- D. the displacement and loss of contact of articulating surfaces.

The answer is B.

A is incorrect—Weakening of bone due to loss of calcium occurs with osteoporosis. C is incorrect—Inflammation of joints and surrounding tissue occurs with arthritis. D is incorrect—Displacement and loss of contact of articulating surfaces occurs with dislocation of a joint.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Confidentiality/Information Security

Maintain client confidentiality/privacy

573. The nurse is working on the pediatric unit when a call is received from a school teacher asking about the condition of one of her students who is hospitalized on the unit. The nurse should:
- A. give only general information about the child.
 - B. encourage the teacher to contact the child's parents.
 - C. transfer the call to the hospital administrator.
 - D. answer her questions if the nurse can verify that the person on the phone is the child's teacher.

The answer is B. No information can be given to the teacher. Only the guardians may receive information about the child.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Assess client for actual or potential side effects and adverse effects of medications

574. Gentamicin is known to be nephrotoxic. The nurse administering gentamicin should independently evaluate the client's:
- A. BUN
 - B. Urinary output
 - C. Fluid intake
 - D. Creatinine clearance

The answer is B. Urinary output provides information about renal functioning. BUN and Creatinine clearance also evaluate

renal functioning but require a physician's order so may not be available for monitoring.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

Identifies deviations from normal in the newborn

575. After a difficult vaginal delivery, a newborn is admitted to the newborn nursery. During the assessment, it is noted that the baby's moro reflex does not include the right arm. Which problem would the nurse suspect?
- Brain damage
 - Fractured radius
 - Erb Duchenne palsy
 - Cephalohematoma

The answer is C. Erb Duchenne Palsy usually is due to pulling the head away from the shoulder. The palsy, which may be permanent, prevents movement of the shoulder and upper arm. There is no evidence of brain damage. A fractured radius would not affect shoulder movement. Cephalohematoma is bleeding into the periosteum of the skull bone.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Central Venous Access Devices

Provide care for client with a central venous access device

576. A client's PICC line will not flush. The nurse is unable to aspirate blood from the line. Which is an appropriate nursing action to restore patency?
- Instill heparin into the line
 - Increase the pump pressure setting
 - Use increased pressure to flush the line with saline.
 - Contact the physician for orders for Activase (alteplase)

The answer is D. Activase is a thrombolytic which breaks down clots. Heparin prevents the formation of clots, it does not break down clots. Increased pressure may cause the clotted line to release an embolus into the client's circulation. Increasing the pump's pressure setting would not cause the clot to disintegrate.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

577. A client has developed a pulmonary embolism. Which factors predispose a client to this problem? (Select all that apply.)

- Bradycardia
- Hypertension
- Hypercoagulability
- Fluid volume overload
- Venous stasis in the lower extremities

The answers are C and E. Hypercoagulability and venous stasis in the lower extremities predispose to development of a pulmonary embolism. The other options are unrelated to pulmonary embolism.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of pathophysiology to illness management

578. A client is admitted to the hospital unit with a diagnosis of hemophilia A. The nurse reviews the client's lab report. Which lab result should the nurse interpret as unexpected and requiring further investigation?
- Low platelet count
 - Low factor VIII values
 - Prolonged bleeding time
 - Prolonged partial thromboplastin time

The answer is A. The client with hemophilia A has insufficient levels of factor VIII which is a component of the clotting cascade. The platelet counts are normal. The other laboratory values would be prolonged due to the inadequacy of the clotting cascade.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Home safety

579. A client is brought to the emergency room for acute lead poisoning. When determining the source of the lead poisoning, the nurse will question the client about which topic?
- Eating lead pencils
 - Recent house painting
 - Using homemade pottery or ceramic dishes.
 - Eating unwashed vegetables from the garden.

The answer is C. Poorly fired pottery and ceramics may be improperly glazed allowing the lead to leak out of the clay. Lead pencils are made of carbon. Paint is now

lead free. Unwashed vegetables do not contribute a risk of lead.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Provide nursing care that includes interventions designed to reduce post procedure complications

580. A client has returned to the cardiac unit following a cardiac catheterization performed through the left femoral artery. Which item is an appropriate part of the nursing care plan for this client?
- Out of bed as soon as awake from anesthesia
 - Neurovascular check to the insertion site times two
 - Pressure dressing and immobility for the insertion site
 - Range of motion exercises to the left leg every two hours.

The answer is C. The site is kept immobile for up to 24 hours after cardiac catheterization to reduce the risk of a severe arterial bleed. Range of motion exercises would be contraindicated. The client would be on bedrest. Neurovascular checks should be performed at least hourly for the first 24 hours due to the risk of thrombosis.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Identify signs and symptoms of client fluid and/or electrolyte imbalance

581. A client with multiple myeloma is beginning chemotherapy. The client's serum calcium level is 15 mg/dL. For which clinical manifestations related to this laboratory finding would the nurse assess?
- Abdominal cramps
 - Confusion and anxiety
 - Lethargy and weakness
 - Muscle twitching

The answer is C. Normal serum calcium range is 8.5–10.5 mg/dL so the client has hypercalcemia. Symptoms of hypercalcemia include lethargy and weakness as well as depressed deep tendon reflexes, anorexia, nausea, vomiting, constipation and dysrhythmias.

A, B, and D are incorrect—Abdominal cramping occurs with hyponatremia; confusion and anxiety occur with hypocalcemia; muscle twitching occurs with hyponatremia.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

582. The nurse is working on the postpartum unit and is assigned to four clients. Which of the four clients is most likely to suffer afterbirth pain based on their obstetrical history?
- Mother of twins
 - Bottle feeding mother.
 - Multipara with a premature infant
 - Primipara with an average for gestational age infant

The answer is A. Factors which increase afterbirth pain include overdistended uterus such as in twins or large infants, breast feeding, and multiparas.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Provide pre- and/or postoperative education

583. A client with a recent below the knee amputation of the left lower extremity is admitted to the rehabilitation unit and will be fitted with a prosthesis. Which is the priority self care instruction to be given to the client?
- Keep a diary of time and type of activity related to the use of the prosthesis.
 - Assess skin integrity of the stump daily.
 - Apply cold compresses to the residual extremity bid.
 - Take analgesics if needed for phantom pain.

The answer is B. Preserving the integrity of the skin over the residual extremity is critical to use of the prosthesis and resumption of mobility. Thus the client is instructed to assess the skin at least daily so any problem is identified and treated early.

A is incorrect—a diary related to the use of the prosthesis is not a standard recommendation. C is incorrect—application of cold is not a standard part of residual extremity care. D is incorrect—although self-administration of analgesic may be required secondary to phantom limb pain it is not considered a priority in client education at this time.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

584. A client arrives in the emergency room with a chief complaint of new onset stiff neck and muscle aches. A physical exam reveals erythema migrans on the right

upper arm. Which is the most likely cause of the client's signs and symptoms?

- A. Gout
- B. Lyme disease
- C. Lupus erythematosus
- D. Polymyositis

The answer is B. Lyme disease, caused by the spirochete *Borrelia burgdorferi* carried and transmitted by ticks, is characterized by erythema migrans or the "bull's eye" rash. Other symptoms of Stage I disease are muscle and joint pain and stiffness. Symptoms of gout are acute pain and inflammation of one or more small joints. Lupus erythematosus can affect virtually every body system. It can cause joint inflammation and myositis. It also can cause a rash but the rash is the dry, scaly, raised "butterfly" rash typically involving the cheeks and bridge of the nose resulting in the butterfly shape. The rash is not a bull's eye rash. Polymyositis is an inflammation of striated muscle causing symmetrical weakness and atrophy. It is not characterized by erythema migrans.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Management of Care

Principles of Management

Supervise care provided by others

585. The charge nurse is observing a newly hired nurse measure jugular venous pressure. Which action on the part of the new nurse requires correction by the charge nurse? The newly hired nurse
- A. positions the client supine.
 - B. raises the head of the bed 30–45 degrees.
 - C. shines a light tangentially across the client's neck.
 - D. measures the vertical distance from the manubrium to the meniscus of the internal jugular vein.

The answer is D. The distance is measured vertically from the sternal angle (angle of Louis) to the meniscus of the internal jugular vein. This distance which is measured in centimeters equals the jugular venous pressure which usually does not exceed 4 cm.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

Assess client for drug/alcohol related dependencies, withdrawal, or toxicities

586. When examining a two and a half year old, which assessment findings would the nurse interpret as consistent with fetal alcohol syndrome?

- A. ___ strabismus
- B. ___ Irritability
- C. ___ Absence of teeth
- D. ___ Hyperactivity
- E. ___ Developmental delay

The answers are A, B, D, and E. Abnormalities associated with fetal alcohol syndrome which would be evident on assessing a two and one half year child include strabismus, myopia, irritability, hyperactivity, poor attention span, developmental delay and growth deficiency. Teeth are malformed not absent. Once in school, poor school performance is characteristic.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/immobility

587. You are caring for a 40-year-old male who is on complete bed rest following a traumatic injury to his pelvis. The data collected during your morning assessment include elevated oral temperature (100°F), diminished lung sounds in right lower lobe and oxygen saturation of 90% on room air. The most likely cause of these findings:
- A. hypostatic pneumonia
 - B. atelectasis
 - C. bronchitis
 - D. asthma

The answer is A. immobility results in respiratory complications which include pooling of respiratory secretions.

B is incorrect—atelectasis is a collapse of a single lobe or an entire lung. C is incorrect—bronchitis is the acute inflammation of airway passages. D is incorrect—asthma is not caused by immobility.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Modify approaches to care in accordance with client's developmental stage

588. An 11-year-old boy is admitted to the hospital unit following a bicycle accident. A fractured femur is diagnosed and the child is placed in traction. The best room assignment for this child would be a room:
- A. with other boys of the same age as roommates.
 - B. near the nurse's station so the child can be closely supervised.

- C. away from other children so that the child can rest adequately.
- D. with an alert adult roommate who can respond to the child's needs.

The answer is A. Boys of this age are usually active. This child has restricted activity and will be easily bored. The child will enjoy the company of the other children.

This child's condition is not a high risk condition so any room location on the unit would be acceptable. It is not the job of other clients to care for a client who is immobilized so option D would be incorrect.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

589. Which statement made by the parent of a 15-year-old girl receiving doxorubicin (Adriamycin) to treat leukemia indicates that information regarding side effects of the medication was understood?
- A. "My daughter is lucky that the major side effects of her medication are headache and drowsiness; they could be a lot worse."
 - B. "It will be hard to see my daughter confused and hallucinating from the medication but at least these side effects won't last forever."
 - C. "I hope my daughter's heart isn't damaged from this medication; she is already going through so much that would just be awful for her."
 - D. "I worry about the effect of the medication on my daughter's kidneys but the important thing is to cure the cancer then we will deal with the rest."

The answer is C. heart damage is one of several side effects of doxorubicin (Adriamycin) so this statement indicates the client's parent understands this fact.

Answer A is incorrect—headache and drowsiness are side effects of methotrexate. Answer B is incorrect—hallucinations and confusion are side effects of ifsoamide (Ifex). Answer D is incorrect—kidney damage is a side effect of carboplatin (Paraplatin).

PHYSIOLOGICAL INTEGRITY

Reduction of Risk

Potential for complications of diagnostic Tests/Treatments/Procedures

590. A client is admitted for an arthrogram of the right knee. Which is the most important information to obtain as part of the admission history?

- A. Allergies to iodine, seafood, or local anesthetic
- B. Current pain level to right knee
- C. Previous experience with arthrogram
- D. Time of last meal or fluid intake

The answer is A. it is important to know if the client has any of these allergies because a radiopaque dye, administered IV, is given to visualize the joint.

B and C are incorrect—Although collecting information related to pain and previous experience with an arthrogram should be included, it is not the most important information. D is incorrect—The client does not have to be NPO prior to this diagnostic test.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communication

Use therapeutic communication techniques to provide support to client and/or family

591. A woman has recently been diagnosed with a terminal illness. Although her physical condition is stable at this time, the client seems depressed. Which approach by the nurse would be most effective in encouraging the client to talk about her feelings?
- A. "You seem down today."
 - B. "Why are you feeling so depressed?"
 - C. "What can I do to make you feel better?"
 - D. "Would you like to talk to the hospital chaplain?"

The answer is A. The nurse has made a statement of his or her perceptions. The client can agree or deny these perceptions.

The client is never asked to explain feelings so asking why is an incorrect response. In option C, the nurse offers his or her self but this does not get at the client's feelings. Option D limits the conversation and is a way for the nurse to get out of an uncomfortable situation.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological agents/actions

592. A client is admitted to the hospital with a diagnosis of disseminated intravascular coagulation (DIC). The physician orders the client treated with heparin. A family member asks why heparin is being given to the client who is bleeding internally. The nurse's response is based on the knowledge that heparin:
- A. increases the production of clotting factors.
 - B. preserves the platelets to prevent the client from bleeding out.

- C. activates the clot disintegration process which breaks up the clots that have formed.
- D. promotes neutralization of thrombin and prevents the conversion of fibrinogen to fibrin.

The answer is D. This action blocks the coagulation cascade at the common pathway and stops the intravascular coagulation disorder. The other responses do not accurately describe the effect of heparin.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate client/family about medications

593. A client is being placed on long-term corticosteroid therapy. Which information should be included as part of the client's discharge teaching?
- A. Drink lots of water daily
 - B. Do not stop the medication suddenly
 - C. The medication may cause weight loss
 - D. It is critical not to not smoke while on corticosteroid therapy

The answer is B. Corticosteroids depress the body's natural production of corticosteroids. Sudden stopping of the medication could be fatal. The other responses are not correct.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

594. In caring for a client with a serum calcium level of 15 mg/dl, which instruction would be given to the client?
- A. Increase the amount of calcium rich foods eaten each day
 - B. Incorporate fiber into the daily diet to decrease constipation
 - C. Avoid foods high in sodium content
 - D. Limit fluid intake of water

The answer is B. Normal serum calcium range is 8.5– 10.5 mg/dl so the client has hypercalcemia. Hypercalcemia can cause constipation.

A, C, and D are incorrect—Increasing calcium food consumption is indicated for hypocalcemia; a decrease in sodium intake is appropriate for hypernatremia; free water intake is indicated with hyponatremia.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Educate client/family/staff on infection control measures

595. A client goes to a clinic requesting to be tested for Acquired Immunodeficiency Syndrome (AIDS). The test was positive. Instructions to avoid spreading the infection will include:
- A. Avoid sharing toothbrushes and razors
 - B. Do not share a bathroom with other individuals
 - C. Keep your dishes separate
 - D. Keep fresh flowers and plants out of the home to reduce the accumulation of mold.

The answer is A. Body fluids can be spread by sharing toothbrushes and razors. Sharing a bathroom is acceptable. Others do not need to wear gloves during casual contact with the client.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate client/family about medications

596. A client with sickle cell anemia has been treated with several blood transfusions. Now Deferoxamine (Desferal) has been ordered and the client asks the nurse the purpose of this medication. Which is the correct answer for the nurse to give?
- The medication will:
- A. prevent the RBCs from sickling.
 - B. remove excessive iron from the body.
 - C. improve the longevity of the red blood cells.
 - D. increase the oxygen carrying capacity of the blood.

The answer is B. When repeated blood transfusions are given, the RBCs will eventually be broken down. The body retains the iron from these donated cells leading to iron toxicity. All other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Provide postoperative care

597. A client has a cesarean section and delivers a healthy infant. Which of the following interventions are useful

in preventing pulmonary embolism in the postoperative mother?

- A. Low salt diet and exercise
- B. Compression stockings and leg exercises
- C. Daily aspirin and daily breathing exercises
- D. Low fat diet and rehabilitation therapy

The answer is B. Pulmonary emboli would result from thrombus formation. The pregnant woman is at greater risk for the development of thrombus. All surgical clients would also have this risk while bed ridden. Compression stockings and leg exercises would be most effective in preventing circulatory stasis.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Assess client for alterations in mood, judgment, cognition, and reasoning as evidence of psychopathology

598. Nurses working with a client with which type of personality disorder must be particularly alert for splitting behavior?
- A. Antisocial
 - B. Borderline
 - C. Narcissistic
 - D. Histrionic

The answer is B. Splitting is an unconscious mechanism characteristic of the client with a borderline personality disorder. The client is unable to accept imperfections in others and sees people as all good or all bad with the result that persons are set up against one another. For example, nurses may be good if they say only positive things to the client; nurses are bad if they provide negative feedback even when appropriate. Splitting is a coping behavior.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/immobility

Provide nursing care that incorporates knowledge of the risks associated with immobility

599. A client has been bed ridden for several months due to the effects of Alzheimer's Disease. For which musculoskeletal problem is the client at risk?
- A. Deep vein thrombosis
 - B. Osteoporosis
 - C. Avascular necrosis of hip
 - D. Embolism

The answer is B. prolonged bed rest result in loss of calcium leading to osteoporosis.

A is incorrect—this is a complication of the vascular system due to bed rest. C is incorrect—avascular necrosis is due to trauma and/or chronic steroid use. D is incorrect—an embolism is a cardiovascular complication from long term bed rest.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

600. An elderly client develops disuse osteoporosis. The client's adult son asks why his parent has this disease. The nurse would explain that disuse osteoporosis occurs because of:
- A. a decrease in calcium intake.
 - B. contractures to the lower extremities.
 - C. lack of stress to weight-bearing activity.
 - D. stiff and painful joints of the extremities.

The answer is C. calcium loss in the bones occurs due to lack of weight-bearing activity to the bones.

A is incorrect—a decrease in calcium content does not directly have an impact on disuse osteoporosis. B is incorrect—contractures of lower extremities can be the result of immobility. D is incorrect—immobility will eventually result in stiff and sore joints.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

601. A 13-month-old child is to receive an oral medication. The child starts crying as soon as the nurse enters the room with the medication despite the fact that his mother is telling him a story. After checking the child's identification bracelet, how should the nurse proceed with administering the medication?
- A. Blow gently across his face with a soft whistling sound to stop the crying.
 - B. Allow the mother to administer the medication.
 - C. Delay giving the medication until the child is calmer.
 - D. Hold the child on his or her lap in a semi-Fowler's position.

The answer is B. After the nurse checks the bracelet, the mother can be allowed to administer the medication while the nurse watches. The nurse would not blow across the child's face; microorganisms can be spread in this way. Medication must be given in a timely fashion to

be effective. The child would be held upright to prevent choking.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Assist the client to achieve an appropriate outcome

602. A mother asks the nurse when she should begin toilet training her toddler. Which is an appropriate response for the nurse to give?
- An indication that a child is ready to begin toilet training is that the child
- pulls on the diaper when it is wet.
 - has a BM at the same time every day.
 - doesn't want to lay down for diaper changes.
 - hides behind the living room chair when having a BM

The answer is D. This indicates the child is aware that he is about to have a BM, a necessary step in toilet training. A indicates the child is aware that he has eliminated, but does not show anticipation of the event. Having a BM at the same time every day makes toilet training easier for mother, but does not indicate readiness. Toddlers are so busy they often complain about the need to have diapers changed. It doesn't indicate readiness.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Use clinical decision making/critical thinking when calculating dosages

603. What is the maximum daily dose of acetaminophen in mg/Kg of body weight that can safely be given to children? Record your answer in a whole number.
_____ mg/Kg.

The answer is 90 mg/Kg. The maximum daily dose for adults is 4 gm.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapy

Expected effects/outcomes

604. The nurse is comparing laboratory results on admission with laboratory results following treatment of a client

with DIC. Which change in laboratory values from admission indicates a positive response to therapy?

- Decrease in platelet count
- Increase in fibrinogen level
- D-dimer assay increase
- Decreased bleeding time

The answer is B. Heparin is used in the treatment of DIC. If therapy is effective, the heparin should stop the process of intravascular coagulation thereby allowing the fibrinogen level in the blood to increase. Platelet count would increase not decrease with effective therapy. D-dimer assay is a global marker of coagulation activation measuring a fibrin degradation product. Clotting time, not bleeding time, is a reliable indicator of effective therapy for DIC.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to client and/or family

605. A woman has given birth to a preterm infant. The infant is doing well in the high risk nursery. The woman states to the nurse: "I am so worried about my baby." The best response by the nurse would be:
- "You're worried about your baby?"
 - "Don't be worried, your baby is doing fine."
 - "God will take care of your baby if it is meant to be."
 - "Babies born at the gestation of your baby usually do very well."

The answer is A. It is reflective and encourages the mother to provide more information. The other responses are not therapeutic.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Parenteral/Intravenous Therapy

Monitor and maintain infusion site(s) and rate(s)

606. The nurse is scheduled to administer 500 mg of ampicillin IV by secondary line. The drug is to be infused over 20 minutes. The ampicillin is in a 50 ml baggie of D5W. The IV drop factor for this IV is 15. How many drops per minute should the nurse regulate the IV to infuse at over the required 20 minutes?
- 20 gtts/min
 - 30 gtts/min
 - 40 gtts/min
 - 60 gtts/min

The answer is B. 50 ml in 20 minutes or 2½ ml per minute. Each ml contains 12 drops so 12 times 2½ = 30 gtts/min.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical emergencies

607. When performing the Heimlich maneuver on a pregnant or markedly obese client, the nurse should position her hands in which area? Mark the spot with the letter "X".

Correct response:

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and Electrolyte Imbalances

Identify signs and symptoms of client fluid and/or electrolyte imbalance

608. A child has been admitted to the pediatric unit with gastroenteritis. Which laboratory finding indicates the child is dehydrated?
- Elevated reticulocyte count
 - Elevated white blood cell counts
 - Decreased urine-specific gravity
 - Elevated hemoglobin and hematocrit

The answer is D. Since both hemoglobin and hematocrit are comparisons of solids to liquids, dehydration causes an increase in these values. The other responses do not indicate dehydration.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for client

609. A client is transferred from the operating room to the postpartum unit following a cesarean section for fetal distress. When the nurse performs the postpartum assessment, the client complains of pain and asks the nurse not to palpate the fundus. Which is the appropriate nursing action?
- Ask a more experienced nurse to palpate the fundus.
 - Palpate the fundus anyway while avoiding the incision area.
 - Avoid palpating the fundus as long as the vital signs are stable.
 - Explain the need for fundal palpation and then palpate the fundus from the side.

The answer is D. Fundal palpation is essential for the well-being of the client. Contraction of the fundus occludes open blood vessels and prevents excessive bleeding from the site of placental implantation. The client will be more cooperative if the client understands the rationale.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alterations in body systems

610. An 84-year-old female is brought to the E.R. presenting with confusion, restlessness and altered mental status. Which nursing action is appropriate?

- A. Ask the client about the medications she is currently taking.
- B. Give electrolyte replacing fluids.
- C. Refer the client for a psychiatric evaluation.
- D. Prepare for a physical exam including a chest x-ray, EKG, UA, and CBC.

The answer is D. Changes in mental status such as confusion and restlessness are typical signs of acute illness in older adults requiring physical exam and lab work to r/o UTI, MI, pneumonia.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Mobility/immobility

611. An elderly client has been hospitalized for two weeks and develops the beginning of a pressure ulcer on the coccyx. The nurse recognizes that pressure ulcers in older adults are considered:
- A. primary changes
 - B. secondary changes
 - C. normal changes
 - D. expected changes when hospitalized

The answer is B. Primary, normal, and expected changes are the same thing and pressure ulcers are not a normal sign, rather a pathological one.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Accident Prevention

Identify and facilitate correct use of infant and child safety seats

612. The nurse is teaching a prenatal class on child safety. Where would the nurse instruct the expectant mothers to put their baby's car seat?
- A. Front passenger seat
 - B. Middle of the back seat
 - C. Back seat behind the driver
 - D. Back seat behind the passenger

The answer is B. The middle of the back seat is the safest place for the infant car seat.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

613. A client had a left total knee replacement two days ago and is now having dyspnea and appears to be very apprehensive. Pulse rate is 110 and she is diaphoretic. Which problem does the nurse suspect?
- A. Infection
 - B. Pneumonia
 - C. Fat embolus
 - D. Anaphylaxis

The answer is C. These are symptoms of a fat embolus which is a risk when the marrow cavities of long bones are opened due to accidental trauma or surgery.

A is incorrect—the symptoms listed are not indicators of infection, B is incorrect—Data collected does not include temperature. D is incorrect—information provided does not include drug history.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of impaired cognition

614. A client with schizophrenia says “skipping, whipping, tripping” over and over during his waking hours. Which would be a correct label for the nurse to use when documenting this communication?
- A. word salad
 - B. clang association
 - C. neologism
 - D. echolalia

The answer is B. Clang association. Clang association refers to repeating words and phrases which sound alike but are otherwise unconnected. Word salad refers to the meaningless connection of words and phrases. A neologism is a new word coined by the client and with meaning only to the client. Echolalia is the repetition of words or phrases heard from another person.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapy

Pharmacological interactions

615. A client is on anticoagulant therapy following a pulmonary embolism. During the first visit to the client's

home, the home health nurse asks the client to take out all the medications that he has on hand. Which medication is a cause for concern when taken by a client on an anticoagulant?

- A. Ferrous sulfate (Iron)
- B. Acetylsalicylic acid (Aspirin)
- C. Isoniazid (INH)
- D. Phenytoin (Dilantin)

The answer is B. Aspirin can potentiate the effects of anticoagulants. Ferrous sulfate does not affect anticoagulants; it is used for RBC production. INH is an antitubercular product and does not affect clotting time. Phenytoin is an antiseizure med and does not affect clotting time.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Central Venous Access Devices

Access implanted venous access devices

616. While visiting the area from another state, a client presents to the emergency room with severe pain secondary to a kidney stone. The physician orders an IV line started with 125 ml per hour of D5 1/4 NS and morphine for pain. The client shows the nurse his chest where he states he has a Subcutaneous venous port and asks the nurse to start the IV there. Prior to starting an IV line in this port, the nurse would need to verify that the:
- A. Brand of subcutaneous port.
 - B. Medications can be given by central line.
 - C. Port internal tip lies in the superior vena cava.
 - D. Intravenous fluids can be administered by central line.

The answer is C. Prior to administering anything through a central line, the location of the internal tip must be verified. Since this client is not known in the area, the tip location can be verified by x-ray if the client does not have a card documenting this information. Any medication and intravenous fluids that can be administered by peripheral line can be administered in a central line.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission Based/Other Precautions

Evaluate infection control precautions implemented by staff members

617. A client is on contact isolation due to a MSRA abscess. The charge nurse observes all of the following nursing

activities. Which nursing activity fails to safely protect others from the client?

The nurse:

- A. washes hands after removing gloves.
- B. does not wear gloves when changing the bed.
- C. does not wear a gown when checking the IV level.
- D. covers the client with a sheet when being transported to x-ray.

The answer is B. The abscess could have drained onto the bedding. The nurse does not need to wear a gown unless contact with items in the room is expected. Hands should always be washed or disinfected after removing gloves. Covering the client with a sheet when out of the room will reduce exposure to others.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

618. The nurse is assessing an elderly client and notes the following findings. Which assessment findings would the nurse identify as a normal signs of aging? Mark all that apply.
- A. Increase in diastolic blood pressure
 - B. Reduced lens elasticity
 - C. Reduced vital capacity
 - D. Decreased force of myocardial contraction

The answers are B, C, and D. Decreases in lens elasticity, vital capacity and force of myocardial contraction all occur normally with aging. Mild increase in systolic BP also occurs, however an increase in diastolic BP is pathological and requires monitoring.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications

Provide nursing care that incorporates knowledge of adverse effects of selected pharmaceutical agents

619. A client presents to the emergency department, dehydrated and with metabolic acidosis. An overdose of which drug can result in these problems?
- A. Digitalis
 - B. Aspirin
 - C. Insulin
 - D. Acetaminophen

The answer is B. Aspirin toxicity causes hyperventilation leading to respiratory alkalosis which leads to metabolic acidosis and dehydration. In digitalis toxicity, the major symptoms would be bradycardia. Insulin overdose would lead to hypoglycemia. Acetaminophen toxicity would result in symptoms of liver damage including AST and ALT elevations.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

620. The charge nurse is orienting a new nurse to the mother baby unit. The charge nurse explains that gloves should be worn (select all that apply):
- A. when changing diapers.
 - B. for the initial newborn bath.
 - C. when changing the bag of IV fluids.
 - D. while performing initial assessment on a newborn.
 - E. when assisting the new mother to the bathroom for the first time after delivery.

The answers are A, B, D, and E. The nurse would be at risk for exposure to bloodborne pathogens during all these events. Newborns are covered with amniotic fluid and blood. Diaper changes might expose the nurse to body fluids. The first time the mother is out of bed, a large amount of blood usually escapes from the vagina. Combine that with the fact that many new mothers become weak or faint when first up, gloves at this time provide protection for the nurse.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Central Venous Access Devices

Provide care for a client with a central venous access device

621. A client has had a PICC line for 2 weeks which is being used for intermittent infusion of an antibiotic. Between uses, the PICC line is heparinized and locked. The nurse is ready to administer the PM dose of antibiotic. The nurse flushes the line which flushes easily, but is unable to aspirate blood. The nurse should:
- A. administer the medication as planned.
 - B. ask for x-ray verification of the PICC placement.
 - C. discontinue this PICC line and insert a new PICC line.
 - D. hold the dose until the physician sees the client in the AM.

The answer is A. PICC lines have a very small lumen and blood aspiration is often not possible after several weeks of use. The easy flush with no other complaints usually indicates that the PICC is intact. X-ray verification is used whenever the location of the tip is in question. Only specially trained nurses can insert PICC lines. Holding the dose until the next day would allow the client's blood level to drop and could allow the organism to become resistant.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assist client/family/significant others to integrate new members into family structure

622. A young teenage girl has just given birth to a baby girl. She has decided to keep her baby. The nurses are concerned about bonding between mother and infant. To promote bonding, the nurse will:
- A. tell the mother her baby is beautiful.
 - B. delay eye prophylaxis immediately after birth.
 - C. leave the mother and baby alone to get acquainted.
 - D. keep the lights in the room on bright so the mother can see her infant clearly.

The answer is B. Bonding is supported when the mother looks at her infant and the infant looks back. Delaying eye prophylaxis and lowering the lights in the room will promote the infant looking back.

The mother may be afraid to be alone with her infant. Telling the mother the baby is beautiful is not the best intervention to promote bonding.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Total Parenteral Nutrition

Provide client/family/significant others with information on TPN

623. A 4-year-old child with cystic fibrosis has difficulty maintaining adequate nutrition and has had a subcutaneous venous port surgically implanted for home administration of total parenteral nutrition. The child receives the TPN for 8 hours each night and is disconnected from the IV line during the day. The home health nurse teaches the mother to:
- A. Calculate the drip rate since a pump will not be needed.
 - B. Check the child's blood glucose every two hours during the night.
 - C. Limit the child's intake during the day so the child will not become obese.

- D. Start the TPN slow and taper up to the desired rate each night and then taper off each morning.

The answer is D. TPN is always tapered on and tapered off. Sudden onset will cause hyperglycemia, sudden stopping will cause hypoglycemia. An electronic infusion pump is always used with TPN. It is not necessary to check the child's glucose as often as every two hours. Limiting the child's daily intake would be inappropriate as the child is malnourished.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

624. A 67-year-old female is returning to the medical clinic for a follow-up visit due to complaints of back pain, frequent fevers and weight loss. CBC and serum chemistry disclosed high serum calcium and protein levels and low levels of hemoglobin, red blood cells, platelets, and white blood cells. With which problem are these signs and symptoms consistent?
- Anemia
 - Arthritis
 - Multiple myeloma
 - Systemic lupus erythematosus

The answer is C. Multiple myeloma is correct.

A is incorrect—there is only a decrease in hemoglobin and hematocrit with anemia. B is incorrect—these tests would not be performed to diagnose arthritis. D is incorrect—these tests are not performed to diagnose lupus erythematosus.

HEALTH PROMOTION AND MAINTENANCE

Principles of Teaching/Learning

Assess readiness to learn, learning preferences, and barriers to learning

625. A nurse is preparing to teach a newly diagnosed diabetic about the disease. Which is the initial step the nurse should take?
- Identify the client's willingness to learn.
 - Find out what the client knows about the disease.
 - Determine the client's level of formal education.
 - Select written material available for the client's use.

The answer is B. The initial step is always to begin where the client is. All other responses may be helpful, but initially determining the client's current knowledge is most important.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-Specific Assessment

Perform focused assessment

626. The nurse is checking Homan's sign on a client suspected of having a venous thrombosis. Which action should the nurse take?
- Flex the client's hip and the knee
 - Flex the client's hip while extending the knee
 - Ask the client to point the toes while bending the knee
 - Push the client's foot forward toward the knee while maintaining the knee in extension

The answer is D. A positive Homan's sign is calf pain on dorsiflexing the foot while maintaining the knee in extension. If Homan's is positive, a venous thrombosis is suspected. The other responses do not describe the appropriate technique to assess for Homan's sign.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Use precautions to prevent further injury when moving a client with a musculoskeletal position

627. A client has had spinal surgery and the physician has ordered the client to be "log-rolled." To be log rolled, the nurse will:
- have the client turn slowly and stiffly.
 - use a draw sheet to maintain body alignment.
 - only position the client prone or supine to prevent spinal trauma.
 - ask for assistance from another nurse to maintain the body alignment.

The answer is D. Log rolling will require two nurses or more to maintain alignment of the spine and prevent trauma. The other actions are not the correct methods for log-rolling.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs of acute and chronic mental illness

628. The nurse would expect to encounter withdrawal and odd eccentric behaviors when caring for a group of clients with which cluster of personality disorders?
- Paranoid, schizoid, schizotypal
 - Antisocial, borderline, histrionic, narcissistic

- C. Avoidant, dependent, obsessive-compulsive
- D. Passive-aggressive, masochistic

The answer is A. Withdrawal and odd, eccentric behaviors are characteristic of clients with paranoid, schizoid, and schizotypal personality disorder. Attention seeking and erratic behaviors are characteristic of clients with antisocial, borderline, histrionic and narcissistic personality disorders. Clients with avoidant, dependent or obsessive compulsive personality disorder are attempting to avoid or minimize anxiety or fear.

Clients with passive-aggressive or masochistic personality disorder are covertly aggressive against self or others.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

629. A woman is admitted to the emergency room with bleeding from a stab wound in the right chest area. Which assessment findings would the nurse interpret as indicating the initial phase of hypovolemic shock? Mark all that apply.
- A. Increased hematocrit
 - B. Narrowed pulse pressure
 - C. Elevated heart rate
 - D. Oxygen saturation of less than 80%
 - E. Increased rate and depth of respiration
 - F. Absent superficial peripheral pulses
 - G. Slowed capillary refill

The answers are B, C, and G. Pulse pressure narrows because in the initial stage of hypovolemic shock the body attempts to compensate for the blood loss through vasoconstriction which decreases the size of the vascular bed. Vasoconstriction increases the diastolic blood pressure but not the systolic, thus the pulse pressure is decreased or narrowed before the systolic pressure drops from loss of volume. Heart rate also increases as part of the compensatory effort. The increased heart rate is an attempt to maintain cardiac output despite the fact that stroke volume is decreased. Capillary refill or the time taken for color to return to the nail bed after being pressed until it blanches is slow or even absent in shock.

Hematocrit and hemoglobin are decreased in shock caused by hemorrhage; they are increased in other types of hypovolemic shock. Oxygen saturation of less than 80% is not a sign of initial shock; it is a sign of later progressive shock. Increased respiratory rate is a sign of initial shock but depth does not increase until shock has progressed to the point that lactic acidosis is present. Superficial peripheral pulses may be difficult to locate and easily obliterated in initial shock but absent superficial peripheral pulses are a sign of later shock.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Provide preoperative care

630. A child is scheduled for surgery. Which are nursing actions to be carried out prior to surgery? (Select all that apply.)
- A. Check the child for loose teeth.
 - B. Remove finger nail polish from fingers and toes.
 - C. Have appropriate lab reports available on the chart.
 - D. Verify that the parents have signed an informed consent.
 - E. Check that the child has been NPO for a specified period of time.

The answers are A, B, C, D, and E. All responses are correct and should be included in the presurgery routine.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body System

631. A 44-year-old client is admitted to the emergency department with burns to the neck and face received from an explosion while working on a gas pipeline. During the nurse's initial assessment, highest priority should be given to:
- A. Noting signs of increased intracranial pressure (ICP)
 - B. Monitoring hourly intake and output
 - C. Assessing changes in circumference of the neck
 - D. Replacing fluid loss since based on weight

The answer is C. Assessing circumference of the neck will identify increases in girth and potential restriction of the airway from edema. ICP not pertinent in the absence of head injury and would not replace maintenance of a patent airway as a priority. Monitoring I&O is important but not the initial priority. Replacing fluid is essential in burn therapy but not a priority over airway.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

632. Which precaution measures would be instituted when a client has a Mycoplasma pneumoniae infection? (Mark all that apply.)

- A. ___ Client is placed in a private, negative airflow pressure room.
- B. ___ Client is placed in a private room or with other clients with infection caused by the same organism.
- C. ___ Use mask at all times while in the client's room.
- D. ___ Use mask when working within 3 feet of the client
- E. ___ Use gown and protective barriers when giving direct care.
- F. ___ Mask on client if transported out of room.
- G. ___ Use gloves at all times when caring for clients.
- H. ___ Use gloves when there is risk of exposure to blood or body fluids.

The answers are B, D, F, and H. *Mycoplasma pneumoniae* is spread by droplet transmission. Transmission-based precautions for droplet transmission require a private room or a room shared with someone infected with the same organism. Those entering the room and coming within 3 feet of the client need to wear a mask and the client wears a mask if taken out of the room. Standard precautions, which involve wearing gloves whenever there is the risk of touching something wet that comes from the body surface or a body cavity, i.e., when there is the risk of contact with blood or body fluids, are used at all times for all clients.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

Perform emergency care procedures

633. A client comes into the Emergency Room with a heavily bleeding thigh wound. Which is the priority nursing action?
- A. Start oxygen
 - B. Put pressure on the wound
 - C. Establish an IV line
 - D. Determine the cause of the wound

The answer is B. The first priority is to put pressure on the wound to stop the bleeding and prevent further blood loss which can lead to hypovolemic shock. Oxygen is given to aid maintenance of tissue oxygenation. An IV line is established for fluid replacement and the cause of the wound would be determined as a guide to management. However none of these is the first priority.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Dosage calculations

634. Using the Parkland formula (4 ml of lactated ringer's solution/% TBSA burn/kg body weight/24 hours), the nurse would calculate fluid replacement for a 70-kg client with a 50% TBSA burn over 24 hours as
- A. 1400 ml
 - B. 14,000 ml
 - C. 6720 ml
 - D. 700 ml

The answer is B. 14,000 ml is the correct number. $4 \times 50 = 200$ ml/kg. Client weighs 70 kilograms so $70 \times 200 = 14000$ ml.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Informed Consent

Ensure that client has given informed consent for treatment

635. The physician has ordered IVIG (intravenous immunoglobulins) to be administered to a client on a monthly basis. Prior to starting this therapy, the nurse would make certain that the client:
- A. is aware of the importance of being NPO the morning of the infusion.
 - B. has signed an informed consent for a blood product.
 - C. understands that once started, the therapy cannot be stopped.
 - D. recognizes that he or she will be contagious for 2 days after receiving the IVIG product.

The answer is B. IVIG are antibodies removed from the blood of blood donors. One dose of IVIG can contain antibodies from 60,000 individuals. All other statements are not correct.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Educate client and family about medications

636. Due to a severe asthma attack, a client has been on corticosteroids for more than 2 weeks. Which information should the nurse give the client about when the time comes to stop the medication?

- A. Fluid intake will need to be limited.
- B. The dose of medication will be tapered down slowly.
- C. Extra calcium will be needed for a week to ten days.
- D. Vitamin supplements will be needed to prevent bone loss.

The answer is B. Corticosteroids suppress the body's own production of corticosteroids by the adrenal gland. Sudden stopping of the medication could be fatal. The other responses are incorrect.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of acute and chronic mental illness

637. Which symptoms would the nurse expect to find when assessing a client in the prodromal stage of schizophrenia?
- A. social isolation and withdrawal
 - B. impaired role function
 - C. Speech aberration
 - D. peculiar beliefs
 - E. markedly odd behavior

The answers are A, B, C, D, and E. Social isolation withdrawal, impaired role function, speech aberration, peculiar beliefs, and markedly odd behavior are all symptoms that can occur in the prodromal phase of schizophrenia. Speech disturbance may be manifested as vague or circumstantial speech, over elaborate speech, or poverty of speech and content. Other prodromal symptoms include unusual perceptual experience and marked lack of initiative, interests and energy. At least two of these symptoms persisting continuously for six months must occur for the diagnosis of prodromal schizophrenia to be made.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptations

Fluid and electrolyte imbalances

638. A client arrives in the emergency department after having been burned with hot oil over the upper entire anterior chest and right leg. When the client is being triaged, which is the most important question for the nurse to ask?
- A. "What time did the burn occur?"
 - B. "Have you had any pain meds since the burn?"

- C. "How did you stop the burning process?"
- D. "What caused this burn initially?"

The answer is A. The time the burn occurred will determine the amount of fluid replacement.

The other questions may be asked but none is more important than the time of the burn because fluid replacement is of critical importance and none of the other questions provide information needed to determine it. Pain assessment is important but fluid replacement is priority. Knowing how the burning process was stopped is not critical in fluid replacement. Option D is important but not priority.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

639. A visitor falls to the floor in front of the nursing station. Which assessment findings are indicative of sudden cardiac death?
- A. Fixed, dilated pupils
 - B. Absent respirations
 - C. Absent pulses
 - D. Absent blood pressure
 - E. Loss of consciousness

The answers are B, C, D, and E. Absence of respirations, pulses and blood pressure along with loss of consciousness are signs of full cardiac arrest. Pupils become fixed but not necessarily dilated.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Use of Restraints/Safety Devices

Comply with federal/state/institutional policy regarding the use of client restraints and/or safety devices

640. A 2-year-old child has had a cleft palate repair. Elbow restraints have been placed on the child's arms to prevent the child from damaging the suture line. How does the nurse manage the restraints?
- The nurse
- A. never removes the restraints.
 - B. removes both restraints at the same time every 2 hours.
 - C. removes the restraints one at a time when providing range of motion.

- D. removes the restraints only when there is another adult present to prevent suture damage.

The answer is C. The restraints are removed every two hours, one at a time. At that time the underlying skin is evaluated and range of motion exercises are provided.

A is incorrect as the restraints need to be removed periodically. B is incorrect as the restraints would be removed one at a time. D is incorrect as the nurse does not need another adult to remove the restraints.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

Counsel/teach client/family/significant others about managing client health problem

641. A 3-month-old infant has been diagnosed as being at risk for sudden infant death and apnea monitors are being used in the home. Parent teaching will include:
- A. infant CPR.
 - B. heimlich maneuver for infancy.
 - C. postural drainage techniques.
 - D. use of portable oxygen.

The answer is A. Unless the parents know infant CPR, they will be unable to respond if their child has an apneic period. The other responses are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

642. A newborn infant has been diagnosed with Down's syndrome. The parents have been informed that the child will have mental retardation. The parents ask the nurse what they can expect of their child's development. The best response by the nurse would include the information that their child will:
- A. develop in an undeterminable pattern.
 - B. never develop basic skills due to the mental retardation.
 - C. develop in the same pattern as other children but at a slower rate.
 - D. will follow the same developmental time frame as other children but will stop developing before the other children.

The answer is C. Mentally retarded children develop in the same order as other children—they will learn to sit before

they stand, stand before they walk, etc. The other answers are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Teach client about managing illness

643. A child has been diagnosed with scabies. In addition to washing the child with the prescribed medication, the nurse would instruct the mother to:
- A. wash all bed linens in hot soapy water.
 - B. wash all fruits and vegetables before use.
 - C. have the family's dog checked for evidence of infestation.
 - D. discard all of the child's clothing and replace with new clothing.

The answer is A. All bed linens and clothing should be washed in hot soapy water to kill the itch mites. This itch mite is not acquired from food sources. The dog does not transmit the itch mite to humans. It is not necessary to discard all clothing.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical emergencies

644. An industrial nurse responds to an emergency in the plant where a worker is burned. Which is the correct sequence of nursing actions?
- A. Eliminate the source of the burn, ensure airway patency, observe for and treat associated injuries, treat burn shock.
 - B. Eliminate the source of the burn, ensure airway patency, cool the burn wound, apply topical antibiotic cream.
 - C. Ensure airway patency, insert a nasogastric tube, insert a bladder catheter, start IV fluid infusion.
 - D. Treat burn shock, ensure airway patency, start IV antibiotics and put the client in reverse isolation.

The answer is A. The appropriate sequence of nursing actions for clients with major burn injuries is to eliminate the source of the burn, ensure airway patency, assess for and treat associated injuries, and treat burn shock. Options B, C, and D may be appropriate during care of such a client, but response (A) represents the correct sequence for initial assessment.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

645. Why are clients who have had back surgery, such as a laminectomy or spinal fusion, turned by log rolling?
- Guard against wound dehiscence
 - Prevent excess pressure on the operative site
 - Maintain body alignment
 - Protect against skin breakdown

The answer is C. In log rolling, the client is turned all at once with the back as straight as possible. This maintains proper body alignment and avoids disruption of the surgical site. Other answers are incorrect.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Confidentiality/Information Security

Maintain client confidentiality/privacy

646. The nurse is working in the emergency department when a call is received from a police officer asking about the condition of one his colleagues who has been injured while on duty. Which is an appropriate nursing action?
- Give only general information about the client.
 - Encourage the officer to contact a member of the client's family.
 - Transfer the call to the hospital administrator.
 - Answer his questions once the identity of the officer is confirmed.

The answer is B. Sharing of a client's health information is governed by the HIPPA regulations. No information can be given to a friend or coworker. Referring the officer to a family member does not guarantee that this person has or will share information but does not violate the privacy requirements.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

647. Your client has an external fixator to the right lower extremity to stabilize an open fracture of the tibia and

fibia with extensive soft tissue damage. The client is complaining of a tingling sensation in the foot. Which is the priority nursing action in response to the client's new complaint?

- Administer pain medication
- Assess pain level using a pain scale
- Notify physician of client's status
- Perform neurovascular assessment

The answer is D. Prior to any of the other interventions, the nurse will need to do a full assessment of the status of the leg. The physician will need the additional information to determine the appropriate medical intervention.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

648. A client suffered blunt trauma to the chest in a motor vehicle accident (MVA) and is later diagnosed with adult respiratory distress syndrome (ARDS). The nurse is formulating a plan of care for this client and knows that the nursing goal with the highest priority should relate to which area?
- Improving nutritional status and decreasing protein wasting
 - Administering diuretics and antibiotics to combat infection
 - Maintaining oxygenation and eliminating underlying cause of ARDS
 - Monitoring the client's blood pressure and PaCO₂ levels

The answer is C. Airway and oxygenation are always the first priority. Maintaining oxygenation takes the priority over monitoring blood pressure and ensuring good nutrition.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs of acute and chronic mental illness

649. The nurse would expect to encounter attention seeking and erratic behaviors when caring for a group of clients with which cluster of personality disorders?
- Paranoid, schizoid, schizotypal
 - Antisocial, borderline, histrionic, narcissistic
 - Avoidant, dependent, obsessive-compulsive
 - Passive-aggressive, masochistic

The answer is B. Attention seeking and erratic behaviors are characteristic of clients with antisocial, borderline, histrionic and narcissistic personality disorders. Withdrawal and odd, eccentric behaviors are characteristic of clients with paranoid, schizoid, and schizotypal personality disorder. Clients with avoidant, dependent or obsessive compulsive personality disorder are attempting to avoid or minimize anxiety or fear.

Clients with passive-aggressive or masochistic personality disorder are covertly aggressive against self or others.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

650. The nurse is caring for a client with ARDS. To reduce oxygen consumption in this client, the nurse should provide
- ample time for rest and relaxation
 - 100% oxygen per nasal cannula
 - increased daily caloric intake
 - 21% oxygen per mask as needed

The answer is A. It is the only response that considers and reduces oxygen consumption.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

651. A suicidal client has ingested a large amount of an unknown poison. The client has no signs of injury to the mouth but is difficult to arouse. Which would be the appropriate intervention for this client?
- Administer syrup of ipecac immediately
 - Initiate gastric lavage after assessment
 - Give milk or water orally to dilute gastric content
 - Call the poison control center for an antidote

The answer is B. Gastric lavage would be instituted to remove the poison. Gastric lavage would not be used if signs of injury from a corrosive poison are present because the lavage tube might perforate the burned esophagus. Syrup of ipecac should not be given to induce vomiting with a difficult to arouse client because of the risk of aspiration. Giving oral fluids also is contraindicated because of the risk of aspiration. Since the poison is unknown, calling the Poison control center for an antidote is not possible.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Identify expected physical, cognitive, psychosocial, and moral stages of development

652. The nurse is observing a group of preschoolers in a day care. The nurse recognizes that the child who is showing signs of a developing conscience is the child who:
- tattles on a classmate.
 - stays close to the teacher.
 - ignores other children's toys.
 - carries a security object with them at all times.

The answer is A. When a child is developing a sense of conscience, they often tattle because of their recognition of right and incorrect in others. None of the other behaviors are related to the development of conscience.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness Management

Apply knowledge of pathophysiology to illness management

653. A newborn was diagnosed with osteogenesis imperfecta. When handling the infant, the nurse would:
- wear gloves to prevent contamination.
 - maintain the infant in semi-fowler's position.
 - restrain the infant to prevent trauma to the bones.
 - use the palms of the hands to handle the infant's extremities.

The answer is D. Children with osteogenesis imperfecta have fragile bones and must be handled by the palms of the hands. None of the other responses are appropriate for this child.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

654. Which of the following principles of growth and development is being addressed when the nurse explains to the parent that the infant will develop control of the head before control of the torso and legs?
- Cephalocaudal
 - Proximodistal

- C. Mass to specific
- D. Simple to complex

The answer is A. Cephalocaudal means head to tail and refers to the fact that development occurs from the head downward. Normal development simultaneously occurs from midline to periphery which is proximodistal. Mass to specific refers to differentiation. Simple to complex refers to operations in which simple precedes complex ones and is similar to mass to specific.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

655. A 78-year-old male in the late stages of Alzheimer's disease is in an extended care facility. He complains to the nurse that he is tired and his neck is sore from working in the field all day. Which of the following is the best response from the nurse?
- A. "You know you don't work in the field anymore"
 - B. "What type of motion caused the soreness"
 - C. "You're 78-years-old, You've been here all day with me, you haven't worked in the field in years"
 - D. "Would you like me to rub your neck and apply a warm compress?"

The answer is D. Validating the client's reality is the most appropriate intervention for later stages of Alzheimer's disease. He is not a candidate for reality orientation. The nurse is responding to what she can help with, his sore neck. The other answers are confrontational and close off communication.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

656. A client is transported to the emergency department following multiple traumatic fractures from a motor vehicle accident. Which assessment findings would be a priority for the nurse to report to the physician 6 hours after a spica body cast has been applied?
- A. Pedal pulses are equal but weak.
 - B. The lower extremities are cool to touch.
 - C. The client is complaining of itch under the cast.
 - D. The client complains of pain with respirations

The answer is D. Pain with respirations could mean restricted lung expansion and compartment syndrome. This is the priority because it involves airway and oxygenation.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Palliative/comfort care

657. The client in the burn unit is complaining of severe pain in the first 24 hours following the burn injury. Which of the following is the usual method of dealing with pain during this period?
- A. Liquid narcotics are given via the NG (nasogastric) tube as needed.
 - B. Narcotics are administered via the intramuscular route into non-burned tissue.
 - C. Intravenous narcotic agents are administered for pain as needed.
 - D. No medications are given during this period because of respiratory depression.

The answer is C. The client will have IV access as a component of the resuscitation process. Intravenous administration allows for quick results of the narcotic. Narcotics administered through the NG or IM route would be slower in providing relief. Although respiratory depression would be monitored, narcotic pain relief would still be given.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

658. A client is seen in the emergency room following an industrial accident involving chemical burns. The nurse recognizes that the severity of a chemical burn depends on which factors?
- A. The mechanisms of action.
 - B. Penetrating strength and concentration.
 - C. The amount and duration of exposure.
 - D. The age of the client
 - E. The occupation of the client

The answers are A, B, C, and D. Factors related to the chemical itself, type of chemical, concentration, amount and duration of exposure, all affect the severity of the burn. The age of the skin affects how easily it is injured as well as healing ability. Age affects general condition of client. The occupation will have no effect.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of acute and chronic mental illness

659. When assessing a client newly admitted with a diagnosis of active phase schizophrenia, which are positive

symptoms at least one of which the nurse would expect to find?

Mark all that apply.

- A. ___ disorganized speech
- B. ___ flat affect
- C. ___ delusion
- D. ___ impaired attention
- E. ___ bizarre behavior
- F. ___ hallucination

The answers are A, C, E, and F The positive signs of active phase schizophrenia are delusion, hallucination, disorganized speech, and bizarre or disorganized behavior. At least one of these positive signs must be present for at least one month for a diagnosis of active phase schizophrenia to be made. Flat affect and impaired attention are negative symptoms of schizophrenia.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

660. A client with burns on the face and neck is at risk for airway obstruction. Which of the following would be most indicative of a potential airway obstruction?
- A. Singed nasal hairs
 - B. Neck and face pain
 - C. PaO₂ of 80 mm Hg
 - D. Coughing up large amounts of thick, white sputum

The answer is A. Singed nasal hairs indicate the client breathed in hot gases. This can lead to edema of the oral mucus membranes. Pain in these areas does not indicate airway problems. PaO_x of 80 is low normal. Thick white sputum would not indicate airway burns.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

661. A client with a suspected pulmonary embolus is admitted to a medical unit from the emergency department. The client complains of shortness of breath and severe chest pain. Which other signs and symptoms would support the diagnosis of pulmonary embolism?
- A. Low grade fever
 - B. Productive white sputum
 - C. 2 degree AV block
 - D. Frothy sputum

- E. Tachycardia
- F. Blood-tinged sputum

The answers are A, E, and F Chest pain and dyspnea are cardinal signs and symptoms of pulmonary embolism. Clients may also have a low grade fever, tachycardia which is a compensatory mechanism for decreased oxygen supply, and blood tinged sputum. Productive white sputum is not suggestive of pulmonary embolism. Frothy sputum would indicate pulmonary edema.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

662. An older gentleman reports that he has needed to use more salt than usual to make his food taste good. He asks the nurse what this could mean. The nurse's response should be based on the knowledge that
- A. the number of taste buds decreases with age.
 - B. older persons need more sodium to ensure good kidney function.
 - C. increased sodium is needed to compensate for lost fluids.
 - D. the client may be confused due to his advancing age.

The answer is A. The taste buds begin to atrophy at age 40 and after age 60 there is an insensitivity to taste qualities. There are also studies that indicate that there are changes in the salt threshold in some elderly individuals. The other options are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Identify common developmental patterns of a pediatric client

663. When observing a two year old in the hospital playroom, which type of play would the nurse interpret as representative of normal development?
- A. Solitary
 - B. Parallel
 - C. Associative
 - D. Dramatic

The answer is B. Solitary play is seen in the infant, associative play is seen in a preschooler. A school age child may demonstrate dramatic play.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical emergencies

664. The client is admitted to the emergency room with massive bleeding and a gunshot wound to the chest in severe respiratory distress. Which nursing action has the highest priority when managing the emergency?
- Establish and maintain an open airway
 - Start cardiopulmonary resuscitation
 - Initiate oxygen therapy via nasal cannula
 - Apply pressure to wound to control bleeding

The answer is A. Establish airway is the correct response. Without a patent airway, all other measures are not critical. CPR is not appropriate since the client is not pulseless. Oxygen therapy via nasal cannula is not appropriate for severe respiratory distress. Applying pressure to the wound to control bleeding is critical but does not take priority over establishing and maintaining an airway.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

665. A client is being discharged home on anticoagulant therapy. Which instructions should the nurse include as part of discharge teaching? (Select all that apply.)
- Avoid use of aspirin containing drugs while receiving Coumadin.
 - Do not keep fresh flowers in the home.
 - Report dark, tarry stools to primary health care provider.
 - Avoid brushing teeth to prevent bleeding gums.
 - Avoid inactivity for prolonged periods of sitting with legs crossed.
 - Change positions frequently while traveling; walk occasionally; exercise legs and ankles.
 - Continue anticoagulants for length of time ordered.

The answers are A, C, and G. Aspirin has an anticoagulant effect and as a result enhances the effect of Coumadin. Therefore it is contraindicated for clients taking Coumadin. Dark tarry stools need to be reported because bleeding is an adverse effect of anticoagulation and bleeding in the upper GI tract can present as dark, tarry stools as a result of the presence of blood which has been exposed to digestive secretions. It is important that clients for whom anticoagulants are prescribed follow the directions for taking the medications precisely; this includes taking the medication for the length of time ordered. Fresh flowers are not contraindicated for clients on Coumadin; they

are contraindicated for clients who are immunocompromised. Brushing the teeth should be done regularly, not avoided. However, a soft bristled toothbrush should be used. Moving and avoiding inactivity are instructions that would be given to clients at risk for venous thrombosis.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

666. A client suffered deep partial-thickness and full-thickness burns over 40% of his body approximately 12 hours ago. Urine output is 22 ml/hour and the hematocrit is 50%. ABG values show pH, 7.32; paO_2 , 95 mm Hg; PaCO_2 , 35 mm Hg; and HCO_3^- , 18 mEq/L. Based on this data, which conclusion can the nurse draw about the client's status?

The client

- is hypovolemic from fluid shift and has metabolic acidosis.
- is in the early stages of heart failure caused by over hydration.
- is adequately hydrated, but in acute renal failure and respiratory acidosis
- has developed a polycythemia as the body attempts to compensate for metabolic acidosis and renal failure.

The answer is A. During the first 24 hours after a burn injury, fluid is lost from the intravascular space into the tissues causing hemoconcentration and diminished urine output.

There is no indication of over hydration. The client does not show symptoms of respiratory alkalosis. The condition is hemoconcentration not polycythemia.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

Assess client for drug/alcohol related dependencies, withdrawal, or toxicities

667. When examining a neonate on admission to the newborn nursery, which assessment findings would the nurse interpret as consistent with fetal alcohol syndrome? Mark all that apply.
- Elongated palpebral fissures
 - Strawberry hemangioma
 - Thick upper lip
 - Cleft palate
 - Congenital hip dislocation

The answers are B, D, and E. Malformations associated with fetal alcohol syndrome which would be evident in the neonate include strawberry hemangioma, low set posteriorly rotated

ears, cleft lip/cleft palate, pointy chin, thin upper lip, short palpebral fissures, microcephaly, joint dysfunction including congenital hip dislocation, abnormal palmar creases, thoracic cage abnormalities, atrial and ventricular septal defects.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alterations in body systems

668. The client is admitted to the emergency room for acetaminophen overdose. The nurse should prepare to
- place an intravenous catheter and administer 1000cc D5W intravenously.
 - induce gastric emptying by inserting a nasogastric tube for lavage.
 - give syrup of ipecac and follow with activated charcoal.
 - insert a Foley catheter and start diuresis immediately.

The answer is C. Removal of the poison by inducing vomiting followed by preventing absorption is standard treatment for a non-caustic poisoning. Gavage would be unnecessary as a way to remove the poison. The other two options have nothing to do with poison removal.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

669. When examining a 3-year-old, which part of the health assessment should be done first?
- Abdominal palpation
 - Otoscopic examination
 - Oral examination
 - Chest auscultation

The answer is D. Chest auscultation is the least intrusive part of the physical examination and should be done first to provide time for the child to adjust somewhat to being examined and to delay upsetting the child.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

670. An 18-year-old client is brought to the emergency room for a hornet sting. Which symptoms suggest that the client is having an anaphylactic reaction?

- rhinorrhea
- wheezing
- local edema
- urticaria
- angioedema
- generalized pruritus

The answers are A, B, D, E, and F. Signs of anaphylaxis which is a hypersensitivity reaction, typically begin with feelings of apprehension and impending doom. Generalized pruritus, urticaria, and sometimes swelling of the eyes, lips, and tongue (angioedema) follow. Respiratory congestion, rhinorrhea, wheezing and dyspnea occur as a result of bronchoconstriction, mucosal edema and production of excess mucus. Laryngeal edema is associated with hoarseness and stridor. Full blown shock may ensue.

PSYCHOSOCIAL INTEGRITY

Therapeutic Environment

671. A new mother of a 1-month-old infant is concerned that she is spoiling the baby “because she carries her around the house in an infant sling against her chest.” The nurse’s best response would be:
- “You should not carry her in the sling except when you are going out and need to take her.”
 - “She should spend at least half of her waking time on a firm surface by herself.”
 - “Spoiling an infant is difficult; cuddling and holding are essential for normal development.”
 - “Carrying an infant in a sling is not advised because of potential problems with development of the spine.”

The answer is C. Cuddling and holding along with meeting other basic needs builds trust and is essential for normal growth and development. The child can be carried in the infant sling at home as well as when the mother goes out. There is no set time the infant should be alone and on a flat surface. Use of a sling has not been shown to cause problems with the spine.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

Provide nursing care in a safe and effective manner

672. The nurse would question an order for a mydriatic medication to be administered to a client with which disorder?
- Narrow angle glaucoma
 - Drug overdose

- C. Blunt force head injury
- D. Suspected spinal cord injury

The answer is A. A mydriatic medication dilates the pupils. Pupil dilation is contraindicated with narrow angle glaucoma so an order for a mydriatic would be questioned because of its ability to cause harm. Pupil dilation does not have the potential for injury in relationship to the other disorders.

HEALTH PROMOTION AND MAINTENANCE

Expected Body Image Changes

673. During the routine well check up of an 18 month old, the mother asks the nurse about her son's protruding abdomen. Which fact should form the basis of the nurse's response?
- A. The abdomen protrudes as a result of increased food intake at this age
 - B. Underdeveloped abdominal muscles are the reason for the protruding abdomen.
 - C. A protruding abdomen indicates a possible abnormal curvature of the spine.
 - D. A protruding abdomen is uncommon in toddlers and requires further assessment.

The answer is B. Underdeveloped abdominal musculature gives the toddler the characteristic protruding abdomen.

A is incorrect because during toddlerhood food intake decreases. C is incorrect because, although it's normal, it doesn't provide the answer to the mother's question. D is incorrect as protruding abdomen is common in toddlers.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for alterations in body systems

674. The client with which problem would be at greatest risk for developing a pulmonary artery thrombosis?
- A. Fluid volume overload
 - B. Ventricular fibrillation
 - C. Increased cardiac output
 - D. Polycythemia

The answer is D. Polycythemia predisposes to stasis of blood as a result of increased viscosity secondary to the increased numbers of red blood cells. None of the other problems predispose to thrombosis.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

675. A client presents to the emergency department with a foreign object in the eye. Which action should the nurse take?
- A. Remove the object after an x-ray is taken.
 - B. Remove the object after notifying the ophthalmologist.
 - C. Leave the object untouched while awaiting the ophthalmologist.
 - D. Flush the eye with saline to dislodge the object.

The answer is C. The nurse would make no attempt to remove the foreign body until the client has been examined by an ophthalmologist.

HEALTH PROMOTION AND MAINTENANCE

Techniques of Physical Assessment

Choose physical assessment equipment and technique appropriate for the client

676. The nurse is admitting a 2-year-old child to the hospital unit for a minor surgical procedure. When examining the child, which approach is most appropriate?
- A. Have the parent wait in the next room
 - B. Have the toddler sit on the parent's lap
 - C. Allow the child to remain clothed.
 - D. Keep equipment to be used out of sight

The answer is B. The child will be more cooperative if his or her parent holds the toddler on lap for the exam. Separating the child from the parent will most likely increase the child's distress and there is no reason to do so. It is not possible to perform an effective physical examination with clothing in place. The child should not only see but be allowed to handle equipment to decrease fear and anxiety.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs of acute and chronic mental illness

677. The nurse would expect to encounter clients who are covertly aggressive against self or others when working with a group diagnosed with which types of personality disorder?

- A. Paranoid, schizoid, schizotypal
- B. Antisocial, borderline, histrionic, narcissistic
- C. Avoidant, dependent, obsessive-compulsive
- D. Passive-aggressive, masochistic

The answer is D. Clients with passive-aggressive or masochistic personality disorder are covertly aggressive against self or others. Withdrawal and odd, eccentric behaviors are characteristic of clients with paranoid, schizoid, and schizotypal personality disorder. Attention seeking and erratic behaviors are characteristic of clients with antisocial, borderline, histrionic and narcissistic personality disorders. Clients with avoidant, dependent or obsessive compulsive personality disorder are attempting to avoid or minimize anxiety or fear.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

678. Which statement made by a client taking methotrexate for rheumatoid arthritis indicates that information regarding side effects of the medication was understood?
- A. "It's too bad medications have to have side effects but I guess I can deal with headache and nausea."
 - B. "I don't know how my husband will cope if I become confused and hallucinate from this medication."
 - C. "I already have a heart murmur; I am afraid that this medication will make it worse and I will end up needing heart surgery."
 - D. "I know this medication is very likely to cause kidney damage but the symptoms of the rheumatoid arthritis are so bad that I have to take it anyway."

The answer is A. Side effects of methotrexate include headache and nausea and this statement indicates the client understands that fact. Heart damage is one of several side effects of doxorubicin (Adriamycin). Hallucinations and confusion are side effects of ifsoamide (Ifex). Kidney damage is a side effect of carboplatin (Paraplatin).

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

679. While being helped out of bed to a chair, a client who is two days postoperative from abdominal surgery starts to cough forcefully and the surgical

wound eviscerates. What is the priority nursing intervention?

- A. Cover the wound with a moist sterile dressing
- B. Start intravenous fluids and antibiotics
- C. Apply an abdominal binder
- D. Notify the physician.

The answer is A. The wound should be covered with a moist sterile dressing. Moisture prevents the wound from drying out and becoming necrotic prior to surgery. Wound evisceration is a surgical emergency and while one nurse is with the client and covering the wound, a second should be notifying the surgeon. If a client is at known risk for evisceration, sterile dressing and sterile saline should be available in the client's room. Intravenous fluids and antibiotics will be part of the client's care but are not the immediate priority. Abdominal binders are not appropriate and could cause damage to wound.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

680. A toddler is hospitalized for medical treatment. When the mother leaves, the child screams and cries for his mother. He refuses to be comforted and will not eat while mother is not present. The nurse interprets the child's behavior as indicative of which stage of toddler hospitalization reaction?
- A. Protest
 - B. Despair
 - C. Detachment
 - D. Regression

The answer is A. Protest is a stage of anger at the separation from the parent. Despair is mourning the loss of the parent. The child would no longer display anger but would be saddened by the loss. Detachment is a stage where the toddler appears to be the "good client"—appears happy with the parent present.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

681. The client is diagnosed with a life-threatening condition characterized by inadequate blood flow to the tissues and cells of the body to meet metabolic demands. Nursing care should focus on:
- A. restoring circulating volume
 - B. maintaining adequate IV access

- C. monitoring intake and output
- D. weighing daily
- E. observing for fluid overload

The answers are A and B. These activities are designed to restore circulation while observing for complications of nursing interventions.

Responses C, D and E are assessment tools to evaluate the success of the interventions.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Rest and sleep

682. Which information should the nurse include when teaching the parent of an 8-year-old child about bedtime schedules?
- A. The child's need for sleep is greater now than in adolescence.
 - B. Minimum requirement for optimal growth and development is 10 hours of sleep a night.
 - C. The child is often unaware of his own fatigue level.
 - D. Nightmares and night tremors are common in this age group.

The answer is C. School-age children are often unaware of their own fatigue level. If allowed to stay awake they will be tired the next day.

Because of slowed growth rate, during the school-age period less sleep, not more, is required than in adolescence. Eight-year-old children do not require a minimum of 10 hours of sleep. Nightmares and night terrors are common in the preschool period.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication administration

683. A client is requiring resuscitation secondary to a respiratory arrest. During the code, epinephrine is ordered. The most effective route of administration would be:
- A. Intravenously
 - B. Endotracheally
 - C. Intradermally
 - D. Subcutaneously

The answer is B. The quickest and most effective route would be via endotracheal tube.

The IV route is slower but effective. Subcutaneous or intradermal administration is inappropriate.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

684. The nurse is discussing readiness for toileting with a child's parents. Which factor would the nurse identify as a contraindication to beginning toilet training at this time?
- A. The toddler wakes up dry from a nap
 - B. The toddler stays dry for up to 3 hours
 - C. The toddler wants to have a soiled diaper changed promptly.
 - D. The toddler has a toilet adjacent to his bedroom in the family's brand new home.

The answer is D. Moving is a stressful and toilet training should not be initiated during stressful period.

Choices A, B, and C are all signs of readiness for toilet training.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in body systems

685. A child is admitted to the emergency room with multiple blunt trauma to the chest, and crushing wounds to the abdomen, and legs. Which are the priority nursing assessments?
- A. Level of consciousness and pupil size
 - B. Abdominal contusions and other wounds
 - C. Pain, respiratory rate, and blood pressure
 - D. Quality of respirations and presence of pulses

The answer is D. These are top priorities in trauma management; basic life functions must be maintained or reestablished. Level of consciousness and pupil size are part of the assessment for head injury. Assessment for head injury and assessment for abdominal injury and pain follow appraisal of airway, breathing, and circulation.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

686. Which instructions would the nurse give to a client starting on Pentoxifylline (Trental)? Mark all that apply.
- A. Take on an empty stomach
 - B. Report any unusual bleeding or bruising

- C. ___ There may be toxic drug effects if taken with Theophylline
- D. ___ Drug reduces red blood cell aggregation

The answers are B, C, and D. Pentoxifylline (Trental) should be taken with food to decrease GI symptoms. Information in all other answers should be included in client teaching regarding self administration of Pentoxifylline (Trental).

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

687. Which precaution measures would be instituted when a client has tuberculosis? (Mark all that apply.)
- A. ___ Client is placed in a private, negative airflow pressure room.
 - B. ___ Client is placed in a private room or with other clients with infection caused by the same organism.
 - C. ___ Use mask at all times while in the client's room.
 - D. ___ Use mask when working within 3 feet of the client.
 - E. ___ Use gown and protective barriers when giving direct care.
 - F. ___ Mask on client if transported out of room.
 - G. ___ Use gloves at all times when caring for clients.
 - H. ___ Use gloves when there is risk of exposure to blood or body fluids.

The answers are A, C, E, and H. Tuberculosis is spread in small particle droplets by airborne transmission. Airborne precautions require a private room with negative airflow and adequate filtration; those entering the room wear a mask and if the client leaves the room, a mask is worn. Standard precautions, which involve wearing gloves whenever there is the risk of touching something wet that comes from the body surface or a body cavity, i.e., when there is the risk of contact with blood or body fluids, are used at all times for all clients.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alteration in body systems

688. A client is admitted to the emergency room with a diagnosis of acute respiratory distress syndrome. Which assessment findings would the nurse expect?

- A. A systolic blood pressure greater than 170
- B. Tenacious thick greenish yellow sputum
- C. An altered level of consciousness
- D. Slow abdominal breathing

The answer is C. Cognition and level of consciousness are reduced secondary to cerebral hypoxia which accompanies ARDS. Blood pressure may be reduced. Sputum is not tenacious, but may be frothy if pulmonary edema is present. Breathing will be rapid and shallow not slow and abdominal.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

689. After administering an IM injection to 3-year-old child the nurse puts an adhesive bandage on the site. The reason for applying the bandage is based on the fact that:
- A. the child will “pick” at the injection site.
 - B. the bandage will relieve pain at the site.
 - C. the preschool child is afraid his “insides will fall out” and the bandage prevents “insides from leaking.”
 - D. the bandage will remind the nurses that the child has received an injection recently.

The answer is C. Preschoolers want a bandage on any scrape or bruise to prevent their insides from leaking out. Most children will not pick at the site, bandages do not relieve pain, and nurses should not need a reminder that a child has received an injection.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

690. Which type of delivery system would the nurse use when administering oxygen to a client who has experienced a cardiac arrest?
- A. A nasal cannula at 1 liter per minute.
 - B. A 100% non-rebreather mask.
 - C. A 28% venti-mask
 - D. A face mask at 4 liters per minute

The answer is B. A non-rebreather mask provides the highest concentration of oxygen available. All other choices would provide insufficient oxygen. With a simple face mask, the flow rate must be at least 5 liters per minute to flush the mask of carbon dioxide.

PSYCHOSOCIAL INTEGRITY

Family Dynamics

Assist client/family/significant others to integrate new members into family structure

691. A very young teenager has just given birth to a healthy infant. The nurse is concerned about bonding. To promote bonding, the nurse would:
- Encourage early parent–infant interaction and close body contact.
 - Allow mother infant interaction only when a nurse can be present.
 - Require the new mother to breastfeed the infant.
 - Tell the new mother how bright and alert her baby is.

The answer is A. Studies have shown that immediately after birth is the best time for maternal infant bonding.

B, C, and D are incorrect because maternal-child contact would not be limited; the mother has the right to choose to breast feed or not; telling the mother her baby is bright and alert does not promote bonding.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

692. A client with disseminated intravascular coagulation has a severe reaction to a unit of packed cells and develops a humoral immunity. The nurse knows that humoral immunity:
- Is produced by T-cell activity
 - Involves immunoglobulins
 - Occurs only in anaphylactic reactions
 - Involves the thymus

The answer is B. Humoral immunity is mediated by B lymphocytes and is involved in an anaphylactic reaction. A is incorrect as it is B cell activity. Humoral immunity can also involve immunocomplex hypersensitivities. The thymus is not involved.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

693. Which symptoms occurring in a 4-week-old male infant are consistent with a diagnosis of pyloric stenosis?
- Metabolic alkalosis
 - Uninterested in feeding

- Vomiting bile stained fluid.
- 2 ounce weight loss over last 3 days.
- Peristalsis observed over the abdomen.

The answers are A, D, and E. A and D are related to the vomiting that occurs. Peristalsis may be visible on the abdomen as the stomach tries to push formula past the obstruction. The infant will be hungry, vomiting will not be bile stained.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

694. A client has been admitted to the hospital unit for stasis venous ulcers. Which nursing intervention would be included in the plan of care?
- Performing Burger-Allen Exercises
 - Providing bedrest with legs in a dependent position
 - Placing a foot board on the bed
 - Placing the client in a high fowler's position

The answer is C. Use of a footboard keeps pressure off of the ulcer. Burger-Allen Exercises are done for Buerger's disease. Keeping legs in a dependent position increases edema. High Fowler's position increases pressure and kinking on the vascular system.

PSYCHOSOCIAL INTEGRITY

Sensory/Perceptual Alterations

Assess needs of clients with altered sensory perception

695. When planning care for a client with hallucinations, the nurse would consider that the client is most likely to harm self or others in which stage of the hallucinatory process?
- comforting
 - condemning
 - threatening
 - controlling

The answer is D. Controlling. There are four stages in the hallucinatory process. In stage 1, the hallucination is familiar and comforting and anxiety level is mild. In stage 2, the hallucination is condemning; it is accusing and makes the person feel guilty and isolated. In stage 3, the hallucination is threatening and begins to rule all different aspects of behavior. In the fourth or controlling stage, anxiety has increased to the panic level and the individual is unable to control behavior. It is in this stage that the risk of harm to self or others is greatest.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

696. A maternity client is seen for her regular checkup at 20 weeks gestation. On assessment, the nurse notes that the uterus is at the level of the xiphoid process. The nurse would suspect:
- Oligohydramnios
 - Multiple Gestation
 - Intrauterine growth retardation
 - Fetal demise

The answer is B. At 20 weeks gestation, the fundus should be at the level of the umbilicus. This finding indicates the fundus is above the expected location. The only response that would cause the fundus to be higher than normal is B. All other conditions would lead to a fundus below the expected level.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

697. The parent of a 3-year-old child tells the nurse that she is worried because the child has irrational fears. "My child is afraid to go to bed, afraid of the neighbor's gentle Golden Retriever, every day there's a new fear" Which of the following is the best response from the nurse?
- "Preschool children have the most fears; try a night light to help going to bed and know that being afraid of large dogs is very common in this age group."
 - "Your child should be growing out of these irrational fears by now, let's get her involved in some play and see what seems to be going on."
 - "Don't make too much of it; just be patient; this phase will pass soon"
 - "Going to bed is often a problem, let her fall asleep in your bed and then carry her back to her bed when she is sleeping"

The answer is A. The preschool years are the time when children have the most fears. Option A reassures the mother her child's behavior is normal and it gives the mother information that will help her deal with the child's fear.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

698. A 4-month-old infant puts a toy in their mouth and begins to choke. Which is the appropriate nursing action?

- Position infant head down and provide back blows.
- Elevate the infant's head and provide back blows.
- Position the fist below the navel, then using both fists perform four abdominal thrusts.
- Place one fist on the sternum and perform chest thrusts.

The answer is A. The infant is positioned head down and back blows are given. Back blows are used on the conscious infant. Trendelenburg position is used to assist with foreign body removal. The other responses are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

699. Which suggestion could the school nurse make to the parents of a 10-year-old child who want to promote their child's psychosocial development?
- Encourage the child to start a collection of model cars, baseball cards, or other similar items.
 - Meet the needs of the child in a consistent manner.
 - Avoid disciplining the child during this difficult period.
 - Reinforce that the child is a good person even if behavior is bad.

According to Erikson, the school age child's task is to develop industry vs. inferiority. A child's sense of industry is enhanced by building a collection. Being consistent helps meet the needs of the infant. Informing the child that he is a good person even if his behavior is bad is appropriate for a toddler. All children need discipline as they are uncomfortable when there are no rules.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

700. While providing nursing care, the client has a respiratory arrest. Which are the priority interventions for the resuscitation of this client?
- Intubating with an endotracheal tube
 - Starting 100% oxygen
 - Drawing serial arterial blood gases
 - Checking the Glasgow coma scale
 - Monitoring oxygen saturation level

The answers are A and B. Both of these actions would promote oxygenation.

C and D are assessment measures that would be done but they are not the priority. Response E is unrelated to a respiratory arrest.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

701. A client returns to the hospital unit following an appendectomy. Which finding on the postoperative admission assessment should be reported to the physician immediately?
- Oral temperature 99°F
 - Pulse 98 and thready
 - Complaints of nausea
 - Absent bowel sounds

The answer is B. A pulse of 98 and thready is suggestive of hemorrhage. Oral temperature may be slightly elevated as a result of the procedure. Nausea is common in the postoperative period. Absent bowel sounds are common in the immediate postoperative period.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

702. An 89-year-old man came to the clinic for his annual checkup. Which finding related to pulmonary function would the nurse expect?
- An increase in functional alveoli
 - A reduction of residual volume
 - A decrease in vital capacity
 - Blood gases that show mild acidosis

The answer is C. A decrease in vital capacity because loss of elastic forces in the lung lead to an increase in residual volume, and a decrease in vital capacity.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications of diagnostic tests/treatments/procedures

703. A client in the emergency department is intubated and connected to a mechanical ventilator. She becomes extremely anxious, and the pressure alarm sounds with each inspiration. Which is the priority nursing intervention?
- Increase the tidal volume
 - Increase the oxygen concentration

- Disconnect the ventilator and manually ventilate the client using a ventilator bag for a few breaths.
- Administer the prescribed diazepam or morphine sulfate as needed.

The answer is C. This allows the nurse to assess for a mucus plug which would occlude the ET tube causing the increased pressure alarm. The other interventions would be inappropriate.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

704. The nurse is teaching self care to a client who has been diagnosed with Raynaud's disease. Which instruction best meets the goal of maintaining optimal tissue perfusion?
- Inspect skin daily for breakdown
 - Alleviate factors that increase pain
 - Wear mittens when going out into the cold
 - Elevate extremities when color changes occur due to vasoconstriction

The answer is C. Keeping the hand warm enhances vasodilation and tissue perfusion. Inspection of the skin is important to prevent complications but does not enhance vasodilation. Alleviating factors that increase pain promotes comfort and may help prevent further decreases in tissue perfusion but does not optimize it. Elevating extremities decreases circulation to the extremity.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs and symptoms of impaired cognition

705. The nurse says to a schizophrenic client "Swallow your pills, John." The client responds by saying "Swallow your pills John; swallow your pills John; swallow your pills John; swallow your pills John" Which would be a correct label for the nurse to use when documenting this communication?
- word salad
 - clang association
 - neologism
 - echolalia

The answer is D. Echolalia. Echolalia is the repetition of words or phrases heard from another person. Word salad refers to the meaningless connection of words and phrases.

Clang association refers to repeating words and phrases which sound alike but are otherwise unconnected. A neologism is a new word coined by the client and with meaning only to the client.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

706. A teenager has been admitted to the hospital unit with a diagnosis of appendicitis. While awaiting the start of surgery, it becomes apparent that the appendix has ruptured. At this time, in what position will the nurse maintain the client?
- Prone
 - High Fowlers
 - Left side-lying
 - Trendelenburg

The answer is B. High Fowlers position utilizes gravity to collect the infectious material in one area of the abdomen reducing the extent of peritonitis. The other responses would not be correct.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

707. A client is admitted to the emergency room with a blood pressure of 72/42 mm HG and a diagnosis of septic shock. Which assessment finding would best confirm this diagnosis?
- Hot, dry skin with poor skin turgor
 - ABG analysis revealing metabolic alkalosis
 - Temperature of 105°F (40.6°C) and a pulse rate of 122 beats/minute
 - Urine output of 30 ml/hour and central venous pressure of 8 cmH₂O

The answer is C. Septic shock is related to the presence of endotoxins or exotoxins released from bacteria. Symptoms include fever, tachycardia, increased respiratory rate and shock and coma. The other responses are not related to septic shock.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Identify expected physical, cognitive, psychosocial, and moral stages of development

708. When planning care for a 4-year-old, the nurse considers the fact that the child does not yet comprehend which concepts?

- Alternative points of view
- Conservation
- Reversibility
- Object permanence

The answers are A, B, and C. A 4-year-old child is egocentric and doesn't understand another's view yet. Conservation, which is permanence of mass and volume, is not comprehended nor is the concept of reversibility i.e. if $2 + 3 = 5$, then $5 - 3 = 2$. Object permanence is mastered and understood in toddlerhood.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

709. A client is experiencing septic shock and the attending physician wants to titrate medications to be regulated so that a mean arterial pressure (MAP) between 75 and 85 mmHg is maintained. When evaluating the response of the drug, which of the blood pressure readings meet the goal?
- 135/90
 - 125/80
 - 115/70
 - 110/60

The answer is C. The formula for mean arterial pressure (MAP) is $SBP + 2 DBP$ divided by 3. The blood pressure with mean arterial pressure between 75 and 85 is 115/70 (MAP), $(115 + 70 + 70 = 255/3 = 85)$ is 85.

A, B, and C are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

710. A 24-year-old post partum client is transferred to the ICU after developing disseminated intravascular coagulation (DIC). The nurse develops a care plan in collaboration with the physician knowing that the care of a client with a bleeding/clotting disorder usually includes:
- Monitoring core body temperature
 - Initiating heparin therapy
 - Administering blood
 - Restricting dairy products in the diet

The answer is B. Heparin is given because the abnormal clotting that occurs with DIC uses up available clotting factor. Heparin inhibits clotting and therefore allows clotting factor to be replenished. Monitoring core body temperature is not a priority with DIC. Blood is not administered because the problem is clotting, not bleeding. Dairy products are unrelated to DIC.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

711. Which finding when reviewing the record of an elderly client would the nurse interpret as a normal occurrence with aging?
- Very concentrated urine
 - Microscopic hematuria
 - Occasional urinary incontinence
 - Decreased glomerular filtration rate

The answer is D. Changes in the renal tubules cause a dramatic decrease in the glomerular filtration rate. Hematuria, either microscopic or gross, is always abnormal. Incontinence is also abnormal.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

712. After diagnosis of diverticulitis, a client has been taught about the appropriate dietary changes. Which statements by the client indicate that teaching was successful?
- "I will eat a low-fiber diet."
 - "Milk will increase my episodes of diverticulitis."
 - "Whole grains are better for me than refined grains."
 - "Starches, fruits and vegetables will increase my flatus and diarrhea."

The answers are B and C. A diet to prevent constipation is recommended. Milk can be constipating so it can contribute to increase episodes of diverticulitis. Whole grains are better than refined grains because they provide more fiber. Option A is incorrect because a high fiber not a low fiber diet is needed to prevent constipation. Starches, fruits and vegetables are good sources of fiber so they decrease not increase symptoms.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complications of Diagnostic Tests/Treatments/Procedures

713. A 20-year-old male suffered a broken jaw in an automobile accident. The jaw has been wired shut. The nurse will ensure that which of the following equip-

ment will be available at the client's bedside for safety?

- Call light
- Wire cutters
- Clear liquids
- Paper and pencil

The answer is B. If the client should vomit, he could choke and aspirate. Wire cutters would need to be immediately available. The call light is appropriate for all clients. Clear liquids would not be a safety feature. Paper and pencil may aid communication but are not emergency supplies.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

Provide symptom management for clients experiencing withdrawal or toxicity

714. When planning care for a client withdrawing from cocaine, which is a critical nursing intervention?
- Monitor for seizures
 - Protect from self harm
 - Orient to time and place
 - Monitor for hypotension

The answer is D. Protect from self harm. The client withdrawing from cocaine or another central nervous stimulant experiences severe dysphoria, anxiety, disturbed sleep and is at significant risk for suicide. Hence a priority nursing intervention is to prevent self harm. Seizures and confusion can occur with withdrawal from alcohol, sedatives/hypnotics, and anxiolytic drugs. Hypertension, not hypotension is a risk with cocaine withdrawal.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical emergencies

715. A client is brought into the emergency department complaining of severe back pain. He is diaphoretic, pale, tachycardic, and has absent pedal pulses. Which is the immediate nursing intervention?
- Start an IV with a 16 gauge catheter
 - Get a stat back x-ray
 - Prepare the client for insertion of hemodynamic monitoring
 - Get a 12 lead ECG

The answer is A. The client is showing signs of shock and needs immediate vascular access. The other interventions could be done later.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

716. A 2-week-old infant has returned from surgery for repair of a unilateral cleft lip. The nurse instructs the mother to comfort the baby when the baby becomes upset and starts to cry. The mother asks why it is important that the baby not cry. The nurse's response would be based on the knowledge that crying:
- puts strain on the suture line.
 - may prevent the infant from developing trust.
 - causes the infant to swallow air and may cause vomiting.
 - simulates coughing in the post operative infant.

The answer is A. A crying infant will open the mouth wide putting strain on the sutures in the upper lip. Although meeting the infant's needs in a timely fashion is important in the development of trust, it is not the correct response in this situation. Crying does cause the infant to swallow air, but that is not the primary reason for comforting the child. Crying stimulates coughing but is not appropriate for this child.

PSYCHOSOCIAL INTEGRITY

Coping Mechanisms

717. A 15-year-old boy was admitted to the pediatric unit following an injury to his leg. When told that the complicated fracture would require surgical repair and prevent a return to the football team for an unknown extended period of time, the boy throws an apple from the lunch tray at the nurse. Which type of coping behavior is the teenager exhibiting?
- Reaction formation
 - Projection
 - Denial
 - Displacement

The answer is D. Displacement is shifting focus from an undesired object or feeling to a more acceptable object or feeling. Reaction formation is acting opposite to how one feels. Projection occurs when one attributes one's own unacceptable feelings to another. In denial one ignores unacceptable realities.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic tests

718. A client is suspected of having osteoporosis. Which test will provide the best information regarding this problem?

- Serum calcium
- X-ray of pelvis
- CT scan of spine
- DEXA scan

The answer is D. Dual energy x-ray absorptiometry (DEXA) measures bone mineral density. It allows detection of early osteoporotic changes in the wrist, spine and/or hip. It is the best diagnostic tool available for osteoporosis. There are no laboratory tests that definitively diagnose primary osteoporosis. Serum calcium is one of a battery of laboratory tests used to rule out secondary osteoporosis or other metabolic disease. X-rays and CT scans do not provide an accurate picture of the mineral content in bone that denotes bone density and do not detect early bone changes.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

719. Which assessment finding on a 78-year-old woman most likely reflects age-related decreased blood vessel elasticity and increased peripheral resistance?
- An irregular peripheral pulse
 - An increase in blood pressure
 - Night time confusion
 - Wide QRS complexes on the ECG

The answer is B. Thickening of the blood vessels and less distensible arteries and veins cause impeded blood flow and increased vascular resistance, leading to hypertension.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication administration

720. The nurse is pushing IV medications during a "code blue." Which is a critical step in the procedure?
- Check the orders with the chart
 - Inspect the IV site for infiltration
 - Evaluate the peripheral pulses
 - Flush the line with dextrose between drugs

The answer is B. Inspecting the IV site for infiltration is critical because medication will not be effective if administered into the tissue rather than the blood stream. Orders are usually verbal during a code situation. Pulses are generally absent if in a code blue situation. Lines should be flushed with sodium chloride.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Develop and maintain therapeutic relationships with client/family/significant others

721. Which is an appropriate guideline for the nurse to utilize when communicating with an adolescent?
- Reassure that what he or she is going through is understood.
 - Invite the parents to be present when talking with the adolescent.
 - Ask meaning of expressions if not clearly understood as a result of teen culture.
 - Share with the parents information received in their absence.

The answer is C. Understanding the meaning of the adolescent's expression will aid in understanding the communication and display interest in the adolescent's point of view.

A is incorrect as this statement will discourage further comments. B is incorrect as the adolescent may not be willing to talk in front of his parents. The child will feel betrayed if the nurse reports the conversation to the parents.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

722. A child is admitted to the hospital unit with a diagnosis of pyloric stenosis. On admission, the nurse would expect to see which electrolyte imbalance?
- Hypokalemia
 - Hypernatremia
 - Hyperchloremia
 - Hypomagnesemia

The answer is A. Potassium is lost by vomiting. All other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected effects/outcomes

723. A client is being treated for Gastroesophageal Reflux Disease (GERD). When the nurse administers famotidine (Pepcid) to the client, the client asks how this medication will help. The nurse's reply will be based on the knowledge that the medication will:
- Decrease gastric acidity reducing irritation to the esophagus.

- Relax the lower esophageal sphincter (LES) preventing further reflux.
- Increase intraabdominal pressure to maintain positive pressure in the esophagus.
- Decrease the intra-gastric pressure putting less strain on the lower esophageal sphincter (LES).

The answer is A. Symptoms of the disease are due to the regurgitation of stomach acids into the esophagus. By reducing the acidity of stomach contents, symptoms will be reduced.

The other responses are incorrect. The activity described in B and C would increase the symptoms.

HEALTH PROMOTION AND MAINTENANCE

Disease Prevention

724. Working on a geriatric unit, the nurse knows that the bed bound hospitalized older adult is at risk for pressure ulcers. Which factors seen in the unit's clients would increase the risk for pressure ulcers?
- Diminished sensory perception
 - Dry fragile skin
 - Decreased mobility
 - Indwelling urinary catheter
 - Decreased appetite since hospitalization
 - Nursing assessment every shift

The answers are A, B, C, and E. Dry fragile skin increases the risk for skin breakdown. Diminished sensory perception diminishes the amount of normal shifting and movement, not allowing for the relief of pressure, increasing the risk for skin breakdown. This is true with decreased mobility as well. Incontinence, not an indwelling catheter would increase the risk of pressure ulcers. Nursing assessment and interventions including a turning and positioning schedule, bed bath and massage, ROM exercises, and providing appetizing nutritious foods with adequate protein that the client likes, is key to the prevention of pressure ulcers.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body System

725. In preparing a discharge teaching plan for a client diagnosed with thrombophlebitis and being treated with warfarin, which instructions would the nurse include?
- Eat a diet high in fiber and leafy green vegetables
 - Start a progressive exercise program
 - Drink at least eight glasses of fluid daily
 - Do not use oral contraceptives

The answers are B, C, and D. The instruction to eat a diet high in leafy green vegetables would not be included because green leafy vegetables contain vitamin K, which can affect the needed dose of warfarin. All other instructions are appropriate and would be included in discharge plan.

PSYCHOSOCIAL INTEGRITY

Psychopathology

Recognize signs of acute and chronic mental illness

726. The nurse would expect to encounter clients who are attempting to avoid or minimize anxiety or fear when working with a group diagnosed with which types of personality disorder?
- Paranoid, schizoid, schizotypal
 - Antisocial, borderline, histrionic, narcissistic
 - Avoidant, dependent, obsessive-compulsive
 - Passive-aggressive, masochistic

The answer is C. Clients with avoidant, dependent or obsessive compulsive personality disorder are attempting to avoid or minimize anxiety or fear. Withdrawal and odd, eccentric behaviors are characteristic of clients with paranoid, schizoid, and schizotypal personality disorder. Attention seeking and erratic behaviors are characteristic of clients with antisocial, borderline, histrionic and narcissistic personality disorders. Clients with passive-aggressive or masochistic personality disorder are covertly aggressive against self or others.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

727. The nurse is caring for a client with Alzheimer's disease (AD), the most common form of dementia in older adults. Which factors are associated with AD? Select all that apply:
- Acute onset
 - Impaired memory
 - Confusion
 - Difficulties with language
 - Reversible organic disorder
 - Amyloid plaques

The answers are B, C, D, and F. AD is a progressive, irreversible, organic disorder, characterized by confusion, disorientation, impaired memory and cognition. Personality changes are seen, and in later stages eventual dependency for all ADLs and IADLs. Amyloid plaques and neurofibrillary tangles are found in the brains of AD clients.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological agents/actions

728. A child has been admitted to the hospital unit for gastroenteritis. The child has been having diarrhea for 3 days and is moderately severely dehydrated. The stool cultures indicate a rotovirus as the cause of the diarrhea. The mother questions the nurse why her child isn't on antibiotics like the other children on the unit with GE. The nurse's response would be based on the knowledge that:
- antibiotics will make the diarrhea worse.
 - the diarrhea has probably already run its course.
 - antibiotics are not used for rotovirus gastroenteritis.
 - the child is too dehydrated for antibiotics to be effective.

The answer is C. Antibiotics are used to treat bacterial infections not viral. Diarrhea is often a side effect of antibiotics but is not the correct response here. The other responses are incorrect.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Recognize behaviors associated with psychosocial development

729. Which of the following behaviors indicates a 3 month old infant is developing a sense of trust?
- Eats and sleeps well
 - Makes cooing noises
 - Has developed object permanence
 - Clings to mother and cries when she is not present

The answer is A. A sense of trust indicates trust in the world around them that basic needs will be met. Cooing noises occur because a child can hear himself. Object permanence is a component of Piaget's theory and not related to trust versus mistrust. Clinging to the mother occurs after object permanence develops in a much older infant.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Develop and maintain therapeutic relationships with client/family/significant others

730. A toddler is hospitalized for minor surgery. The parents are unable to stay with the child. The child reacts to the separation with a saddened expression, refusal to eat and continues to cry for momma. How should the nurse respond?

- A. Encourage the child to forget mom and dad.
- B. Hold the child and tell him mommy loves him and will come back.
- C. Ignore his cries as they do not represent physical discomfort.
- D. Avoid mentioning parents while holding and comforting the child.

The answer is B. This is the despair phase of toddler hospitalization reaction. The appropriate response is for the nurse to provide physical comfort and reinforce that the parents will return. The child's psychological needs can not be ignored. The child needs the parents for healthy development.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic procedures

731. After an infant has a barium enema reduction of intussusception, the nurse will know the reduction was successful when the infant:
- A. smiles at mother.
 - B. passes a solid stool.
 - C. falls asleep without medications.
 - D. takes his regular amount of formula.

The answer is B. In addition to pain, the symptoms of intussusception include passing a "currant jelly" stool followed by intestinal obstruction. Passing a solid stool would indicate the obstruction has cleared. The other responses do not address the pathology.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

732. A 22-year-old man has accidentally ingested about 200 ml of a lye-based liquid drain cleaner. Which treatment should the nurse be prepared to administer when the client arrives at the emergency department?
- A. A cathartic to promote elimination of the poisonous substance
 - B. 30 ml of ipecac syrup followed by 240 ml of water to induce vomiting
 - C. 150 ml of milk or water to dilute the ingested substance
 - D. 75 g of activated charcoal to absorb the ingested chemical

The answer is C. The goal is to dilute the lye based product because it is caustic and tissue burn can result from contact with the agent. Diluting the product decreases the burn. Vomiting is contraindicated because the caustic product would come into contact with tissues of the esophagus, throat and mouth a second time and do more damage. Absorption of the chemical into the body is not the immediate concern so activated charcoal is not used.

HEALTH PROMOTION AND MAINTENANCE

Health and Wellness

733. A home health nurse sees many elderly clients and is concerned about their nutritional status. The nurse recognizes that the following factors contribute to the risk of malnutrition in older adults:
- A. Gastrointestinal changes including diminished saliva, decreased gastric acid and digestive enzyme secretions
 - B. Chronic illness
 - C. Poor dentition
 - D. Inadequate financial resources
 - E. Decline in functional ability
 - F. Moving to an Assisted Living Facility

The answers are A, B, C, D, and E. Poor dentition, GI changes, and chronic illness result in inadequate intake, poor ingestion and digestion of food. The older adult may believe that limited resources will prevent them from purchasing nutritional foods and eat junk food instead. The nurse needs to educate regarding affordable nutritional foods and work as case manager and arrange for food stamps. Functional ability is the extent to which one is able to perform Activities of Daily Living (ADLs) & Instrumental Activities of Daily Living (IADLs). Decline in ADLs includes the ability to prepare meals; a decline in IADLs includes the ability to go food shopping. With functional limitations, the nurse as case manager can arrange for meals on wheels. Assisted living provides balanced meals that promotes good nutrition.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Use the "six rights" when administering client medications

734. A dose of intravenous acyclovir should be administered over what period of time? Record your answer as a whole number of minutes in the space provided.
- _____minutes

Answer is 60 minutes.

Acyclovir is nephrotoxic. It is excreted primarily by glomerular filtration and tubular secretion. To decrease the risk of nephrotoxicity, the client must be well hydrated; the drug must be administered over a period of 60 minutes; and urinary output must be measured for two hours after the infusion. Output of less than 500 mL of urine per gram of acyclovir must be reported immediately.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

735. The nurse preparing a client for a cardiac catheterization and revascularization should include which information in the pre-op teaching.
- The client will be asleep during the procedure
 - The client may experience a hot flash as the dye is injected
 - There may be a sand bag placed over the cannulated site following the procedure
 - The client will be on fluid restrictions until the gag reflex returns
 - The client may experience chest pain when the balloon is inflated
 - The client will experience a headache as the dye is injected

The answers are B, C, and E. The client is generally awake during the procedure and fluid intake is encouraged in order to assist the kidneys with excretion of the dye. Generally a client may experience a metallic taste in the mouth or a hot flash when the dye is injected.

PSYCHOSOCIAL INTEGRITY

Coping Mechanisms

Assess client response to illness

736. An 8-year-old child is hospitalized and undergoing diagnostic testing. Her parents can spend very little time with her because of the demands of work and four younger children at home. Nonetheless the child appears calm, does not complain, and seems unperturbed by all the stress. How would the nurse interpret this behavior?
- The child is mature for her age and is dealing well with hospitalization.
 - A child of this age is not invested in health or family matters; peers are the concern and she will be receiving a lot of attention from them.

- The child is employing reaction formation which is a primary defense mechanism for her age.
- The child is coping by regressing.

The answer is C. The primary defense mechanism at this stage is reaction formation, which is acting brave, when really being quite frightened.

A, B, and D are incorrect—The child is interested in peers, but the rest of the comments are not true. Regression is seen in younger children and the symptoms of this child are not those of regression but are typical in reaction formation.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

737. The client is receiving Heparin IV at 1200 units/hour as part of the treatment regime for pulmonary embolism. The nurse notes that the urine has become bright red in color. The nurse would prepare to administer which of the following medications?
- Protamine Sulfate
 - Aquamephyton (vitamin K)
 - Warfarin (Coumadin)
 - Acetylcysteine (Mucomyst)

The answer is A. The antidote for Heparin is protamine sulfate. Bright red urine suggests hematuria which is a potential adverse effect of anticoagulation. Aquamephyton is the antidote for Coumadin overdose and Acetylcysteine is the antidote for acetaminophen poisoning.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

Incorporate knowledge of theories of development in planning care for the client

738. A chronically ill adolescent has been hospitalized frequently for extended periods of time. Because of the severity of the illness and as a result of the hospitalization, the adolescent has been unable to develop a sense of who he is or what he will become. According to Erikson, these deficiencies will result in which of the following:
- role diffusion
 - inferiority
 - isolation
 - stagnation

The answer is A. The adolescent is working on developing a sense of identity. Other answers are for other stages.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications and side effects

739. A client who is in the Cardiac Care Unit complains of mediastinal chest pain, dyspnea, and anxiety. The nurse gives the client a nitroglycerine tablet sublingual. The client now complains of being dizzy. Which is the priority nursing intervention?

- A. Get a 12 lead ECG
- B. Raise the side rails on the bed
- C. Open the D5W IV to 100 cc per hour
- D. Take vital signs including pulse oximetry

The answer is B. Safety is the priority.

C would not be correct because it is not an isotonic solution and would not help to maintain circulating volume. A would be done but would not be the priority. D is not the priority.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

740. Which of the following would the nurse identify as normative signs of aging, as opposed to pathologic signs?

- A. Increase in diastolic blood pressure
- B. Decrease in glomerular filtration rate
- C. Reduced lens elasticity
- D. Reduced vital capacity
- E. Dulled sense of taste
- F. Pressure ulcers

The answers are B, C, D, and E. A mild increase in systolic BP is expected, however an increase in diastolic BP is pathological. Normative changes in renal tubules cause a dramatic decrease in glomerular filtration rate. There is a normal decrease in lens elasticity. A normative decrease in chest wall compliance and atrophy of respiratory muscles contributes to reduced vital capacity. There is a normative dulled sense of taste, touch, and pain. Pressure ulcers are a pathological sign.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

741. Which is an indication of a successful outcome for a client who is recovering from an abdominal aortic aneurysm repair?

- A. Capillary refill of the toes >5 seconds
- B. Pulse Oximetry of the foot = 88%

C. BP diastolic = 80 mm Hg.

D. Urine output = 15 cc per hour

The answer is C. Diastolic blood pressure of 80 mm Hg. High BP puts pressure on the surgical site. Capillary refill should be ≤ 3 seconds. Pulse oximetry should be $\geq 95\%$. Urine output should be ≥ 30 cc per hour.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assist client with achieving and maintaining self-control of behavior

742. Which statement made by the parent of a suicidal client indicates the need for further explanation about a “no suicide” contract?

- A. The contract provides a boundary.
- B. The contract gives the client responsibility for control.
- C. These contract serve to reinforce to the client that life is valuable.
- D. Verbal as well as written contracts have been shown to be effective.

The answer is C. No suicide contracts do not directly reinforce that life is valuable. Therefore this is an incorrect statement and indicates that the parent needs further explanation.

All other statements about a no suicide contract are correct. A “no suicide” contract is a way of providing boundaries. Contracts help place control in the domain of the client. Both verbal and written “no suicide” contracts have proven effective.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

743. Which symptoms identified during the assessment of a 4-week-old male infant are consistent with the diagnosis of pyloric stenosis?

- A. Metabolic alkalosis
- B. Lack of interest in feeding
- C. Vomiting bile stained fluid.
- D. 2 ounce weight loss over last 3 days.
- E. Peristalsis observed over the abdomen.

The answers are A, D, and E. Metabolic alkalosis, weight loss, and visible peristalsis are signs of pyloric obstruction. Metabolic alkalosis and weight loss result from vomiting that occurs with pyloric stenosis. A and D are related to the vomiting that occurs. Peristalsis may be visible on the abdomen as the stomach tries to push formula past the obstruction. The infant will be hungry, vomiting will not be bile stained.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

744. When doing an intake assessment on the older adult, which factor should the nurse consider?

The older adult

- A. responds with increased emotion to questions related to family history.
- B. often has diminished auditory acuity and may impede communication.
- C. is uncomfortable with the physical assessment because of multiple physical changes.
- D. has an increased response to pain requiring extreme caution with the physical assessment.

The answer is B. Diminished auditory acuity is common and communication is affected. Response to pain is decreased. Other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Nutrition and oral hydration

745. A two week old infant has had several periods of apnea. After work-up, the physician diagnoses the infant with GERD and instructs the nurse to teach the mother feeding techniques to diminish reflux. The nurse will teach the mother to:

- A. avoid burping the baby to discourage reflux.
- B. keep the infant in an upright position after feeding.
- C. rock the baby during the feeding to keep him calm.
- D. place the baby prone after feeding to prevent aspiration if reflux occurs.

The answer is B. Upright position uses gravity to assist in formula retention. Burping would be more frequent in the GERD infant. Rocking will mix air with the formula making vomiting more likely. Prone position would put pressure on the abdomen and may increase vomiting.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

746. The nurse knows the older adult has an increased risk for drug toxicity. Which of the following contributing factors increase the risk for drug toxicity?

- A. Impaired renal function
- B. Decrease in blood flow to the kidneys
- C. Polypharmacy

- D. Urinary incontinence
- E. Possibility of multiple chronic conditions requiring medications
- F. Using many physicians and lack of communication between physicians

The answers are A, B, C, E, and F. The decline in renal function in the older adult results in inefficient excretion of active drug, allowing toxic levels of drug to accumulate, placing the older adult at risk for drug toxicity. Polypharmacy is the concurrent use of many drugs, which is common in older adults as a result of: increased number of chronic conditions, using many physicians, changing physicians frequently, using more than one pharmacy, lack of information about over the counter medications, and assumption that once a drug is started it must be finished.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct client on medication self-administration procedures

747. Which information/instruction would the nurse include when teaching the mother of child diagnosed with ADD about the proper use of the prescribed stimulant medication?

- A. Take the medication before a meal.
- B. If a dose is missed, take it as soon as remembered.
- C. Expect heavy sweating and heat intolerance as side effects of the medication.
- D. Follow up visits for lab tests or other monitoring are needed.

The answer is D. Follow up visits are critical so that the effects of the prescribed medication can be monitored. Monitoring may include laboratory studies, vital sign checks or EKGs. Stimulant medications should be taken after eating to avoid problems with appetite or indigestion. If a dose is missed, it is not “made up”, the next dose is simply taken as scheduled. Side effects of stimulant medications are anorexia, nausea and vomiting, insomnia, tachycardia and chest pain, headache, and irritability, nervousness or confusion.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

748. An elderly client in an extended care facility hollers from her bed “Nurse, help me. They are throwing

dishes at me.” Which is the best response on the part of the nurse?

- A. “What kind of dishes is someone throwing at you?”
- B. “Have a drink of water and by then it will be over.”
- C. “I don’t see anyone throwing dishes but it must be scary for you; you are safe here.”
- D. “Why do you think anyone would want to throw dishes at you? You have never hurt anyone have you?”

The answer is C. This response is empathetic; acknowledges the client’s feeling; and offers reassurance. Responses A and D encourage the client to get more involved and add detail to the delusion and this is not therapeutic. Response B makes light of the client’s experience and has an element of false reassurance.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications of diagnostic tests/treatments/procedures

749. A client has just had an arthroscopy of the right knee for diagnostic evaluation of chronic knee pain. Which assessment finding has the highest priority for being reported to the surgeon?
- A. Report of pain is 7 out of 10 on pain scale
 - B. Strength of right pedal pulse is decreased.
 - C. Capillary refill time is 3 seconds..
 - D. Pain is unrelieved by application of ice.

The answer is B. The decrease in pedal pulse could be indicative of obstruction to arterial flow to the foot.

A, C, and D are not correct because pain immediately following the arthroscopy is expected. Capillary refill time of three seconds is normal and indicates good blood flow through the capillaries. In older individuals, up to 5 seconds is considered normal.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

750. A 35-year old man is brought to the emergency department by EMS personnel after he was found sitting in the car in an enclosed garage with the motor running. He is unresponsive and hypotensive, and his skin is bright red. Which intervention would have the greatest priority?

- A. Administration of oxygen
- B. Placing the client in a prone position.
- C. Administration of Narcan
- D. Initiating CPR.

The answer is A. Being found in an enclosed space in a car with its motor running with symptoms of bright red skin and unresponsiveness is indicative of carbon monoxide poisoning. The immediate intervention is to remove the client from exposure to carbon monoxide and administer oxygen. Oxygenation is always the first priority. Placing the client in a prone position is inappropriate. Narcan is an opiate antagonist; it is not used in the treatment of carbon monoxide poisoning. The client does not need CPR because his heart is beating if he is hypotensive.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Unexpected response to therapies

751. The nurse is performing post operative assessments on a client who has had a femoral artery revascularization. Which is the most critical finding?
- A. A quarter sized area of bright red drainage on the dressing
 - B. An apical pulse of 100 beats per minute
 - C. Complaint of numbness of the toes on the operative leg
 - D. An ankle-brachial index (ABI) of 1.0

The answer is C. Numbness is a symptom of arterial occlusion therefore it is the most critical finding as it can result in death of tissue. A quarter size area of bright red drainage on the dressing is not immediately critical; the nurse would circle the area and observe for continued bleeding. The apical pulse of 9 and the ABI pf 1.0 are both within normal range.

PSYCHOSOCIAL INTEGRITY

Abuse/Neglect

752. The home care nurse is providing an in-service on elder abuse to the home health aides that will be going out in the field. Which should be identified as potential signs of abuse? (Select all that apply.)
- A. Bruises in various stages of healing
 - B. Malnutrition and dehydration
 - C. Poor personal hygiene, disheveled unkempt appearance
 - D. Burns and broken bones

The answers are A, B, C, and D. All responses are possible signs of abuse.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

753. A nurse is a guest on a health related radio show. A listener calls in and asks what is the most common symptom of esophageal cancer. Which is the correct reply?
- Projectile vomiting.
 - Progressive indigestion.
 - Progressive dysphagia.
 - Hoarseness progressing to loss of voice.

The answer is C. Progressive dysphagia is the most common symptom of esophageal cancer. It is insidious in onset and often the client simply eliminates foods from the diet which are difficult to swallow and so remains unaware of the problem until suddenly realizing that only liquids can be swallowed. Projectile vomiting is associated with increased intracranial pressure, not with cancer. Progressive indigestion is associated with GERD and hiatal hernia. Hoarseness and ultimately voice loss is associated with laryngeal cancer.

HEALTH PROMOTION AND MAINTENANCE

High Risk Behaviors

754. When teaching about accidental injury to adolescents, what does the nurse identify as the most common cause of injury?

Answer: Motor vehicle accidents.

The adolescent is prone to Motor Vehicle Accidents due to reckless driving and speeding to show off, driving under the influence of drugs or alcohol (doing drugs and alcohol to be part of the gang), and failure to use seatbelts because it isn't 'cool'.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

755. The nurse is reviewing laboratory findings for a client who has Congestive Heart Failure. Which laboratory value should be reported to the physician immediately?
- Cholesterol level of 240 mg/dl
 - Digoxin level of 2.5ng/ml
 - Troponin 1 level of 0.30 ng/ml
 - Triglyceride level of 160 md/dl

The answer is B. Normal digoxin level is <2ng/ml and 2.5 ng/ml is a toxic level. Cholesterol level is slightly high but not critical. Troponin 1 level is normal. Triglyceride level is borderline high but not critical.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Home safety

756. The home care nurse is concerned with reducing the risk of falling for an 86-year-old client. Which statement represents the most appropriate approach to the problem?
- "I understand that you are concerned about finances, however adequate non glare lighting is very important to keep you safe. Can I speak to your son about trying the new florescent bulbs that are much less expensive to use."
 - "This house is not safe, it has years of accumulated clutter. Why don't you consider selling the house and move to a nursing home, where you will be safe and well fed."
 - "The old rug in the dining room under the table will have to go, it's worn out anyway."
 - "Never leave your room, when you are home alone, sit in the lounge chair or stay in bed, I'll set up a bed side commode for you."

The answer is A. When reading questions on communication listen to the tone of the response, abrupt, impolite, overly paternalistic responses can be eliminated. Responses with absolute terms such as all or never can be eliminated. Option A offers not only information needed but helps discover options within the client's means.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

757. A nurse is speaking to a community group on the early detection of cancer. A member of the audience asks what is a symptom of cancer of the larynx. Which is the correct response for the nurse to give?
- Projectile vomiting.
 - Progressive indigestion.
 - Progressive dysphagia.
 - Hoarseness progressing to loss of voice.

The answer is D. Hoarseness and ultimately voice loss is associated with laryngeal cancer.

Projectile vomiting is associated with increased intracranial pressure, not with cancer. Progressive indigestion is associated with GERD and hiatal hernia. Progressive dysphagia is the most common symptom of esophageal cancer.

HEALTH PROMOTION AND MAINTENANCE

Health Screening

Perform targeted screening examination

758. The nurse is performing health screening at the local junior high school for scoliosis. Which test should the nurse perform?
- Ask the child to stand on one foot to see if the pelvis shifts down.
 - Have the child bend at the waist to see if there is a difference between the sides.
 - Have the child twist at the waist from side to side to see if there is pain with the motion.
 - Ask the child to stretch toward the ceiling first with the left, then with the right side to see if one hand reaches higher.

The answer is B. This test is called the Adam's Forward Bend Test. Children with scoliosis will have a prominence on one side or the other. The other responses are not tests for scoliosis.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

759. A registered nurse and an LPN are working as a team to provide care for a group of clients. Which action by the LPN requires the RN to intervene?
- The LPN raises the knee gatch on the bed of a client who has an intraaortic balloon pump in order to relieve pressure on the client's back.
 - The LPN prepares to administer Lasix (furosimide) to a client whose potassium level is 4.2 mEq/L.
 - The LPN returns a client to bed after the client's heart rate increases from 72 to 96 beats per minute while ambulating in the hall.
 - The LPN brings breakfast to a client who is scheduled for an echocardiogram later in the morning.

The answer is A. The knee gatch should not be raised because it could cause the balloon catheter to be kinked off. All other actions are appropriate and do not require corrective intervention by the RN.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

760. Which disorder places the client at risk for tissue necrosis and breakdown of bone structure with decalcification?
- Osteoarthritis
 - Osteomyelitis
 - Osteoporosis
 - Osteogenesis

The answer is B.

A is incorrect—osteoarthritis or degenerative joint disease. C is incorrect—osteoporosis is a loss of bone density. D is incorrect—osteogenesis refers to the formation of bone in the body.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

761. A 5-year-old child has just returned from a tonsillectomy. The child's mother is at the bedside and caring for her child. Which observation made by the nurse while taking vital signs, requires nursing intervention?
- The child is lying supine.
 - An ice collar is lying on the child's neck.
 - The mother is offering the child ice chips from a spoon.
 - The child is drooling and the mother is wiping the child's mouth with a wash rag.

The answer is A. The child should not be in a supine position because of the risk of aspirating blood if the surgical wound should ooze. Nursing intervention is required to reposition the child in a side lying position and to explain to the mother the importance of maintaining the child in this position. None of the other options indicate the need for nursing intervention.

HEALTH PROMOTION AND MAINTENANCE

Aging Process

762. Many body systems manifest deteriorative changes to a greater or lesser degree with aging. The expected, normal signs of aging are called _____ changes.

Answer: Primary.

Primary changes are the expected normal changes associated with aging. An example of a primary change is

decreased elasticity of the skin. Pathological or disease related changes are referred to as secondary changes.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

763. A client has rheumatoid arthritis and is receiving hydroxychloroquine (Plaquenil). Which instruction should be given to the client prior to discharge home?
- Take this medication on an empty stomach.
 - Expect your urine to be greenish-yellow in color while taking this medication.
 - Report a weight gain of more than 5 lbs. to your physician.
 - Notify your physician if you experience any changes in vision.

The answer is D. because hydroxychloroquine can produce over time changes in vision due to ocular toxicity or retinopathy. These manifest as episodes of misty or foggy vision, “disappearing words” when reading, light flashes before the eyes, or seeing only half of the visual field. Hydroxychloroquine can be taken with meals to minimize gastrointestinal side effects. Hydroxychloroquine may discolor urine red or brown not green. Weight gain is not related to use of hydroxychloroquine.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Diagnostic tests

764. The CCU nurse notices that a client’s T wave has become inverted. Which is the priority nursing intervention?
- Give the client nitroglycerine sublingual, 1 tablet every 5 minutes three times
 - Start oxygen at 2–4 liters per minute via nasal cannula
 - Check for T wave elevation in the V1 lead
 - Check the client and verify lead placement

The answer is D. The leads may have gotten moved. It is priority to always check your client to verify that monitoring data is correct.

HEALTH PROMOTION AND MAINTENANCE

Health Screening

765. You are assessing an infant brought to the pediatric clinic. Which assessment finding would indicate that

follow up is needed because of possible developmental dysplasia of the hip?

- Outward turning of both legs
- Limited range of motion in the hip joint
- Crying and other signs of pain on flexing the hips
- Asymmetrical thigh and buttock skin creases

The answer is D. Asymmetrical thigh and buttock skin creases are an obvious sign of developmental dysplasia of the hip.

A is incorrect—there is no outward turning of the legs. B is incorrect—there is no limited range of motion in the hip. C is incorrect—developmental hip dysplasia is not painful.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

Identify client status based upon pathophysiology

766. Which interpretation should the nurse assign to assessment findings of delayed capillary refill, cyanosis and clubbing?
- Arterial oxygen levels are chronically low.
 - Carbon dioxide levels in the blood are elevated.
 - Compensatory polycythemia has developed.
 - Vital capacity has progressively decreased over time.

The answer is A. Delayed capillary refill, cyanosis and clubbing are signs of chronically decreased arterial oxygen levels. Elevated carbon dioxide levels (hypercarbia) is not always associated with hypoxemia and does not cause these signs. Polycythemia is an increase in red blood cells which does occur as a compensatory effort in clients with chronic hypoxemia; it does not cause the signs. Changes in vital capacity which is the amount of gas that can be expired after a maximum inspiration do not cause delayed capillary refill, cyanosis or clubbing.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

767. On assessing a client who has had coronary artery bypass grafting the nurse finds: T 100.2°F; pulse 110 beats per minute; BP 96/60 mm Hg; Respirations 20 per minute; distended neck veins; muffled heart sounds. Based on this assessment data, which is the priority nursing action?
- Increase frequency of client monitoring.
 - Ask the client about pain.
 - Report findings immediately to the physician
 - Call the lab to draw blood cultures

The answer is C. The client is displaying signs and symptoms of cardiac tamponade which is a medical emergency. Increased monitoring will occur but calling the physician is the priority. Pain may cause tachycardia but it wouldn't cause JVD. Lab cultures are usually not done until the temperature is 102°F or above.

PSYCHOSOCIAL INTEGRITY

Chemical and Other Dependencies

768. A client in a methadone program, is admitted with a broken pelvis following an automobile accident. Which fact should be considered when planning care for this client?
- The client is likely to be euphoric at intervals.
 - Methadone should continue to be given while the client is in the hospital.
 - The client will not need pain medication if he is receiving methadone.
 - If methadone is stopped, delusions or hallucinations may ensue.

The answer is B. Methadone maintenance should be continued while the client is in the hospital if at all possible. Methadone does not cause euphoria so if it is continued, the client will not have intervals of euphoria. Methadone does not adequately relieve acute pain so it will not eliminate the need for pain medication; it can be used with success in the management of chronic pain. Delusions and hallucinations are not symptoms of withdrawal from methadone and other opiates; delusions and hallucinations are associated with withdrawal from alcohol, sedatives/hypnotics, and anxiolytics.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

769. Which is the most common side effect of salicylates and NSAIDs used in the management of the pain and swelling associated with rheumatoid arthritis?
- Anorexia
 - Dizziness
 - Gastrointestinal distress
 - Weight loss

The answer is C. Long term use can result in irritation of the stomach lining.

Answers A, B, and D are incorrect because they are side effects for different classes of medication.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

770. The nurse is providing discharge instructions for a client who has been diagnosed with stable angina and has a prescription for nitroglycerine sublingual tablets. Which statement by the client indicates that further teaching is needed?
- "I should keep my pills in the original container."
 - "I need to replace my pills every month."
 - "I should go to the hospital if the pain is not relieved after taking a nitroglycerine."
 - "I should stop all activity and rest when having chest pain."

The answer is B. Pills should be replaced every 3–6 months. A, C, and D are all correct.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

771. According to Piaget's theory of cognitive development which of the following cognitive developmental skills are mastered between the ages of 7 and 11 (school-age years)?
- Concrete thought
 - Conservation
 - Complex classification
 - Abstract thinking
 - Sees another's point of view

The answers are A, B, C, and E. The stage of concrete operations is between 7 and 11 years of age. Thought becomes logical, concrete, and based on tasks in the here and now. The school-age child masters conservation and complex classification and is also starting to understand that other's have a different point of view from their own. Abstract thinking and reflecting on theoretical matters begins in the preadolescent years.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

772. The nurse on the hospital unit receives a call from admitting stating a client with a question of an intestinal obstruction is being admitted. In preparing for

the arrival of the client, the nurse will gather equipment for:

- A. Gastric lavage
- B. Morphine drip
- C. Gastric decompression
- D. Soap suds enema

The answer is C. The client will be NPO in preparation for surgery and a NG tube will be inserted for gastric decompression. There is no reason to lavage the stomach. Morphine and other opioids are generally withheld until after the diagnosis is established. Soap suds enema are contraindicated.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing priorities

773. Which client being treated in the emergency room requires the most immediate intervention?
- A. A client whose initial assessment disclosed elevated T waves and a serum potassium level of 6.1.
 - B. A client whose x-ray showed a fractured radius.
 - C. A client with a stab wound to the thigh covered with a bloody gauze pad.
 - D. A woman who is 30 weeks pregnant with abdominal pain.

The answer is A. An elevated T wave is suggestive of a cardiac problem and the potassium is dangerously elevated. Thus this client is in a potentially life threatening situation and requires rapid intervention. All of the other clients are in need of treatment for significant problems but none are in immediate danger.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-specific assessment

774. Which assessment findings would the nurse expect when examining a client with chronic low arterial oxygen levels? Mark all that apply.
- A. ___ cyanosis
 - B. ___ skin tenting
 - C. ___ positive Cullen's sign
 - D. ___ delayed capillary refill
 - E. ___ clubbing
 - F. ___ muffled heart sounds

The answers are A, D, and E. Delayed capillary refill, cyanosis and clubbing are signs of chronically decreased arterial oxygen levels. Skin tenting is an indicator of dehydration. A positive Cullen's sign is bluish discoloration around the umbilicus and is indicative of bleeding into the peritoneal cavity. Muffled heart sounds are not a sign of chronic low arterial oxygen levels.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

775. The nurse is doing the neurologic assessment of the newborn infant. Which would be normal findings?
- A. ___ Sucking in response to touching infant's lips; strong and coordinated
 - B. ___ Blinking in response to light or touch
 - C. ___ Gag in response to stimulation of the posterior pharynx by food or tube
 - D. ___ Asymmetrical sporadic movement of the extremities
 - E. ___ Extremities extended when prone
 - F. ___ Minimal head lag when pulled to a sitting position

The answers are A, B, and C. Sucking, blinking, and gag reflexes are present at birth. Sucking reflex disappears at 3–4 months, blinking and gag reflexes persist for life. Movements are symmetrical, sporadic and involve all extremities. Extremities are flexed and knees are flexed under abdomen in the newborn. The neonate has minimal head control therefore there is significant head lag when pulled to a sitting position.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and electrolyte imbalance

776. A client has a CVP reading of 12mmHg. Which physical assessment finding is consistent with this measurement?
- A. Increased JVD
 - B. 1+ peripheral pulses
 - C. Tachycardia
 - D. Crackles in the lung bases

The answer is A. Increased JVD is an indication of volume overload. Tachycardia, not bradycardia, is the physiologic response to decreased cardiac output. Crackles in the lung bases are indicative of pulmonary overload.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for complications from surgical procedures and health alterations

777. The nurse teaches new parents about nutrition for the first year of life. What information does the nurse include in her teaching plan?
- Breast milk is a complete and healthful diet for first 6 months of life.
 - Commercially prepared fortified infant formula is a good alternative if breast feeding is not desirable or feasible.
 - No additional fluids are needed for first 4–6 months with breast or formula fed infant.
 - In the second 6 months skim or regular cow's milk may be used depending on infant's weight pattern.
 - Solid foods are started with cereals at 2 months, and then fruits, vegetables and meats are gradually introduced over next 4 months.
 - Honey is not given for the first year because it is a source of botulism.

The answers are A, B, C, and F. Breast feeding and fortified commercially prepared infant formulas are the best and only sources of nutrition appropriate for the first 6 months of life and continue to be the primary source of nutrition in the second six months of life as well. Cows' milk, skim or regular, and imitation milks are not acceptable during the first year, as they are difficult to digest and lack the nutrients needed for growth. Solid foods are generally introduced at 5 to 6 months starting with cereals and progressing and gradually progressing to fruits, vegetables and meats. Honey is not given in the first year as it is associated with botulism.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Medical Emergencies

778. While shopping the nurse observes a school age child put something in his mouth and immediately begins coughing. Which would be an appropriate initial action for the nurse to take?
- Ask the child if he is choking.
 - Place the child in reverse Trendelenburg position.
 - Perform the Heimlich maneuver.
 - Check pulse and respirations.

The answer is A. Asking for a response is a method of determining if the airway is obstructed and immediate emergency intervention is needed. If a person can speak the airway is not obstructed. Reverse Trendelenburg position in which the

client is supine with feet lower than the head would serve no purpose. A Heimlich maneuver is performed if a foreign body is occluding the upper airway. Checking pulse and respirations serves no purpose in the immediate situation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and electrolyte imbalance

779. A client has a CVP reading of 12mm Hg. Which physician order for fluids would the nurse question?
- 5% Dextrose and Normal Saline IV at 100 cc hr
 - Oral fluid restrictions of 1500 cc per 24 hours
 - Normal Saline at 20 cc hr.
 - Nitroglycerine IV drip at 5 mcg per minute

The answer is A. D₅NS is a hypertonic IV solution and would pull more fluid into the vascular system which is already overloaded. Fluid restrictions would help decrease fluid overload. Normal Saline at 20 cc/hr would only keep the vein open and would not add to overload. Nitroglycerine would cause vasodilation and decrease circulating volume.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing priorities

780. The nurse has just received report on assigned clients. Which client should the nurse see first?
- A 23-year-old admitted two hours ago with a gunshot wound; 3 cm area of dark drainage noted on the dressing.
 - A 38-year-old with a collapsed lung due to an accident; no drainage noted in the previous 3 hours.
 - A 47-year-old who had a stab wound to the abdomen one day ago; client complains of chills and fever.
 - A 34-year-old with a mastectomy two days ago; 15 cc of serosanguineous fluid noted in the Hemovac drain. Complaining of pain in axilla.

The answer is C. Because the client is at risk for internal bleeding, infection, or peritonitis. This client should be assessed for further symptoms of infection.

The client in option A would not be first because there is apparently no active bleeding as indicated by the small amount of drainage on the dressing. The client in option B has no more than the expected amount and color of drainage. The client in option D has no unexpected signs or symptoms.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

781. Which problem associated with Hirschsprung's Disease in a newborn is the most critical?
- Respiratory distress.
 - Abdominal distention.
 - Vomits several feedings.
 - Failure to pass meconium by 48 hours of life.

The answer is A. Respiratory distress can occur with Hirschsprung's disease as a result of abdominal distention. Because respiratory distress can be immediately life threatening it is the most critical problem associated with the disease. All of the other responses are symptoms of Hirschsprung's Disease but none are immediately life threatening.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Disaster planning

782. As a nurse manager at the area medical center you have been asked to participate as a member of the team to develop the community's disaster preparedness plan. As you begin to think through the steps of a sound plan you identify the following key phases in a disaster management program:
- Preparedness, mitigation, response, recovery, and evaluation
 - Planning, organizing, leading, controlling
 - Assessment, analyzes planning, implementation, evaluation
 - Prevention, warning, rehabilitation, reconstruction

The answer is A. There are five basic phases to a disaster management program, there may be some overlapping between the phases but each phase has a specific component relating to disaster management.

B lists the four concepts of the management process, C lists the components of the nursing process, and D is a listing of terms that are not related to each other.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Alterations in Body Systems

Evaluate achievement of client treatment goals

783. How would the nurse best evaluate the effectiveness of a client's oxygen therapy?

- Hematocrit
- Hemoglobin
- Arterial blood gases
- Pulmonary function tests

The answer is C. Oxygen is used to treat hypoxemia and hypoxia. The best measure of its effectiveness in reversing these conditions is ABG analysis.

PHYSIOLOGICAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to client and/or family

784. A client standing in the doorway to his room, screams at the nurse as she comes down the hall "How long am I supposed to wait for someone to straighten my bed? Do you know how much this room is costing me per day? I want my bed fixed and I want it done now." How should the nurse respond?
- Say "I don't think you need your bed straightened this minute. . ."
 - Place a hand on the client's arm and lead him to a chair in his room.
 - Ask the client if he really thinks this type of behavior will help him feel better.
 - Acknowledge the distress and obtain more information about what the patient needs.

The answer is D. Acknowledging a person's distress is therapeutic. Dismissing a person's feelings is nontherapeutic and interferes with establishing an effective nurse-client relationship. Obtaining more information about the situation allows for discussion of a solution.

A is incorrect—Disagreeing/arguing with the angry client can lead to escalation of angry behavior. B is incorrect—Touching an angry client or entering the client's personal space can also escalate anger. C is incorrect—it is patronizing and this type of response increases anger.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

785. A client has a pulmonary artery pressure catheter inserted for hemodynamic monitoring. The client's cardiac output reading is 2 liters per minute. Which physical assessment finding is consistent with this measurement?
- Increased JVD
 - 1+ peripheral pulses
 - Bradycardia
 - Crackles in the lung bases

The answer is B. 1+ peripheral pulses. The normal CO is 4–7 liters per minute so the client would display signs and symptoms of decreased cardiac output. Increased JVD is an indication of volume overload. Tachycardia, not bradycardia, is the physiologic response to decreased cardiac output. Crackles in the lung bases are indicative of pulmonary overload.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Fluid and electrolyte imbalances

786. A 4-week-old infant boy has been admitted to the pediatric unit with a diagnosis of “rule out pyloric stenosis.” For signs of which electrolyte imbalance would the nurse monitor the infant?
- Hypokalemia
 - Hypernatremia
 - Metabolic acidosis
 - Respiratory alkalosis

The answer is A. Vomiting causes the loss of potassium, hence hypokalemia would occur as well as metabolic alkalosis from the loss of stomach acids.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse effects/contraindications

787. A physician writes the following orders for a client being evaluated for a possible bowel obstruction. Which order would the nurse question?
- Intake and Output
 - NG tube to suction
 - IV, D₅1/4 NS at 125 ml/hr
 - Morphine q 3 hours prn pain

The answer is D. Morphine suppresses peristalsis and would increase the bowel obstruction. Morphine and other opioid analgesics are usually withheld during the diagnostic period because of the effect on peristalsis and also because they can cause vomiting. Vomiting can complicate the diagnosis and determination of the plan of care because vomiting is also a sign of worsening bowel obstruction and of N/G tube obstruction.

HEALTH PROMOTION AND MAINTENANCE

Ante-/Intra-/Postpartum and Newborn Care

788. The nurse is assessing a newborn. A sudden noise causes the newborn infant to extend and then flex the

arms and fingers. The nurse would document this as a positive:

- Moro reflex
- Gag reflex
- Babinski reflex
- Tonic neck reflex

The answer is A. The Moro reflex occurs in response to a sudden noise or movement. The infant extends arms and legs and then flexes them. The infant's hands form a C with the thumb and fingers.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Alterations in Body Systems

Evaluate achievement of client treatment goals

789. Which would be an expected effect of resistive breathing training in a client with COPD?
- Energy conservation
 - Increased oxygen saturation
 - Decreased hypercarbia
 - Increased respiratory muscle strength

The answer is D. Resistive breathing training is used for clients with exercise induced dyspnea and may be done as part of a pulmonary rehabilitation program. In resistive breathing the client breathes against a set resistance with the goal of developing strength and endurance in the respiratory muscles. The goal of resistive breathing is not energy conservation, increased oxygen saturation, or decreased hypercarbia.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to client and/or family

790. The daughter of a nursing home client comes to the nurse's station and shouts angrily “My mother's condition is a disgrace—this place should be closed down and you all should lose your licenses.” How should the nurse respond?
- Say “I was just into your mother and there is nothing disgraceful about her condition.”
 - Place a hand on the daughter's arm and lead her to a chair.
 - Ask the daughter if she really thinks this is a proper way for an adult to behave.
 - Acknowledge the distress and obtain more information about the problem.

The answer is D. Acknowledging a person's distress is therapeutic; dismissing a person's feelings is non-thera-

peutic and interferes with establishing an effective nurse-client relationship. Determining the immediate trigger of the daughter's anger allows the possibility of addressing the problem and opening the door to discussion of underlying issues.

Response A is inappropriate because it disagrees/argues with the angry daughter and this can lead to escalation of angry behavior. Similarly response B is incorrect because touching an angry client or entering the client's personal space can also escalate anger.

Response C is incorrect because it is patronizing and this type of response increases anger.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

791. The parents of a child with Tetralogy of Fallot are very upset by the cyanotic "tet" spells and asks the nurse what causes them. Which fact should be the basis of the nurse's response?
- The aorta carries mixed deoxygenated and oxygenated blood into the systemic circulation.
 - Low hemoglobin and circulating iron levels of the newborn cause low oxygen saturation.
 - A left to right shunt increases blood return to the lungs.
 - Increased heart rate causes a ventilation/perfusion mismatch when the child becomes stressed.

The answer is A. Increased right ventricular pressure creates right to left shunt. The hemoglobin and iron levels are not one of the factors associated with Tetralogy of Fallot. A left to right shunt involves an acyanotic defects. Ventilation/perfusion mismatch occurs in pulmonary embolisms.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Expected effects/outcomes

792. The CCU nurse admits a client from ER who has been diagnosed with an evolving MI and has received thrombolytic therapy with T-PA, tissue plasminogen activator, and heparin. Which is an expected client outcome?
- ST elevation of 2 mm in two chest leads
 - PTT level of 1.5–2.5 times the control
 - An INR value of 2–3
 - A cardiac ejection fraction of 30%

The answer is B. PTT level of 1.5–2.5 times the control is the therapeutic range during heparin therapy. ST elevation is an indication of cardiac tissue injury. INR is for warfarin (Coumadin) therapy. Normal cardiac ejection fraction is 60% or higher.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Legal rights and responsibilities

793. A nurse is explaining to a client that she has the right to be treated in a certain manner, receive adequate information, and have her confidentiality maintained while hospitalized. The client asks what gives her these rights. Which document should the nurse refer to in responding to the client's question?
- Client Constitution
 - Client Bill of Rights
 - Client Medical Record
 - Client Self-Determination Act

The answer is B. The Client Bill of Rights is a document published by the American Hospital Association to promote the rights of hospitalized clients.

Client Constitutions is not a document but is a form of law—constitutional law. The Medical Record is the record of the hospitalization includes medical tests, procedures and nursing documentation. The Client Self-Determination Act is a legal act that requires every competent adult be informed in writing upon admission to a health care institution about the client's rights to accept or refuse treatment.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Therapeutic Procedures

Provide nursing care of surgical clients

794. A client has just returned from surgery for colorectal cancer. In assessing the client, the nurse notes that the perineal dressing is soaked with bright red drainage. Which action should the nurse take?
- Reinforce the existing dressing.
 - Change the dressing using sterile technique.
 - Apply a pressure dressing using clean technique.
 - Cover the existing dressing with waterproof material.

The answer is A. The first dressing following surgery is changed by the surgeon. The nurse would reinforce the dressing. If the drainage continues, the nurse would notify the surgeon. The other responses are incorrect.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

795. The mother of an 8-week-old infant is telling the pediatric nurse that her baby has colic and cries all the time. The mother is visibly tired and frustrated. In helping the mother to cope with an infant with colic, the nurse can remind the mother that colic usually disappears by the age of:

- A. 3 months
- B. 6 months
- C. 9 months
- D. 12 months

The answer is A. Colic is a short-term complaint and the infant usually outgrows it by 3 months of age.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Pharmacological Agents/Actions

Use clinical decision making/critical thinking when addressing actions of prescribed pharmacological agents on clients

796. A client receiving chemotherapy for cancer also has epoetin alfa prescribed. The client's spouse asks what the epoetin alfa will do for the client. The nurse's response is based on the knowledge that the therapeutic goal of therapy with epoetin alfa for clients receiving chemotherapy for cancer is to:

- A. Potentiate the chemotherapy drugs
- B. Decrease the need for transfusions.
- C. Bolster immune system activity
- D. Protect against renal damage

The answer is B. Epoetin alfa is used to treat chemotherapy induced anemia and reduce the need for transfusions in clients with cancer who will receive chemotherapy for two months or more. It does not potentiate chemotherapeutic drugs. Like endogenous erythropoietin, It stimulates the production of red blood cells not immune system cells. Epoetin alfa is used to treat the anemia associated with chronic renal failure; it does not protect against kidney damage.

HEALTH PROMOTION AND MAINTENANCE

Disease Prevention

797. The nurse teaches new parents about infant dentition and care of the teeth.

Which of the following will the nurse include in the teaching plan?

- A. Beginning signs of tooth eruption are not seen before 10–11 months
- B. A frozen teething ring may be used to reduce inflammation and relieve discomfort
- C. Prevent dental carries by avoiding having infant fall asleep with bottle
- D. Fluoride should not be supplemented in the first year
- E. Infant Tylenol may be given with practitioners approval, for teething pain disrupting sleep and feeding
- F. Teeth may be cleaned with damp cloth

The answers are B, C, E, and F. Beginning signs of tooth eruption are commonly seen by 5 or 6 months. In areas where water supply is not adequately fluorinated, supplemental fluoride begins at around 6 months. A frozen teething ring is used to reduce inflammation and manage pain. Infant Tylenol may be used for severe pain disrupting function with practitioners order. Teeth may be cleaned with a damp cloth.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct client on medication self-administration procedures

798. The nurse is giving a client instructions on the use of an inhaled beta 2 agonist for mild symptoms associated with emphysema and chronic bronchitis. The nurse cautions that the maximum number of puffs to be taken in 24 hours is how many?

- A. 12–16
- B. 8–12
- C. 6–10
- D. 4–8

The answer is B. For mild symptoms 1–2 puffs of a beta 2 agonist can be taken every 2 to 6 hours PRN not to exceed 8 to 12 puffs in any 24 hour period.

HEALTH PROMOTION AND MAINTENANCE

Health and Wellness

799. The nurse is teaching parents of toddlers about nutritional needs, food preferences and expected appetite patterns. Which information would the nurse include in the teaching plan?

- A. ___ Do not overwhelm the toddler with large portions.
- B. ___ Serve stews with meat and vegetables in one bowl to maximize nutrition with minimal fuss.

- C. ___ It is important to encourage eating because growth is increasing and appetite is decreasing.
- D. ___ Toddlers are very concerned with the plate or cup used.
- E. ___ Serve foods that are new and interesting to the toddler as often as possible.
- F. ___ Substitute cow's milk if meat isn't eaten.

The answers are A and D. Toddlers are easily overwhelmed by large portions. Toddlers prefer single foods and often refuse mixtures such as stews. The toddler will even refuse foods that are touching each other. In toddlerhood growth slows, and appetite is diminished, with periods of physiologic anorexia. The toddler has a favorite cup, spoon, dish, and will often refuse a well-liked food because it's not served in the favorite dish. Repeat a set of nutritious foods often so they will be recognized by the toddler, and better received. Cow's milk is a poor source of iron and interferes with iron absorption leading to iron deficiency anemia if not curtailed.

SAFE AND EFFECTIVE CARE ENVIRONMENTS

Safety and Infection Control

Standard/Transmission-Based/Other Precautions

Apply principles of infection control

800. Which precaution measures would be instituted when a client has shigella? Mark all that apply.
- A. ___ Client is placed in a private, negative airflow pressure room.
 - B. ___ Client is placed in a private room or with other clients with infection caused by the same organism.
 - C. ___ Use mask at all times while in the client's room.
 - D. ___ Use mask when working within 3 feet of the client.
 - E. ___ Use gown and protective barriers when giving direct care.
 - F. ___ Mask on client if transported out of room.
 - G. ___ Use gloves at all times when caring for clients.
 - H. ___ Use gloves when there is risk of exposure to blood or body fluids.

The answers are B, E, and G. Shigella is a serious disease that is easily transmitted through direct contact. Contact precautions require a private room or a room shared with someone infected with the same organism. Gloves are worn at all times and gowns and protective barriers are used if direct contact is required. Since gloves are worn at all times, the requirements of standard precautions, which involve wearing gloves whenever there is the risk of touching something wet that comes from the body surface or a body cavity, i.e., when there is the risk of contact with blood or body fluids, are met.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

801. A client who has Rheumatic Fever is being admitted to your floor. Admitting has assigned the client to share a room with a client who is a fresh post-operative client. As the charge nurse, you would
- A. arrange for the new client to be reassigned to a private room.
 - B. ask that the new client be assigned to a room with a non-surgical client.
 - C. admit the client to the room assigned.
 - D. move the postoperative client to a room with another postoperative client.

The answer is C. The client can be admitted to the room assigned because rheumatic fever is an autoimmune response to a streptococcal infection and is not contagious.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Laboratory values

802. A client is admitted for hemorrhagic gastritis of prolonged standing. The nurse reviews the lab results on this client. Which lab result would the nurse question?
- A. Hematocrit 29
 - B. Hemoglobin 9.9
 - C. Guaiac negative
 - D. Reticulocyte count elevated

The answer is C. Guaiac evaluates blood in the stool which should be positive. The client with hemorrhagic gastritis would likely be anemic from chronic bleeding so low hemoglobin and hematocrit would be expected. An elevated reticulocyte count is the body's attempt to replace lost blood cells.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Implement procedures to counteract adverse effects of medications and parenteral therapy

803. Guarding against suicide is a priority nursing intervention for which client?
- A client who is withdrawing from
- A. Methylphenidate (Ritalin)
 - B. Alprazolam (Xanax)

- C. Propoxyphene (Darvon)
- D. Butabarbital (Butisol)

The answer is A. Methylphenidate (Ritalin) is a central nervous system stimulant and like other CNS stimulants such as cocaine and the amphetamines, clients who are withdrawing from it are severely dysphoric, anxious and at risk for suicide. Suicide is not a withdrawal effect of any of the other drug options.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

804. When teaching new mothers about play and stimulation for the first 6 months, which of the following toys would be recommended?
- A. Unbreakable mirror in a soft black and white frame
 - B. Large brightly colored balloon
 - C. 5" doll with removable clothing and shoes
 - D. Push-pull toy
 - E. Soft cuddly stuffed toy
 - F. Musical Mobile

The answers are A, E, and F. Balloons are a choking hazard. Push-pull toys will be useful later on when the child can manipulate the toy. With a 5" doll the removable shoes and possibly other accessories are too small and therefore a choking hazard. Mirrors, toys with contrasting colors, musical mobiles and soft stuffed toys are appropriate for the first 6 months.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct client on medication self-administration procedures

805. Which directions should be given to a patient taking Fosamax?
- Mark all that apply.
- A. ___ Take with a full glass of water
 - B. ___ Take at bedtime
 - C. ___ Take on an empty stomach
 - D. ___ Avoid fatty foods.
 - E. ___ Avoid heavy lifting
 - F. ___ Do not lie down until after eating once the pill is taken.
 - G. ___ Do not eat for 30 minutes

The answers are A, C, F, and G. Fosamax should be swallowed, not chewed or sucked, with a full glass of water on an empty stomach after getting up for the day. After taking Fosamax, the client should not eat, drink, or take another medication for at

least 30 minutes. Clients should not lie down once the pill is taken until 30 minutes has passed and they have eaten. Fosamax should not be taken at bed time or before getting up for a day. If a dose is missed, a tablet should be taken the morning after the client remembers and then the usual dosage schedule followed. Two tablets should not be taken on the same day.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Disaster planning

806. During a disaster the director of the command post sends a nurse to the emergency department to assist in triaging casualty victims as they arrive. Which is the priority concern of this nurse?
- A. Meet the needs of the largest number of victims
 - B. Provide care to the most seriously injured
 - C. Record names of victims as they arrive
 - D. Place victims in zones according to their color coded tags

The answer is A. Triage is the process of prioritizing which clients are to be treated first during a disaster. Triage is based on making decisions that will do the greatest good for the greatest number. Treating the most seriously injured is describing "daily triage." The victim is expected to arrive at the hospital with a tag already filled out. Victims are evaluated and a color coded tag is applied for easy identification of the victims status.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

807. A client with delusions says to the nurse "The aliens are after me because they think I am going to take over their planet." Which is the most appropriate response for the nurse to make?
- A. "I don't know anything about aliens. Do you feel afraid that people are trying to harm you?"
 - B. "Why would the aliens think you are going to take over their planet?"
 - C. "You are a good person; no one wants to kill you."
 - D. "What makes you think the aliens want to kill you?"

The answer is A. This is an empathetic response that acknowledges the client's feeling.

Responses B and D encourage the client to get more involved and add detail to the delusion and this is not therapeutic. Response C has an element of false reassurance and cliché as well as disagreement with the client's delusion. Disagreeing can result in a defensive reaction with the client sticking even more firmly to the delusion.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Illness management

808. After being diagnosed with diverticulitis, a client has been taught about the appropriate dietary changes. The nurse recognizes that additional teaching is needed when the client states:
- A. "I will follow a high-fiber diet."
 - B. "Milk will decrease my episodes of diverticulitis."
 - C. "Whole grains are better for me than refined grains."
 - D. "Fruits and vegetables are good for me but not nuts and seeds."

The answer is B. A diet to prevent constipation is recommended. Milk can be constipating. A high fiber diet helps to prevent constipation. Whole grains are a good source of fiber. Fruits and vegetables are good sources of fiber but nuts and seeds should be avoided because of the risk of them getting trapped in a diverticulum and serving as a source of inflammation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Pathophysiology

809. A client has recently been diagnosed with cancer of the tongue. Client teaching about oral cancer has been completed. Which comment by the client indicates the need for additional client teaching?
- A. "My type of cancer metastasizes quickly because of the rich lymph and blood supply in the area."
 - B. "Like me, most clients don't have early symptoms of tongue cancer."
 - C. "The doctor may need to do a neck resection to get to the lymph nodes there."
 - D. "I never thought that smoking would get me, but they tell me that studies show a direct link between smoking and cancer of the tongue."

The answer is D. Smoking has been linked to all oral cancers except that of the tongue. All other responses are correct.

PHYSIOLOGICAL INTEGRITY

Basic Care and Comfort

Elimination

810. The nurse is teaching a group of pregnant clients about hemorrhoid prevention. Which risk factors would the nurse identify?
- A. Constipation
 - B. Straining on elimination

- C. Sitting for prolonged periods
- D. Excessive roughage in the diet.
- E. Standing for prolonged periods

The answers are A, B, C, and E. Constipation and straining on elimination increases the pressure in the rectal area. Maintaining one position for an extended period will cause stasis of circulation. Roughage is encouraged to prevent constipation so is not a risk factor for hemorrhoids.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

811. The nurse teaches parents about fears in the preschool years. Which information does the nurse include in the teaching plan?
- A. Past fears of the toddlerhood years are gradually disappearing
 - B. The preschool child is no longer bothered by imagined fears; fears are more realistic
 - C. The preschool child is no longer afraid to go to bed as in the toddler years
 - D. The preschool child finds large dogs and other animals frightening
 - E. The preschool child is afraid of mutilation and pain
 - F. Playing out fears with dolls that helped in toddlerhood is not effective for the pre-schooler.

The answers are D and E. The preschool child experiences a greater number of real and imagined fears than in any other time of childhood. The child is afraid of the dark, being alone at bedtime, large dogs, ghosts, thunderstorms, pain, and mutilation. Playing out fears with dolls is useful in alleviating fears as well as desensitization.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Medication Administration

Instruct client on medication self-administration procedures

812. What is the primary reason why the nurse teaches a client to wear a glove or finger cot when applying topical acyclovir to a herpetic lesion?
- A. Prevent suprainfection
 - B. Prevent autoinoculation
 - C. Prevent overdose from excess absorption
 - D. Prevent unnecessary staining of the skin

The answer is B. Herpes can spread by autoinoculation. Wearing a glove to apply medication to the lesions helps

prevent this. Even when wearing a glove or finger cot, clients must also be taught the importance of hand washing before and after each application of medication. Use of a barrier also helps prevent possible bacterial contamination and suprainfection but is not the primary reason for teaching the use of a barrier rather than just hand washing alone.

PSYCHOSOCIAL INTEGRITY

Therapeutic Communications

Use therapeutic communication techniques to provide support to client and/or family

813. The nurse asks a client with Alzheimer's Disease "Do you want some orange juice?" The client responds "Wha...". What should be the nurse's response?
- "Do you want a glass of orange juice?"
 - "Are you thirsty—do you want some juice?"
 - "Have a nice cold glass of juice; it will taste good."
 - "Do you want some orange juice?"

The answer is D. "Do you want some orange juice?" This is the same question the nurse asked first. When communicating with a client with Alzheimer's disease one guideline to be followed is repeat questions if needed but do not rephrase them because this would only further confuse the client. Other guidelines for communicating with the client with Alzheimer's disease are: use simple words and short sentences; ask only one question at a time; give only one direction at a time; speak slowly and clearly.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

814. The nurse teaches new parents about gross motor and fine motor development of the infant. What can the mother expect by 6 months?
- Head lag at 6 months
 - Can usually roll from prone to supine and supine to prone
 - Can transfer cube from one hand to the other hand
 - Can pull self to stand
 - Crude pincer grasp
 - Palmer grasp with fingers encircling object

The answers are B, C, and F. Head lag at 6 months is an ominous sign and should be reported for follow up. The 6 month old can roll from the prone to supine and supine to prone position. With the new practice of placing infants on their

backs for sleep, as opposed to the abdomen, because of SIDs, there is a noted delay in many infants in rolling from abdomen to back, but by 6 months infants have accomplished this task. The 6-month-old has a palmer grasp and is beginning to transfer a cube from one hand to the other. The infant pulls himself to stand, and develops a crude pincer grasp at 9 months.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Monitoring conscious sedation

815. The nurse is caring for a client who has received conscious sedation for elective cardioversion. Following the procedure the arterial blood gas results are as follows: pH 7.32; PaO₂ 95mm Hg; PaCO₂ 62 mm Hg; HCO₃ 19 meq/L; O₂ Sat 95%. Based on these values which action would the nurse take?
- Chart the values and continue assessing the client
 - Start supplemental oxygen at 2 liter per minute via nasal cannula
 - Have the client perform deep breathing exercises
 - Have the client breathe into a paper bag

The answer is C. Deep breathing exercises will help the client blow off carbon dioxide and bring down the PaCO₂ level.

A is incorrect because the blood gas results are showing respiratory acidosis.

O₂ is not needed because the O_s 2 level is within the normal range. Breathing into a paper bag is used when the client is experiencing respiratory alkalosis.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Management of Care

Establishing priorities

816. The nurse assigned to a client being admitted for rectal bleeding, must establish priorities of care. In which order would the nurse carry out the following care activities?
- Start an intravenous
 - Observe the client's level of anxiety
 - Continue to monitor the client for rectal bleeding
 - Teach the client self care in preparation for her discharge
 - Assess the client's skin, blood pressure, heart rate, and urine output
 - Teach the client about the diagnostic tests ordered during the next 48 hours

Record your answer by placing the letter of each activity in proper sequence in the space provided.

Correct order of priorities: E, A, B, C, F, D. Physical needs precede psychological needs. Client teaching would be the last priority in this situation.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

817. A 3-week-old infant has been diagnosed with Hirschsprung's Disease and has just returned from surgery with a double barreled colostomy. The mother cries when she sees the colostomy stoma and says: "My poor baby, to have to go through life with that thing on his abdomen." The nurse's response would be based on the knowledge that
- colostomy care is not as difficult as it may seem.
 - the colostomy will not be permanent.
 - the child will never have known anything but the colostomy.
 - colostomy stomas are hidden easily under clothing.

The answer is B. A double barreled colostomy indicates the intention to reconnect the bowel at a later time so the mother's misconception needs to be addressed. All the other options are inappropriate as the basis of the nurse's response because the colostomy is not going to be permanent. Colostomy care during infancy is relatively simple as the child would not be continent anyway. Stomas can be hidden under clothing. The child would eventually know that he or she is different.

HEALTH PROMOTION AND MAINTENANCE

Developmental Stages and Transitions

818. The nurse is planning a class to promote effective parenting of toddlers. Which topics should the nurse plan to discuss?
- Negativism
 - Ritualism
 - Egocentrism
 - Temper Tantrums
 - Possessiveness
 - Altruism

The answers are A, B, C, D, and E. These are all topics pertinent to toddler behavior. Negativism refers to strongly expressed emotions: 'no'. Ritualism is seen as the toddler having a favorite doll, favorite blanket and various rituals of behavior, especially at bedtime. Egocentrism refers to the fact that the toddlers can

not comprehend that others think differently than they do. Temper Tantrums which are characteristic of toddlers are attention seeking and best dealt with by ignoring them. Possessiveness indicates the toddler's beginning awareness of ownership, as shown by the use of the word "mine." Altruism is not a characteristic of toddlerhood.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Adverse Effects/Contraindications and Side Effects

Assess client for actual or potential side effects and adverse effects of medications

819. Which is the priority factor for the nurse to assess when a client is receiving IV acyclovir?
- mental status
 - cardiac rhythm
 - urinary output
 - temperature

The answer is C. Monitoring urinary output is critical when acyclovir is given systemically because it is excreted primarily by glomerular filtration and tubular secretion and therefore can be nephrotoxic. To decrease the risk of nephrotoxicity, the client must be well hydrated; the drug must be administered over a period of 60 minutes; and urinary output must be measured for 2 hours after the infusion. Output of less than 500 mL of urine per gram of acyclovir must be reported immediately.

Confusion and hallucinations along with tremors and seizures are some of the serious adverse reactions to systemic acyclovir but they are uncommon. Cardiac rhythm is unaffected. Temperature may be monitored because of existing infection but not directly because of the acyclovir; it does not present an immediate threat so does not take priority over monitoring urinary output.

SAFE AND EFFECTIVE ENVIRONMENT

Management of Care

Establishing priorities

820. Vital signs on a client who has just been admitted to the unit are: BP 162/84, Pulse 100 and irregular, Respirations 16, and Pulse Oximetry 88%. Which would be the immediate nursing intervention?
- Place the client on cardiac telemetry
 - Call the physician to report the vital signs
 - Start a saline lock for IV medication access
 - Start oxygen at 2–4 liters per minute per nasal cannula per protocol

The answer is D. The client's oxygen level is very low. All other interventions would be done later.

PHYSIOLOGICAL INTEGRITY

Pharmacological and Parenteral Therapies

Evaluate appropriateness/accuracy of medication order for client

821. A nurse would question an order for misoprostol to prevent gastric ulcers for which client?
- A client allergic to shellfish
 - A pregnant client
 - A client taking warfarin sodium
 - A client with a history of hepatitis

The answer is B. Misoprostol is a synthetic form of prostaglandin E which is used to prevent NSAID-induced gastric ulcers in high risk clients. It is a pregnancy category X drug because of its abortifacient action and therefore the order would be questioned if the client is pregnant. Before beginning treatment with misoprostol women of childbearing age must have a negative serum pregnancy test within two weeks of start of treatment which should be on day 2 or 3 or menses. They must also be warned both orally and in writing that the drug causes uterine contractions and miscarriage and be able and willing to use an effective form of contraception.

HEALTH PROMOTION AND MAINTENANCE

Health Promotion Programs

822. The nurse teaches new parents about nutrition for the first year of life. What information does the nurse include in her teaching plan?
- Breast milk is a complete and healthful diet for the first 6 months of life.
 - Commercially prepared fortified infant formula is a good alternative if breast feeding is not desirable or feasible.
 - No additional fluids are needed for the first 4–6 months when the infant is breast or formula fed.
 - In second 6 months skim or regular cow's milk used depending on infant's weight pattern.
 - Solid foods starting with cereals at 2 months, and gradually introducing fruits, vegetables and meats over next 4 months.
 - Honey is not given for the first year because it is a source of botulism.

The answers are A, B, C, and E Breast feeding and fortified commercially prepared infant formulas are the best and only sources of nutrition appropriate for the first 6 months of life and continues to be the primary source of nutrition in the second 6 months of life as well. Cows' milk, skim or regular, and imitation milks are not acceptable during the first year, as they are difficult to digest and lack the nutrients needed for growth. Solid foods are generally introduced at 5–6 months starting with cereals with gradual introduction of fruits, vegetables and meats. Honey is not given in the first year as it is associated with botulism.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Hemodynamics

823. The nurse is caring for a client when the cardiac monitor shows that cardiac pattern has changed from a normal sinus rhythm. QRSs are now widened and bizarre at a rate of 160 beats per minute. The client begins complaining of being dizzy. Which is the nurse's immediate action?
- Call a code
 - Administer a precordial thump
 - Give Lidocaine 50–100 mg. IV push
 - Assess the client's vital signs

The answer is D. The nurse needs to assess the client to determine cardiac perfusion and to be sure of what the monitor is showing. The nurse would not call a code because the client has not arrested. Precordial thump is only used with a witnessed arrest. Lidocaine would be the drug of choice if the client were in a sustained Ventricular Tachycardia and was symptomatic.

SAFE AND EFFECTIVE CARE ENVIRONMENT

Safety and Infection Control

Handling hazardous and infectious materials

824. The nurse is serving on a safety committee which is currently examining policies regarding the proper handling and storage of dangerous chemicals. Which guidelines would the nurse expect the policies to address?
- ___ Label the containers containing materials
 - ___ Maintain an inventory list of the materials
 - ___ Keep older products in the front, newer products in the back
 - ___ Store chemicals on open shelves
 - ___ Segregate chemicals alphabetically

The answers are A, B, and C. Containers containing hazardous chemicals need to be clearly labeled with the full chemical name. Current hazard waste inventory list is required to be maintained. Older chemicals need to be used before newer products.

Chemicals stored on open shelves could be accidentally knocked off the shelf. Chemicals also need to be stored based on compatibility and not necessarily alphabetically.

PHYSIOLOGICAL INTEGRITY

Physiological Adaptation

Alterations in Body Systems

825. A client has a permanent colostomy for colon cancer. The client is struggling to learn colostomy care. In frustration, the client throws the equipment and says, "It's not worth it. I might as well be dead." Which interpretation of this behavior should be the basis of the nurse's initial response to the client?
- The client has not developed an adult level of self control.
 - The client does not want to learn.
 - The approach to teaching is incorrect for this client.
 - The client is having difficulty coping.

The answer is D. The most likely interpretation of this behavior and the one that should serve as the basis of the nurse's first response is that the client is displaying signs of inadequate coping with his life threatening disease and the need for a colostomy. It is possible that the client is lacking in self control or doesn't want to learn but these are not as likely as difficulty coping given the client's health problems. It is also possible that the approach to teaching is not ideal for this client and this may need to be addressed but it is not the most likely cause of the behavior.

HEALTH PROMOTION AND MAINTENANCE

Growth and Development

826. The nurse at a day care is observing pre-school children at play. Which types of play observed would the nurse evaluate as normal for a preschooler?
- Playing house and doing housekeeping chores.
 - Jumping, running or climbing
 - Riding a tricycle
 - Having an "imaginary playmate"
 - Playing dress up

The answers are A, B, C, D, and E. Imitative, imaginary and dramatic play are characteristic of the pre-school period. Playing house, dress up, and housekeeping chores are examples of imitative, imaginary and dramatic play. Imaginary playmates are a normal healthy and useful part of the preschoolers play. Parents can even set a place setting for a "friend," but can not allow the child to avoid responsibility by blaming "friend" for mess.

Activities for motor development should also be encouraged including: running, jumping, climbing and tricycle riding. Reading or watching an educational video are examples of mutual activities that can be enjoyed with a parent.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

System-specific assessment

827. To calculate central venous pressure from the jugular venous pressure, how many centimeters are added to the JVP? Record your answer as a whole number in the space provided.

The answer is 4 cm. Four centimeters are added to the jugular venous pressure to obtain the central venous pressure.

PSYCHOSOCIAL INTEGRITY

Behavioral Interventions

Assess client appearance, mood, and psychomotor behavior and identify/respond to inappropriate/abnormal behavior

828. What is the most important reason for monitoring a client with a borderline personality disorder and depression for a sudden change in mood?
- Mood change can be the first indication that therapeutic gains are being made.
 - Mood change can indicate a need for change in medication.
 - Mood change can herald a decision to commit suicide.
 - Mood change can signal the appropriate time to introduce group therapy.

The answer is C. A mood change can indicate a decision to commit suicide. Client safety is always the priority hence this is the most important reason for monitoring mood. Change in mood may indicate any of the other options but they are not the priority over protecting the client's life.

PHYSIOLOGICAL INTEGRITY

Reduction of Risk Potential

Potential for Complication of Diagnostic Tests/Treatments/Procedures

829. Following eye surgery, the client is told by the physician that care must be taken to avoid elevating intraocular pressure. Which activities would the nurse identify as those the client needs to avoid? Mark all that apply.

- A. ___ Blowing the nose
- B. ___ Straining at stool
- C. ___ Wearing a tight collar
- D. ___ Bending over at the waist
- E. ___ Coughing
- F. ___ Keeping the head down

The answers are all A, B, C, D, E, and F. All of these activities increase pressure within the eyeball as does sneezing, vomiting and sexual intercourse.
