DEDICATION

Dedicated with all my love—first and foremost to the memory of my husband, William T. Monahan, also to my family and friends who support and tolerate me while I work and bring meaning and happiness to my days:

- Michael M. Monahan, my son;
- Kerryane T. Monahan, my daughter, and Robson Diniz, my son-in-law;
- John Donovan, my brother;
- Gerard Donovan, my brother, and Anita Donovan, my sister-in-law;
- Claire T. Torpey, my aunt;
- Suzanne M. Reynolds;
- Mary Ellen Wyllie;
- Josephine and James Hammer.

Many thanks to all of them.

PREFACE

Dear **Soon-to-be Registered Nurse**,

The purpose of this book is to help you be successful on the NCLEX-RN® examination so that you can obtain your license as a registered nurse. You have worked long and hard to successfully complete your basic nursing program. Now the one thing between you and your license is the NCLEX-RN examination.

This book is designed to guide your review study. There is a vast amount of nursing knowledge and it can be organized and focused upon in different ways. This book is designed to review the content most likely to appear on the examination and approach it from the perspective of the examination. Thus, the book begins with a discussion of the test itself to direct your focus. Because time is a limited and valuable commodity for all of you as you begin life after nursing school, strategies for studying in the most effective, time-efficient manner also are discussed.

A unique feature of this text is a preparatory chapter on language. Despite advanced study, you may often have a few words whose meanings were never clearly mastered. Encountering one of these words in a test question can result in a wrong answer. Hence, some of the words that are often used in nursing but are prone to being misunderstood are identified, defined, and their use illustrated in sentences reflective of nursing practice. There is also a chapter on test-taking strategies. You may have already used many of these, but reviewing them as a unit helps to ensure that you are approaching the NCLEX-RN with the sharpest test-taking skills possible. The chapter even provides exercises to allow you to practice key skills.

The next 30 chapters of the book present the review of nursing content. The title of each chapter consists of one of the major NCLEX-RN test plan categories followed by the subcategories and topics from the plan to be covered in that chapter. Precise headings found on the NCLEX-RN test plan have been used to help you think about the content in the same way that the test is organized and the questions are designed. There are separate sections in the text dealing with the child-bearing client and with gerontology just as there are in the test plan. Care of the pediatric client is incorporated throughout the text. *Icons in the margin are alerts that the information applies specifically to a pediatric client or a child-bearing client.*

To help you recognize and learn critical points of content, the following alerts, which highlight key pieces of information, have been included in the chapters:

Assessment Alerts are key considerations related to assessing a particular type of client. These are factors with potential for significant impact on the client's health status if they not recognized and usually represent variations from the norm.

Nursing Intervention Alerts are dos and don'ts of practice that have significant import for the client's well being and that apply to a specific client problem not to all clients.

Clinical Alerts are specific items of information unique to a health problem, treatment, or test, which if not known can lead to incorrect interpretation of a clinical situation and an incorrect nursing action.

Practice Alerts are critical guidelines such as legal requirements or standards, which relate to the practice of nursing in general.

In addition to the alerts, complications and client teaching are highlighted areas because each is a separate section on the NCLEX-RN test plan. A complications heading follows the Rx heading in the presentation of health problems, surgery, treatments, and diagnostic tests whenever there are significant complications that should be known. In addition, there is a table summarizing complications related to major disorders. A section on client teaching, which lists specific information that needs to be taught to the client, is part of the presentation of virtually every health problem and major diagnostic or treatment modality.

Think Smart—Test Smart boxes found throughout the book are designed to make you stop and think about the differences between similar or frequently confused words or concepts, the different ways the information could be worded, how questions could be asked in different ways to test the same content, or to identify a memory trick related to content to be learned.

Also unique to this book are worksheets at the end of each chapter. These worksheets allow you to actively engage with the content; help to further “cement” content into memory; and provide a check of your understanding of basic facts and concepts. This is important because NCLEX-RN is primarily a test of application of knowledge and one cannot apply what one does not know.

Of course, the book also contains hundreds of practice questions. Practice questions are given at the end of each chapter as well as in the last chapter of the book, which consists of 198 pages of questions. Questions are in NCLEX-RN format and consist of both traditional multiple choice as well as the newer alternative style items. For all questions, the correct answer is explained; for multiple-choice questions, reasons why options are incorrect are also given. In many cases, these explanations are “mini lectures,” which serve to synthesize and or highlight an area of information. Thus the

content review chapters and the final question chapter work together to present key concepts for review.

I believe that this book will help you be successful on the NCLEX-RN. It is based on more than 25 years of teaching nursing students and giving NCLEX-RN review classes. I wish you success on the examination and hope that you find nursing a fulfilling and rewarding profession.

Sincerely,

Fran Monahan, PhD, RN, ANEF

Part I

TESTING SMART

This page intentionally left blank

Preparing for NCLEX-RN®

PART 1: THE TEST

Purpose of NCLEX-RN®

The purpose of this examination is to protect the safety of the public. The examination is designed to determine whether candidates for licensure as registered nurses have the minimum level of knowledge needed to practice competently, knowledgeably, and safely at an entry level.

In preparing for the examination, key words from the stated purpose of the examination that you should think about are minimum level, safely, and entry level. These words can help focus your preparation and ease your mind. What they tell you is that the examination questions will test general principles and commonly encountered patient care situations. The focus will not be on testing obscure pieces of knowledge applicable only rarely in practice. Neither will the test focus on situations that demand a complexity of judgment, which can be expected only with time and experience. What can be expected to be stressed are nursing assessments and actions that protect patients from harm. This means that in preparing, you must give special attention to facts and procedures that promote physical safety, emotional safety, and protection from, or early identification of, disease complications or iatrogenic problems.

Development of the NCLEX-RN®

Knowing the basic process by which the examination is developed will further help direct your preparation. It will reinforce the fact that the questions focus on critical information regularly used by new graduates in daily practice.

NCLEX-RN® has been developed by the National Council of State Boards of Nursing (NCSBN) and is updated on the basis of a work-study analysis of what new graduates do in the workplace. All aspects of nursing practice are observed and then classified into categories and subcategories. These categories and subcategories then form the basis of the test plan, which specifies the content to be covered and the number of questions to be asked related to each area. Job analyses are done periodically and the test plan is

changed, if required, according to the results. This ensures that the test remains accurate and consistent with current practice. Content of the examination is matched to the scope of practice.

In selecting the content to be tested, there are two major considerations: the frequency with which the information is needed in day-to-day practice and the criticality of the information to the patient.

The test questions are written by nurses who practice in a setting where they work with new graduates. The questions are carefully edited for any type of bias. They are also reviewed for clarity and correctness of the key by other practitioners. This ensures that the questions and answers represent accepted principles of safe practice and not a regional practice or opinion.

The Test Plan Content

The content is organized around four categories of human needs, which have been identified by the NCSBN. The four categories and their related subcategories are as follows:

- Safe, effective care environment
 - Management of care
 - Safety and infection control
- Health promotion and maintenance
 - Growth and development through the lifespan
 - Prevention and early detection of disease
- Psychosocial integrity
 - Coping and adaptation
 - Psychosocial adaptation
- Physiological integrity
 - Basic care and comfort
 - Pharmacological and parenteral therapies
 - Reduction of risk potential
 - Physiological adaptation

Each of these subcategories constitutes 5–13% of the test except for Reduction of Risk Potential and Physiological Adaptation each of which accounts for 12–18% of the total questions.

Integrated throughout each of the client needs categories are the steps of the nursing process, caring, communication and documentation, and teaching and learning.

NCLEX-RN® Style

In preparing for any examination, it is always helpful to have some idea of what to expect in terms of style. This helps prevent surprises, which can be distracting and can create anxiety. Knowing about the examination style in advance, helps free your mind to focus on the content of the questions. Some key points about the style of the NCLEX-RN® are that it

- uses the term “client,” not “patient,” to refer to the recipient of care.
- is an integrated examination, that is, it covers clients of all ages, backgrounds, and levels of health or illness.
- is gender neutral.
- is reviewed to remove any culturally biased terms.
- has primarily a multiple-choice format: stem and four options only one of which is the answer to the question.
- includes some other types of questions, for example,
 - those that require the test taker to fill in the blanks with numerals or words rather than selecting an answer from a list of four options.

Example:

What is the normal heart rate in a newborn?
 _____beats per minute.

- those that contain pictures/diagrams and ask the test taker to identify a particular site by touching the correct area on the diagram.

Example:

Where would the nurse auscultate for the apical pulse?
 The test taker has to touch an area on a diagram of the chest. If the test taker touches the correct area or “hot spot,” the answer is correct.

- those that present a list of assessment findings or nursing actions, etc., and ask the test taker to identify all those that are appropriate for a particular type of patient.

Example:

Which of the following are risk factors for cancer of the breast?

Mark all that apply.

- Family history
- Nulliparity
- Age over 50 years
- Late menopause
- Breast-feeding
- Cigarette smoking
- Provides a drop-down calculator as needed.

Administration of the NCLEX-RN®

To be admitted to the NCLEX-RN®, you need

- an Authorization to Text letter (This is sent to you upon receipt of application and fees and verification of eligibility.)
- two forms of ID—one of which must be a photograph ID and both of which must be signed

NCLEX-RN® is administered by computer. Taking the test on the computer is not complicated; it only requires use of the SPACE bar, the ENTER key, and for fill-in-the-blank answers, the keyboard. For multiple-choice and other similar questions, the cursor is moved to highlight the option selected as the answer by pressing the SPACE bar. When the option(s) selected is highlighted, the ENTER button is pressed. Then there is an opportunity to check your answer selection. If the option(s) highlighted is not the answer you want to give, you may change to another. If the answer you wish to give is highlighted, you press the ENTER key a second time to register your answer. Some very important points for you to remember about taking the examination are that

- after the ENTER key is pressed a second time to register your answer, there is no returning to the question or changing the answer.
- every question must be answered; you cannot skip a question.
- there is no penalty for guessing.

Number of Questions on the NCLEX-RN®

As a test taker, you of course, would like to know as part of your mental preparation and planning for the examination, how many questions you will be asked. For the NCLEX-RN®, there is no precise answer to this question because it is a computer adaptive test (CAT). This means that the computer selects the next question based on whether your answer to the previous question was right or wrong. If the previous answer was correct, the computer will select a slightly more difficult question for the next one; if the answer was incorrect, the computer will present a slightly easier question. Thus, each person takes a unique test. The maximum number of questions a candidate can have is 265. However, the computer is programmed to make a decision of competent or incompetent based on the level of difficulty of questions answered correctly or incorrectly so relatively few candidates receive 265 questions. The minimum number of questions a candidate can receive is 75. Of these 75, 15 pretest items, i.e., items that are being tested for future use, are interspersed. These pretest items do not influence your passing or failing.

Examination Time

In preparing for an examination, it is also important to know how much time you will be allowed to complete it. The total time allowed for the NCLEX-RN® is 6 hours. If at the end of 6 hours, you have not answered enough questions for the

computer to determine whether you are competent, you fail by default. Based on the maximum of 265 questions and the maximum time of 6 hours (360 minutes), there is slightly more than one and a third minutes allowed per question. However, since few candidates receive the maximum allowable number of questions, the time available is generally more. Nonetheless, time is not unlimited so you should not spend excessive time on any one question.

Report of Pass—Fail

Forty-eight hours after you take the test, the Board of Nursing in the state where you are applying for licensure gets the pass/fail result. The Board then checks that all other requirements for licensure are met, and then sends out your results. Results are only reported in writing and never by telephone.

If you have failed the examination, it may be taken again in 3 months. How many times the test may be repeated depends on the State Board of Nursing.

NCLEX Myths

The NCLEX-RN® is one of the most important examinations that nurses ever take. To reach the point of taking the examination, much time, energy, and money have been invested and many sacrifices have been made. Because of these facts, you will hear many stories about the examination and receive much advice. This type of impromptu shared information often contributes to “myths” about the NCLEX-RN®, which serve as sources of undue anxiety. Some of the more common myths, and the corrections to them, are presented below.

The number of questions one receives indicates pass or fail.—This is not true. Candidates can answer the minimum number of questions, all of which are difficult, correctly and pass. Other candidates can answer the minimum number of questions, all of which are easy, and fail. It is not the number of items but the difficulty of the items that determines pass or fail.

Extra long tests are given randomly to selected test takers.—This is not true. The number of questions is determined by the difficulty of questions you answer correctly or incorrectly.

One needs to memorize everything.—This is not true. The test is looking at determining safe, entry-level practice based on the job analysis of what new graduates actually do in the work place. It is also testing generally accepted standards/methods of care. It is not testing rare, regionally variable information.

How good you are with the computer determines how well you do on the examination.—The Educational Testing Service has done research on the question as to whether computer skill influences examination performance. The results show that the test-taker’s computer skill does not influence the score on the examination.

For more information about NCLEX, see the NCLEX Candidate Bulletin which can be accessed at the NCSBN Web site www.ncsbn.org.

PART 2: STUDYING FOR THE TEST

Study smart and study well! Remember, this is your future. It represents short-term sacrifice for a long-term gain.

Identify Areas for Intensive Review

Evaluate your own strengths and weaknesses. Often, it is a temptation to spend most of your study time reviewing material you already know quite well. This is because what you know best is most often material that you like, find easy, and are interested in (that is why you learned it well in the beginning). It is comfortable material and makes you feel good about taking the examination. *Avoid this pitfall. Spend most of the time on what you do not know so well.*

Begin identifying what you do not know so well by thinking about what areas you did least well on in nursing school or had the least experience with—write them down. These may be broad areas of practice, for example, pediatrics or mental health/psychiatric nursing or specific topics such as acid—base balance, burns, or problems of the nervous system. If you are not a recent graduate, also identify those things that you did well in nursing school but have not had any recent experience with; these areas will need review but not as much time as those areas you did not know really well in the beginning. Be careful about assuming that since you have a lot of experience in a practice area you do not need to review. Remember NCLEX is a theory/textbook-oriented examination. The questions and answers are based on what “should be” in practice, not on the shortcuts and improvisations that “are.” Whether you are a new or a not-so-new graduate, review the list of topics in the NCLEX-RN® test plan found in this book and judge your level of comfort with each, referring of course to the list you made as the first part of this exercise. Mark with two checks those topics you feel you really do not know; make one check by those that you probably do not know really well. This will serve as a guide to make sure you review the areas most important to you.

Select Backup Review Materials

This book, like all review books, is written in an abbreviated format that assumes basic understanding and focuses on key points. If you never mastered an area well or you encounter content in this book that you do not understand the basis of, it is important to go to a basic classroom text for clarification and additional discussion.

NCLEX-RN® utilizes selected texts as references. Lists of text books are sent to schools of nursing with directions to indicate those which are used in the curriculum and to add any that are used but do not appear on the list. Reference texts are selected based on the extent of use in schools of nursing. Questions are designed to address basic principles of practice about which all texts agree, not to test about uncommon pieces of information, which are debatable. The current list can be accessed at the NCSBN Web site.

Develop a Realistic Schedule for Review

Dividing up material into achievable goals is smart. Each time you meet a goal, you feel more positive about yourself and your ability to deal with the material and the examination. This reduces stress and hence supports your ability to be successful. There are different ways to develop a realistic schedule. One way is to determine the number of days until you are scheduled to take the NCLEX-RN®. Also, determine how many hours on how many of these days can you realistically study. Be sure to allow for down time. After all, no one can study without a break and everyone must eat, sleep, bathe, etc. Tally total available study times/hours. Now assign study times/hours to the topics for review. Working from the test plan topics that you have marked according to how well you feel you know them, assign hours first to the topics needing in-depth review. These are the most important topics to review because you have already acknowledged that you do not feel you know them. Next, assign study times to those topics, which you decided you probably do not know well, and then to those needing a less-detailed review. Finally, place the topics in the order you will study them. Alternate hard and easy topics and topics you like with those you do not like—this will help keep you from shortening your scheduled study time.

To have enough time to study well you may need to make some temporary changes in your lifestyle. You may need to take time off from work, negotiate sharing of household tasks with others in the house, delay some projects or activities, and limit your social life. Only you can determine what is the best approach to ensure the time you need for study but as you consider your options remember—cramming is not one of them. It will not work. There is way too much material.

Select a Study Place That Works for You

Your study place should be quiet and convenient. A place you will be undisturbed but with space for your study materials. It should have good light to facilitate reading without developing eyestrain and/or a headache, a comfortable seat, and an ambient temperature that is not so warm that it makes you sleepy and not so cold that it distracts you from studying. Lying in bed or on a couch to study is not a good idea as it is at best relaxing, and at worst, sleep-inducing. A certain level of awake alertness is necessary for successful studying.

Select a Study Time That Works for You

Different people are most alert at different times of the day. Some people are “morning people” and concentrate best on first getting up; others are night people and concentrate best in the evening. Some people have periods of best function at two different times of the day. Analyze yourself to determine when your most productive intellectual periods are and then

plan to study the most challenging material during these times. Plan to review material that needs less intense study at other times. If you have family responsibilities around which you must organize study time, involve family members in planning how to make your best study times available for working on your NCLEX-RN® review.

Make Use of All Available Time for Study

You can learn a great deal, relatively painlessly, by making good use of small amounts of available time throughout the day. You may have done this during nursing school. If so, recall some of your strategies. If not, begin to develop time-effective study techniques now.

Examples of how you can capitalize on bits of unused time:

- Review a brief set of laboratory values, the principles of a nursing procedure, or assessment parameters for a specific disease in the 5 minutes before you take a shower, then use the time in the shower to repeat them to yourself.
- Write information to be learned on an index card(s) and study when standing in line at the grocery store or when waiting to pick children up at the school bus, etc.

Prepare Yourself for Studying

Collect your notes, books, pens, highlighters, etc.

Eliminate potential distractions: Shut off the cell phone; get out of range of the land phone; shut off the TV, CD player, and radio.

Go to the bathroom.

Refresh yourself: Wash your face and hands. Brush your teeth.

Get something to drink.

Do whatever you need to do so that you will not feel uncomfortable or have to interrupt your studying.

Study Effectively

When you study, engage yourself with the content; mechanical reading of notes is useless. Research shows that the more actively you engage with the content, the better you learn. So take notes, underline or highlight, repeat content out loud; walk back and forth while you memorize; try to think what questions could be asked about the subject being reviewed.

Use a sequence of study—rest/reward—review. For example, study for 50 minutes. Take a 10-minute break. Reward yourself. Have a cup of tea or take a shower. Do not get involved in a mentally demanding activity that will cause you to lose your focus on the examination material. Take 10 minutes to review the material you just studied. As you review, mark any areas for which you think, “I don’t really know that” or “I had forgotten about that.” Go back and review the marked areas at the beginning of your next day’s study.

To keep up your motivation, you can also do things like putting signs on your wall that say “You can do it.” or “This will be over in__days.” You can plan to go out to eat or buy a new dress if you meet your goal. Again, think about what motivational tricks work for you and use them.

Know When to Stop

When scheduling study, it is also important to recognize when you have studied to your capacity. Your time is valu-

able and you do not want to waste it by trying to study when you are beyond your ability to concentrate. It is better to take a break or accomplish something else that needs to get done and then return to studying with refreshed concentration. You will learn more in the end. So, again analyze yourself. You did a lot of studying in nursing school. What is the length of time you can usually concentrate? What are the telltale signs of when you are no longer learning effectively? Take these factors into consideration as you schedule study.

WORKSHEET

QUESTIONS

Do you have key facts from this chapter on your NCLEX-RN® knowledge ring? Complete the worksheet below to help you check.

1. Why is passing the NCLEX-RN® a requirement for being licensed as a registered nurse?
2. At what level of practice is the NCLEX-RN® designed to measure competence?
3. What are the two major considerations in the selection of content to be tested on the NCLEX-RN®?
4. Who are the writers of NCLEX-RN® test questions?
5. What is the predominant type of question found on the NCLEX-RN®?
6. How many questions does one have to get right in order to pass the NCLEX-RN®?
7. What is the maximum length of time that one can take to complete the NCLEX-RN®?
8. Do you need to be proficient in use of a computer in order to do well on NCLEX-RN®?
9. Can you skip a question on NCLEX-RN® and go back to it if you are not sure of the answer?
10. Does having the test stop when only 75 questions have been answered mean that you have failed?

ANSWERS & RATIONALES

WORKSHEET ANSWERS

1. Why is passing the NCLEX-RN® a requirement for being licensed as a registered nurse?

Answer

To protect the safety of the public by limiting the practice of Registered Nursing to those individuals who have passed an examination, which documents ability to practice competently, knowledgeably, and safely.

2. At what level of practice is the NCLEX-RN® designed to measure competence?

Answer

Entry-level Registered Nurse Practice.

3. What are the two major considerations in the selection of content to be tested on the NCLEX-RN®?

Answer

Frequency with which the information is needed in day-to-day practice and the criticality of the information to the patient.

4. Who are the writers of NCLEX-RN® test questions?

Answer

Registered nurses who work with new graduates in their practice.

5. What is the predominant type of question found on the NCLEX-RN®?

Answer

Multiple-choice question.

6. How many questions does one have to get right in order to pass the NCLEX-RN®?

Answer

It varies because NCLEX-RN® is a computer adaptive test and the decision on whether a test taker passes or fails is based on the difficulty of the questions answered and not on the absolute number.

7. What is the maximum length of time that one can take to complete the NCLEX-RN®?

Answer

6 hours.

8. Do you need to be proficient in use of a computer in order to do well on NCLEX-RN®?

Answer

No, studies have shown that computer proficiency has no effect on passing or failing.

9. Can you skip a question on NCLEX-RN® and go back to it if you are not sure of the answer?

Answer

No, a question cannot be skipped and once a question has been answered and the ENTER key has been hit the second time to register the answer, one cannot go back to the question.

10. Does having the test stop when only 75 questions have been answered mean that you have failed?

Answer

When the test stops after the minimum of 75 questions have been answered can mean one either passed or failed. The pass/fail decision is based on the difficulty of the questions answered correctly or incorrectly, not on the number.

Test and Language Basics

To answer an examination question correctly, knowing the subject content is not enough. You have to clearly understand each part of the question in the context of nursing and correctly interpret the meaning of the question itself. Because nursing is a practice profession and the NCLEX-RN is measuring basic practice competencies, questions typically contain a clinical scenario followed by the question stem. In the case of multiple-choice questions, options follow.

When taking an examination, it is important for you to recognize each of these question parts, so read the following definitions and look at the example carefully.

- *Clinical scenario*: This part of the question tells you about the clinical situation.
- *Stem*: This part of the question contains the actual problem/question to be answered.
- *Options*: These are the answer choices provided. Options are also called alternatives and in the case of traditional multiple-choice questions, consist of one correct answer (the key) and three distracters or incorrect answers.

It is important that you read and understand each of these parts correctly for a lot of reasons.

- Facts provided in the scenario are often critical to selecting the best answer to the question. If these facts are not correctly understood, it is difficult to select the best answer.
- If the question being asked is not correctly understood, distracters, which sometimes answer a different question than the one asked in the stem or assume information not provided in the stem or in the scenario, are more likely to be perceived as the correct answer.
- Most questions also contain key words. These are words that direct the answer; hence, attention to them along with clear understanding of their meaning is essential.

KEY WORDS

Because key words are so important in determining the correct answer to a question, a list of frequently used key words

is presented below for your review. Note that some of the words are negative.

First
Priority
Next
Best
Most
Least
Appropriate
Inappropriate
Last
Suitable
Not
Early
Late
Immediately
Initial
Only
After
Every
Expected
Contraindicated
Partial
Unexpected
Independently
Common
Uncommon

The following question illustrates the use and importance of a key word:

When giving medications to a client, what should the nurse do first?

1. Position the client
2. Check the client's identity
3. Explain what he/she is going to do
4. Ask how the client is feeling

In this example, all options are correct nursing actions when giving medications but which one is the correct

answer is determined by the qualifying word “first.” The first action is to check the client’s identity.

Practice identifying key words by completing the following exercise:

WORKSHEET 1: IDENTIFICATION OF KEY WORDS

Directions: Read each of the following questions. If the question contains a key word, underline it.

1. Which clinical manifestation would the nurse expect when assessing a client admitted with a diagnosis of bacterial pneumonia?
2. Which sign should alert the nurse to a potential problem in a client with a history of a CVA?
3. What is the primary goal for the hospice care of a client with lung cancer?
4. Which nursing intervention should be given priority in the plan of care for a teenager with sickle cell anemia?
5. The nurse is assessing the nutritional status of a client who is 3 months pregnant. Which information is most important for the nurse to obtain?
6. The nurse is obtaining a health history of a debilitated client with sacral pressure ulcers. Which question should the nurse ask to elicit information effectively about the client’s dietary intake?
7. Which behavior by a client with a newly created colostomy should alert the nurse to the need for teaching regarding skin care?
8. What is the best way to assess for shortness of breath in a 3-year-old client with congenital heart disease?
9. The nurse is assessing a family’s ability to provide emotional support to a family member diagnosed with cancer. Which observation is most essential?
10. In analyzing a teenage primipara’s need for teaching, the clinic nurse should ask which question?
11. Which finding should the nurse expect when checking urinary output of a client with SIADH?
12. Which information would be most helpful when preparing to do a home assessment prior to discharge of a low birth weight newborn?
13. Why is it important to monitor pulse rate in a client on digoxin?
14. A 25-year-old woman comes to the clinic complaining of lower left abdominal pain. Which additional information should the nurse obtain initially?
15. Which assessment question should receive priority?

FREQUENTLY MISUNDERSTOOD/MISREAD ENGLISH WORDS

Almost everyone has one or more words that he/she somehow learned incorrectly and as a result misunderstands its precise meaning. These can be very common, simple words and often the person is unaware of the error. This can be a particular problem when English is a person’s second language, or is not the language of the household. Words that are similar in spelling and in pronunciation are particularly at risk of being misread, misused, or misunderstood. Because errors of this type can cause an NCLEX-RN question to be answered incorrectly, a list of potentially misleading, common English words follows. Each word is followed by its definition and a sentence illustrating its use in nursing practice. You should read each one carefully and ask yourself if you were clear about the use of the word and its meaning. If your answer is Yes—great! If the answer is No, mark the word to be reviewed again.

Accept—to agree or receive.

Examples:

The client accepted the diagnosis of breast cancer with surprising calm.

The client accepted the nurse’s recommendation that all his drugs be ordered at the same pharmacy.

Except—indicates something is to be omitted or left out.

Example: All the assessment findings except the rash are consistent with a lower respiratory infection.

Advice—suggestion, guidance, or counsel.

Example: The client asked the nurse for advice on the best way to apply the ileostomy bag.

Advise—to give a suggestion, guidance, or counsel.

Example: The nurse advised the new mother to nap in the afternoon when the baby is sleeping.

Assent—to agree to.

Example: The nurse assented to a change in unit assignment for the day.

Ascent—to rise or to climb.

Example: The ascent of carbon monoxide levels in an enclosed area when a car is left running is rapid and can result in fatality.

Breath—air pulled into the lungs in one inhalation.

Example: Take a deep breath and hold it while I listen with the stethoscope over your lungs.

Breathe—the act of inhaling and exhaling air from the lungs.
Example: Breathe in slowly and deeply through your mouth.

Caster—wheel on a swivel.
Example: Many pieces of hospital equipment such as IV pumps and over-the-bed tables are on casters for ease of transport.

Castor—oil from castor beans, used as a laxative.
Example: A single dose of castor oil was ordered as part of the prep for the client's upcoming bowel surgery.

Charted (Not chartered)—entered in the client record.
Example: The nurse charted the appearance of the wound in the client's record.

Sight (Not site or cite)—vision.
Example: Eyesight typically declines with age.

Site (not cite)—location.
Example: The planned donor site for the skin graft was the left, upper, outer thigh.

Coarse (not course)—rough, uneven.
Example: The skin of clients with hypofunction of the thyroid is often coarse in texture.

Course—progression, order, direction.
Example: The course of the disease is characterized by exacerbations and remissions.

Compliment—praise.
Example: The supervisor complimented the nurse on her efficient handling of the multiple emergency admissions, which occurred during her shift.

Complement—add to or mix well.
Example: Participation in a support group can complement individual counseling.

Complaint—expression of something wrong.
Example: The client's chief complaint was a sharp pain in the left chest.

Compliant—willing to follow requirements or directions.
Example: The client verbalized a desire to be compliant with the medication regimen but stated he could not be because he could not afford to buy the medications ordered.

Continuous—going on without stopping.
Example: The client was receiving continuous feedings via a nasogastric tube.

Continually—happening at regular intervals or again and again.
Example: The client continually complained of nausea while receiving the antibiotic.

Defective—faulty or abnormal.

Example: The neonate was diagnosed with a defective mitral valve.

Deficient—lack of.

Example: Genetic syndromes characterized by deficient chromosomal material are more often fatal than those characterized by excess chromosomal material.

Dessert (not desert)—sweet foods served at the end of a meal.

Example: The nurse advised the client to eliminate desserts as a step in controlling weight.

Uninterested (not disinterested)—not caring.

Example: The client appeared markedly uninterested in learning about the prescribed diet.

Elicit—draw out information.

Example: The nurse's questions while obtaining the client history are designed to elicit complete, accurate information on which to base a nursing diagnosis.

Illicit—illegal.

Example: When obtaining a history, questions should be asked about the use of prescription drugs, over-the-counter drugs, herbal preparations, nutritional supplements, and illicit drugs.

Imminent (not Eminent)—about to happen.

Example: An aura, unique to the individual, is often the sign of an imminent seizure.

Farther—greater distance.

Example: The client should be ambulating farther than the bathroom.

Further—more.

Example: Before discharging the client, the physician decided further discussion with the family concerning plans for home care was necessary.

Former—the first of two. (Latter refers to the second of two.)

Example: Nausea and vomiting are common side effects to some medications. The former is a symptom because it cannot be seen, felt, or heard by an external observer; the latter is a sign because it can be observed.

Healthy—not ill, well.

Example: The child appeared healthy.

Healthful—promoting wellness.

Example: Adequate daily intake of calcium is healthful.

Lose—misplace, be deprived of.

Example: Clients lose central vision with macular degeneration; they lose peripheral vision with glaucoma.

Loose—opposite of tight.

Example: Loose bowel movements can be a problem for clients following an intestinal resection.

Nauseous—inducing a feeling of nausea.

Example: The nauseous smell of the drainage made the dressing difficult to change.

Nauseated—experiencing nausea.

Example: The client became nauseated 2 hours after the chemotherapy was administered.

Past—time gone by, ago.

Example: The time is past that medications could have helped; now surgery is the only option.

Passed—moved along, went away, departed, succeeded on a test.

Examples:

The suppository passed the rectal sphincter without difficulty.

The client passed a renal calculus last evening.

Patient—recipient of care.

Example: The patient thanked the nurse for making her comfortable.

Patience—tolerance or understanding.

Example: Patience is often needed when dealing with sick children.

Peace—calmness, tranquility.

Example: Helping the client achieve peace of mind is a goal of the hospice nurse.

Piece—part or section.

Example: The piece of the Foley catheter that inflates to hold the catheter in the urinary bladder is called the balloon.

Personal—private.

Example: Use of personal information about clients is governed by the HIPAA regulations.

Personnel—employees.

Example: Nurses are licensed health care personnel.

Prescribe—order for.

Example: The nurse practitioner prescribed the antibiotic Cipro for the client with a urinary tract infection.

Proscribe—prohibit.

Example: Leaving the unit with the narcotics key is proscribed.

Principal—of major importance.

Example: A principal use of digitalis is to strengthen the contraction of the myocardium in cases of heart failure.

Principle—a truth.

Example: The principle underlying use of a fan for cooling is that one of the ways heat is lost from the body is by convection.

Proceed—go on, continue.

Example: The nurse proceeded with the dressing change after the client had stopped coughing.

Precede—go before.

Example: Mild signs of an upper respiratory infection preceded the development of the rash.

Quite—a great deal.

Example: The client was quite verbal regarding his opinion of his care.

Quit—leave or stop.

Example: The client stated he wished he could quit smoking.

Rise—get oneself up.

Example: The client who had a CVA said to the nurse “I look forward to the day I can rise out of the bed in the morning without assistance.”

Raise—lift or elevate an object or person.

Example: During a breast examination, the client needs to raise her arms over her head so the contours of the breast can be inspected.

Stationary—not moving.

Example: The brake on the wheelchair should be set when the client is being moved in or out of the chair in order to keep the chair stationary and help prevent the client from falling.

Stationery—paper.

Example: Official letters should be written on stationery imprinted with the agency letterhead.

Statute—legal restriction.

Example: The statute of limitation for malpractice cases differs state to state.

Stature—person’s size.

Example: The client’s stature was consistent with a diagnosis of hypopituitary dwarfism.

Adequate—sufficient.

Example: It is the nurse’s responsibility to determine if the client’s 24-hour fluid intake and output is adequate.

Aggravate—make worse.

Example: Straining at stool will aggravate hemorrhoids.

Allay—put at rest or cause to subside.

Example: Providing the client with information about a procedure to be done can allay anxiety.

Anticipate—take up or use ahead of time.

Example: Prior to entering an isolation room, it is important that the nurse anticipate client needs so that she is prepared with knowledge and equipment to provide the needed care.”

Avoid—keep away from.

Example: Immunosuppressed clients need to avoid crowds because of the risk of exposure to infection.

Competitive—contest between rivals.

Example: In competitive inhibition of enzyme activity, the inhibitor competes with the substrate for binding on the enzyme.

Compromised—to endanger.

Example: Circulation to the lower extremities is compromised when the client is in lithotomy position.

Assume—take for granted.

Example: The nurse should never assume the client has understood instructions; validation of understanding by repeating the instructions or by return demonstration is always necessary.

At least—the very minimum.

Example: If the client refuses to lie in the prone position, at least have him lie on his side.”

Confer—consult or to bestow.

Example: The Client Care team conferred to determine the best approach to manage the bladder retraining program of a newly admitted client.

Deny—declare not to be true.

Example: Clients sometimes deny use of illegal drugs because they fear the reaction of the health care provider.

Determine—to come to a decision or to obtain first hand knowledge.

Example: To determine the causative organism of a wound infection, a culture is done.

Differentiate—discriminate or identify differences.

Example: When examining the chest, it is important to differentiate between crackles and wheezes.

Exacerbate—worsen.

Example: Exposure to cold and damp can exacerbate the symptoms of a sinus infection.

Enhance—augment.

Example: Comfort measures such as clean linen, a back rub, and pleasant music can enhance the action of pain medications.

Excessive—more than acceptable, exorbitant.

Example: The bleeding was excessive following the surgery.

Expectorate—cough up and spit out mucus.

Example: To prevent spread of infection, the nurse instructed the client to expectorate into a tissue and dispose of it in the provided plastic bag.

Flushed—any tinge of red.

Example: The client’s face was flushed and he was warm to the touch.

Flaccid—without resistance.

Example: A flaccid muscle is one with less than normal tone.

Tense—rigid, feeling nervous.

Examples:

A sign of increased intracranial pressure in a neonate is a tense fontanelle.

The client complained of feeling extremely tense whenever an interview with the psychiatrist was scheduled.

Hoarseness—grating sounds.

Example: Hoarseness is a characteristic symptom of laryngitis.

Impinge—come into close contact.

Example: The CAT scan showed that the tumor was impinging on the recurrent laryngeal nerve thus accounting for the hoarseness.

Inept—not apt, unable to do well.

Example: The client remained inept at handling the insulin syringe, so additional teaching was planned.

Insulation—prevent transfer of electricity, heat, or sound.

The insulation in the walls of hospital rooms helps clients to rest by decreasing noise heard from other areas of the unit.

Intact—without injury.

Example: The client’s skin remained intact despite the long period of bed rest.

Isolation—loneliness, separation.

Examples:

Clients having intracavitary radiation treatments are at risk for feelings of isolation.

Clients presenting with active, drug resistant tuberculosis are placed in isolation.

Lead to—results in.

Example: An untreated streptococcal sore throat can lead to glomerulonephritis in susceptible children.

Least likely—in the smallest degree, lowest chance.

Example: The client least likely to develop constipation is the one with a liberal fluid and roughage intake, who exercises regularly, and obeys the urge to defecate.

Most likely—to the greatest degree, highest chance.

Example: Of antibiotics, diuretics, or calcium channel blockers, the drugs most likely to cause allergic reactions are the antibiotics.

Liberally—freely, unchecked.

Example: The client should be encouraged to use the Calamine lotion liberally to control the itch of the poison ivy.

Predispose—create a tendency to.

Example: Use of immunosuppressant drugs predisposes the client to infection.

Permit—let.

Example: Elevating a Foley catheter drainage bag above the level of the client's pelvis permits backflow of urine into the bladder.

Profuse—pouring forth.

Example: Vaginal drainage was yellow, profuse, and malodorous.

Refrain—keep oneself from doing.

Example: The client was instructed to refrain from lifting anything over 5 lbs following repair of his hernia.

Sparingly—frugally.

Example: It is important to apply the skin preparation sparingly in accordance with the directions.

Spasm—involuntary contracture.

Example: The client complained of repeated leg spasms during the night.

Sedentary—physically inactive.

Example: A sedentary lifestyle predisposes to obesity.

Check your basic test vocabulary by completing the following vocabulary exercise.

WORKSHEET 2: VOCABULARY

Directions: Match the definitions in column B with the words in column A.

Column A

1. ____ Site
2. ____ Coarse
3. ____ Imminent
4. ____ Deficient
5. ____ Former
6. ____ Enhance
7. ____ Impinge
8. ____ Tense
9. ____ Predispose
10. ____ Sedentary
11. ____ Except
12. ____ Principal
13. ____ Loose
14. ____ Exacerbate
15. ____ Profuse

Column B

- a. something to be left out
- b. progress
- c. without intending to
- d. rough
- e. create a tendency to
- f. saturate
- g. location
- h. a truth
- i. at any time
- j. unable to do well
- k. inactive
- l. shaky
- m. opposite of tight
- n. eliminate
- o. pouring forth
- p. easy going
- q. of major importance
- r. cause discomfort
- s. rigid
- t. worsen
- u. about to happen
- v. first of two
- w. misplace
- x. augment
- y. lack of
- z. come into close contact

WORKSHEET 3

QUESTIONS

Do you have key facts from this chapter on your NCLEX-RN knowledge ring? Complete the worksheet below to help you check.

Directions: For items 1 to 5, read each question. If the question contains a key word, underline it.

1. Which nursing intervention should be given priority in the plan of care for a client with newly diagnosed tuberculosis?
2. In formulating a teaching plan for home care of a client with lung cancer, which information is most essential to include about the use of oxygen?
3. In caring for a client receiving outpatient chemotherapy for metastatic breast cancer, which instruction should the nurse include about the care of the central line?
4. When administering an IM medication using Z-track technique, what is the next step the nurse should take after injecting the medication into the muscle?
5. When assessing a client's response to Toprol XL, which finding would be unexpected?

Directions: For items 6 through 10, read each sentence carefully and decide if the underlined word is used correctly or incorrectly in the sentence. Write Correct or Incorrect at end of each sentence.

6. The client's nutritional status was compromised when he eliminated almost all sources of protein from his diet.
7. The nurse reported that the client was inept after reviewing laboratory reports that showed immunosuppression.
8. The medication allayed the pain as indicated by the client's statement that her pain was almost gone.
9. On first encountering a client, statute should be noted as part of the general assessment survey.
10. After the client drew up the incorrect amount of insulin and then contaminated the needle, the nurse concluded that the client needed further teaching.

ANSWERS & RATIONALES

ANSWERS FOR WORKSHEET 1: IDENTIFICATION OF KEY WORDS

Directions: Read each of the following questions. If the question contains a key word, underline it.

1. Which clinical manifestation would the nurse expect when assessing a client admitted with a diagnosis of bacterial pneumonia?

Answer

Which clinical manifestation would the nurse expect when assessing a client admitted with a diagnosis of bacterial pneumonia?

(continued)

2. Which sign should alert the nurse to a potential problem in a client with a history of a CVA?

Answer

Which sign should alert the nurse to a potential problem in a client with a history of a CVA?

3. What is the primary goal for the hospice care of a client with lung cancer?

Answer

What is the primary goal for the hospice care of a client with lung cancer?

4. Which nursing intervention should be given priority in the plan of care for a teenager with sickle cell anemia?

Answer

Which nursing intervention should be given priority in the plan of care for a teenager with sickle cell anemia?

5. The nurse is assessing the nutritional status of a client who is 3 months pregnant. Which information is most important for the nurse to obtain?

Answer

The nurse is assessing the nutritional status of a client who is 3 months pregnant. Which information is most important for the nurse to obtain?

6. The nurse is obtaining a health history of a debilitated client with sacral pressure ulcers. Which question should the nurse ask to elicit information effectively about the client's dietary intake?

Answer

The nurse is obtaining a health history of a debilitated client with sacral pressure ulcers. Which question should the nurse ask to elicit information effectively about the client's dietary intake?

7. Which behavior by a client with a newly created colostomy should alert the nurse to the need for teaching regarding skin care?

Answer

Which behavior by a client with a newly created colostomy should alert the nurse to the need for teaching regarding skin care? No keyword.

8. What is the best way to assess for shortness of breath in a 3-year-old client with congenital heart disease?

Answer

What is the best way to assess for shortness of breath in a 3-year-old client with congenital heart disease?

9. The nurse is assessing a family's ability to provide emotional support to a family member diagnosed with cancer. Which observation is most essential?

Answer

The nurse is assessing a family's ability to provide emotional support to a family member diagnosed with cancer. Which observation is most essential?

10. In analyzing the need for teaching a teenage primipara, the clinic nurse should ask which question?

Answer

In analyzing the need for teaching a teenage primipara, the clinic nurse should ask which question? No keyword.

11. Which finding should the nurse expect when checking urinary output of a client with SIADH?

Answer

Which finding should the nurse expect when checking urinary output of a client with SIADH?

12. Which information would be most helpful when preparing to do a home assessment prior to discharge of a low birth weight newborn?

Answer

Which information would be most helpful when preparing to do a home assessment prior to discharge of a low birth weight newborn?

13. Why is it important to monitor pulse rate in a client on digoxin?

Answer

Why is it important to monitor pulse rate in a client on digoxin? No keyword.

14. A 25-year-old woman comes to the clinic complaining of lower left abdominal pain. Which additional information should the nurse obtain initially?

Answer

A 25-year-old woman comes to the clinic complaining of lower left abdominal pain. Which additional information should the nurse obtain initially?

15. Which assessment question should receive priority?

Answer

Which assessment question should receive priority?

ANSWERS FOR WORKSHEET 2: VOCABULARY

Column A Column B

- | | |
|-------------------------|-----------------------------|
| 1. <u>g</u> Site | a. something to be left out |
| 2. <u>d</u> Coarse | b. progress |
| 3. <u>u</u> Imminent | c. without intending to |
| 4. <u>y</u> Deficient | d. rough |
| 5. <u>v</u> Former | e. create a tendency to |
| 6. <u>x</u> Enhance | f. saturate |
| 7. <u>z</u> Impinge | g. location |
| 8. <u>s</u> Tense | h. a truth |
| 9. <u>e</u> Predispose | i. at any time |
| 10. <u>k</u> Sedentary | j. unable to do well |
| 11. <u>a</u> Except | k. inactive |
| 12. <u>q</u> Principal | l. shaky |
| 13. <u>m</u> Loose | m. opposite of tight |
| 14. <u>t</u> Exacerbate | n. eliminate |
| 15. <u>o</u> Profuse | o. pouring forth |
| | p. easy going |
| | q. of major importance |
| | r. cause discomfort |
| | s. rigid |
| | t. worsen |
| | u. about to happen |
| | v. first of two |
| | w. misplace |
| | x. augment |
| | y. lack of |
| | z. come into close contact |

ANSWERS FOR WORKSHEET 3

Do you have key facts from this chapter on your NCLEX-RN knowledge ring? Complete the worksheet below to help you check.

Directions: For items 1 to 5, read each of the following questions. If the question contains a key word, underline it.

1. Which nursing intervention should be given priority in the plan of care for a client with newly diagnosed tuberculosis?

Answer

Which nursing intervention should be given priority in the plan of care for a client with newly diagnosed tuberculosis?

2. In formulating a teaching plan for home care of a client with lung cancer, which information is most essential to include about the use of oxygen?

Answer

In formulating a teaching plan for home care of a client with lung cancer, which information is most essential to include about the use of oxygen?

3. In caring for a client receiving outpatient chemotherapy for metastatic breast cancer, which instruction should the nurse include about the care of the central line?

Answer

No keyword.

4. When administering an IM medication using Z-track technique, what is the next step the nurse should take after injecting the medication into the muscle?

Answer

When administering an IM medication using Z-track technique, what is the next step the nurse should take after injecting the medication into the muscle?

5. When assessing a client's response to Toprol XL, which finding would be unexpected?

Answer

When assessing a client's response to Toprol XL, which finding would be unexpected?

Directions: For items 6 through 10, read each sentence carefully and decide if the underlined word is used correctly or incorrectly in the sentence. Write Correct or Incorrect at end of each sentence.

6. The client's nutritional status was compromised when he eliminated almost all sources of protein from his diet. *Correct*

7. The nurse reported that the client was inept after reviewing laboratory reports that showed immunosuppression. *Incorrect*, inept means unable to do well. The client was inept at changing his dressing is a correct use of the term.

8. The medication allayed the pain as indicated by the client's statement that her pain was almost gone. *Correct*

9. On first encountering a client, statute should be noted as part of the general assessment survey.

Incorrect, the word should be stature.

10. After the client drew up the incorrect amount of insulin and then contaminated the needle, the nurse concluded that the client needed farther teaching.

Incorrect, the word should be further.

Sharpening Your Test-Taking Skills

To be as sharp as possible when answering test questions, follow these steps:

- Identify the parts of a question
 - the scenario which tells you about the situation
 - the stem which contains the actual problem/question to be answered
 - for multiple choice questions, the options or alternatives, which consist of one correct answer (the key) and three distracters or incorrect answers. Distracters sometimes answer a different question than the one asked in the stem or they may assume information not provided in the stem. As a result, they can seem like a good choice and hence are good distracters. Remember that if any part of an option is incorrect, the whole answer is wrong.
- Read the words in the question carefully. Identify “tricky” English words and think about their meaning. Jot down the meaning over each such word and then reread using the definition.
- Determine what the question is asking—read twice and try rephrasing it in easier terms. Once you identify the specific question and its subject, then you can focus on what you know about it.
- Identify what facts provided in the stem or scenario are relevant to the question.
- Ask if the option makes sense for this client—eliminate the option from consideration if the answer is No—even if under other circumstances it is a high-priority action.
- Look for key words—those that direct the answer—when you read the question. Take special note of a negative key word.
- As you read the question, think of your answer and then see if it is among the choices. Do not select the first answer that looks right; however, read all the options carefully.
- Always select an answer within the RN scope of practice.

Example:

Which of the following is a basic nursing responsibility related to drug administration?

1. Monitoring the client’s response to the administration of the drug *Correct*

2. Determining the appropriate drug dosage
 3. Selecting the best route of administration of the drug
 4. Ordering the drug from the pharmacy
- When not certain of an answer, select the most complete option.

Example:
Which is the best definition of a medication?

 1. Chemical that treats symptoms of disease
 2. Drug used for a therapeutic effect *Correct*
 3. Pharmacological preparation used to reverse disease
 4. Plant, animal, or mineral substance which prevents disease
 - Do not change your answer unless you are certain it is incorrect.

APPROACHES TO SPECIFIC TYPES OF QUESTIONS

Questions That Require Priority Setting

Guidelines for establishing priorities are as follows:

- The nurse should always assess (gather pertinent data) before deciding on and taking an action. This is reflected in the steps of the Nursing Process: assess, diagnose, plan, intervene, and evaluate.
- Physiological needs must be met first. The client must be kept alive for anything else to be important. Next in importance are safety needs and then come psychological needs. This is outlined in Maslow’s hierarchy.
- When prioritizing physiological needs remember your ABCs: airway, breathing, and circulation.
- Which answer will keep the client safe/prevent client harm? It is especially relevant when the question deals with laboratory values, drug administration, and nursing procedures.
- Assessment of equipment never takes precedence over assessment of the client.

Communication Questions

Therapeutic communication promotes expression of feelings and ideas and also conveys acceptance and respect. Like any communication, it involves both verbal and nonverbal components. Major techniques to facilitate therapeutic communication are as follows:

- Communicate in an accepting and respectful manner. Address (refer to) the client by his/her given name—not by a nickname, a room number, or “sweetie.” Names other than the given name should only be used upon the client’s request or permission. Clients should be asked, not told, whenever appropriate. This allows for client decision making and hence communicates respect for the client as an able, intelligent individual.

Examples:

What would you like to do first?

What would you like to talk about?

- Use open-ended questions. These are questions that cannot be answered with a Yes or a No.

Examples:

What do you think about this plan?

What questions do you have?

How do you feel about going home tomorrow?

Tell me about your headaches.

- Reflect feelings expressed by the client. Remember that feelings are expressed verbally and nonverbally. These may be contradictory but feelings expressed nonverbally are usually true because nonverbal communication is harder to control. Reflection indicates empathy, allows validation of the perceived feelings, and allows the client to “look at” his/her feelings. Words used in reflection should be neutral unless the client uses an emotionally charged word.

Examples:

You seem sad.

You seem unsure.

You must feel lonely sometimes.

I get the feeling you are upset.

Do not say:

You are depressed.

You can’t make a decision.

It must be awful being alone all the time.

You must be really mad at your neighbor.

- Focus the conversation on important areas.

Examples:

Let’s talk a little more about . . .

You were talking about the problem you had with changing your dressing, let’s go back and explore that further.

- Paraphrase or restate what the client has said in your own words. This allows the client to validate the message or correct misunderstanding.

Examples:

What you are saying is . . .

Let me make sure I understand . . .

What I hear you saying is . . .

- Summarize the communication.

Therapeutic communication also involves (a) active listening, (b) stating observations made about the client but never any that would embarrass or anger the client (“You look rested” or “You seem quiet today.” Not “You look terrible.”), (c) reflecting empathy or an understanding of the importance of a situation to the client in a neutral, nonjudgmental manner (“It must be very disheartening . . .”), (d) sharing hope, humor, and feelings, (e) using touch and silence, (f) asking pertinent questions, and (g) giving information.

Nontherapeutic (blocking) communication techniques hinder further communication and expression of feelings and may induce negative responses. Some examples of nontherapeutic communication techniques are:

- Asking unnecessary personal questions: “Why are you just living with Mary rather than marrying her?” “Why are you still living at home?” “How come you haven’t bought a house?”
- Giving personal advice or opinions: “If I were you I would make my son move out.” “I think you should stop cooking for the whole family.”
- Flip or automatic responses, use of clichés: “Everything will work out.” “Don’t worry.” “It happens all the time but it doesn’t mean anything.”

Redirecting the conversation or changing the subject, expressing sympathy, asking “why,” verbalizing approval or disapproval, responding defensively, passively or aggressively, and arguing also block therapeutic communication.

When answering a communication question, begin by reviewing the above principles. Then determine what the question is asking. If the question is asking what is the nurse’s best response, what is the most appropriate response, what is the most therapeutic response, or what response will best support a therapeutic relationship, eliminate nontherapeutic options. Do this by identifying options that involve nontherapeutic responses: options that give opinions, options that brush off the client’s concerns; options that contain emotionally charged, defensive, accusatory, or otherwise upsetting or offensive wording, and options that contain judgmental wording.

Example:

A client who has been hospitalized for 2 weeks says to the nurse “I can’t stay here anymore, I have to get back to my family.” Which is the most appropriate response for the nurse to make?

- a. “Don’t worry. Your family will be fine.”

- b. “If I were you, I’d take advantage of the rest you’re getting while away from the family.”
- c. “Would you like to talk about how you feel?” *Correct*
- d. “Is your family unable to get along without you?”

In some cases, the question may be asking you to identify the nontherapeutic or inappropriate response. Be alert for this when reading questions and then select the option containing a response that would be incorrect for the nurse to make as the answer.

Example:

A client states “My family doesn’t seem to understand my illness.” Which response on the part of the nurse would most likely block further discussion?

- a. “They may not seem to, but I’m sure they do.” *Correct*
- b. “In what way do they react to give you that feeling?”
- c. “Your family doesn’t seem to understand.”
- d. “What makes you think that?”

Client-Teaching Questions

There are different types of client-teaching questions. Some are very straightforward simply asking what should the nurse teach. This type of question addresses the planning or implementation phase of the nursing process.

Example:

Which instruction/information should the nurse include in the teaching plan for a client with genital herpes?

Which instruction/information should the nurse give to a client with genital herpes?

A variation on this type of question asks you to identify not what needs to be taught but *when* or *by whom*, teaching is needed.

Example:

Which client should be taught about the need for potassium in the daily diet?

- a. Client taking daily NSAIDS for arthritis
 - b. Client taking Toprol XL daily for hypertension
 - c. Client taking Fosamax weekly for osteoporosis
 - d. Client taking Hydrodiuril daily for fluid retention
- Correct*

Other client-teaching questions ask not what should be taught but how does the nurse know the teaching was understood. These are client-teaching questions that address the evaluation phase of the nursing process. Was the teaching effective? Did the client learn? These questions may be phrased in a positive or negative way.

Positive questions ask you to select an answer that is a correct statement or activity—something that should be done or said.

Examples of positively phrased questions:

Which statement made by a client with hepatitis B following discharge teaching indicates that instruction was effective?

Which statement made by a client with hepatitis B indicates that discharge instructions were understood?

Negatively phrased questions ask you to identify the answer that indicates the client does not know, has misunderstood, or has not learned. It requires that you identify an incorrect statement—not a correct one. Negative questions require that you choose from the options the one that is incorrect or should not be said or done. Note that negative questions do not necessarily have a negative word (not, no, incorrect, etc.) in the stem.

Examples of negatively phrased questions:

Which statement made by a client taking Fosamax once a week for the treatment of osteoporosis indicates that the directions for taking the medication were not understood?

Which action taken by a client who has been taught to self-administer insulin indicates that further teaching/instruction is necessary?

Which statement made by the mother of a child diagnosed with bronchiolitis indicates a need for teaching?

A client’s daughter is assisting her to the bathroom. Which observation by the nurse suggests that teaching is needed?

Delegation Questions

These typically ask what duties can be assigned to a nurse aide or an LPN/LVN and when a physician, social worker, respiratory therapist, or other member of the health-care team should be notified or consulted.

WORKSHEET

IDENTIFYING FACILITATING AND BLOCKING RESPONSES

Directions: Read each statement or set of statements and decide if therapeutic communication is being facilitated or blocked. Write your decision at the end of each.

- Client: "I'm so worried about my surgery."
Nurse: "We do 10 of these procedures every week and they all come out fine."
- Client: "I keep thinking about my husband and how he is managing at home by himself."
Nurse: "You just have to put him out of your mind and concentrate on getting better."
- Client: "I don't know how I am going to cope with all the bills from being in the hospital."
Nurse: "I'll have a social worker stop by to go over your insurance."
- Client's daughter: "I don't know how I am going to arrange care for my mother at home while I work."
Nurse: "If it were me I would put her in a nursing home where she would have round-the-clock care."
- Client: "I am such a burden on everybody since I had the stroke."
Nurse: "What makes you say that?"
- Client: "I'll never learn how to give myself this injection."
Nurse: "Of course you will."
- Infant client's mother: "I'm afraid that I will forget how to correctly prepare the baby's formula when I get home."
Nurse: "Would you like me to go over the procedure with you one more time?"
- Client: "Having that test was the worst experience I've had in my whole life."
Nurse: "Tell me what happened."
- Client: "I have to begin to have my husband help with the housework when I get home."
Nurse: "Do you have a plan in mind as to how you are going to do this?"
- Client: "I can't use a diaphragm anymore; it's just too messy and inconvenient."
Nurse: "Would you like information on other forms of birth control?"
- Client: "My son doesn't want to visit me anymore. He says I am always complaining."
Nurse: "Children expect their parents to be perfect. He'll get over it."
- Client: "I can't do anything right."
Nurse: "You shouldn't feel that way. Things will be different when you're better."
- Client: "I am so upset about my roommate's visitor tripping over my slippers yesterday."
Nurse: "My advice to you is to forget it—she didn't get hurt."
- Client: "My son-in-law refused to bring my granddaughter to visit me."
Nurse: "That's mean; it must make you angry."
- Client: "I don't think I am going to make it out of here. I am just so weak."
Nurse: "You are very depressed."

ANSWERS & RATIONALES

IDENTIFYING FACILITATING AND BLOCKING RESPONSES

Directions: Read each statement or set of statements and decide if therapeutic communication is being facilitated or blocked. Write your decision at the end of each.

- Client: "I'm so worried about my surgery."
Nurse: "We do ten of these procedures every week and they all come out fine."
Blocked. This response provides false reassurance and may even be interpreted as flip. It does not acknowl-

edge the client's concern nor encourage further sharing.

- Client: "I keep thinking about my husband and how he is managing at home by himself."
Nurse: "You just have to put him out of your mind and concentrate on getting better."
Blocked. This response does not acknowledge the client's concern and is a form of personal advice. It effectively shuts off further discussion.

3. Client: "I don't know how I am going to cope with all the bills from being in the hospital."

Nurse: "I'll have a social worker stop by to go over your insurance."

Blocked. This response indicates that the topic of the client's concern has been heard but it offers a solution which may or may not be acceptable to the client. It does not offer the client a choice or the opportunity to further specify or discuss concerns or feelings.

4. Client's daughter: "I don't know how I am going to arrange care for my mother at home while I work."

Nurse: "If it were me I would put her in a Nursing Home where she would have round the clock care."

Blocked. This response gives advice and shuts down further discussion of the problem.

5. Client: "I am such a burden on everybody since I had the stroke."

Nurse: "What makes you say that?"

Facilitated. This is an open ended question that encourages the client to explore his or her feelings.

6. Client: "I'll never learn how to give myself this injection."

Nurse: "Of course you will."

Blocked. This response gives false reassurance and constitutes a cliché.

7. Infant Client's Mother: "I'm afraid that I will forget how to correctly prepare the baby's formula when I get home."

Nurse: "Would you like me to go over the procedure with you one more time?"

Facilitated. This response recognizes the mother's concern and offers, not dictates, an appropriate option.

8. Client: "Having that test was the worst experience I've had in my whole life."

Nurse: "Tell me what happened."

Facilitated. This response indicates willingness to hear the client and encourages exploration of feelings and events.

9. Client: "I have to begin to have my husband help with the housework when I get home."

Nurse: "Do you have a plan in mind as to how you are going to do this?"

Facilitated. This question can be answered yes or no but it opens the floor for the nurse to guide the client in the discussion and evaluation/revision/development of a plan.

10. Client: "I can't use a diaphragm anymore; it's just too messy and inconvenient."

Nurse: "Would you like information on other forms of birth control?"

Facilitated. This response recognizes the client's concern and offers an appropriate option in response.

11. Client: "My son doesn't want to visit me anymore. He says I am always complaining."

Nurse: "Children expect their parents to be perfect. He'll get over it."

Blocked. This response is cliché in nature and does not recognize the validity of the client's concern.

12. Client: "I can't do anything right."

Nurse: "You shouldn't feel that way. Things will be different when you're better."

Blocked. This response although somewhat "gentle" in its wording, offers false reassurance, may be construed as judgmental, and does not allow the client to further explain his or her feelings and concerns. It also contains an element of cliché.

13. Client: "I am so upset about my roommate's visitor tripping over my slippers yesterday."

Nurse: "My advice to you is to forget it - she didn't get hurt."

Blocked. This response offers advice and trivializes the client's concern.

14. Client: "My son in law refused to bring my grand daughter to visit me."

Nurse: "That's mean; it must make you angry."

Blocked. This response is judgmental and presumes to know what the client is feeling.

15. Client: "I don't think I am going to make it out of here. I am just so weak."

Nurse: "You are very depressed."

Blocked. This response makes a judgment about the client. It does not encourage the client to discuss feelings nor does it seek to validate interpretation of the client's communication.

LEGAL RIGHTS AND RESPONSIBILITIES

PROFESSIONAL LEGAL ISSUES

Legal controls on the practice of nursing are to protect the public. Law provides a framework for

- identifying what nursing actions are legal,
- differentiating the nurses' responsibilities from those of other health care professionals,
- establishing the boundaries of independent nursing actions, and
- assisting in maintenance of a standard of nursing practice.

Nurse Practice Act

- This is a set of laws defining the scope of nursing practice.
- Each state has its own Nurse Practice Act usually administered by the State Board of Nursing.
- Most Nurse Practice Acts address performing services for compensation, specialized knowledge bases, use of the nursing process, and components of nursing practice.

Practice Alert

The nurse needs to obtain and read the Nurse Practice Act for the state that she/he intends to practice in.

Licensure

- License is a legal credential conferred by a state granting permission to an individual to practice a given profession.
- It is commonly required for professions requiring direct contact with clients.
- Licensure requires that a level of competency be demonstrated by the individual seeking a license; for an RN license this is done by passing the NCLEX-RN.
- Mandatory licensure for registered nursing is the standard in the United States—one must have a valid nursing license to work in any state, territory, or province.
- RN Nurse Licensure Compact (NLC) is a mutual recognition licensure model which allows a nurse to be licensed in his or her state of residence but to practice physically or electronically in other compact states. Practice in compact states is subject to each state's practice law and regulation.
- Each state or jurisdiction establishes its own licensing laws, which usually require graduation from an approved nursing educational program, passing score on the NCLEX-RN, a good moral character, good physical and mental health, and disclosure of criminal convictions.

Standards of Care

- Standards of care are authoritative statements that define an acceptable level of patient care (professional practice).
- These are used to evaluate the quality of care provided by the nurse and, therefore, become legal guidelines for nursing practice.
- American Nurses Association (ANA) has developed general standards and guidelines for more than 20 specialty nursing practice areas.
- State Nurse Practice Acts describe standards of practice that apply to a nurse in the particular state.
- Individual health care agencies may have developed standards of care for selected patient problems, e.g., critical pathways, clinical pathways.

Malpractice

- Malpractice is the term used when a nurse while performing her/his responsibilities commits an act of negligence resulting in harm to the patient.
- Harm must be based on the failure to act in a *prudent professional* manner and within professional standards.
- Nurse must have had a professional duty toward the person receiving the care for malpractice to have occurred.

Practice Alerts

Regulation of the practice of nursing serves two purposes: protection of the public and accountability of the individual practitioner's actions.

Malpractice is present only if a breach of duty was the cause of the injury.

LEGAL ISSUES AFFECTING PATIENTS

Legal issues affecting patients are those that occur when a wrong has been committed against a patient or a patient's property.

Defamation of Character

- Defamation of character occurs when information about an individual is detrimental to his/her reputation.
- The communication, which is considered to be malicious and false, may be spoken (slander) or written (libel) and may be about patients or other health care providers.

- The nurse must
 - document only objective information in the medical record,
 - use professional terms,
 - avoid discussing patients and other health care providers in public places where there is the possibility of being overheard, and
 - use only acceptable avenues to confidentially report behavior of patients or other health care providers.

Privileged Communication

- Privileged communication is the information shared by an individual with certain professionals and that does not need to be revealed in a court of law.
- The nurse needs to know what the state she/he is practicing in says about privileged communications.

Practice Alert

All states do not recognize the nurse–patient relationship as one of privileged communication. States that do recognize the relationship as privileged may not recognize all communications between patient and nurse as privileged.

Emergency Care

- Certain actions provided by a health care professional may be legal in emergency situations and not legal in nonemergency situations.

- During a true emergency, *consent* is implied as the court considers that a reasonable person in a life-threatening situation would give permission for treatment.
- “Good Samaritan Acts” protect the nurse against negligence when she/he provides voluntary assistance to an individual in an emergency situation.
- Within a health care agency, the emergency policies and procedures of the institution govern what the nurse can do, and so a nurse must know these. The courts have held that a nurse can do things immediately necessary, even if the activity is normally considered a medical function, provided she/he has the expertise to carry out the act. The nurse is protected from a charge of practicing outside the scope of practice if the *protocols* established by the institution’s medical staff are followed.

Practice Alert

Hospitals and health care agencies are expected to have policies and protocols to be followed during an emergency situation, e.g., “code.” The standard of “reasonable care” is used when emergency care is given in a *noninstitutional* setting.

Refusing Treatment

- This issue arises out of the belief in and respect for the autonomy of the patient.
- The two forms of refusing treatment are when the patient discharges himself/herself from the hospital against medical advice *or* when he/she refuses certain treatment when in the hospital.

CLIENT RIGHTS

Patients have the right to expect they will be treated in a certain way, receive adequate information, and have their confidentiality maintained when they are interacting with the health care system.

DIGNITY

- Dignity is the right to receive compassionate nursing care.
- It is an essential professional nursing value.
- The nurse demonstrates respect for the worth and uniqueness of individuals—patients and colleagues.
- The nurse advocates for the respect and dignity of human beings.

AUTONOMY

- Autonomy is the right of self-determination.
- The nurse must respect the patient’s right to make decisions about and for himself/herself.
- Examples of respect for an individual’s autonomy are obtaining informed consent, facilitating patient choice for treatment, allowing patient to refuse treatment, and maintaining confidentiality.
- Individuals may lose autonomy when they fall ill; family interactions may leave the patient out of the decision-making process.

PATIENT'S BILL OF RIGHTS

- This document was developed by the American Hospital Association (AHA) in 1972 and was revised in 1992.
- It outlines an individual's right to inspect his/her medical record and to receive information about the medical care received during a hospital stay. In addition, the Bill speaks for the right to respectful care, relevant and understandable information, advance directive, consideration of privacy, consent or decline participation in research, continuity of care, and information of hospital policies and practices.
- In 2001, the McCain-Edwards-Kennedy/Ganske-Dingell Patients' Bill of Rights was passed. The Bill addresses such additional issues as shared decision making, the right to be informed of all medical options, and the right to refuse treatment.

ACCESS TO MEDICAL RECORD

The medical record

- contains medical information as well as personal information about the patient.

- is considered the property of the health care agency, but the patient has a legal interest and right to the information.
- can be accessed by those with a legitimate interest, which is generally accepted as referring to patient care, professional education, administrative functions, auditing functions, research, public health reporting, and criminal law requirements.

Practice Alert

Information may be shared between health care providers who are responsible for patient care within a health care facility. Health care agencies have a responsibility to establish policies and procedures to protect patient confidentiality as well as falsification or alteration of the medical record. Nurses are held accountable for upholding the Patient's Bill of Rights. Under conditions of danger to another human being, autonomy would not be absolute.

CONFIDENTIALITY/INFORMATION SECURITY

A patient's privacy will be respected and information that is shared about a patient to a health care provider will not be made public without the patient's consent.

HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT (HIPAA)

- The Act is a federal privacy standard that protects the patient's medical records and other identifiable health information whether maintained on paper, computer, or orally communicated.
- It requires the maintenance of confidentiality and ensures the privacy of patients.
- Patients can obtain copies of their medical records.
- Providers must provide patients with written notice of practices and patients' rights.
- Limitations are placed on information shared: what, where, and with whom.

COMPUTERIZED MEDICAL DATABASE

- Serious concern arises around patient privacy and confidentiality as health care information becomes more and more electronically accessible.
- ANA supports nine principles in keeping with patient advocacy and trust in regard to advances in technology and patient's health information.

Practice Alert

Health care agencies need to have policies and procedures in place to ensure privacy and confidentiality of computerized patient information. Ultimately, patients will have increased control over their own information and there will be significant penalties in place if the policies are violated.

INFORMED CONSENT

- An individual has the right to understand the choices being offered around medical treatment and the right to voluntarily agree or refuse treatment.
- The client must receive a description of the procedure, alternatives for treatment, risks involved in treatment, and probable results. The law holds obtaining *consent for medical treatment* to be the responsibility of the physician, **but** the nurse has a responsibility of notifying the physician if she/he determines that the client does not seem to understand.
- Consent can be oral or written, although a written consent is usually preferred.
- A blanket consent for “any procedure deemed necessary” is not usually considered adequate for specific procedures.
- *Consent for nursing care* is implied when the nurse asks the client to do something and the client does not refuse the care.
- To give consent, a person must be competent, i.e., able to make judgments based on rational understanding.
- Clients have the right to change their mind and can *withdraw consent*; if this occurs, the nurse must notify the physician.
- *Consent for a minor* to receive treatment is usually provided by a parent or legal guardian.

Practice Alerts

The nurse may witness the signing of the consent form for medical treatment.

The client has the right to refuse any aspect of care offered.

ADVANCED DIRECTIVES

These are the wishes of an individual expressed in a legal document when the individual is no longer capable of giving his/her own consent in certain health care situations. The document is prepared in *advance* of the situation and *directs* others how to act on behalf of the individual.

LIVING WILL

- Provides preferences around end-of-life care.
- “*If-Then*” plan: “If” something happens, then “I want X done.” “If” must be a diagnosis made by a physician.
- States vary in their requirements—originally, living wills were advisory for families and physicians, but now some states have laws that require the physician to honor the living-will stipulation. If a physician does not agree with the patient’s decision, then she/he must withdraw from the case and refer the patient to another physician.

DURABLE POWER OF ATTORNEY

- This is a legal document that designates a substitute decision maker for general or specific health care and medical decisions should the individuals not be able to decide for themselves.
- Durable power of attorney can be combined with a living will. This document is considered the most flexible as the individual who has been assigned the durable power of attorney can make decisions as the situation changes.

PATIENT SELF-DETERMINATION ACT

- Effective as of 1992, the Act requires health care facilities receiving Medicare and Medicaid reimbursement to recognize advance directives.
- Patients on admission to a health care agency must be given the opportunity to determine what lifesaving or life-prolonging actions they want to have carried out. The health care agency must follow the patient’s advance directives. The agency is required to provide the individual with enough information to make an informed decision.
- Issues that are usually addressed in an advanced directive are specific treatment to be refused or desired, when the directive is to take effect, and specific hospitals and physicians to be consulted. As a clinical advocate, the nurse helps the family members determine a course of action.
- Frequently, it is the nurse who has to assess a client’s level of understanding and provide the education as well as obtain the client’s signature. ANA has come out with a statement that the nurse should have a primary role in education, research, patient care, and advocacy.

Practice Alert

Nurses are expected to learn the law regarding advance directives in the state in which they are practicing as well as the policies and procedures of the health care agency in which they are working.

ETHICAL PRACTICE

- It involves reasoning that is rational, systematic, and based on ethical principles and codes rather than on emotions or intuition.
- Ethical decision making has the patient's well-being at the center of it.
- Nurses have a responsibility for ethical considerations to patients, employing agency, and physicians.

PROFESSIONAL ETHICAL CODES

- Ethical codes are guidelines that provide a framework for ethical behavior, which in turn provides direction to moral reasoning and action. Nursing ethics focus on the practice of nursing.
- Codes provide direction; however, they do not eliminate moral dilemmas.
- The individual health care professional must be motivated to act morally.

ANA Code of Ethics

- The ANA Code of Ethics was adopted in 1950 and its last revision was in 2001.
- It contains general moral standards for nurses to follow.
- It is considered to be nonnegotiable with regard to nursing practice.
- It is patient focused, whether the patient is an individual, family, group, or community.

ICN Code of Nursing Ethics

- The ICN Code of Nursing Ethics was adopted in 1953.
- It contains four principal elements: standards for nurses and people, practice, profession, and coworkers.
- These elements provide a framework for standards of conduct.

The Codes use the word “patient” versus “client” in identifying the recipient of nursing care. Patients are the center of nurses' practice.

RELATIONSHIPS

Nurses need to be concerned about their relationships with colleagues (nurses and physicians) as well as patients in order to provide compassionate care. All the nurses' relationships ultimately affect the patient.

Nurse–Patient–Family Relationship

- When patients enter the health care system, they have no option but to trust the nurse when they need care—unavoidable trust. An uneven power structure is created between patients and nurses, and patients and nurses and families. Nurses promise to be the best nurses they can be. They promise to be candid, sensitive, attentive, and never to abandon the patient.
- A second component of the nurse–patient–family relationship is patient advocacy. The nurse identifies unmet needs and follows up to address the needs appropriately. When advocating for a patient, the nurse moves from the patient to the health care system to address the health care needs of the patient.

Nurse–Nurse Relationship

- Nurses are a community that works together for a common good using professional traditions to guide its practice.
- When a nurse has reason to believe a colleague is placing a client in jeopardy or another colleague in harm, she/he has a responsibility to deal with the offending coworker.

Nurse–Physician Relationship

Physicians and nurses are members of the health care community working together for the health and well-being of the patient.

Practice Alert

Nurses can never take for granted the fragility of a client's trust. The best interests of the client are not served if the nurse and physician do not view themselves as members of a common community.

BIOETHICAL ISSUES

Bioethics is the domain of ethics that focuses on moral issues in the field of health care.

Acquired Immune Deficiency Syndrome

- AIDS bears a social stigma due to its association with sexual behavior and drug use.

- The primary ethical issues are testing for the presence of HIV and maintaining privacy, which include questions of whether health care providers and patients should undergo required or voluntary testing and how much information should be released to others.
- Statutory laws provide direction to the duty to warn sexual partners of individuals with HIV.
- There are only a few situations in which a nurse could ethically refuse to care for a patient with HIV; one example might be if the nurse was pregnant.

Abortion—Pro-Choice/Pro-Life

- The central ethical dilemma is the right to life of the fetus or the women's right to control her own body by choosing whether or not to have a baby. The question is—is the fetus a person a or nonperson?
- Abortion is legal during the first trimester. The US Supreme Court in *Roe v. Wade* ruled that states cannot ban abortion in the first and second trimester, except for certain reasons during the second trimester.

Child Abuse

- Physical, sexual, emotional abuse, and neglect are actions considered to be forms of family violence.
- Neglect is the most common form of child abuse.
- The nurse must be alert for the signs of abuse and is required to report possible abuse. The responsibility to maintain confidentiality is waived when child abuse is suspected.
- All states have mandatory child abuse reporting laws. Abuse does not need to be confirmed in order to be reported. There is legal protection for nurses in most states who report suspected cases in good faith.
- There are legal sanctions for health care providers who fail to report suspected abuse cases.

End of Life—Right to Die

Technology and the increased elderly population have raised many ethical dilemmas. Nurses are involved in

ethical decision making around such things as euthanasia, assisted suicide, and termination of life-sustaining treatment.

Genetic Screening

- Genetic screening involves the professional counseling of individuals or couples about their risk for genetically linked diseases.
- Information obtained from genetic screening may be useful for individuals and couples; however, it can create a situation where the individuals involved do not know what to do with the information.
- Stem cell research offers hope for correction of genetic diseases.

Organ Transplant

- Organs may come from living donors or from donors who have just died.
- Ethical issues include such concerns as allocation of organs, selling of body parts, children as potential donors, and clear definition of death. Two major twenty-first century issues are (a) societal pressure for organ harvesting due to global demand for organs and (b) individuals questioning their own moral beliefs about death and the legal definition of death as it relates to organ donation.
- Bioethicists continue to search for answers to philosophical questions about life and death.

Practice Alert

Nurses need to learn the laws around bioethical issues in the state where they are practicing as well as the institution's policies where they are employed.

CONCEPTS OF MANAGEMENT

- Management is a process to achieve organizational goals.
- Nursing management is the process of getting nursing staff to provide care to patients.
- The nurse manager plans, organizes, directs, and controls financial, material, and human resources in order to provide the most effective care possible to groups of patients and their families.

PLANNING

Planning is the determination of what needs to be done. Its essential elements are

- objectives,
- strategic planning,

- budget, and
- setting priorities.

Objectives

- Objectives are the specific measurable statements that flow from the philosophy and mission of the institution that identify what needs to be achieved by the nursing unit.
- When the statement refers to the institution, it is called a goal.

Strategic Planning

- Strategic planning refers to the long-range planning by a health care organization; it provides the direction that the organization will go in over the next 3–5 years.
- It is based on the values, philosophy, and mission of the health care organization and the vision of its leaders.

Budget

- Budget is the allocation of resources on the basis of forecasted needs.
- It is a numerical expression of expected revenues and expenditures of the nursing service department.
- The objective for making a budget is to ensure the attainment of desired goals in the most cost-effective manner.
- There are two types of budgets: operating budget and capital budget. The operating budget includes manpower resources, supplies, minor equipment, overhead expenses, salaries, and benefits while the capital budget includes items of considerable expense, such as major pieces of equipment.

Practice Alert

The nurse manager is accountable for maintaining the nursing service department budget and needs to monitor the department budget reports.

Setting Priorities

The nurse leader determines the importance of activities and establishes the order in which the activities will be carried out. Setting priorities involves decision making.

ORGANIZING

Organization involves determination of how the planning is to be accomplished, how the parts are to be arranged into a

functioning whole, and how the activities are to be coordinated to achieve a goal. Hence it is a means to an end, not an end in itself. Its essential elements are

- organizational structure
- position/job descriptions
- team building
- staffing

Organizational Structure

The formal organizational structure is the official arrangement of positions (organizational chart) and should be based upon goals of the institution and philosophy and objectives of the department.

The informal organizational structure is the unofficial personal relationship among workers, which influences their working effectiveness.

Practice Alert

The nurse manager needs to be able to use both the formal and the informal structure.

Organizational principles

- Unity of Command—an employee should be responsible to only one supervisor.
- Requisite Authority—when responsibility is delegated to a subordinate, the subordinate must also be given authority over the resources needed to accomplish the task.
- Continuing Responsibility—when a superior delegates responsibility to a subordinate, it does not diminish the superior's responsibility for the function.
- Organizational Centrality—an individual has more information available when she/he interacts directly with more individuals in the organization and becomes more powerful.

Position/Job Description

- Position/job description is a formal written document that describes the principal duties and scope of responsibilities for a particular position.
- It facilitates wage and salary administration, manpower planning, and assists with recruitment, selection, placement, orientation, and evaluation of employees.

Team Building

- Team building focuses on both task and relationship aspects of a group's functioning and is intended to increase efficiency and productivity.

- Team building involves data gathering about the team and its functioning, diagnosing strengths and areas needing development, and addressing team problems.
- Successful teams reflect open and effective communications, members that are committed to the team, clearly identified roles and responsibilities of the members, and trust and collegiality.

Practice Alert

The most important activities in team building are data gathering and diagnosing.

Staffing

- The purpose of staffing is to provide the nursing unit with the appropriate number and type of persons to perform the tasks required for patient care.
- Assignment methods are functional, team, primary, and modular.

Practice Alert

There needs to be a uniform staffing pattern for the nursing service department versus a different one for each individual nursing unit.

LEADING

Leading is the process of getting the organization's work done. Its essential elements are

- leadership,
- supervision,
- decision making,
- shared governance,
- change agent,
- managing conflict,
- power—authority, and
- time management.

Leadership

- Leadership is the ability to influence other people. A nurse leader can inspire the nursing staff to work together to accomplish the nursing unit's goals.
- Formal leadership is when the nurse has legitimate authority as defined by the health care organization.

- Informal leadership is when a staff member exercises leadership without the management role.
- Present-day theories of leadership evolve from the principles of quantum mechanics and reflect a fusion of the earlier theories of leadership: trait, behavior, and contingency theories.
- Six perspectives of quantum leadership are charismatic, transactional, transformational, connective, shared, and servant leadership.

Supervision

- Supervision refers to the guidance, oversight, and evaluation of a member of the nursing team to whom the nurse leader has delegated an activity. It is an opportunity for the nurse to encourage the development of team members.
- Effective supervision utilizes the skills of communication, human relations, and teaching.
- Supervision is a mutual effort on the part of the individual being supervised and the person supervising.

Decision Making

- The decision-making process involves a series of steps that the nurse manager goes through to make a logical, well-informed, rational choice.
- Decision making always involves evaluating several possible solutions and making a choice.

Practice Alert

A decision not to do something is still a decision.

Shared Governance

- Shared governance is based on a philosophy that nursing practice is best determined by nurses.
- It involves a network of nurses making nursing practice decisions in a decentralized environment.
- The outcome is that nurses participate in an accountable forum to control their own practice.
- Such forums can be in the form of councils or advisory boards.

Practice Alert

Shared governance allows staff nurses significant control over major decisions affecting nursing practice.

Change Agent

- Change is a continual unfolding process.
- This process begins with the present state, moves through a transition state, and comes to the desired state. Having once arrived at the desired state, the process starts again.
- Change agent is the individual who helps to achieve the results during the dynamic process.
- Planned change has four steps: designing the change, planning the implementation, implementing the change, and integrating the change. Choosing change strategies depends on the amount of resistance anticipated and the degree of power the change agent has over the situation.
- Resistance to change occurs for a variety of reasons and comes from three major sources: technical concerns—concern about the change being a good idea, psychosocial needs—Maslow’s hierarchy of needs, and threats to a person’s position and power.

Practice Alert

A leader uses interpersonal skills to influence others to accomplish the specific objectives.

Managing Conflict

- Conflict management begins with a decision of “if and when” to intervene.
- It deals with conflict of issues, not personalities.
- Participants are responsible for working toward solutions and an open and full discussion of the problem is required.

Strategies

- Maintain equity in each party’s presentation of their information.
- Establish an environment where positive as well as negative feelings can be expressed.
- Engage in active listening of all parties.
- Restate key themes and encourage both parties to provide feedback.
- Develop alternative solutions and a plan to carry them out. Follow up on the plan.
- Provide positive feedback.
- Never blame.

Practice Alert

Failure to intervene during a conflict can escalate the situation. Conflict management is a difficult process that consumes time and energy.

Power—Authority

- Power is the ability to influence other people even when there is resistance on the part of the other person.
- There are four types of power: authority—the power granted to a nurse or a group of nurses by virtue of position; reward—the promise (by the nurse manager) of money, goods, services, recognition, or other benefits; expertise—the special knowledge an individual (nurse) is believed to have; coercion—the threat (by the nurse manager) of physical, economic, or psychological pain or harm.

Time Management

- In time management, what is really being managed is not time but how time is being used.
- An important aspect of time management is establishing one’s own goals and time frames.
- There are seven principles of time management: goal setting, time analysis, priority determination, daily planning, delegation, interruption control, and evaluation.
- Assignment sheets that reflect the patient care assignments for each staff member as well as staff member’s individual worksheets are tools to assist one in organizing time.

Practice Alert

Establish a “to-do” list to assist in organizing your time. Learn to say no to low-priority demands on your time.

CONTROL

Control is the process of establishing standards of performance, measuring performance, and evaluating performance and providing feedback.

Information Systems

- Information systems are complex automated systems that are integrated through networked computers to process data.
- The common information systems are management information system, hospital information system, and nursing information system.
- Automated systems offer efficient organization, management, and storage and retrieval of information.

Total Quality Management

- Total quality management is the framework for the nurse manager to manage both costs and quality of patient care.

- It is a management philosophy that emphasizes a commitment to excellence.
- Total quality management is the umbrella philosophy that supports the process of continuous quality improvement.
- Continuous quality improvement is the process that systematically determines ways to improve patient care.
- Joint Commission on the Accreditation of Healthcare Organizations (The Joint Commission) provides standards that help health care institutions focus on the quality improvement efforts.
- Components of quality management are developing a comprehensive plan, setting standards and benchmarks, carrying out performance appraisals, and focusing on intradisciplinary and interdisciplinary assessment and improvement.

Performance Appraisal

- Performance appraisal is the formal evaluation of an employee by a nurse manager.
- The employee's behavior is evaluated against a standard that identifies what the employee is expected to perform.

- The position description is the basis for the performance behaviors.
- The main reason for conducting a performance appraisal is to provide constructive feedback to the employee.
- Performance appraisals are frequently used in the decisions for salary increases and promotions.

Appraisals need to be in writing, done once a year, and shared with the employee. Employees should have the opportunity to respond and have an avenue for appeal. The manager needs to have adequate opportunity to observe the employee and should keep anecdotal notes as well as the staff nurse's self-assessment.

Practice Alert

The performance appraisal focuses on behaviors *not* personality traits or characteristics. Performance appraisals are part of the employee's permanent record.

DELEGATION

- Delegation is the process where responsibility and authority are transferred to another individual who accepts the responsibility and authority.
 - Responsibility is an obligation to accomplish a task.
 - Accountability refers to accepting ownership for the results.
 - Authority is the right to act. By transferring authority, the delegator is empowering the delegate to accomplish the task. When the delegator retains the authority, the delegate cannot accomplish the task and sets the delegate up for failure.
- Delegation empowers others and builds trust, enhances communication and leadership skills, and develops teamwork.
- Effective delegation enables the delegator to accomplish more and be more productive.

Practice Alert

The nurse can delegate only those tasks for which she/he is responsible. Along with responsibility, she/he must transfer authority.

DELEGATION PROCESS

The delegation process involves five steps:

- Define the complexity of the task and its components.
- Determine to whom to delegate; ask such questions as: Are specific qualifications necessary? Is performance restricted by practice acts, standards, or position description? Is training or education required? Match the task to the individuals' abilities and who is available to perform the task.
- Provide clear communications about expectations: describe the task, provide a reason for the task, identify on what standards the task will be evaluated, and identify any constraints for completing the task.
- Reach mutual agreement about the task, validate understanding.
- Monitor and evaluate the results; the leader/manager needs to remain accessible. If problems develop, handle privately. Give praise when it is due.

Practice Alert

When defining the task and expectations clearly establish where, when, and how. Analyze performance with respect to the established goals.

ACCEPTING DELEGATION

- Determine if you have the skills required and if not is the delegator willing to educate/train you.
- Make sure you are clear on the time frame, feedback mechanisms, and other expectations.
- Keep the delegator informed on a continual basis.

Practice Alert

Accepting delegation means you accept full responsibility for the outcome and its benefits or liabilities.

OBSTACLES TO DELEGATION

- Potential barriers to delegation can be environmental or the delegator's beliefs.
 - Environmental barriers include organizational culture, poor communication and interpersonal skills, and human and fiscal resources.
 - Majority of barriers to delegation arise from the delegator herself/himself and involve three conflicts: trust versus control, approval versus affiliation, and democratic ideal versus classic.

Practice Alert

Delegation takes time but a failure to delegate wastes time.

ESTABLISHING PRIORITIES

- Establishing priorities is the process of determining a preferential sequencing of activities.
- Classifications:
 - High, moderate, or low.
 - Urgent and important, important but not urgent, urgent but not important, busy work or wasted time.
- The nurse needs to have a rationale for priority setting and must use knowledge of the biological and behavioral sciences in deciding how activities will be prioritized.
- Two theories most commonly utilized are
 - Maslow's Hierarchy of Needs, which centers on five needs: physiological, safety, belonging, esteem, and self-actualization. Needs are organized hierarchically and the focus is on meeting lower-level needs before higher-level needs can be met.
 - Levine's Conservation Principles, which stresses four components necessary for a meaningful existence: conservation of energy, structural integrity, personal integrity, and social integrity.

FACTORS AFFECTING PRIORITY SETTING

- *Time management*: When time is managed effectively, the level of productivity will increase. Knowing how long an activity will take will influence the planning process.
- *Policies and procedures*: Provide a framework for the nurse to know what to do in a given situation.
- *Experience*: Past experiences of the nurse will influence the way she/he sets priorities.
- *Patient preferences*: Patient's likes and dislikes, as well as wishes, can influence priority setting.

Practice Alert

Because the nurse is responsible for a large number of activities in the course of a day, she/he needs to write down the priorities.

CONTINUITY OF CARE

- Continuity of care refers to the coordination of health care services for patients when they move from one health care setting to another as well as among different health care providers.
- Continuity of care enables uninterrupted care.

DISCHARGE PLANNING

- Getting discharged is the process of leaving one level of health care for another, such as leaving the hospital for home, or leaving the hospital for another health care facility.
- Effective discharge planning involves ongoing, comprehensive assessment of the patient, development of nursing diagnoses, and establishment of individualized plans of care.
- Client, family or significant other, and health professional are included in the planning.

Practice Alert

Discharge planning begins on admission to a health care facility. Discharge planning includes the client and family or significant other in the planning process. Discharge planning includes all health professionals involved in the care of the individual.

RESOURCES

- Preparing referrals is a systematic problem-solving approach to identify community resources needed in the care of patients.
- As much information as possible about the patient should be provided in the process of making a referral: personal and health data, activities of daily living, disabilities/limitations, financial resources, and community supports.
- When making a referral, a nurse uses problem-solving, priority-setting, coordinating, and collaborating skills.

Practice Alert

When making a referral, instructions must be written clearly and be easily understood by the client and family members.

CONSULTATION

- Consultation is a method for obtaining information about the client.
- The nurse discusses client needs with other health care providers.
- Nurses also consult with client's family members to obtain information.

Practice Alert

Community-based nursing involves nursing care that extends beyond institutional boundaries and involves a network of services.

COMMUNITY-BASED HEALTH CARE

- Community-based health care is a system that provides health-related services within the context of where people spend their time.
- It is holistic in nature designed to provide services that focus on restoring and promoting health and preventing illness.
- *Integrated health care system* is one type of community-based framework whose goal is to facilitate care across health care settings.

INFORMATION TECHNOLOGY

- It replaces or supplements the written medical record.
- Computerized Medical Record provides for the retrieval of patient data by individuals who require the information.
- Data about the individual is constantly available, quality is monitored, and individuals can share activities influencing their health status.

Practice Alert

Nurses need to assume accountability as they collaborate with other health care professionals.

RESOURCE MANAGEMENT

- Resource management is the process used to determine fiscal, human, and material needs of the nursing service department and nursing unit.
- Effectiveness of resource management depends on the ability of the nurse leader to make decisions.
- Decentralization model requires the nurse leader to be knowledgeable about resources.
- Staffing needs are determined by nurse–patient ratios, nurse–shift ratios, and staff mix ratios.
- Recruitment and retention of nurses are important components of the staffing process.
- Patient classification systems are used for determining workload requirements and staffing needs.
- A component of staffing is scheduling, i.e., determination of which staff member works which shift and on which days of the week.

BUDGET

- It is a plan for the acquiring, distributing, and using the money necessary to run the organization.
- Budgets provide a foundation for managing and evaluating fiscal performance of the organization and each nursing unit receives a portion of the total organization budget.
- The nurse leader sets goals and objectives for the nursing unit in order to plan effectively for the fiscal needs of the unit and be able to submit an appropriate budget.
- The budgeting process consists of the operating budget (revenues and expenses for the upcoming year) and the capital budget (equipment and renovations to meet long-term goals).

Practice Alert

To be fiscally responsible, the nurse is required to become familiar with the language of budgeting.

Practice Alert

Staffing and scheduling involve planning to meet the needs of the nursing unit.

SUPPLIES AND EQUIPMENT

- Supplies are the materials related to client care needed to operate the nursing unit.
- The nurse leader needs to determine the amount of materials necessary to carry out the activities of the nursing unit without having excess materials.
- Nurse leaders also are being asked to be involved in product selection.

Practice Alert

Nurses need to educate themselves about the particular products being used within their nursing unit.

STAFFING

- It is the process of determining the appropriate number and type of nursing staff needed to deliver quality nursing care and meet the nursing unit's objectives.

CASE MANAGEMENT

- This involves management of the type of nursing care delivery system that provides for the assessment, planning, implementing, coordinating, monitoring, and evaluating services received by clients provided by the entire health care team.
 - It advances multidisciplinary collaboration.
 - It emphasizes quality and cost-effective care.
- Case Manager*—Nurses often assume the role of case manager. A nurse carries a client caseload from admission to dis-

charge and may also oversee clients in the outpatient setting following discharge. The case manager's key role is to assess, plan, facilitate, and advocate for patients. The case manager may have a client load but more frequently supervises and collaborates with the primary caregiver assigned to the clients. Case managers act as client advocates.

Practice Alert

Critical thinking, communication, planning, and evaluation are skills needed by the case manager.

CRITICAL PATHWAYS

- Critical pathways are the guidelines that provide direction for optimum daily patient care.
- They standardize care and reduce variation in patient care.
- They outline care activities as well as expected outcomes all of which are developed by a multidisciplinary team.

- Based on nursing diagnosis and critical pathways, the case manager immediately knows if expected outcomes are being met.

MULTIDISCIPLINARY TEAM

- Each member of the team is equal and respected for his/her unique contribution(s).
- Collaboration, which involves sharing information and knowledge, is critical to team function.
- Nurses often play key roles in multidisciplinary teams as team leader and team member.

Practice Alert

Collaboration requires nurses to understand what other health professionals have to offer and what they bring to the situation.

PERFORMANCE IMPROVEMENT (QUALITY IMPROVEMENT)

Performance improvement is a model that represents actions and processes used by a health care organization to reduce costs and improve quality of health care.

QUALITY ASSURANCE (QUALITY ASSESSMENT AND IMPROVEMENT)

Quality assurance is a systematic process used to assure excellence in the health care provided to clients. Three components of evaluation are involved: structure, process, and outcome evaluation. Structure evaluation focuses on the setting where care was provided. Process evaluation looks at how the care was given. Outcome evaluation focuses on demonstrating the changes that have occurred as a result of the nursing care provided.

TOTAL QUALITY MANAGEMENT/ CONTINUOUS QUALITY IMPROVEMENT

Total quality management involves a systematic process focusing on improving the quality of care. Individuals from a variety of departments determine how care needs to be provided. They decide what outcomes are desired.

Practice Alert

TQM/CQI are focused on establishing procedures for improving the quality of care and not on identifying mistakes.

NURSING AUDIT

- Nursing audit is a review of client records to determine if specific criteria have been met.
- The audit is either *retrospective*—evaluation of a client's chart after discharge—or *concurrent*—evaluation of the patient's care while the individual is still receiving it.
- Nursing audit reflects the performance of a group of individuals versus a single individual.

Practice Alert

Quality is everyone's responsibility.

STAFF EDUCATION

Staff education is the process of enhancing staff performance.

ORIENTATION

- Orientation involves acquainting the new graduate or employee with the workplace to socialize and reduce anxiety.
- It usually is a shared responsibility between the Staff Education Department, which focuses on organization-wide information, and the nursing manager or delegate who focuses on the particular nursing unit.
- It can last for several weeks to several months.
- Preceptorship or mentorship are two methods that are used to orient new employees. Preceptors are selected from experienced staff nurses to assist new graduates to obtain the necessary knowledge and skills structured to their particular needs. Mentors are experienced nurses who support, guide, and nurture a person over a much longer period of time than just orientation. A mentor instills a sense of self-confidence and self-esteem in the mentee.

IN-SERVICE EDUCATION (ALSO REFERRED TO AS “ON-THE-JOB TRAINING”)

- In-service training consists of programs offered by the institution to keep staff members current with the protocol

that has changed and new equipment used within the organization.

- It can be a cost-effective method for assuring that the staff is maintaining current levels of expertise.

CONTINUING EDUCATION

- Educational programs offered outside the health care agency which nurses attend to maintain expertise throughout their professional careers.
- They can be workshops, seminars, conferences, short courses, or online courses.
- Contact hour is the system for recognizing participation in a nonacademic credit offering.

Practice Alert

Mandatory continuing education is related to renewing of a nurse's professional licensure and a predetermined number of contact hours are required by many states. Voluntary continuing education is not related to relicensure.

WORKSHEET

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all False statements in the space provided.

- | | | |
|---|------------------|------------------|
| 1. Case management, a type of nursing care delivery model, advances multidisciplinary collaboration. | <u> </u> T | <u> </u> F |
| 2. Critical pathways are guidelines that delineate patient care activities as well as outcomes, and standardize and reduce variation in patient care. | <u> </u> T | <u> </u> F |
| 3. Information shared by an individual with certain professionals that does not need to be revealed in a court of law is called privileged communication. | <u> </u> T | <u> </u> F |

| | | |
|---|------------------|------------------|
| 4. The standard of “reasonable care” is used when emergency care is given in a health care setting. | <u> </u> T | <u> </u> F |
| 5. Nursing audit is when patient records are reviewed to determine if specific criteria or standards have been met. | <u> </u> T | <u> </u> F |
| 6. The process used to determine fiscal, human, and material needs of the nursing unit is called resource management. | <u> </u> T | <u> </u> F |
| 7. Staffing needs are determined by nurse–patient ratios, nurse–shift ratios, and staff mix ratios. | <u> </u> T | <u> </u> F |
| 8. The budgeting process consists of the operating budget, which includes equipment and renovations to meet long-term unit goals, and the capital budget, which focuses on revenues and expenses of the nursing unit for the upcoming year. | <u> </u> T | <u> </u> F |
| 9. Ethical decision making has the patient’s well-being at the center of it. | <u> </u> T | <u> </u> F |
| 10. Neglect is the most common form of child abuse. | <u> </u> T | <u> </u> F |
| 11. The professional counseling of individuals or couples about their risk for genetically linked diseases is called genetic screening. | <u> </u> T | <u> </u> F |
| 12. AIDS bears a social stigma due its association with the right to life of the fetus and organ harvesting. | <u> </u> T | <u> </u> F |
| 13. When a patient is undergoing a medical procedure, she/he needs to receive a description of the medical procedure, alternatives for treatment, risks involved in the treatment, and probable results. | <u> </u> T | <u> </u> F |
| 14. Discharge planning begins on admission to a health care facility. | <u> </u> T | <u> </u> F |
| 15. A computerized medical record replaces or supplements the traditional written medical record. | <u> </u> T | <u> </u> F |
| 16. The process of determining a preferential sequencing of activities is called delegation. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Match the following

- | | |
|----------------------------------|--|
| 17. ___ CEU | a. Defines the scope of nursing practice |
| 18. ___ Accountability | b. Employee is responsible to only one supervisor |
| 19. ___ In-Service Education | c. Philosophy that emphasizes a commitment to quality of patient care |
| 20. ___ Patient’s Bill of Rights | d. Determination of what needs to be done |
| 21. ___ Nurse Practice Act | e. Continuing Education Unit |
| 22. ___ Standards of Care | f. Document that describes the duties and responsibilities for a particular position |
| 23. ___ Strategic Planning | g. Formal evaluation of an employee by a nurse manager |

(continued)

- | | |
|----------------------------------|---|
| 24. ___ Planning | h. Individual's right to inspect his/her medical record and to receive information about medical care |
| 25. ___ Position Description | i. Statements that define an acceptable level of care |
| 26. ___ Unity of Command | j. Accepting ownership for the result |
| 27. ___ Leadership | k. Individual that helps achieve the results during the dynamic process of change |
| 28. ___ Change Agent | l. Ability to influence other people |
| 29. ___ Total Quality Management | m. Programs offered by the health care facility to keep staff current |
| 30. ___ Performance Appraisal | n. Long-range planning |

APPLICATION QUESTIONS

- An advance directive is a legal document that allows an individual to express his/her wishes prior to the health care situation occurring. The two most common advance directives are:
 - living will and durable power of attorney
 - informed consent and confidentiality
 - Nurse Practice Act and licensure
 - Patient's Bill of Rights and standards of care
- Case management is a type of nursing care delivery system. It consists of the client, case manager, and support services and resources. The circles reflect the organization of the case management delivery system. Place an X in the circle indicating where the case manager would be, a Y in the circle indicating where the client would be, and a Z in the circle indicating where the support services and resources would be.

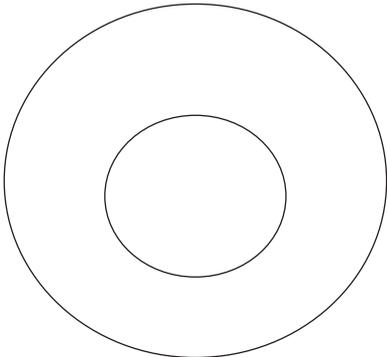

- Which of the following are advantages of the case management nursing care delivery system? (Select all that apply.)
 - promotes multidisciplinary team collaboration
 - is cost effective
 - increases quality of care
 - is time consuming
- Case management is a type of nursing care delivery model that incorporates assessment, planning, implementation, coordinating, monitoring, and evaluation into the services received by clients by means of which primary concept?
 - multidisciplinary team collaboration
 - patient-focused care
 - managed care
 - differentiated practice
- Four broad management functions that a nurse manager uses to achieve nursing organizational goals are:
 - planning, organizing, directing, and controlling.
 - strategic planning, team building, leadership, and performance evaluation.
 - situational, interactional, transformational, and contingency processes.
 - autocratic, democratic, and laissez-faire behaviors.
- A staff nurse has the responsibility for the care of five clients. She is working with a nursing assistant in the care of the clients. The staff nurse will assign specific

Figure 4-1.

care for clients to the nursing assistant. The nursing assistant will carry out the necessary care on the assigned clients and report back to the staff nurse. This is an example of how the nursing assistant does what? (Select all that apply.)

- a. assumes responsibility
 - b. is accountable
 - c. makes decisions
 - d. delegates to another individual
7. The ability to influence other people is called:
- a. leadership
 - b. management
 - c. decision making
 - d. supervision
8. The following organizational chart depicts which management principle?
- a. chain of command
 - b. division of labor
 - c. staff organization
 - d. case method

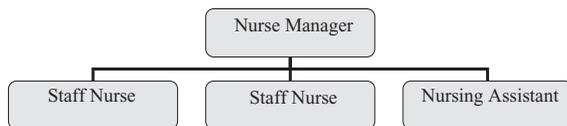

Figure 4-2.

9. The first thing a nurse does when planning for effective use of time is to:
- a. assess his/her actual use of time
 - b. establish goals and priorities
 - c. consider what activities can be delegated
 - d. write down his/her client care assignment
10. The potential effectiveness of a decision depends on which of the following? (Select all that apply.)
- a. personal value system of the decision maker
 - b. kind of data used in making the decision
 - c. defensibility of the decision
 - d. selling the decision
11. Some decisions are best made by a group rather than by the nurse alone. What is an advantage of group decision making?
- a. promotes ownership of decision
 - b. individual opinions are influenced by others
 - c. dependency is fostered
 - d. formal and informal role and status positions evolve
12. The Health Insurance Portability and Accountability Act (HIPAA) protects the
- a. patient's medical and health information
 - b. patient's right to refuse treatment
 - c. patient from third-party payers
 - d. patient's need to have liability insurance
13. The coordination of health care services for patients when they move from one health care setting to another is called:
- a. continuity of care
 - b. discharge planning
 - c. consultation
 - d. integrated health care system
14. Delegation is the process where one individual can accomplish the necessary tasks with and through another. Place the five steps of delegation in the correct order.
- a. communicate the expectations
 - b. define the task
 - c. determine to whom to delegate
 - d. supervise and evaluate the result
 - e. reach agreement about the task
15. The American Nurses Association (ANA) Code of Ethics addresses moral standards for nurses to adhere to and is patient focused. The phrase "patient focused" means it encompasses the:
- a. patient, family, and group or community
 - b. patient only
 - c. patient and family
 - d. patient and nurse
16. A nurse's relationships center on three specific types: nurse-patient-family relationship, nurse-nurse relationship, and nurse-physician relationship. Which phrase best describes the nurse-nurse relationship?
- a. Working together for a common good through respect.
 - b. Working together as members of a common community.
 - c. Working together to meet unmet needs and to address them.
 - d. Working together.
17. Mandatory continuing education is a/an:
- a. requirement for renewal of a nurse's professional license in some states.
 - b. component of the Nurse Practice Act.
 - c. system for receiving nonacademic credit for attendance.

(continued)

- d. institutional offering to keep professional staff current.
18. The concept of decentralized decision making is often associated with which of the following?
- shared governance
 - team nursing
 - interdisciplinary practice model
 - primary nursing
19. When a nurse delegates, she/he gets the legal authority for the delegation from:
- Nurse Practice Act
 - American Nurses Association Standards of Practice
 - American Nurses Association Code of Ethics
 - Public Health Act
20. As a nurse manager, you have been asked to delegate the preparation of the daily staffing assignment to your assistant. The task has been determined to be one that could be delegated to someone else and free you up for other responsibilities. You recognize the experience your assistant has working on the nursing unit; you also recognize that the individual is able to handle the new responsibility. However, you find that you are unwilling to delegate the daily staffing assignment. Which answer might explain your reluctance to delegate? (Select all that apply.)
- You question if this is a good use of your assistant nurse manager's time and skill.
 - You feel that your assistant nurse manager is already overloaded and this new assignment would just add to an already difficult situation.
 - You fear that your assistant may not know all the specifics that go into developing a staffing assignment and that staff members who are used to certain patients will no longer be assigned them.
 - You know that this would be an opportunity for your assistant to develop in the role of nurse manager.
21. The legal credential conferred by a state that allows the nurse to practice nursing is called:
- license
 - certification
 - advanced practice
 - Nursing Practice Act
22. What do the initials CEU stand for?
- Continuing Education Unit
 - Chief Executive for Urbanization
 - Code of Ethics for the Uninsured
 - Collective Education Union
23. A sound planning process is important to the success of any health care organization. One type of planning is called strategic planning. Which statement best describes the process of strategic planning?
- Strategic planning is the effort by a hospital to plan the direction the organization will go in, taking into consideration the hospital's mission, philosophy, values, and stakeholders. It is a proactive process. It looks at future goals and strategies to meet the opportunities and threats of the external and internal environment.
 - Strategic planning is when a group of people with a common purpose and common goals come together to discuss an idea that needs to be accomplished. A communication pattern is established to ensure that information is disseminated. All members of the group are encouraged to actively participate.
 - Strategic planning is when resources to manage patient care are determined and monitored.
 - Strategic planning is when a staffing pattern is developed that considers the availability of qualified staff and the acuity levels of the patients. The planning often utilizes patient-classification systems, benchmarking data, and regulatory requirements for decision making.
24. When a nurse in performing her/his responsibilities commits an act of negligence it is called
- malpractice
 - tort
 - misdemeanor
 - criminal negligence
25. Critical pathways can be defined as
- guidelines that provide direction for optimum daily patient care.
 - collaboration where nurses are equal team members.
 - acting as a patient advocate.
 - information shared by professionals that does not have to be revealed in a court of law.

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all False statements in the space provided.

1. Case management, a type of nursing care delivery model, advances multidisciplinary collaboration. *True*
2. Critical pathways are guidelines that delineate patient care activities as well as outcomes, and standardize and reduce variation in patient care. *True*
3. Information shared by an individual with certain professionals that does not need to be revealed in a court of law is called privileged communication. *True*
4. The standard of “reasonable care” is used when emergency care is given in a health care setting. *False*
“Reasonable care” standard is used in emergency situations that occur outside a health care institution.
5. Nursing audit is when patient records are reviewed to determine if specific criteria or standards have been met. *True*
6. The process used to determine fiscal, human, and material needs of the nursing unit is called resource management. *True*
7. Staffing needs are determined by nurse–patient ratios, nurse–shift ratios, and staff mix ratios. *True*
8. The budgeting process consists of the operating budget, which includes equipment and renovations to meet long-term unit goals, and the capital budget, which focuses on revenues and expenses of the nursing unit for the upcoming year. *False*
The operating budget is the component that focuses on revenues and expenses of the nursing unit and the capital budget is the component that focuses on long-term unit goals.
9. Ethical decision making has the patient’s well-being at the center of it. *True*
10. Neglect is the most common form of child abuse. *True*
11. The professional counseling of individuals or couples about their risk for genetically linked diseases is called genetic screening. *True*
12. AIDS bears a social stigma due its association with the right to life of the fetus and organ harvesting. *False*
The social stigma of AIDS is due to its association with sexual behavior and drug use.
13. When a patient is undergoing a medical procedure, she/he needs to receive a description of the medical procedure, alternatives for treatment, risks involved in the treatment, and probable results. *True*
14. Discharge planning begins on admission to a health care facility. *True*
15. A computerized medical record replaces or supplements the traditional written medical record. *True*
16. The process of determining a preferential sequencing of activities is called delegation. *False*
Setting priorities is the process of determining a sequencing of activities

MATCHING ANSWERS

Match the following:

- | | |
|---|---|
| 17. <u> e </u> CEU | a. Defines the scope of nursing practice |
| 18. <u> j </u> Accountability | b. Employee is responsible to only one supervisor |
| 19. <u> m </u> In-Service Education | c. Philosophy that emphasizes a commitment to quality of patient care |
| 20. <u> h </u> Patient's Bill of Rights | d. Determination of what needs to be done |
| 21. <u> a </u> Nurse Practice Act | e. Continuing Education Unit |
| 22. <u> i </u> Standards of Care | f. Document that describes the duties and responsibilities for a particular position |
| 23. <u> n </u> Strategic Planning | g. Formal evaluation of an employee by a nurse manager |
| 24. <u> d </u> Planning | h. Individual's right to inspect his/her medical record and to receive information about medical care |
| 25. <u> f </u> Position Description | i. Statements that define an acceptable level of care |
| 26. <u> b </u> Unity of Command | j. Accepting ownership for the result |
| 27. <u> l </u> Leadership | k. Individual that helps achieve the results during the dynamic process of change |
| 28. <u> k </u> Change Agent | l. Ability to influence other people |
| 29. <u> c </u> Total Quality Management | m. Programs offered by the health care facility to keep staff current |
| 30. <u> g </u> Performance Appraisal | n. Long-range planning |

APPLICATION ANSWERS

1. An advance directive is a legal document that allows an individual to express his/her wishes prior to the health care situation occurring. The two most common advance directives are:
- living will and durable power of attorney
 - informed consent and confidentiality
 - Nurse Practice Act and licensure
 - Patient's Bill of Rights and standards of care

Rationale

Correct answer: a.

- A living will provides for an individual's preferences around end-of-life care; durable power of

attorney designates a substitute decision maker for health care and medical decisions should the individual not be able to decide.

Incorrect answers: b, c, and d.

- Informed consent is the right of an individual to understand the choices being offered around medical treatment and the right to agree or disagree; confidentiality is when the patient's privacy will be respected and information about the patient will not be made public.

- c. Nurse Practice Act is a set of laws defining the scope of nursing practice; licensure is a legal credential conferred by a state that grants permission to an individual to practice a given profession.
- d. Patient's Bill of Rights outlines the individual's right to inspect his/her medical record and to receive information about medical care; standards of care are statements that define an acceptable level of professional practice.
2. Case management is a type of nursing care delivery system. It consists of the client, case manager, and support services and resources. The circles reflect the organization of the case management delivery system. Place an X in the circle indicating where the case manager would be, a Y in the circle indicating where the client would be, and a Z in the circle indicating where the support services and resources would be.

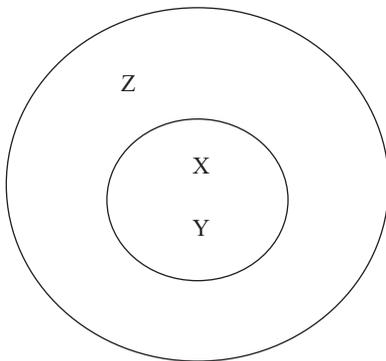

Figure 4-3.

Rationale

Correct answer: X and Y in the center circle and Z in the outside circle.

X—The case manager is the individual in the center, along with the patient, of the nursing care delivery system. She/he is responsible for the assessment, planning, implementing, coordinating, monitoring, containing costs, and evaluating services received by clients.

Y—The client is the other individual in the center of the nursing care delivery system because the primary focus of case management is the client.

Z—Support services and resources surround the core, they represent all the client's needs.

3. Which of the following are advantages of the case management nursing care delivery system? (Select all that apply.)

- a. promotes multidisciplinary team collaboration
- b. is cost effective
- c. increases quality of care
- d. is time consuming

Rationale

Correct answers: a, b, and c.

- a. An advantage of the case management model is that it promotes a collaborative process for quality cost-effective outcomes; it is a process of interactions within health care network, which enables a client to receive needed services.
- b. An advantage of the case management model is that outcomes result in more effective use of services and lessen costs.
- c. A principal advantage of the case management model is the client receives more services and has fewer unmet needs.

Incorrect answer: d.

- d. A disadvantage of the case management model is that the nurse case manager is responsible for coordinating a broad range of services for a client and managing the individual from admission through discharge and possibly after discharge making the model rewarding but also time consuming.

4. Case management is a type of nursing care delivery model that incorporates assessment planning, implementation, coordinating, monitoring, and evaluation into the services received by clients by means of which primary concept?
- a. multidisciplinary team collaboration
- b. patient-focused care
- c. managed care
- d. differentiated practice

Rationale

Correct answer: a.

- a. The focus of case management is having the entire health team work together to provide the best care possible to the client.

Incorrect answers: b, c, and d.

- b. Patient-focused care is what all models of nursing care delivery are concerned about.
- c. Managed care refers to a system in which the use of health care services are controlled and monitored to ensure that policies are followed and that costs are minimized.
- d. Differentiated practice is the practice of making a distinction between nursing roles based on education, experience, and competencies.

(continued)

5. Four broad management functions that a nurse manager uses to achieve nursing organizational goals are
- planning, organizing, directing, and controlling.
 - strategic planning, team building, leadership, and performance evaluation.
 - situational, interactional, transformational, and contingency processes.
 - autocratic, democratic, and laissez-faire behaviors.

Rationale

Correct answer: a.

- The nurse manager plans, organizes, directs, and controls in order to provide the most effective care to groups of patients and their families.

Incorrect answers: b, c, and d.

- Strategic planning, team building, and leadership, performance evaluation are all essential elements of the management process.
- Situational, interactional, transformational, and contingency are names of leadership theories.
- Autocratic, democratic, and laissez-faire are names of leadership styles.

6. A staff nurse has the responsibility for the care of five clients. She is working with a nursing assistant in the care of the clients. The staff nurse will assign specific care for clients to the nursing assistant. The nursing assistant will carry out the necessary care on the assigned clients and report back to the staff nurse. This is an example of how the nursing assistant does what? (Select all that apply.)

- assumes responsibility
- is accountable
- makes decisions
- delegates to another individual

Rationale

Correct answers: a and b.

- The nursing assistant accepts the responsibility to carry out the necessary care on the assigned patients.
- By reporting back to the staff nurse the nursing assistant demonstrates accountability for her/his actions; the nursing assistant by accepting the assignment has an obligation to periodically report back to the delegator.

Incorrect answers: c and d.

- The staff nurse is the individual using decision making to determine which nursing staff member would be best to delegate the particular patient assignment.
- The nursing assistant is the person being dele-

gated to rather than being the person doing the delegation; the staff nurse is the delegator.

7. The ability to influence other people is called
- leadership
 - management
 - decision making
 - supervision.

Rationale

Correct answer: a.

- Leadership is when a nurse leader can inspire the nursing staff to work together to accomplish the nursing unit's goals.

Incorrect answers: b, c, and d.

- Management is the process of achieving organizational goals.
- Decision making is the process that a nurse goes through to make a logical, well-informed choice.
- Supervision is the process where an individual provides direction to assure that activities are being carried out properly.

8. The following organizational chart depicts which management principle
- chain of command
 - division of labor
 - staff organization
 - case method

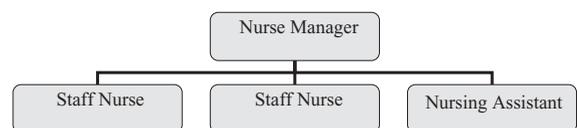

Figure 4-4.

Rationale

Correct answer: a.

- Chain of command represents the path of authority and accountability for decision making; the nurse manager gives direction to the nursing staff; the size of the chain of command will vary depending on the size of the nursing unit.

Incorrect answers: b, c, and d.

- Work that is divided into specific tasks and assigned to individuals or groups.
- Staff assists the line organization to carry out its function; the above diagram depicts the line organization.
- Case method is a nursing delivery system where

a nurse works with only one patient and meets all the individual's needs; today called private duty nursing.

9. The first thing a nurse does when planning for effective use of time is to
 - a. assess his/her actual use of time.
 - b. establish goals and priorities.
 - c. consider what activities can be delegated.
 - d. write down his/her client care assignment.

Rationale

Correct answer: a.

- a. The nurse can only control how time is used; time is a resource that can be managed; it is important to first think about how you go about utilizing time before considering other principles of time management.

Incorrect answers: b, c, and d.

- b. It is appropriate to determine what activities are important and establish outcomes; although important it is not the first thing the nurse thinks about.
- c. At times, delegation is an effective activity of time management; although important to consider it is not the first thing the nurse thinks about.
- d. Writing assignments down is a tool used by the nurse to help organize one's time.

10. The potential effectiveness of a decision depends on which of the following? (Select all that apply.)
 - a. personal value system of the decision maker
 - b. kind of data used in making the decision
 - c. defensibility of the decision
 - d. selling the decision

Rationale

Correct answers: a, b, c, and d.

- a. Many factors enter into the ability for problem identification; one factor that can influence problem identification is the decision maker's personal value system.
- b. The generation of alternatives; if good alternatives are not generated, a good decision cannot be made.
- c. Can the decision maker support the outcome(s) and explain why the particular alternative was chosen if she/he had to support the decision to colleagues and nursing administration.
- d. Acceptance of the decision by those who will be affected by it is a key component to not having the decision fail.

11. Some decisions are best made by a group rather than by the nurse alone. What is an advantage of group decision making?
 - a. promotes ownership of decision
 - b. individual opinions are influenced by others
 - c. dependency is fostered
 - d. formal and informal role and status positions evolve

Rationale

Correct answer: a.

- a. There is greater likelihood of supporting the decision that the members of the group have contributed to.

Incorrect answers: b, c, and d.

- b. Individual opinions influencing others in the group is a disadvantage of group decision making.
- c. Dependency on the group by an individual member is a disadvantage of group decision making.
- d. Role and position hierarchy may occur within the group and influence the decision making process; this possibility is considered a disadvantage to group decision making.

12. The Health Insurance Portability and Accountability Act (HIPAA) protects the
 - a. patient's medical and health information
 - b. patient's right to refuse treatment
 - c. patient from third-party payers
 - d. patient's need to have liability insurance

Rationale

Correct answer: a.

- a. The Act is a federal privacy standard that protects the patient's medical records and other identifiable health information. The Act requires confidentiality and ensures the privacy of patients.

Incorrect answers: b, c, and d.

- b. The right of the patient to refuse treatment is based on belief in the autonomy of the patient; it is not an Act.
- c. Third-party payers are insurance companies and government programs that pay providers for health services provided to individuals.
- d. Liability insurance is purchased by the nurse from an insurance company that accepts the risk of being sued.

13. The coordination of health care services for patients when they move from one health care setting to another is called

(continued)

- a. continuity of care
- b. discharge planning
- c. consultation
- d. integrated health care system

Rationale

Correct answer: a.

- a. Continuity of care enables uninterrupted care when a patient leaves one facility and moves to another.

Incorrect answers: b, c, and d.

- b. Discharge planning is a type of continuity of care where ongoing and comprehensive planning takes place prior to a patient leaving a health care facility.
- c. Consultation is a method for obtaining information about the patient.
- d. Integrated health care system is a type of community-based framework that facilitates care across health care settings.

14. Delegation is the process where one individual can accomplish the necessary tasks with and through another. Place the five steps of delegation in the correct order.

- a. communicate the expectations
- b. define the task
- c. determine to whom to delegate
- d. supervise and evaluate the result
- e. reach agreement about the task

Rationale

Correct answers: b, c, a, e, and d.

- b. Define the complexity of the task and its components.
- c. Match the task to the individual's ability and who is able to perform the task.
- a. Describe the task and provide a reason for the task; identify what standards the task will be evaluated on.
- e. The nurse leader needs to validate that the task and expectations have been understood by the person being asked to carry out the task.
- d. The nurse leader needs to remain accessible and evaluate performance based on the established goals.

15. The American Nurses Association (ANA) Code of Ethics addresses moral standards for nurses to adhere to and is patient focused. The phrase "patient focused" means it encompasses the

- a. patient, family, and group or community
- b. patient only
- c. patient and family
- d. patient and nurse

Rationale

Correct answer: a.

- a. The nurse values and is committed to the uniqueness of the individual patient. When addressing the uniqueness of the patient the nurse must also recognize the patient's place in the family, in a group, or in the community.

Incorrect answers: b, c, and d.

- b. The patient is more than just an individual; the patient can also be a family, a group, or a community.
- c. The phrase "patient focused" includes not only the patient and family but it also encompasses the community in which the patient lives.
- d. The nurse has the commitment to the recipient of nursing and health care.

16. A nurse's relationships center on three specific types: nurse–patient–family relationship, nurse–nurse relationship, and nurse–physician relationship. Which phrase best describes the nurse–nurse relationship?

- a. Working together for a common good through respect.
- b. Working together as members of a common community.
- c. Working together to meet unmet needs and to address them.
- d. Working together.

Rationale

Correct answer: a.

- a. The nurse–nurse relationship requires active listening, acceptance and nonjudgmentalism, feedback, flexibility, and respect

Incorrect answers: b, c, and d.

- b. The nurse and the physician work together as members of a common community.
- c. The nurse identifies unmet needs and follows up to address the needs appropriate in the nurse–patient–family relationship.
- d. Working together is a phrase that speaks to any relationship not specifically to the nurse and his/her relationships.

17. Mandatory continuing education is a/an

- a. requirement for renewal of a nurse's professional license in some states.
- b. component of the Nurse Practice Act.
- c. system for receiving nonacademic credit for attendance.
- d. institutional offering to keep professional staff current.

Rationale

Correct answer: a.

- a. Some State Boards of Nursing regulations require that a certain number of continuing education contact hours be obtained before a nurse's license can be renewed.

Incorrect answers: b, c, and d.

- b. The Nurse Practice Act defines the scope of nursing practice.
- c. Frequently at the end of a continuing education program a certificate will be provided to the attendee that states the number of Continuing Education Units the program has been granted.
- d. In-service programs provided by the institution.

18. The concept of decentralized decision making is often associated with which of the following?

- a. shared governance
- b. team nursing
- c. interdisciplinary practice model
- d. primary nursing

Rationale

Correct answer: a.

- a. Shared governance is when staff members are involved in the decision-making process.

Incorrect answers: b, c, and d.

- b. In team nursing, the team leader assumes a centralized decision-making role.
- c. In this model team, members function independently and make independent decisions.
- d. In primary nursing, decision making is centralized with the primary nurse.

19. When a nurse delegates, she/he gets the legal authority for the delegation from

- a. Nurse Practice Act
- b. American Nurses Association Standards of Practice
- c. American Nurses Association Code of Ethics
- d. Public Health Act

Rationale

Correct answer: a.

- a. State laws and regulations are set forth through individual state's Nurse Practice Act that define the scope of nursing practice.

Incorrect answers: b, c, and d.

- b. ANA Standards of Practice is not a legal documents; it is a document that provides general standards and guidelines for the practice of nursing.
- c. ANA Code of Ethics contains general moral standards that nurses are expected to follow in their professional practice.

d. The Public Health Act is a component of federal legislation that focuses on the public safety.

20. As a nurse manager, you have been asked to delegate the preparation of the daily staffing assignment to your assistant. The task has been determined to be one that could be delegated to someone else and free you up for other responsibilities. You recognize the experience your assistant has working on the nursing unit; you also recognize that the individual is able to handle the new responsibility. However, you find that you are unwilling to delegate the daily staffing assignment. Which answer might explain your reluctance to delegate? (Select all that apply.)

- a. You question if this is a good use of your assistant nurse manager's time and skill.
- b. You feel that your assistant nurse manager is already overloaded and this new assignment would just add to an already difficult situation.
- c. You fear that your assistant may not know all the specifics that go into developing a staffing assignment and that staff members who are used to certain patients will no longer be assigned them.
- d. You know that this would be an opportunity for your assistant to develop in the role of nurse manager.

Rationale

Correct answers: a, b, and c.

- a. As a nurse manager, you are expressing the feeling "I would rather do it myself"; this is a barrier to delegation.
- b. As a nurse manager, you have not assessed the ability of the individual to do the job or the time needed for the individual to do the activity; this is a barrier to delegation.
- c. The nurse manager fears the loss of control; this is a barrier to delegation.

Incorrect answer: d.

- d. This is an example of effective delegation not a barrier to delegation.

21. The legal credential conferred by a state that allows the nurse to practice nursing is called

- a. license
- b. certification
- c. advanced practice
- d. Nursing Practice Act

Rationale

Correct answer: a.

- a. A license is the legal credential that allows an individual to practice nursing.

(continued)

Incorrect answers: b, c, and d.

- b. Certification is the process that grants recognition that an individual has met predetermined criteria specified for practice in his/her area of specialization.
- c. Advanced practice is recognition of advanced education, usually a masters degree, in a specialty area.
- d. Nurse Practice Act is a set of laws that defines the scope of nursing practice.

22. What do the initials CEU stand for?

- a. Continuing Education Unit
- b. Chief Executive for Urbanization
- c. Code of Ethics for the Uninsured
- d. Collective Education Union

Rationale

Correct answer: a.

- a. Continuing Education Unit is the term used to describe the contact hour(s) received for a continuing education program.

Incorrect answers: b, c, and d.

Names do not stand for anything.

23. A sound planning process is important to the success of any health care organization. One type of planning is called strategic planning. Which statement best describes the process of strategic planning?

- a. Strategic planning is the effort by a hospital to plan the direction the organization will go in, taking into consideration the hospital's mission, philosophy, values, and stakeholders. It is a proactive process. It looks at future goals and strategies to meet the opportunities and threats of the external and internal environment.
- b. Strategic planning is when a group of people with a common purpose and common goals come together to discuss an idea that needs to be accomplished. A communication pattern is established to ensure that information is disseminated. All members of the group are encouraged to actively participate.
- c. Strategic planning is when resources to manage patient care are determined and monitored.
- d. Strategic planning is when a staffing pattern is developed that considers the availability of qualified staff and the acuity levels of the patients. The planning often utilizes patient-classification systems, benchmarking data, and regulatory requirements for decision making.

Rationale

Correct answer: a.

- a. Strategic planning is long-range planning that provides the direction the organization will go in, over several years.

Incorrect answers: b, c, and d.

- b. The statement describes team building.
- c. The statement describes the budget process.
- d. The statement describes the staffing process.

24. When a nurse in performing her/his responsibilities commits an act of negligence it is called

- a. malpractice
- b. tort
- c. misdemeanor
- d. criminal negligence

Rationale

Correct answer: a.

- a. Malpractice is the term used to describe negligence by a nurse; malpractice is professional negligence.

Incorrect answers: b, c, and d.

- b. Tort is a civil wrong committed by one person against another.
- c. Misdemeanor is a crime of lesser infraction of the law and is punished by imprisonment of less than a year or a fine.
- d. Criminal negligence is when the crime falls outside the boundaries of a simple error and reflects a serious lack of concern to the safety of the patient.

25. Critical pathways can be defined as

- a. guidelines that provide direction for optimum daily patient care.
- b. collaboration where nurses are equal team members.
- c. acting as a patient advocate.
- d. information shared by professionals that does not have to be revealed in a court of law.

Rationale

Correct answer: a.

- a. Critical pathways outline care activities as well as outcomes in providing direction for patient care.

Incorrect answers: b, c, and d.

- b. This type of collaboration takes place when the nurse is a member of a multidisciplinary team.
- c. Acting as a patient advocate is associated with the role of the nurse in case management.
- d. The information is considered privileged communication.

| ▶ Error Prevention | 58 | ▶ Security Plan | 57 |
| ▶ Handling Hazardous and Infectious Materials | 60 | ▶ Use of Restraints/Safety Devices | 63 |

ACCIDENT PREVENTION

- The main causes of accidental death in order of frequency are motor vehicle accidents, falls, poisoning, drowning, fires, and burns.
- The type of accident for which an individual is at the greatest risk is related to his/her normal growth and development.
- Most falls occur at home and are the number one cause of hospital admission for trauma among older adults; illness, medications, alcohol use as well as environmental factors cause these falls.
- Over the age of 65, hip fractures account for most admissions for trauma.
- Accident prevention requires client teaching and removal of dangers.

Client Teaching for Self-Care

AGE-RELATED ISSUES

School-age children

- Children must stay away from strangers.
- They must use protective equipment when participating in sports.
- Bicycles and scooter safety: Children should wear helmets, ride proper size bicycles, and know rules of road.

Adolescents (risk takers)

- Car safety: Adolescents are involved in more accidents than any other age group. They should wear seat belts, comply with driving rules, never drive when drunk, and never ride with anyone who is impaired.
- They are likely to experiment with drugs and this increases risk of all other types of accidents.

Adults

- Adults should adopt healthy lifestyle habits, techniques of stress management, and dangers of alcohol and other abuses.

Older adult

- Older adults have an increased risk for falls, burns, and car accidents.
- The risk factors are confusion, sensory deficit (peripheral vision loss, decreased lens accommodation, decreased night vision, cataracts, increased threshold for hot and cold, decreased hearing), impaired judgment, impaired mobility (limited ROM, kyphosis with change in center of gravity, and decreased muscle strength), slow reflexes, uncooperative, incontinence/urgency, anxiety/emotional lability, CV disease with impaired perfusion, respiratory disease with impaired oxygenation, medications affecting level of consciousness or BP, postural hypotension, new to unit, attached equipment.
- Measures to decrease the risk:
 - adequate lighting on outdoor walkways and in halls, stairways, and rooms; nightlights in children's, older adult, and guest rooms.
 - use of nonglare lights.
 - elimination of obstacles such as clutter, doormats, small rugs.
 - control of bathroom hazards through use of grab bars, nonslip strips or tub mat, and raised toilet seat.
 - childproof caps on medications.
 - discard of unused or outdated medications by flushing down the toilet.
 - installation of smoke detectors and fire extinguishers in the home.

DISASTER PLANNING

Disaster Preparedness

- Proactive planning is designed to structure the disaster response prior to its occurrence.
- Effective planning focuses on the problems that have the potential of occurring.
- There are two types of disasters: natural and man-made.
 - Natural disasters are the “result of an ecological disruption or threat that exceeds the adjustment capacity of the affected community”(World Health Organization), for example, earthquakes, floods, hurricanes, and tornadoes.
 - Man-made disasters are emergency situations caused by human beings, for example, biological and bio-

chemical terrorism, chemical spills, and nuclear events.

- Health care facilities may also identify disasters as external or internal.
 - External disasters occur outside the hospital, involve a large number of injured persons who will be sent to the hospital, do not affect health care facilities' infrastructure but do place a strain on their resources.
 - Internal disasters cause disruption of routine services and result in a large number of persons getting injured.
- The two types of disaster planning are “agent-specific approach” and “all-hazards approach.”

- Agent-specific approach focuses on preparing for disasters that are most likely to occur in a community due to such factors as geographic locations (e.g., hurricane).
- All-hazard approach is a conceptual model that incorporates components of disaster management that are consistent across all types of disaster events, as many disasters have similarities.

MAJOR CHALLENGES IN DISASTER PLANNING

- Communication is a major priority in any disaster plan. Planning for ways that health care workers and the public can receive accurate information is critical.
- Leadership responsibilities and the distribution of all types of resources need to be determined in advance.
- Advance warning and evacuation procedures need to be included in the planning.
- Use of mass media to disseminate information to the public, particularly regarding health problems such as water safety or food contamination is important.
- Triage and distribution of patients to health care facilities is crucial at the time of a disaster.

- Patient tracking during a disaster is extremely important.

Practice Alert

Disaster planning cannot take place in a vacuum. It requires the involvement of the hospital, community agencies, and local government officials.

NURSING ROLE

- Nurses should actively participate in the development of the disaster plan.
- They should define their roles across the disaster continuum.
- They should initiate disaster prevention measures such as removal of hazards, establish early warning systems, or develop public awareness campaigns.
- Nurse managers should identify educational needs of the nursing staff and other members of the health care community.
- The nursing department needs to maintain a nursing database to be able to rapidly mobilize nurse resources.

EMERGENCY RESPONSE PLAN

- Purpose: An emergency response plan is needed to have an organizational structure and procedures in place to respond to major emergencies.
- Such a plan addresses all types of emergencies in a systematic and coordinated manner.
- It should identify information systems and protocols necessary to handle all types of disasters.
- It must be comprehensive, simple, and flexible to be effective.
- Agency employees must be educated about the plan.
- Disaster drills need to be carried out to test the plan.

SECURITY PLAN

- A security plan ensures the security of the buildings and grounds of the hospital for the safety and welfare of the clients, employees, and visitors.
- Measures that come within the domain of a security plan include traffic control, employee identification, client, visitor, and vendor identification, security policies and procedures, and liaison with local law enforcement.
- delaying care to people who will not survive or will consume too many resources. The disaster triage nurse determines which patients need care, in what order they should receive care, and which patients will not receive care.
- Daily triage is when decisions are based on identifying and treating the sickest individuals first. This model of triage is used routinely in emergency departments.
- Special condition triage involves weapons of mass destruction and requires the wearing of special protective equipment by the health care personnel.

TRIAGE

Triage is a process used for prioritizing which patients are to be treated first. Categories of triage are disaster triage, daily triage, and special condition triage.

- Disaster triage is when the decisions are based on doing the greatest good for the greatest number. The goal is to treat the needs of the largest number of individuals by

Practice Alert

The first priority in a disaster is human safety.

ERROR PREVENTION

- An error is the failure to complete a planned action or the use of a wrong plan to achieve a goal. Prevention of error focuses on improving the delivery of care and not on placing blame.
- Medical errors are the result of a complex interaction of multiple factors.
- Most medical errors are preventable.
- Frequent types of errors involve the client receiving the wrong medication, incorrect diagnosis leading to an incorrect choice of treatment, equipment failure, infections, blood transfusion-related injuries, and failure to check client identification.

INJURY PREVENTION

Nursing strategies need to be aimed at health promotion. Prevention often involves a lifestyle change for the individual. Falls, burns, poisons, and electrical hazards are common injuries that individuals sustain. The nurse is often the primary person overseeing the environmental factors.

- Regular checks of all equipment are requirements for safety prevention.
- Nurses must be alert for signs of faulty equipment (frayed cords, unusual sounds, etc.) and remove it from use and initiate a follow-up check.

USE OF SAFE EQUIPMENT

- Equipment-related accidents occur when a piece of equipment malfunctions, needs repair(s), is used incorrectly or inappropriately, or when an electrical hazard occurs.

ERGONOMIC PRINCIPLES

- Ergonomics is concerned with designing the job to fit the worker as opposed to forcing the worker to fit the job.
- In ergonomic principles, the focus is on the worker's joints, muscles, nerves, tendons, and bones.
- The goal of application of these principles is to reduce human error, fatigue, discomfort, and stress, and positively impact overall performance.

Following are its essential elements:

- principles of body mechanics
- posture
- lifting techniques
- positioning
- transfer
- assistive devices

PRINCIPLES OF BODY MECHANICS

Practice Alert

Use of good body mechanics reduces fatigue and the risk of injury.

- Maximize stability by using a wide base of support and keeping the center of gravity low.
- Prevent abnormal twisting of the spinal column by facing in the direction of the movement.
- Use both the arms and the legs to balance activity.
- Save work by rolling, turning, or pivoting rather than lifting.
- Use large muscles, for example, muscles of thigh, buttock, and shoulders rather than small muscles, for example, muscles of the spine and arms, which are more susceptible to injury.
- Obtain the assistance of other individuals as necessary.

LIFTING TECHNIQUE

- Begin by assessing the weight to be lifted to determine if additional assistance (human or mechanical) is needed.
- Tighten stomach muscles.
- Bend the knees.
- Keep weight to be lifted close to body.
- Maintain trunk erect and knees bent.
- Avoid twisting the body.

POSTURE

- When the body is in correct body alignment, it is considered to be balanced.
- The center of gravity is the point at which the mass is centered.
- When in a standing position, the center of gravity in humans is located at the center of the pelvis. The wider the base of support and the lower the center of gravity an individual maintains, the greater the stability.

POSITIONING

- Maintenance of proper body alignment while in bed or sitting is important for reducing the risk of injury to the musculoskeletal system.
- Correct body alignment also contributes to a client's psychological and physical well-being.
- Devices used to properly position clients include pillows, sandbags, splints, and bed boards.
- Five common positions are
 - Fowler's position in which head of the bed is elevated by 45—60 degrees and knees are slightly elevated without pressure,
 - supine position, which involves resting on the back with legs extended such that feet are in plantar flexion and heels are touching the bed surface,
 - side-lying position in which (lateral position) body rests on side with weight on the dependent hip and shoulder,
 - Sims' position in which weight is placed on the anterior ilium, humerus, and clavicle; upper shoulder and arm are internally rotated; and upper leg and thigh are adducted and internally rotated, and
 - prone position in which the individual lies flat on the abdomen with the head turned to the side; shoulders, head, and neck are in an erect position; and feet are in plantar flexion.

TRANSFER

- Transfer involves assisting a client to move between bed and chair or wheelchair or between bed and stretcher. Principles to consider are center of gravity, base of support, and maintaining balance.

ASSISTIVE DEVICES

Assistive devices include

- aids for transferring, repositioning, and lifting clients. Some commonly used aids are
 - gait belts,
 - friction-reducing sheets, and
 - mechanical chairs and lifts.
- aids for walking: These enhance the client's balance and ability to bear weight. Some commonly used aids are
 - walkers
 - They need to extend from the floor to the client's hip joint.
 - Elbows need to be flexed about 30 degrees.
 - canes
 - They need to extend from the floor to the client's thigh joint.
 - Elbow needs to be flexed about 30 degrees.
 - Tip of cane should be placed 4 inches to the side of the foot.
 - crutches
 - Length of the crutches as well as the placement of the hand bars needs to be measured.
 - Crutches need to be three fingerbreadths below the axilla for length.
 - Elbow needs to be flexed at a 30-degree angle for the correct positioning of the hand bars.
 - Crutch gait is the gait a person assumes when using crutches.
 - The five crutch gaits are four-point gait, three-point gait, two-point gait, swing-to gait, and swing-through gait.

Nursing Process Elements

- Apply the principles of body mechanics correctly at all times to prevent injury
- Allow the client some control over mobility even when using an assistive device because it is not uncommon for older clients to view the use of assistive devices, particularly walking devices, as a weakness and loss of independence
- Teach the client using a cane to hold the cane in the opposite hand from the leg with the defect. This allows weight to be supported on the stronger leg and the cane

- When transferring a client, be sure that the procedure has been explained to both the client and any person assisting with the transfer

Practice Alert

The nurse should serve as a role model in the practice and teaching of sound body mechanics.

HOME SAFETY

Home environmental assessment checks are often carried out by the nurse.

- The key areas inspected are
 - exterior of the home for hazards such as lighting, broken steps or pavement, nonsturdy handrails, etc.
 - interior with special attention to kitchen, bath, and stairways for inadequate lighting or glare, clutter, small rugs, or mats that can slip. If there are young children in home, are electrical outlets covered, are there window guards, are there safety locks on cabinets where cleaning supplies, etc., are stored, and are they stored in original containers? Can all doors be opened from inside without a key, are telephone emergency numbers accessible, are

there batteries in detectors, are extension cords in good repair and used appropriately, are outlets overloaded, is a flashlight available, is water temperature in normal range, are dials on stove readable, and are combustible materials properly stored (not under stairwells)? Is there lead paint in use and are Radon levels in acceptable range?

- Actual and potential risks related to client safety need to be identified, therefore, the client's developmental stage as well as the client's daily routines must be identified.
- Home safety must be planned with the client, family members, or caregiver.
- Family members or caregivers may need to be taught how to implement a safe environment.

HANDLING HAZARDOUS AND INFECTIOUS MATERIALS

- A hazardous material is a material capable of causing a harmful physical or health effect. Hazardous wastes can be liquids, solids, contained gases, or sludges.
- Resource Conservation and Recovery Act (RCRA) identifies a hazardous waste as one that exhibits at least one of the four characteristics—ignitability, corrosivity, reactivity, or toxicity.
- Federal, state, and local agencies oversee the handling of hazardous materials to protect the public from harm.

HANDLING AND STORAGE

- Hazardous materials need to be stored correctly to prevent spills and uncontrolled reactions, and to minimize employee exposure.
- Three principles form the basis of the plan for safe handling of hazardous materials:
 - minimize exposure to harmful materials through product substitution and keeping limited quantities on hand.

—assume all chemicals are hazardous and handle accordingly.

—use proper control measures, such as, written policies and procedures, education, and protective equipment.

- Hazardous materials need to be stored based on their compatibility and not necessarily in the alphabetical order. Substances need to be stored in their original containers.
- To decrease individual exposure to hazardous materials, common engineering controls, such as, local exhaust and general ventilation can be used. Other protective items that could be employed are safety glasses, gloves, and/or hearing protection.
- Development of a plan for safe handling of the hazardous or infectious material needs to include five elements.
 - Element one requires maintenance of a current hazardous-waste inventory listing, which should include the full chemical name, storage location, quantities, and information regarding the hazard.
 - Element two speaks of the labeling of all containers.
 - Element three addresses maintaining a Material Safety Data Sheet(s).

- Element four plans for employee education and training.
- Element five provides for regular review and updating of the plan.

MATERIALS

Biological Agents

- Agents of concern are highly pathogenic bacteria and viruses.
- The Center for Disease Control (CDC) has classified specific agents as category A, B, or C.
 - Category A agents are the most dangerous (anthrax, botulism, plague, smallpox, tularemia, viral hemorrhagic fever viruses, etc.). These agents are given the highest priority in disaster planning as they pose the most potential threat to the public.
 - Category B agents are the second most dangerous agents (brucellosis, salmonella, melioidosis, psittacosis, Q fever, typhus fever, viral encephalitis, etc.).
 - Category C represents “emerging” agents (Nipah fever, Hantavirus, etc.).
- Client history and physical condition are key tools in assessing the client’s exposure to a biological agent, when making a diagnosis.
- Principles of infection control, beginning with universal precautions, are essential to managing the client.

Radiation

- Radiation is “energy emitted by atoms that are unstable.”
- Radioactive contamination is the “presence of radiation-emitting substances in a place where it is not desired.”
- Radiological incident is when people or the environment is exposed to radiation or radioactivity through accident

or misuse. The exposure may lead to death but more commonly, exposure only requires decontamination and monitoring of the client.

- Nurses need to limit the time spent with radioactive clients, to remain at a distance whenever possible, and to wear protective devices.

OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA)

- OSHA aims to ensure worker safety and health in the United States by working with employers and employees to create better working environments thereby preventing work-related injuries, illnesses, and deaths.
- Since its inception in 1970, OSHA has helped to cut workplace fatalities by more than 60% and occupational injury and illness rates by 40%.
- Guidelines have been developed that require the agency to identify, evaluate, and control safety and health hazards, and provide for emergency response for hazardous-waste operations.
- The agency is also responsible to see that employers develop and implement a written safety and health program for their employees involved in hazardous-waste operations.

Practice Alert

Nurses need to be familiar with established procedures and protocols of the agency for handling hazardous and infectious materials.

MEDICAL AND SURGICAL ASEPSIS

- Asepsis is the absence of disease-causing microorganisms.
- There are two types of asepsis: medical asepsis and surgical asepsis.

MEDICAL ASEPSIS

Medical asepsis requires infection control practices that reduce and prevent the spread of microorganisms. Objects are considered “clean,” which means the absence of almost all microorganisms.

- Hand washing in medical asepsis
 - It is done to remove soil and transient organisms from hands in order to reduce microorganism count.
 - It requires use of a vigorous, rubbing motion of about 10 seconds on all areas of the hands with a soap followed by rinsing under running water.
 - Hands are pointed downward when washing to prevent contamination of arms with dirty water from the hands.

Practice Alert

Hand washing is the single most basic technique in preventing the spread of microorganisms. Contaminated hands are a prime cause of cross infection

- Isolation precautions: standard precautions
 - Standard precautions are considered tier one precautions by the Center for Disease Control and Prevention (CDCP).
 - These precautions apply to blood, fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes of all clients.
 - Hand washing, wearing of gloves, care of equipment and linens, and disposal of sharp instruments and needles are precautions considered under this heading.
 - A private room is not necessary.

Practice Alert

Standard precautions are required to be used for all hospitalized individuals.

- Isolation precautions: transmission-based precautions
 - Transmission-based precautions are used in addition to standard precautions.
 - The three categories of these precautions are “airborne”, “droplet”, and “contact” precautions.
 - A private room is required for airborne precautions and a private room or cohort group for droplet or contact precautions.
 - Depending on the disease and type of precautions, a mask, gown, and gloves may also be needed.
 - Negative-pressure airflow of at least six exchanges per hour plus a mask or respiratory protection device is needed for airborne precautions (pulmonary TB, SARS, measles, etc.).

- Mask is needed for droplet precautions (pneumonia, streptococcal pharyngitis, rubella, etc.).
- Gloves and gowns are needed for contact precautions (colonization or infection with multidrug-resistant organisms, enteric pathogens, and major wound infections).

SURGICAL ASEPSIS

- Surgical asepsis is the elimination of all microorganisms, including pathogens and spores, from an area to render the area sterile.
- Sterile technique is implemented to maintain the sterility of the area.
- It is used in the operating room, for special procedures, and also for many procedures carried out at the bedside.
- A nurse must consider seven principles when maintaining sterile technique:
 - Sterile objects remain sterile only as long as only sterile items touch them.
 - All objects used in a sterile field must be sterile.
 - Sterile objects or a sterile field is considered contaminated if they are out of the nurse’s vision or below the nurse’s waist.
 - Exposure to prolonged airborne microorganisms will contaminate a sterile object or field.
 - Fluid flows in the direction of gravity.
 - Sterile surfaces coming in contact with moisture are considered contaminated due to capillary action.
 - Edges of the sterile field are considered to be contaminated.

Practice Alert

Assemble all equipment that will be needed prior to beginning the procedure. If an object becomes contaminated during the procedure, discard it immediately.

REPORTING OF INCIDENT/EVENT/IRREGULAR OCCURRENCE/VARIANCE

INCIDENT REPORT

An incident (irregular occurrence, event, or variance) report is

- an organization’s tool used in risk management for reporting and recording accidents and unusual occurrences that could potentially affect a client, a family member, or an employee.

- a comprehensive presentation of the occurrence that should be thorough, accurate, and done in a timely manner.
- used to provide information about the incident for statistical data and for future prevention.
- made out by the person who identifies the accident or unusual occurrence; this may not be the person who was actually involved in the incident. Names of any witnesses to the incident are included in the report.

Practice Alert

The incident report must be completed as soon as possible in order to assure the most accurate information.

Risk Management

- Risk management is a system of identifying potential hazards and eliminating them before harm occurs.
- It is a planned program of loss prevention and liability control whose purpose is to identify sources of risks, analyze, classify, and prioritize risks, develop a plan to manage and reduce frequency of risks, and evaluate and develop risk-reduction programs.
- For it to be successful, all departments within the organization must be involved in the risk-management program and commitment from top management as well as the board of directors is needed.
- High risk areas are

- medication errors,
- falls,
- complications following diagnostic procedures,
- faulty electronic monitoring devices,
- dissatisfaction with care, and
- refusal of treatment or refusal to sign for consent of treatment.

Practice Alert

Since nurses are involved with clients 24 hours a day, the nursing department is critical to the success of a risk-management program.

Sentinel Events

The Joint Commission on Accreditation of Healthcare Organization (The Joint Commission) includes a review of organizational activities in relation to a sentinel event, in order to improve quality of health care. A sentinel event is defined by The Joint Commission as an unexpected occurrence involving death or serious physical or psychological injury or any process variation for which a recurrence would carry a significant change of a serious adverse outcome.

The health care agency must

- develop mechanisms for identifying, reporting, and managing these events.
- conduct a timely analysis of the cause of the event, implement steps to reduce the risk, and monitor the effectiveness of the improvements.

USE OF RESTRAINTS/SAFETY DEVICES

- Regulatory guidelines for use:
 - Reason for use must be clearly stated
 - Use must be part of the client's medical treatment
 - All less restrictive interventions must be tried first
 - Other disciplines must be consulted
 - There must be supporting documentation
- Physician's order is required for the use of restraints.
 - The order must be based on an in-person assessment of the client. In case of an emergency, the assessment must be done within 1 hour.
 - The order must state the type of restraint, location, client behaviors for which restraint is to be used, and a specified time frame. It is never ordered PRN. Least restrictive type must be used.
- Risks associated with restraints are
 - they compress and interfere with function of devices or tubes,
 - they damage skin and underlying tissues from friction and pressure,
 - suffocation or choking may occur with improperly applied jacket restraint,
 - impaired ventilation may occur with too tight belt restraint, and
 - neurovascular compromise may occur with extremity restraint.

Nursing Process Elements

- Do a baseline assessment of the condition of area where restraint is to be placed, follow with ongoing and PRN assessment

Practice Alert

Assess proper placement of restraint, skin condition, temperature, color, and sensation of restrained area at least once every hour. When an extremity restraint is used, if extremity distal to restraint is cold, pale, cyanotic, numb, tingling, or painful, remove restraint stat, notify physician, and stay with the client to protect extremity from further injury.

- Pad skin and bony prominences.
- Use quick release tie.

Practice Alert

Attach restraints to bed frame, which moves when height of head or foot of bed is changed, and never to side rails.

Think Smart-Test Smart

This chapter contained a lot of information about safety issues and the prevention of different types of injuries. Remember that regardless of the type of threat to safety, the nurse's first priority and therefore first intervention is to remove the client from immediate danger.

- Periodically release restraints to check condition of restrained parts.
- Determine if restraint is still needed at least q 24 hours.
- Document behavior requiring restraint, type of restraint, time applied, procedure used in applying, condition of body part restrained, response to the restraint, time of releases and assessments with findings, and family understanding of restraint.

Practice Alert

Application of restraint may be delegated but RN is responsible for assessment of need, selection of alternative interventions, evaluation of effectiveness, and assessment for complications.

Alternatives to Restraints

- Repeated orientation to surroundings, activities, and treatments.
- Use of orientation cues such as family pictures, clocks, and calendars.
- Provision of appropriate amounts of sensory stimulation.
- Use of relaxation techniques.
- Assessment of the effectiveness of medications and initiate change PRN.
- Elimination of uncomfortable treatments.
- Scheduled toileting, exercise, and ambulation.

WORKSHEET

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. A tool used in risk management to report an accident or unusual happening is called an incident report.

T F

2. Risk management is a system of identifying potential hazards and eliminating them before harm occurs.

T F

| | | |
|---|------------------|------------------|
| 3. Only the nursing department is involved in risk-management programs. | <u> </u> T | <u> </u> F |
| 4. The abbreviation The Joint Commission stands for the “Joint Commission on Accreditation of Healthcare Organizations. | <u> </u> T | <u> </u> F |
| 5. A sentinel event is defined as an unexpected occurrence involving death or serious physical or psychological injury or risk of injury. | <u> </u> T | <u> </u> F |
| 6. The purpose of hand washing is to remove all microorganisms from the hands. | <u> </u> T | <u> </u> F |
| 7. Standard precautions are classified as tier one precautions and require the person to be in a private room. | <u> </u> T | <u> </u> F |
| 8. A client diagnosed with active tuberculosis would be placed on airborne precautions in conjunction with standard precautions. | <u> </u> T | <u> </u> F |
| 9. Contaminated hands are a prime cause of cross infection. | <u> </u> T | <u> </u> F |
| 10. The procedure used to eliminate all microorganisms, including pathogens and spores, is called surgical asepsis. | <u> </u> T | <u> </u> F |
| 11. One principle of surgical asepsis states that “edges of a sterile field or container are considered to be contaminated.” | <u> </u> T | <u> </u> F |
| 12. A sterile field is an area free from microorganisms that is able to receive sterile and nonsterile items. | <u> </u> T | <u> </u> F |
| 13. Most medical errors are considered to be preventable. | <u> </u> T | <u> </u> F |
| 14. The nurse uses critical thinking in the assessment of actual and potential environmental risks to client safety. | <u> </u> T | <u> </u> F |
| 15. When assessing actual and potential environmental risks it is helpful for the nurse to get a sense of the client’s daily routines at home. | <u> </u> T | <u> </u> F |
| 16. According to the National Fire Prevention Association, home fires are a major cause of death and injury. | <u> </u> T | <u> </u> F |
| 17. The risk of motor vehicle accidents is highest among teen drivers than any other age group. | | |
| 18. The Joint Commission for Accreditation of Healthcare Organization sets standards to address the nurse’s responsibility for maintaining client safety. | <u> </u> T | <u> </u> F |
| 19. One of the first questions the nurse would ask when doing a “fall assessment” on a client would be “Does the client have a history of falling?” | <u> </u> T | <u> </u> F |
| 20. There are two types of disasters: man-made and natural. | | |
| 21. An earthquake is classified as a man-made disaster. | <u> </u> T | <u> </u> F |
| 22. “Agent-specific” approach to disaster planning focuses on preparing for disasters that are most likely to occur in a community. | | |
| 23. Communication is a major priority in disaster planning. | <u> </u> T | <u> </u> F |

(continued)

| | | |
|---|-------------------------|-------------------------|
| 24. The purpose of an Emergency Response Plan is to have an organizational structure and procedures in place to respond to major emergencies. | <u> </u> T | <u> </u> F |
| 25. Triage is the process for prioritizing which patients are to be treated first. | <u> </u> T | <u> </u> F |
| 26. Disaster triage is when decisions are based on identifying and treating the sickest individuals first. | | |
| 27. The first priority in a disaster is human safety. | <u> </u> T | <u> </u> F |
| 28. A hazardous material is a material capable of causing a harmful physical or health effect. | <u> </u> T | <u> </u> F |
| 29. Hazardous materials are removed from their original containers and placed in agency-specific containers for storage. | <u> </u> T | <u> </u> F |
| 30. The Center for Disease Control (CDC) has classified hazardous agents as Category A, B, or C. Category A is the most dangerous agent. | <u> </u> T | <u> </u> F |
| 31. The standard of “reasonable care” is used when emergency care is given in a health care setting. | <u> </u> T | <u> </u> F |

APPLICATION QUESTIONS

- Which of the following events would be considered a “natural disaster?” (Select all that apply.)
 - Flood
 - Meteorological phenomena
 - Fire
 - Nuclear event
- When does a communicable, infectious disease outbreak management become disaster management?
 - Once public health officials determine that the outbreak exceeds the capability and resources available to handle it
 - At the beginning of the outbreak as communicable diseases are a serious threat to the population
 - The disaster plan would need to be implemented only if the outbreak was a Category A biological agent
 - When it is determined that the outbreak is an internal disaster
- In handling a chemical, you accidentally spilled a small amount of the contents on your hand. What would be the best course of action for you to take?
 - Immediately wash the affected hand and remove any clothing that the chemical might have come in contact with
 - Call the Poison Control Center to determine what medication needs to be applied to the area to counteract the chemical
 - Wrap your hand in a towel to protect it from exposure to the air
 - Do nothing
- While making rounds, the nurse finds that a client’s IV of Ringer Lactate was running at 75 ml/hr. The kardex stated that the IV ordered was D5W. The nurse’s notes in the chart stated that the IV had been changed 2 hours ago and the drip rate had been set. The first thing the nurse would do is
 - change the IV solution
 - inform the person who hung the incorrect IV about the occurrence
 - make out an incident report
 - report the incident to the nurse in charge
- A planned program of loss prevention and liability control is called
 - risk management
 - critical pathways
 - peer review
 - quality assurance
- A client is admitted to the nursing unit with a diagnosis of mycoplasma pneumonia. The admitting physician did not order the client to be placed on any form of precautions. Which isolation precautions would be best for the client to be on?

- a. Transmission-based precautions
 - b. Universal precautions
 - c. Sterile precautions
 - d. Standard precautions
7. Mr. Smith is one of the 10 clients on your team. You are making out the team assignment and must decide whom to assign Mr. Smith. The CNA is new to the unit and you have not worked with her that much; RN1 has been caring for two postoperative patients; RN2 will be attending a continuing education program for about 1 hour during the shift. Select the most appropriate staff member to take care of Mr. Smith.
- a. RN2
 - b. CNA
 - c. RN1
 - d. Request a float nurse
8. Which of the following activities would be an example of implementing medical asepsis? (Select all that apply.)
- a. Mopping the floor
 - b. Hand washing
 - c. Covering hair with a cap
 - d. Wearing sterile gloves
9. Disinfection and sterilization processes are two methods of eliminating microorganisms. Place a “D” in front of the methods that are examples of disinfection and an “S” in front of methods that are examples of sterilization.
- a. ___ alcohol
 - b. ___ moist heat
 - c. ___ ethylene oxide gas
 - d. ___ boiling water
10. A nurse would use surgical asepsis at the client’s bedside in the following situations. (Select all that apply.)
- a. Inserting an IV
 - b. Applying a sterile dressing
 - c. Inserting a urinary catheter
 - d. Suctioning the oropharynx and trachea
11. A nurse fills out an incident report in situations when someone could have been or did get hurt. The incident report needs to maintain the same qualities as all other types of documentation. Important guidelines the nurse needs to follow are (select all that apply):
- a. Document an objective description of the incident
 - b. Document accurate information about the incident
 - c. Document the incident in a timely manner
 - d. Document the information in an organized manner
12. A “sentinel event” is defined as
- a. an unexpected occurrence involving death or serious physical or psychological injury or risk of injury
 - b. an emergency treatment that is provided to a client without his/her consent
 - c. a situation where a client’s behavior requires the use of restraints
 - d. a system of identifying potential hazards and eliminating them before harm occurs
13. A safe environment is an environment that includes which of the following factors? (Select all that apply.)
- a. Basic needs are met
 - b. Physical hazards are reduced
 - c. Sanitation is maintained
 - d. Nursing standards of care are implemented
14. Falls are one of the leading environmental hazards reported in hospitals. One of the most common occurrences that precipitates a client fall is
- a. getting out of bed to go to the bathroom
 - b. leaving the side rails down
 - c. experiencing stress, anxiety, and fatigue
 - d. slipping on a wet floor
15. If a client falls, the nurse’s first responsibility is to
- a. assess the client’s injury
 - b. notify the physician
 - c. write up an incident report
 - d. report the incident to the nurse manager
16. When caring for a restrained client, the nurse at least would plan to assess the placement of the restraint and the condition of the restrained area at which interval?
- a. ½ hour
 - b. 1 hour
 - c. 2 hours
 - d. 8 hours
17. When applying a restraint, which information must the nurse document? (Select all that apply.)
- a. Type of restraint
 - b. Time applied
 - c. Condition of area to which restraint is applied
 - d. Family understanding of the restraint
 - e. Client response to the restraint
18. When assessing a client with upper extremity restraints, the nurse notes the right hand is pale and cold and the client is complaining that it pains. Which is the appropriate initial action for the nurse to take?
- a. Loosen the restraint

(continued)

- b. Remove the restraint
c. Notify the MD
d. Document findings
19. Which direction represents a task that an RN may legally delegate to an unlicensed assistant?
a. “Decide if a less restrictive restraint will be effective for Ms. ___.”
b. “Apply mitten restraints to Ms. ___.”
c. “See if Ms. ___ needs a restraint.”
d. “Check if Ms. ___’s wrist restraint is affecting circulation to her hand.”
20. Which interventions can the nurse use to help eliminate the need for restraints? (Select all that apply.)
a. Orient at regular intervals to surroundings
b. Have a clock in plain view
c. Provide adequate sensory stimulation
d. Void on a regular schedule
e. Ambulate on a regular schedule
21. How often would the nurse manager expect assessment data related to the need for a restraint to be recorded in the client’s record?
a. Every shift
b. Every 24 hours
c. Every 48 hours
d. Every 72 hours
22. One reason a nursing history is taken is to determine a client’s level of wellness. Which of the following aspects might the nurse include in the history to determine if there are any underlying conditions that might threaten a client’s safety? (Select all that apply.)
a. Gait
b. Development status
c. Medications
d. Vision
23. When caring for a client with an abscessed buttock infected with MRSA, which protective equipment would be used when removing the packing from the wound? (Select all that apply.)
a. Respiratory protective device
b. Mask
c. Gloves
d. Gown
24. Which new admission should the nurse plan to place in a private room with negative-pressure airflow?
a. Client with rubella
b. Client with strep throat
c. Client with measles
d. Client with TB of the bone
25. When caring for a client on droplet precautions, which protective equipment would the nurse use? (Select all that apply.)
a. Respiratory protective device
b. Mask
c. Gloves
d. Gown

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all False statements in the space provided.

1. A tool used in risk management to report an accident or unusual happening is called an incident report. *True*
2. Risk management is a system of identifying potential hazards and eliminating them before harm occurs. *True*
3. Only the nursing department is involved in risk-management programs. *False*

Risk management involves all departments within the agency including top management and the board of directors.

4. The abbreviation The Joint Commission stands for the “Joint Commission on Accreditation of Healthcare Organizations.” *True*
5. A sentinel event is defined as an unexpected occurrence involving death or serious physical or psychological injury or risk of injury. *True*
6. The purpose of hand washing is to remove all microorganisms from the hands. *False*
Hand washing reduces and controls the number of microorganisms.
7. Standard precautions are classified as tier one precautions and require the person to be in a private room. *False*
Standard precautions do not require a person to be in a private room.
8. A client diagnosed with active tuberculosis would be placed on airborne precautions in conjunction with standard precautions. *True*
9. Contaminated hands are a prime cause of cross infection. *True*
10. The procedure used to eliminate all microorganisms, including pathogens and spores, is called surgical asepsis. *True*
11. One principle of surgical asepsis states that “edges of a sterile field or container are considered to be contaminated.” *True*
12. A sterile field is an area free from microorganisms that is able to receive sterile and nonsterile items. *False*
A sterile field will receive only sterile items; nonsterile items placed on a sterile field will contaminate the field.
13. Most medical errors are considered to be preventable. *True*
14. The nurse uses critical thinking in the assessment of actual and potential environmental risks to client safety. *True*
15. When assessing actual and potential environmental risks it is helpful for the nurse to get a sense of the client’s daily routines at home. *True*
16. According to the National Fire Prevention Association, home fires are a major cause of death and injury. *True*
17. The risk of motor vehicle accidents is highest among teen drivers than any other age group. *True*
18. The Joint Commission for Accreditation of Healthcare Organization sets standards to address the nurse’s responsibility for maintaining client safety. *False*
The American Nurses Association (ANA) standards of nursing practice set the standards for nursing practice.
19. One of the first questions the nurse would ask when doing a “fall assessment” on a client would be “Does the client have a history of falling?” *True*
20. There are two types of disasters: man-made and natural. *True*
21. An earthquake is classified as a man-made disaster. *False*

An earthquake is a natural disaster.

(continued)

22. “Agent-specific” approach to disaster planning focuses on preparing for disasters that are most likely to occur in a community. *True*
23. Communication is a major priority in disaster planning. *True*
24. The purpose of an Emergency Response Plan is to have an organizational structure and procedures in place to respond to major emergencies. *True*
25. Triage is the process for prioritizing which patients are to be treated first. *True*
26. Disaster triage is when decisions are based on identifying and treating the sickest individuals first. *False*
Disaster triage is when decisions are based on doing the greatest good for the greatest number.
27. The first priority in a disaster is human safety. *True*
28. A hazardous material is a material capable of causing a harmful physical or health effect. *True*
29. Hazardous materials are removed from their original containers and placed in agency-specific containers for storage. *False*
Hazardous substances need to be stored in their original containers.
30. The Center for Disease Control (CDC) has classified hazardous agents as Category A, B, or C. Category A is the most dangerous agent. *True*
31. The standard of “reasonable care” is used when emergency care is given in a health care setting. *False*
“Reasonable care” standard is used in emergency situations that occur outside a health care institution.

APPLICATION ANSWERS

1. Which of the following events would be considered a “natural disaster?” (Select all that apply.)
- Flood
 - Meteorological phenomena
 - Fire
 - Nuclear event

Rationale

Correct answers: a and b.

- A flood is a natural disaster as it is the result of an ecological disruption.
- A meteorological phenomena is also a natural disaster.

Incorrect answers: c and d.

- A fire is an emergency situation caused by human beings.
- A nuclear event is a man-made disaster.

2. When does a communicable, infectious disease outbreak management become disaster management?
- Once public health officials determine that the outbreak exceeds the capability and resources available to handle it
 - At the beginning of the outbreak as communicable diseases are a serious threat to the population
 - The disaster plan would need to be implemented only if the outbreak was a Category A biological agent
 - When it is determined that the outbreak is an internal disaster

Rationale

Correct answer: a.

- Disaster management would be put into place after public health officials recognize a communicable disease outbreak is occurring, determine the

source, mode of transmission, and risk factors, and implement control measures and the outbreak exceeds their capacity and resources.

Incorrect answers: b, c, and d.

- b. Public health officials would investigate and assess the situation first.
- c. Any communicable disease outbreak could warrant the implementation of a disaster management plan.
- d. Internal disease is a way that health care facilities often classify a disaster.

3. In handling a chemical, you accidentally spilled a small amount of the contents on your hand. What would be the best course of action for you to take?

- a. Immediately wash the affected hand and remove any clothing that the chemical might have come in contact with
- b. Call the Poison Control Center to determine what medication needs to be applied to the area to counteract the chemical
- c. Wrap your hand in a towel to protect it from exposure to the air
- d. Do nothing

Rationale

Correct answer: a.

- a. Physical removal of the chemical is the highest priority because there is a direct relationship between contact time and effect for most chemical agents.

Incorrect answers: b, c, and d.

- b. This might be done but is not necessarily the first course of action.
- c. The most effective method is to dilute the chemical or reduce the amount of chemical on the skin.
- d. Physical removal of the chemical is the highest priority, doing nothing is not the best course of action.

4. While making rounds, the nurse finds that a client's IV of Ringer Lactate was running at 75 ml/hr. The kardex stated that the IV ordered was D5W. The nurse's notes in the chart stated that the IV had been changed 2 hours ago and the drip rate had been set. The first thing the nurse would do is

- a. change the IV solution
- b. inform the person who hung the incorrect IV about the occurrence
- c. make out an incident report
- d. report the incident to the nurse in charge

Rationale

Correct answer: a.

- a. The nurse's first action would be to change the IV solution to the solution that had been ordered.

Incorrect answers: b, c, and d.

- b. Correcting the situation needs the nurse to be focused on improving delivery of care and not on placing the blame.
- c. Making out an incident report would be one of the things the nurse would do later to record the incident.
- d. The nurse would report the incident to the nurse in charge but it would not be the first thing that would be done.

5. A planned program of loss prevention and liability control is called

- a. risk management
- b. critical pathways
- c. peer review
- d. quality assurance

Rationale

Correct answer: a.

- a. Risk management is a planned program with the purpose of identifying risks, analyzing and prioritizing risks, and developing a plan to manage risks.

Incorrect answers: b, c, and d.

- b. Critical pathways are guidelines that provide direction for optimum client care.
- c. Peer review involves the evaluation of a person of equal status by a peer.
- d. Quality assurance is an evaluation process with the purpose of assuring excellence in the health care provided to clients.

6. A client is admitted to the nursing unit with a diagnosis of mycoplasma pneumonia. The admitting physician did not order the client to be placed on any form of precautions. Which isolation precautions would be best for the client to be on?

- a. Transmission-based precautions
- b. Universal precautions
- c. Sterile precautions
- d. Standard precautions

Rationale

Correct answer: a.

- a. Transmission-based precautions are used in addition to standard precautions when the person may have an "airborne", "droplet", or "contact" infection.

(continued)

Incorrect answers: b, c, and d.

- b. Universal precautions interfere with the spread of bloodborne pathogens and are used in conjunction with other types of precautions.
- c. Sterile asepsis eliminates all microorganisms from an area rendering it sterile.
- d. Standard precautions are used in the care of all hospitalized clients regardless of the diagnosis.

7. Mr. Smith is one of the 10 clients on your team. You are making out the team assignment and must decide whom to assign Mr. Smith. The CNA is new to the unit and you have not worked with her that much; RN1 has been caring for two postoperative clients; RN2 will be attending a continuing education program for about 1 hour during the shift. Select the most appropriate staff member to take care of Mr. Smith:
- a. RN2
 - b. CNA
 - c. RN1
 - d. Request a float nurse

Rationale

Correct answer: a.

- a. Even though RN2 will be off the nursing unit for 1 hour, the individual would be the most appropriate staff member to care for Mr. Smith.

Incorrect answers: b, c, and d.

- b. The CNA is new to the unit and you do not know the individual's ability to care for clients with infections and on precautions.
- c. Assigning two postoperative clients and a client with an infection could spread the infection.
- d. There is no need to request a float nurse as there are appropriate caregivers on the nursing unit to care for Mr. Smith and the other clients.

8. Which of the following activities would be an example of implementing medical asepsis? (Select all that apply.)
- a. Mopping the floor
 - b. Hand washing
 - c. Covering hair with a cap
 - d. Wearing sterile gloves

Rationale

Correct answers: a and b.

- a. Cleaning the environment to prevent the spread of microorganisms is a form of medical asepsis.
- b. A basic technique in preventing and reducing the spread of infections is hand washing.

Incorrect answers: c and d.

- c. and d are examples of surgical asepsis; they are activities a nurse would do to protect and maintain the sterile field.

9. Disinfection and sterilization processes are two methods of eliminating microorganisms. Place a "D" in front of the methods that are examples of disinfection and an "S" in front of methods that are examples of sterilization.
- a. D alcohol
 - b. S moist heat
 - c. S ethylene oxide gas
 - d. D boiling water

Rationale

Correct answers: Disinfection—a and d.

- a. Alcohol eliminates many microorganisms but not all; it is a chemical disinfectant.
- d. Boiling water is not a method of sterilization as bacterial spores and some viruses resist boiling.

Correct answers: Sterilization—b and c.

- b. Moist heat is steam under pressure (autoclave) and reaches temperatures above boiling point to kill pathogens and spores.
- c. Ethylene oxide gas destroys spores and microorganisms by altering cell's metabolic processes.

10. A nurse would use surgical asepsis at the client's bedside in the following situations. (Select all that apply.)
- a. Inserting an IV
 - b. Applying a sterile dressing
 - c. Inserting a urinary catheter
 - d. Suctioning the oropharynx and trachea

Rationale

Correct answers: a, b, c, and d.

- a. c, d. The cavities are considered sterile; sterile technique is required to not introduce microorganisms into the client's body.
- b. The application of a sterile dressing requires a sterile field to not introduce microorganisms.

11. A nurse fills out an incident report in situations when someone could have been or did get hurt. The incident report needs to maintain the same qualities as all other types of documentation. Important guidelines the nurse needs to follow are (select all that apply):
- a. Document an objective description of the incident
 - b. Document accurate information about the incident
 - c. Document the incident in a timely manner
 - d. Document the information in an organized manner

Rationale

Correct answers: a, b, c, and d.

- a. Objective information is from direct observation by the nurse and measurable; vague terms are discouraged as they suggest opinions instead of facts.
 - b. The use of measurable terms provides a fuller and more accurate picture of what occurred.
 - c. Recording the incident when it is still fresh in the nurse's mind will increase accuracy and decrease duplication.
 - d. Information is expected to be presented in a logical order to facilitate better communications.
12. A "sentinel event" is defined as
- a. an unexpected occurrence involving death or serious physical or psychological injury or risk of injury.
 - b. an emergency treatment that is provided to a client without his/her consent.
 - c. a situation where a client's behavior requires the use of restraints.
 - d. a system of identifying potential hazards and eliminating them before harm occurs.

Rationale

Correct answer: a.

- a. The Joint Commission on Accreditation of Healthcare Organizations states that such events are called "sentinel" because they need immediate investigation and response.

Incorrect answers: b, c, and d.

- b. It is describing an emergency situation, such as performing cardiopulmonary resuscitation, on a client.
 - c. When a physical or mechanical device is needed to limit the freedom of movement of a client.
 - d. A system for identifying potential sources of risks is called risk management.
13. A safe environment is an environment that includes which of the following factors? (Select all that apply.)
- a. Basic needs are met
 - b. Physical hazards are reduced
 - c. Sanitation is maintained
 - d. Nursing standards of care are implemented

Rationale

Correct answers: a, b, and c.

- a. Physiological needs influence a person's safety, for example, sufficient oxygen.
- b. Physical hazards place a person at risk for accidental injury or death, for example, motor vehicle accident.

- c. Adequate disposal of human waste through a proper sewage system is vital to maintaining a safe environment.

Incorrect answer: d.

- d. Nursing standards of care are legal guidelines defined in the Nurse Practice Acts.
14. Falls are one of the leading environmental hazards reported in hospitals. One of the most common occurrences that precipitates a client fall is
- a. getting out of bed to go to the bathroom
 - b. leaving the side rails down
 - c. experiencing stress, anxiety, and fatigue
 - d. slipping on a wet floor

Rationale

Correct answer: a.

- a. It is natural behavior to use the bathroom for elimination purposes.

Incorrect answers: b, c, and d.

- b, c, d. Each of the three occurrences may contribute to client falls but are not the most common reason for falls.

15. If a client falls, the nurse's first responsibility is to
- a. assess the client's injury
 - b. notify the physician
 - c. write up an incident report
 - d. report the incident to the nurse manager

Rationale

Correct answer: a.

- a. The nurse's first responsibility is to the client.

Incorrect answers: b, c, and d.

- b, c, and d. The nurse may perform each of the other activities, however, not as his/her first responsibility.

16. When caring for a restrained client, the nurse at least would plan to assess the placement of the restraint and the condition of the restrained area at which interval?
- a. ½ hour
 - b. 1 hour
 - c. 2 hours
 - d. 8 hours

Rationale

Correct answer: b.

- b. Proper placement of restraints as well as skin condition, color, temperature, and sensation of restraint area must be checked at least once every hour.

Incorrect answers: a, c, and d.

- a. Half-hour intervals provide closer monitoring but the standard is 1 hour.

(continued)

c, d. These intervals are too long and make the risk of injury too great.

17. When applying a restraint, which information must the nurse document? (Select all that apply.)
- Type of restraint
 - Time applied
 - Condition of area to which restraint is applied
 - Family understanding of the restraint
 - Client response to the restraint

Rationale

Correct answers: a, b, c, d, and e.

All factors listed are required to be documented. Also required is the method used in applying the restraint and the times of assessments and the findings.

18. When assessing a client with upper extremity restraints, the nurse notes the right hand is pale and cold and the client is complaining that it pains. Which is the appropriate initial action for the nurse to take?
- Loosen the restraint
 - Remove the restraint
 - Notify the MD
 - Document findings

Rationale

Correct answer: b.

b. The restraint is removed to prevent further tissue damage.

Incorrect answers: a, c, and d.

a. The potential for tissue damage still exists if the restraint is merely loosened.

c and d. These activities are done but neither is the initial response.

19. Which direction represents a task that an RN may legally delegate to an unlicensed assistant?
- “Decide if a less restrictive restraint will be effective for Ms. ___.”
 - “Apply mitten restraints to Ms. ___.”
 - “See if Ms. ___ needs a restraint.”
 - “Check if Ms. ___’s wrist restraint is affecting circulation to her hand.”

Rationale

Correct answer: b.

b. Nurses may delegate application of restraints.

Incorrect answers: a, c, and d.

a, c, d. The nurse cannot delegate selection of type of restraint, determination of need for restraint, or assessment for complications. The nurse also cannot delegate assessment of a restraint’s effect.

20. Which interventions can the nurse use to help eliminate the need for restraints? (Select all that apply.)
- Orient at regular intervals to surroundings
 - Have a clock in plain view
 - Provide adequate sensory stimulation
 - Void on a regular schedule
 - Ambulate on a regular schedule

Rationale

Correct answers: a, b, c, d, and e.

a, b, and c. These help keep the client oriented and thereby decrease the need for restraints.

d and e. These help prevent discomfort which can contribute to restlessness and undesirable activity.

21. How often would the nurse manager expect assessment data related to the need for a restraint to be recorded in the client’s record?
- Every shift
 - Every 24 hours
 - Every 48 hours
 - Every 72 hours

Rationale

Correct answer: b.

b. The need for a restraint must be reassessed and documented every 24 hours.

Incorrect answers: a, c, and d.

a. It is more often than required

c and d. These are not often enough according to regulations.

22. One reason a nursing history is taken is to determine a client’s level of wellness. Which of the following aspects might the nurse include in the history to determine if there are any underlying conditions that might threaten a client’s safety? (Select all that apply.)
- Gait
 - Development status
 - Medications
 - Vision

Rationale

Correct answers: a, b, c, and d.

a. The nurse would observe the client’s mobility and body alignment and assess if the client needed assistance with ambulation.

b. The client’s development status may create threats to client safety.

c. Is the client on any medications that might lead to confusion, disorientation, or other types of risks?

d. Visual acuity, particularly in the elderly, as decreased vision may lead to client injury.

23. When caring for a client with an abscessed buttock infected with MRSA, which protective equipment would be used when removing the packing from the wound? (Select all that apply.)
- Respiratory protective device
 - Mask
 - Gloves
 - Gown

Rationale

Correct answers: c and d.

c and d. A wound infection requires contact precautions and these require use of gown and gloves.

Incorrect answers: a and b.

a and b. Respiratory protective devices are used for airborne precautions. Masks may be used for airborne precautions and always for droplet.

24. Which new admission should the nurse plan to place in a private room with negative-pressure airflow?
- Client with rubella
 - Client with strep throat
 - Client with measles
 - Client with TB of the bone

Rationale

Correct answer: c.

c. Negative-pressure airflow is used for airborne precautions. Measles is spread by airborne transmission and therefore negative-pressure airflow protection is required.

Incorrect answers: a, b, and d.

a, b, and d. None of these diseases are spread by airborne transmission therefore negative-pressure airflow is not needed. Rubella and strep throat are spread by droplets.

25. When caring for a client on droplet precautions, which protective equipment would the nurse use? (Select all that apply.)

- Respiratory protective device
- Mask
- Gloves
- Gown

Rationale

Correct answer: b.

b. Protection from droplet transmission requires use of a mask.

Incorrect answers: a, c, and d.

a, c, and d. Gloves and gown are required for contact transmission. Mask or respiratory protective device is needed to protect against airborne transmission.

| ▸ Intrapartum Period | 88 | ▸ Postpartum Period | 97 |
| ▸ Newborn Care | 100 | | |

ANTEPARTUM PERIOD

TERMINOLOGY RELATED TO PREGNANCY

Gravida: The number of pregnancies a woman has had. It includes the present pregnancy (if she is pregnant now). It does not consider the length or the outcome of the pregnancy.

Primigravida: A woman who is pregnant for the first time or has been pregnant only once.

Multigravida: A woman who has had more than one pregnancy or who is pregnant now and has been pregnant before.

Para: The number of pregnancies a woman has had which ended after 20 weeks. No consideration is given to the outcome of the pregnancy, means of termination of the pregnancy, or number of children involved in the pregnancy. A current, undelivered pregnancy after 20 weeks does not add to the number of paras until after the preg-

nancy has ended. To prevent confusion, the number of paras may not be changed in the chart during the hospitalization for delivery. The number of paras cannot exceed the number of pregnancies.

Stillborn: A baby born dead after the age of viability (20 weeks gestation).

Nulliparas: A woman who may or may not have been pregnant before, but never delivered a term infant.

Multiparas: A woman who has delivered more than one baby after the age of viability (20 weeks gestation).

Abortion: Termination of a pregnancy prior to viability of the fetus. Abortions may be subdivided into elective and spontaneous types.

Elective: The purposeful termination of a pregnancy. Laws often govern when and how an elective abortion can be performed.

Spontaneous: The unplanned termination of a pregnancy. In lay terms, it is called a miscarriage.

TPAL: This acronym provides information about the obstetrical history of a woman. T refers to term births, P is for preterm births, A is for abortions, and L is for living children.

Chadwick's Sign: Bluish discoloration of the cervix due to increased vascularity in these tissues. Its value in determining pregnancy is moderate and thus it is a probable sign of pregnancy.

Goodell's Sign: Softening of the cervix, also due to increased vascularity. It is a probable sign of pregnancy.

Hegar's Sign: A softening of the isthmus or neck of the cervix. It is another probable sign of pregnancy.

Braxton Hicks: Also called false labor contractions, these contractions can be felt by the pregnant woman beginning around the twenty-eighth week. Braxton Hicks contractions are generally described as irregular and painless contractions.

Decidua: The pregnant endometrium of the uterus. The decidua may also be described in relation to the fetus. The decidua basalis lies directly under the fetus and is a component of the placenta. The decidua capsularis covers the developing fetus. The decidua vera is the part of the endometrium not in contact with the fetus.

Leopold's Maneuvers: A system of palpating the maternal abdomen at term that will assist in determining the fetal presentation and position.

PREGNANCY

- Conception occurs with the union of the sperm and ova.
- Both the sperm and the ovum will bring to the union a nucleus with 23 chromosomes, 22 somatic (body) chromosomes and a sex chromosome, either an X or Y from the sperm and an X from the ovum.
- When the sperm fertilizes the ovum, the sex of the baby is determined and the resulting zygote contains 46 chromosomes with the characteristics of both the mother and the father.
- The normal gestation lasts 40 weeks.
- The diagnosis of pregnancy is based on the signs of pregnancy. The signs of pregnancy are categorized as probable, presumptive, and positive based on their significance in the diagnosis.

SIGNS OF PREGNANCY

The three categories of the signs of pregnancy are

- presumptive
- probable
- positive

Presumptive Signs of Pregnancy

Presumptive signs of pregnancy are weak signs that can be caused by other conditions. Because these signs are subjective, they may easily be misinterpreted (see Table 6–1).

Table 6–1 Presumptive Signs of Pregnancy

| Sign | Relationship to Pregnancy | Other Possible Interpretations |
|---------------------|---|---|
| Amenorrhea | Menses usually ceases after conception but absence can be caused by other conditions including stress. | Women with low body fat such as athletes often have amenorrhea. In addition, stress, menopause, and endocrine disorders can contribute to the absence of menses. |
| Nausea and vomiting | During early pregnancy, nausea and vomiting is associated with the elevated hormone levels seen in pregnancy. | Emotional distress and viral or bacterial GI infections are a few of the causes of nausea and vomiting. |
| Urinary frequency | Due to the elevated hormones and pressure of the enlarged uterus and uterine contents on the bladder, urinary frequency is seen in early pregnancy and again in the last trimester. | Urinary tract infections, diabetes, and increased fluid intake can all lead to urinary frequency. |
| Quickening | Quickening refers to fetal movement and is usually felt by the pregnant woman between 16 and 20 wks of pregnancy. The early movements are often described as “butterfly wings.” | Normal peristalsis and abdominal gas from gas-producing foods can be perceived as quickening. Women who want to be pregnant can imagine the feelings of quickening. |
| Fatigue | This subjective sign is a frequent complaint of the woman in the first trimester. | Stress, illness, and overwork can bring on this symptom. |
| Weight gain | Weight gain in early pregnancy is usually minimal. | Weight gain is associated with water retention secondary to hormonal changes. |
| Breast changes | The changes which are noted in the breast are tingling and fullness. | Monthly hormonal changes are often noted in the premenstrual period. |

Probable Signs of Pregnancy

Probable signs of pregnancy are objective and can be noted by a trained health care professional. Probable signs are more frequently associated with pregnancy (see Table 6–2).

Positive Signs of Pregnancy

Positive signs of pregnancy cannot be misinterpreted by the client or the examiner. These signs are the definitive symptoms of pregnancy (see Table 6–3).

PREGNANCY TESTS

Human chorionic gonadotropin (HCG) is a hormone produced by the placenta and present in the maternal blood-

stream and eventually excreted by the kidneys. This hormone is responsible for the maintenance of the pregnancy in the early period and is the basis for the pregnancy tests commonly used (see Table 6–4). False negatives can occur if the test is performed too early in the menstrual cycle. If urine samples are used for testing, the first morning voided is best as the hormone concentration will be highest.

Clinical Alert

False negative results occur fairly frequently. If the results of the home pregnancy test are negative, the test should be repeated in a week if menstruation has not begun.

Table 6–2 Probable Signs of Pregnancy

| Sign | Relationship to Pregnancy | Other Possible Interpretations |
|--|---|---|
| Abdominal enlargement | A feeling of abdominal fullness and tightening of clothes can be noted soon after the first period is missed. | Weight gain and tumors of the abdomen or uterus can also cause this symptom. |
| Changes in pelvic organs <ul style="list-style-type: none"> • Goodell's sign • Hegar's sign • Chadwick's sign | <ul style="list-style-type: none"> • Due to increased vascularity, the examiner will notice a softening of the cervix. • Another symptom related to the increased vascularity of the isthmus (or neck) of the cervix is that the examiner will be able to compress the cervix to a minimum. • Due to the increased vascularity of the cervix, vagina, and vulva, the mucous membranes will assume a bluish coloration. | <ul style="list-style-type: none"> • Any condition that increases the vascularity of the cervix including hormonal changes can cause this symptom. • Like Goodell's sign, this symptom may be associated with conditions such as infections. • Any condition increasing the blood flow to these tissues can give rise to this symptom. |
| Ballottement | Because the fetus floats in amniotic fluid, when the cervix is tapped, the fetus will float away from the cervix and then back toward the cervix producing a rebound tap felt by the examiner. | This symptom may also be associated with uterine polyps or tumors. |
| Braxton Hicks contractions | Most frequently felt by the pregnant woman during the third trimester, these painless, irregular contractions of the uterus are often termed false labor. | Some tumors may cause similar perceptions. |
| Uterine soufflé | This is the sound of blood flowing through the maternal side of the placenta; the rate will be the same as the maternal pulse. | Uterine tumors with increased uterine blood flow can also cause this symptom. |
| Pigmentation changes <ul style="list-style-type: none"> • Chloasma • Darkening of the areola of the nipples • Linea nigra | <ul style="list-style-type: none"> • This refers to a flushing of the face of pregnant women. • Darkening is more common in the dark-haired female and the primigravidas. • Beginning at the pubis, a dark line forms on the skin and progresses up the midline of the abdomen to the top of the fundus. | <ul style="list-style-type: none"> • Oral contraceptives can lead to this symptom. • Hormonal imbalances can cause this symptom. |
| Pregnancy tests | Various tests are available which detect the presence of human chorionic gonadotropin (HCG), a hormone produced by the placenta. | Hydatidiform mole and choriocarcinoma also respond to the tests. |

Table 6–3 Positive Signs of Pregnancy

| Sign | Relationship to Pregnancy | Other Possible Interpretations |
|--|--|--------------------------------|
| Auscultation of fetal heart tones (FHTs) | FHTs can be heard as early as 10 wks with a Doppler ultrasound transducer and by 18–20 wks with a fetoscope. The FHTs must be differentiated from the maternal heart rate. FHTs usually run above 100 while maternal heart rates are slower. | None |
| Fetal movements felt by a trained examiner | The trained examiner is able to differentiate the fetal movements from abdominal gas. | None |
| Confirmed presence of a fetus | The presence of the fetus can be determined by ultrasound as early as 4 wks gestation. | None |

ESTIMATION OF GESTATION

As soon as pregnancy is determined, the woman's first concern is to determine when the baby is due. The due date is called the Estimated Date of Confinement or EDC. There are several means of determining the EDC including Nagele's rule, fundal height, and the use of a gestational wheel.

Nagele's Rule

- It is the most common tool used to determine EDC.
- After determining the first day of the last menstrual period, the examiner would count back 3 months and add 7 days. For example, if the first day of the last menstrual period was September 1, the examiner would subtract 3 months ($9 - 3 = 6$) and add 7 days. The sixth month is June, so the due date would be June 8.
- Inaccurate determinations occur when the date of the last menstrual period cannot be recalled. These are frequently associated with delays in seeking medical attention.

Table 6–4 Pregnancy Tests Commonly Used

| Test | Tests | Diagnostic Period |
|---|----------------|--|
| Radioimmunoassay | Blood or urine | 1 wk after fertilization |
| Enzyme-Linked Immunosorbent Assay (ELISA) | Blood or urine | 10 d after fertilization or 5 d before first missed period |
| Home pregnancy tests | Urine | Varies |

- EDC may be incorrectly defined when the woman missed a cycle before conceiving or had vaginal bleeding after conception. Some women will have a "light period" after conceiving while others have been known to continue to have cycles well into the pregnancy.

Fundal Height Measurement

- In fundal height measurement, the examiner measures the distance from the symphysis pubis to the top of the fundus.
- Measured in centimeters, the fundal height measurement corresponds well with the fetal age in the second and third trimester.
- Women carrying more than one fetus will appear to be further along in their pregnancy with this EDC determination.
- In situations with intrauterine growth retardation in the fetus or oligohydramnios (less than normal amounts of amniotic fluid), the pregnancy may be incorrectly dated as well.

The Gestation Wheel

- It is an easy to use tool to assist the practitioner in determining EDC.
- Since the system utilizes the first day of the last menstrual period, this method has the same difficulties as Nagele's rule.

PHYSIOLOGIC CHANGES IN PREGNANCY

A normal pregnancy lasts for approximately 40 weeks or 10 lunar months. The pregnancy can be divided into three distinct periods or trimesters. The changes in the woman's body can be related primarily to the hormones associated with pregnancy and the growth of the fetus (Table 6–5).

Table 6–5 The Sources and Functions of the Hormones Related to Pregnancy

| Hormone | Source | Function |
|------------------------------------|------------------------|---|
| Follicle stimulating hormone (FSH) | Anterior pituitary | Stimulates ovarian activity and the production of the graafian follicle |
| Luteinizing hormone (LH) | Anterior pituitary | Stimulates the graafian follicle to release the ovum and convert to a corpus luteum |
| Prolactin | Anterior pituitary | Stimulates lactation after delivery |
| Oxytocin | Posterior pituitary | Stimulates uterine contractibility in labor Stimulates the “let-down” reflex or release of milk in the postpartum period |
| Estrogen | Corpus luteum/placenta | Promotes the thickening of the uterus Prepares the breasts for breast-feeding |
| Progesterone | Corpus luteum/placenta | Maintains the endometrium Suppresses uterine activity Prepares the breasts for breast-feeding Relaxes joints of pelvis allowing a slightly enlarged diameter of the birth canal and contributing to the characteristic waddling gait of the pregnant woman |
| HCG | Trophoblast/placenta | Maintains the corpus luteum to continue producing estrogen and progesterone preventing menstruation Once the placenta is producing HCG, the placenta will produce the hormones necessary to maintain the pregnancy |
| Human placental lactogen | Trophoblast | Antagonizes insulin maintaining a higher level of glucose in the maternal circulation to meet the needs of the growing fetus |
| Relaxin | Corpus luteum | Relaxes the uterus, inhibits uterine contractions |
| Prostaglandins | Various body tissues | Unknown |

The hormones associated with pregnancy are estrogen, progesterone, and HCG. Both estrogen and progesterone are produced initially by the corpus luteum on the ovaries. The placenta will eventually take over control of the production of these hormones. While the trophoblast initially produces HCG, this hormone will also eventually be produced by the placenta.

Changes in the Reproductive Organs

Uterus

- In the nonpregnant state, the uterus is a small pear-shaped organ that weighs about 2 oz.
 - At term, the pregnant uterus weighs about 2 lbs. Most of the growth is related to an enlargement of the uterine cells.
 - The uterus is primarily a muscular organ and even in its stretched shape at the end of pregnancy, is very strong. The muscle fibers of the uterus are arranged in all directions, unlike the muscle fibers of the muscles of the arms or legs.
- The concentration of muscle fibers is particularly thick in the fundal area (top of uterus) giving the appearance of a hood and adding to the strength of the fundus.
- The accumulation of blood in the uterus adds to its enlargement. With the accumulation of blood, the uterus becomes a thick carpet in which the embryo can bury itself.
 - The placenta development begins around 3 weeks after conception and is formed from fetal and maternal structures. It develops at the site where the embryo is attached to the wall of the uterus. It serves two functions: (1) provides nutrient exchange between the fetus and mother and (2) produces hormones that are essential for the maintenance of the pregnancy.
 - Braxton Hicks contractions occur irregularly throughout pregnancy but become more noticeable late in pregnancy. At term, these contractions may be confused with labor contractions but differ from labor contractions in that the cervix does not dilate and the contractions usually cease with walking.

- In the nonpregnant state, the uterus lies completely in the pelvis. With the enlargement of the uterus and growth of the fetus, the uterus rises above the pelvis. The fundal height is related to the gestational age of the fetus as illustrated in the following box:

| | |
|-----------|--|
| 12 wks | Fundus rises out of the pelvis. It can be felt above the symphysis pubis |
| 20 wks | Fundus reaches the umbilicus |
| 36 wks | Fundus reaches the xiphoid process. Breathing is difficult |
| 38–40 wks | Fundus drops down as the uterus settles back into the pelvis in preparation for labor. This is termed “lightening.” The woman can now breathe easier, but has pressure on the bladder causing frequent urination |

Cervix

- The cervix also is influenced to enlarge and thicken.
- The glandular tissue of the cervix becomes more active and produces thick mucus, which forms the mucous plug. This plug prevents the ascent of organisms into the uterus. Early in labor, this plug will be lost and will be described as “bloody show.”
- With the increased vascularity, the cervix softens and takes on the distinctive blue discoloration. The diagnosis of pregnancy is often made as a result of observing these changes in the cervix. These changes in vascularity are described as Goodell’s, Hegar’s, and Chadwick’s signs, which are used as pregnancy indicators.

Vagina

- Like the uterus and cervix, the vagina hypertrophies and displays increased vascularization.
- The cells of the vagina are active, producing the vaginal discharge (leucorrhea) that is common in pregnancy.
- The secretions of the vagina become more acidic providing protection from bacterial infections.

Ovaries

- In the nonpregnant state, the ovaries generally release one ovum per month. As the time of release approaches, the site on the ovary containing the ripening ovum is called a graafian follicle. Once the follicle ruptures and releases the ovum, the graafian follicle becomes the corpus luteum. If the ovum is not fertilized, the corpus luteum begins to shrink in about one week and eventually becomes a small scar on the ovary.
- If the ovum is fertilized, the cells that surround the fertilized ovum will begin to produce hormones that cause the corpus luteum to enlarge slightly and remain active in the production of hormones to maintain the pregnancy.

- Once the placenta is well established, it will become the main source of the hormones of pregnancy. The corpus luteum will then degenerate and serve no further function in pregnancy.
- Other than the activity of this corpus luteum, the ovaries remain quiet during the pregnancy and do not continue the cyclic maturation of ova.

Breasts

- The breasts increase in size and the glands will hypertrophy during the pregnancy in preparation for nourishing the newborn.
- Increased pigmentation can be noted in the areola and the Montgomery’s follicles on the areola become prominent.
- Stretch marks, called striae, are visible on the breasts.
- By the second trimester, colostrum can be expressed from the breasts. This colostrum will be the first feedings for the breast-fed baby and is rich in antibodies.

Assessment Alert

Tingling in the nipples and breast fullness are often the first subjective indicators of a pregnancy.

Respiratory System

- Oxygen requirements increase during pregnancy as the woman’s body must provide for both the woman and the fetus.
- As the uterus increases in size, the uterus rises out of the pelvis and puts increasing pressure on the diaphragm.
- In response to the higher levels of estrogen and the pressure on the diaphragm, the ribs flare and the circumference of the chest increases.
- While the respiratory rate is only slightly increased during pregnancy, the tidal volume increases significantly.
- The respiratory center in the brain becomes more sensitive to carbon dioxide levels. Although respiratory function has improved slightly from the nonpregnant state, the woman may report feeling slightly short of breath during late pregnancy.

Cardiovascular System

- The pulse rate increases slightly during pregnancy. The blood pressure decreases during the first trimester and then returns to the prepregnant levels in the third trimester.
- The basal metabolic rate of the pregnant woman increases significantly in pregnancy. The workload of the heart

reaches its maximum around the thirty-second week of pregnancy. If the heart does not have the capacity to compensate, cardiac decompensation may occur. The pregnant cardiac client often delivers as she approaches the thirty-second week of pregnancy.

- Vena cava syndrome occurs when the pregnant woman near term lies in the supine position. The weight of the uterus compresses the inferior vena cava restricting blood returning to the heart. The woman will feel dizzy, be pale and clammy, and be hypotensive. This can be prevented by having the woman lie on her side rather than in the supine position. The left side-lying position is favored as it promotes blood return via the inferior vena cava.
- Both the number of blood cells and blood volume increase during pregnancy. The increase in volume exceeds the increase in the number of RBCs, changing the ratio of solids to liquids in the hemoglobin and hematocrit laboratory values. This change in ratio is the cause of the pseudoanemia seen in early pregnancy.
- The white blood cell count increases in number as the body protects itself from foreign invasion. The WBC count peaks during labor and early postpartum and then returns to the pre-pregnant level.
- Fibrin and clotting factor levels increase in pregnancy as another means of the body's self-protection. This change makes the woman more prone towards the development of venous thrombosis.

Gastrointestinal System

- Women often complain of nausea during early pregnancy. This nausea and its sometimes associated vomiting are termed "morning sickness" although the nausea may be felt anytime during the day. This morning sickness is thought to be caused by the levels of HCG. Morning sickness that leads to weight loss or when it continues into the second trimester is abnormal and should be evaluated.
- Changes in the mouth associated with pregnancy may include ptyalism (excessive salivation) and gingivitis due to an increase in the vascularity of the oral mucus membranes.
- Progesterone slows the motility of the GI tract in the second and third trimesters delaying gastric emptying. This along with the uterine displacement of the stomach and intestines may cause heartburn (pyrosis).
- Progesterone also slows peristalsis and promotes water absorption from the colon leading to constipation.
- Constipation and the weight of the pregnancy can cause hemorrhoids.

Urinary System

- Urinary frequency is a common problem in both the first and third trimester caused by the weight of the uterus. During the second trimester, the uterus rises out of the pelvis

and relieves the pressure seen in the first trimester until the time the uterus returns to the pelvis in preparation for labor. This return to the pelvis is termed "lightening."

- Progesterone and its relaxation potential along with the weight of the uterus may lead to dilation of the ureters making the woman susceptible to urinary tract infections.
- The kidneys as a whole function at a higher capacity with higher glomerular filtration rates.

Musculoskeletal System

- Progesterone contributes to the relaxation of the pelvic joints. The pelvis, normally the stabilizing agent of the body, can no longer maintain the support system and the woman develops a waddling gait. This loosening of the joints provides for a slight increase in the diameter of the birth canal.
- The center of gravity of the body shifts due to the increased uterine weight. The body responds to this shift by increasing the curve of the lumbar spine and causing lordosis. These changes lead to a characteristic walk often termed "the pride of pregnancy." This change also leads to backache in the third trimester.

Integumentary System

- Pigment changes are the most noticeable changes occurring in the integumentary system. The pigment changes include chloasma, a facial rash, noticed primarily on the cheeks and forehead. This rash tends to be more prominent in a dark-skinned woman. Linea nigra is a dark line that develops on the midline of the abdomen and lengthens as the uterus grows.
- Striae or stretch marks occur as the connective tissue is damaged due to tissue stretching. During pregnancy, the striae may appear red but turn to silver after the completion of the pregnancy. Striae are most common on the abdomen, buttocks, thighs, and breasts.
- Hair growth is stimulated during pregnancy and the hair may appear more lustrous. After termination of the pregnancy, the hair follicle will assume a period of rest and the woman may notice some shedding of hair. By 6–12 months after the pregnancy, the hair will return to the prepregnancy appearance.

Endocrine System

- Influenced by the higher levels of estrogen during pregnancy and the increased needs of the pregnant body for nutrition, the endocrine glands increase their activities slightly and then return to their normal level of functioning in the immediate postpartum period.

Changes in Metabolism

- In general, the basal metabolic rate of the pregnant body increases over the nonpregnant state. This increase in

metabolism is both a support of the growing fetus and a response to the increased metabolic needs of the fetus. Estrogen and progesterone both promote the retention of water allowing for a greater volume of blood. As the fetus grows, the demand for protein and carbohydrates increases. Weight gain during pregnancy is in response to the increase in fluid volume and growth of new tissues including the placenta and fetus. Typical weight gain is about 4 lbs in the first trimester and 15 lbs in the second and third trimester. Total weight gain averages about 30–35 lbs. Allowable weight gain varies according to the prepregnancy weight of the woman, but even the overweight woman is encouraged to gain an average of 25 lbs to ensure the fetus receives what it needs for growth. At the time of delivery, this 30–35 lbs weight gain can be divided up to the following:

- fetus ~8 lbs
- placenta ~2 lbs
- amniotic fluid ~2 lbs
- increase in body water (including blood volume) ~8 lbs
- increase in uterus and breasts ~5 lbs
- body stores ~5 lbs

Nursing Intervention Alert

Monitoring weight gain and teaching the woman about the need for adequate nutrition for the fetus is a primary concern for the nurse in the obstetrical office.

Psychological Changes Associated with Pregnancy

Both the expectant mother and expectant father will have developmental tasks associated with the psychological maturation that comes with a pregnancy (see Table 6–6). Although each individual is different in how they handle the changes brought about by a pregnancy and birth of an infant, in general these changes can be divided into the three trimesters of pregnancy.

The Role of Other Family Members in an Expectant Family

Siblings

- Children's understanding and emotions related to the pregnancy vary according to the age and emotional maturity of the child. Young children will not understand the concept of pregnancy and may be surprised by the arrival of the new baby. Adolescents, on the other hand, may be fully aware of the concept of pregnancy and even feel

embarrassment that their parents have so publicly shown that sexual relations are occurring.

- The acceptance of the new arrival will be affected by the age of the siblings as well as their present position in the family. Older children, especially in large families, may dread the addition as a new source of responsibilities. The youngest child may feel that their position in the family has been taken by the new baby. An only child may feel the loss of the parents' attention.
- Preparation of the siblings is important and dependent upon the ages of the children. Young children need to be prepared close to the event while older children can be told of the pregnancy earlier. Whenever possible, include the siblings in the planning. A young child may help fold and put away the new baby's clothes while an older child might enjoy listening to the baby's heartbeat. The older child should never be displaced by the new baby. If, for instance, the older child is still sleeping in a crib, the child should not be moved from the crib for the baby. Instead, the older child is moved from the crib well in advance of the birth and given a bed for "big boys" or "big girls."

Grandparents

- Pregnancy usually results in a closer, more supportive relationship between the expectant couple and their parents regardless of past issues.
- Difficulties for grandparents can relate to determining to what extent the expectant couple want them involved, conflicts with their own life and work demands, and ambivalence over aging as they assume this new role.

Culture

- The cultural values and beliefs of the mother and father as well as the extended family will affect every aspect of childbearing and childrearing.
- How the woman feels about her pregnancy will be influenced not only by her life situation but also by the values placed on pregnancy by her culture.
- Culture can influence the acceptance of the child into the family. For instance, in some cultures, boys are more valued and thus the birth of a girl may be seen as a negative life situation.
- Cultural practices may influence the well-being of the pregnant woman and her fetus. The practice of pica, eating of nonfood substances, may lead to nutritional deficiencies.
- Labor and delivery may be influenced by the cultural acceptance of medication.
- Childrearing beliefs such as an emotionally upsetting event "spoiling" the milk of a breast-feeding mother may lead to a sudden weaning of the infant.
- The nurse's role in working with clients of diverse cultural backgrounds and beliefs is to be open and acceptive of differences.

Table 6–6 Maternal and Paternal Tasks During Pregnancy

| Trimester | Maternal Developmental Tasks | Paternal Developmental Tasks |
|------------|--|---|
| First | <ul style="list-style-type: none"> • Accepting the fact of pregnancy is the primary concept in the first trimester. At this time, the mother is more aware of the fact that she is pregnant than that she is going to have a baby. The expectant woman becomes more aware of others around her who are pregnant. • Ambivalence is a key emotion even in the woman who has had difficulty achieving a pregnancy. Although she may be delighted to be pregnant, doubts may intrude. The woman may think she is not ready or the timing of the pregnancy was not right. • Along with ambivalence, the expectant woman may demonstrate mood swings that can be related at least in part to the hormonal changes occurring in the body. • Body image changes are perceived by the pregnant woman but may not be noticeable to an onlooker. Depending on her acceptance of pregnancy, the woman may look forward to “looking pregnant” or be embarrassed and try to hide or deny the changes. | <ul style="list-style-type: none"> • The expectant father will have difficulty accepting the fact of pregnancy. From his point of view, nothing has changed. The pregnancy is not obvious to onlookers and he is unable to perceive the influence of hormones that convinces the expectant mother that things are changing. • Some expectant fathers may develop some of the pregnancy symptoms that their partners are displaying including nausea, weight gain, backache, and fatigue. This condition is called <i>couvades</i> and is associated with expectant fathers who are more involved in the pregnancy and who assume a more active paternal role. |
| Second | <ul style="list-style-type: none"> • By the second trimester, the pregnant woman should have accepted the fact that she is pregnant. Now she has to accept the reality of the fetus. With fetal movements, the woman recognizes that her body now houses two people. The woman and her family may develop a pet name for the fetus. These names add to the reality that a new person exists. • As the pregnancy grows, the woman may become more introverted, wanting to spend time alone with her fetus. Now the pregnant woman notices new babies everywhere she goes as her focus turns from pregnancy to baby. • The pregnant woman is noticeably pregnant to the onlookers. The woman may now be acceptive of her pregnancy and delighted that others have noticed. | <ul style="list-style-type: none"> • Dependent on his outlook for the pregnancy, the father may be excited and looking forward to caring for his offspring or see the pregnancy as a negative event in his life. • Some men view the pregnancy of their spouses as a validation of their masculinity. |
| Third | <ul style="list-style-type: none"> • The pregnant woman has now accepted the fact of pregnancy and that the pregnancy will produce a new baby. The woman must now prepare herself for delivery and her role as a mother. • Nesting occurs, where the pregnant woman prepares the nursery and gathers baby supplies. • The woman may worry about how she will handle labor and delivery. She is eager to discuss these events with others and to learn what she needs to know to be successful. • As the physical discomforts of pregnancy increase, the woman begins to look forward to and wish for the end of the pregnancy. Women who deliver early may never reach this plateau and actually grieve for the loss of the pregnancy after delivery, even with a healthy child. • Body image again makes a change. The woman may feel that her body is huge and may feel a loss of sexual appeal. Physical discomforts of the third trimester may contribute to a negative body image. | <ul style="list-style-type: none"> • As the time of delivery approaches, the man may be concerned about how he will respond to labor and delivery. Some men choose not to be involved while other men want to be with their expectant spouses for every event. Although excited about the approaching labor and delivery, the man may worry about how he will handle himself. • The expectant father may also worry about the financial role that will be required of him. The medical costs as well as the costs of raising a child may be a source of worry to some men. |
| Postpartum | <ul style="list-style-type: none"> • The psychological changes occur during the postpartal period as well and can be described as “taking in, taking hold, and letting go.” These changes will be discussed at a later point. | |

- Nursing care that is planned to include this acceptance of cultural diversity will be more acceptable to the client and more successful in promoting the health and well-being of the childbearing and childrearing family.

ANTEPARTUM CARE

During the first prenatal visit, the pregnant woman's chief concerns will be the determination of her pregnancy and her due date. The nurse, on the other hand, has a multitude of data to collect and information to provide. During the first prenatal visit, nursing activities will include

- client history determination. Information gained in this interview will include, but not be limited to
 - personal data that may have an influence on the pregnancy. This will include age, marital status, ethnicity, and support system. The occupation of the woman will be a consideration for the safety of the woman and her fetus. Even the presence of a pet cat will be questioned as it may have a negative influence on the outcome of the pregnancy.
 - the attitude toward this pregnancy as well as expectations about delivery, child care, and infant nutrition.
 - previous and current medical history that may provide clues to issues that could arise during the pregnancy or delivery.
 - family medical history, which will suggest additional pregnancy-related issues.
 - previous obstetrical history beginning with the onset of menses and including contraceptive history, previous pregnancies and their outcomes as well as problems which arose during the pregnancy or delivery.
 - current history of this pregnancy, first day of last menses, use of medications including over-the-counter and street drugs and alcohol, drug allergies, and possible teratogenic exposures including X-rays and viral infections.
- mental preparation of the client for the events of this first prenatal visit including the pelvic examination and laboratory testing.
- physical assessments such as
 - checking for vital signs
 - head-to-toe assessment ending with pelvic examination
 - Encourage the woman to empty her bladder prior to examination
- pelvic examination, which includes checking for
 - signs and symptoms of pregnancy
 - fundal height
 - pelvic adequacy
 - Estimation of pelvic size in anticipation of delivery
- laboratory assessments such as
 - determining hemoglobin and hematocrit values or complete blood count
 - Pseudoanemia is a common finding as the client blood volume increase is greater than the increase in blood cells
 - ABO and Rh typing
 - urinalysis
 - Looking specifically for glycosuria and proteinuria
 - screening tests for
 - syphilis testing
 - gonorrhea culture
 - HIV
 - rubella titer
 - hepatitis B
 - sickle cell screen for selected clients
 - Pap smear
 - One of the major roles of the nurse in the obstetrical office or clinic will be “education.” The nurse will provide information, on each prenatal visit, on topics including
 - normal changes of pregnancy
 - best done on a monthly basis,
 - include physical changes for the woman, and
 - fetal growth and development.
 - anticipatory guidance—during this and every prenatal visit, the nurse will be educating the woman about her body and her infant. There is a substantial amount of material to be shared with the pregnant woman and the nurse will need to present it in organized, small bits as the woman's pregnancy progresses. This will include
 - self-care
 - Hygiene: During pregnancy the glands of the body are more active. The pregnant woman will perspire more and have more vaginal secretions. The nurse will provide the client with the information that tub baths are allowed unless the membranes have ruptured. In late pregnancy, because of the changing body proportions, showers may be recommended as a safer activity. Soaking in hot tubs for prolonged periods of time is not recommended as studies have shown an increase in fetal anomalies associated with hot-tub use.
 - Clothing: All clothing should be loose and nonconstricting. The woman is encouraged to wear low-heeled, supporting shoes to reduce backache. A well-fitted support bra is recommended to promote the retention of breast shape.
 - Employment: Consider the activities involved in the job to determine the safety of working during pregnancy. Activities which might contribute to negative pregnancy outcomes include
 - prolonged standing which may lead to preterm delivery,
 - physical strain such as heavy lifting, and

- environmental factors which may be harmful to the fetus including inhalation of gases in an operating room.
 - Travel: Consideration should be given to the length of time the pregnant woman will be unable to move around freely. In automobile travel, the pregnant woman should plan a short rest period from sitting every 2 hours. When traveling in a car, both the lap and shoulder belts should be worn with the lap belt positioned under the abdomen. If long trips are planned close to the due date, consideration should be given to the need for medical care at the destination.
 - Exercise: The pregnant woman will want to continue her normal active lifestyle and should continue to participate in activities that maintain fitness and muscle tone.
 - As pregnancy advances, activities may need to be modified to promote the safety of the woman and her fetus. For instance, if the woman is a regular bicycle rider, as her center of gravity changes, the woman may need to consider other forms of exercise. Strenuous activities may need to be curtailed and activities that include an inherent risk may need to be avoided until after the pregnancy is complete.
 - Specific exercises may be added to the pregnant woman's regimen to assist with the discomforts of pregnancy and to prepare for delivery. The pelvic tilt exercise strengthens the back muscles and may reduce back strain. Kegel exercises will strengthen the perineal floor while sitting cross-legged will stretch the muscles of the inner thigh in preparation for delivery.
 - Sexual relationships: Although there may be changes in the woman's sexual interest, sexual relations are considered safe during pregnancy. In late pregnancy, the enlarged uterus may require changes in position for intercourse.
 - Pregnant women are advised to avoid intercourse once the membranes have ruptured or if there is vaginal bleeding or a risk of preterm labor.
- nutritional guidance
- Pregnancy outcome is influenced by prepregnancy and pregnant nutrition.
 - Maternal weight gain is important for adequate growth of the fetus.
 - Normal weight gain is around 30 lbs.
 - While once considered unnecessary for overweight women to gain during pregnancy, the current practice is for these women to gain up to 25 lbs.
 - When a woman is underweight prior to pregnancy, she needs to gain more than the recommended 30 lbs during pregnancy.
 - Women are concerned that gaining too much weight during pregnancy will lead to obesity. In a normal pregnancy, weight gain can be divided into the following:
 - (1) fetus—7 lbs
 - (2) placenta and amniotic fluid—4 lbs
 - (3) increased blood volume—4 lbs
 - (4) increase breast tissue—3 lbs
 - (5) the remainder is maternal stores
 - Distribution of weight gain throughout the pregnancy:
 - (1) first trimester: 2–5 lbs
 - (2) second and third trimesters: 1 lb per week
 - The food pyramid remains the basic guide for food intake for pregnant women.
 - It is recommended that women increase their caloric intake by 300 kcal in the second and third trimester.
 - Supplements: While a good diet can provide all the elements needed for a successful pregnancy, many physicians place their pregnant women on supplements to ensure the adequacy of the diet. Supplements often include
 - (1) multivitamins
 - (2) folic acid
 - (3) iron
 - (4) calcium

Nursing Intervention Alert

Remind the pregnant woman to take the iron supplement with juice as vitamin C will aid in absorption. Avoid taking iron with milk as it impairs absorption.

- Pica
 - Pica is the practice of eating nonfood substances such as laundry starch, dirt or clay, and ashes. It can also be taken to mean the ingestion of large quantities of nonnutritious dietary items such as ice. These practices may be supported by cultural beliefs and are often passed down through families. The purpose of eating the substance varies with the culture. For instance, some women eat laundry starch to “stiffen” the baby and make it stronger. In some cultures, ice is chewed to cut down on the food intake and keep the baby small to “make labor easier.” In addition to affecting general nutrition, iron-deficiency anemia is a common problem among women who practice pica.

—warning signs: The pregnant woman is given a list of “warning signs” that require immediate notification of the physician (see Table 6–7).

Table 6–7 Warning Signs of Pregnancy

| Symptom | Time of Occurrence | Possible Interpretations |
|--|--|---|
| Severe vomiting | Anytime, especially in the first and second trimesters | Hyperemesis gravidarum |
| Fever, chills | Anytime | Infection |
| Burning on urination | Anytime | Urinary tract infection |
| Abdominal cramping or pain | Anytime | Miscarriage, ectopic pregnancy, or abruptio placenta |
| Vaginal bleeding | Anytime | Miscarriage, ectopic pregnancy, abruptio placenta, or placenta previa |
| Sudden gush of fluid from the vagina, uterine contractions | Before 37 wks | Premature rupture of the membranes |
| Absence of fetal movement | Second and third trimesters | Fetal demise |
| Epigastric pain, muscular irritability, convulsions, headache, visual disturbances, or edema of face and hands | Second and third trimesters | Pregnancy-induced hypertension |

—minor complaints of pregnancy and their relief: As the woman progresses through pregnancy, the nurse will provide instructions about the common complaints of pregnancy and will offer suggestions that will make the pregnant woman more comfortable (see Table 6–8).

SUBSEQUENT PRENATAL VISITS

After the first prenatal visit, pregnant women are generally seen once a month until the eighth month of pregnancy, when the women are seen twice a month. During the ninth month of pregnancy, women are generally seen once a week until delivery.

During these prenatal visits, the health care team will continue their assessment and education of the pregnant woman. During each visit, the woman will be assessed for

- weight gain
- vital signs
- uterine size
- FHTs (after the first trimester)
- edema and the presence of other complications
- glucose and protein in urine
- psychosocial adaptation

Periodically throughout the pregnancy, additional laboratory tests may be ordered to monitor for the development of a high-risk pregnancy. Table 6–9 lists the tests that will be ordered.

INTRAPARTUM PERIOD

SIGNS OF IMPENDING LABOR

Prior to the onset of labor, there will be changes occurring in the pregnant woman that can indicate the approach of labor. As the day of labor approaches, the fetus will most often settle in a head down (vertex) position. The pregnant woman may also notice a decrease in fetal activity, which can be at least partly due to the tightness of the uterus for the term fetus.

Lightening: Lightening is the settling of the presenting part into the pelvis. In the woman who is pregnant for the first time, this may occur two weeks prior to delivery. In the multipara client, lightening may occur closer to or with the onset of labor.

- As a result of the uterus moving down into the pelvis, the woman will note that breathing is easier as the top of the fundus is no longer at the level of the xiphoid process.

Table 6–8 Minor Complaints of Pregnancy and Nursing Interventions

| Trimester | Complaint | Cause | Nursing Interventions |
|------------------|--|--|---|
| First | Nausea and vomiting (morning sickness) It can occur anytime during the day. It usually ends around the end of the first trimester. | Hormones—HCG | Consume small meals more often than thrice a day Eat dry crackers Do not mix liquids with solids Avoid fatty or highly seasoned foods Be aware that food/cooking odors may contribute to nausea |
| First | Breast tenderness | Estrogen and progesterone | Wear well-fitted bra |
| First and Third | Fatigue | Cause unknown Weight of pregnancy and nocturnal sleep deprivation may be contributing factors | Nap as needed |
| First and Third | Urinary frequency Nocturnal urination | Pressure of uterus on the bladder | Void as needed Decrease fluids as bedtime approaches |
| First | Ptyalism (excessive salivation) | Unknown | Suck hard candy Chew gum |
| Throughout | Leukorrhea | Hyperplasia of vagina and activity of cervical glands | Do not douche. Wear cotton-lined underpants to add to comfort |
| Second and third | Heartburn | Slowing of GI tract due to progesterone Pressure of growing uterus on stomach | Maintain good posture Do not lie down after meals Avoid spicy, fatty foods Eat small frequent meals Take antacids as recommended by physician |
| Second and third | Hemorrhoids and constipation | Pressure of uterus Slowing of peristalsis by progesterone | Use topical agents and sitz baths for hemorrhoids Increase fluid intake Add fiber to the diet Exercise Take stool softeners as recommended by physician |
| Second and third | Backache | Shift in center of gravity Lordosis Joint relaxation due to hormones | Maintain good posture Avoid high heels Select supportive shoes Do pelvic rock exercise Rest at frequent periods |
| Third | Leg cramps | Calcium/phosphorus imbalance | Take calcium supplements Dorsiflex foot when cramp occurs |
| Third | Postural hypotension/faintness Vena cava syndrome | Sudden changes in position Weight of uterus on ascending vena cava | Change positions slowly Prefer side-lying resting position Do not sleep on back |
| Third | Shortness of breath/dyspnea | Enlarging uterus | Maintain good posture Sleep in semi-Fowler's position |

Table 6–9 Additional Tests Ordered During Pregnancy

| Test | Source | Timing | Possible Findings |
|---------------------------------------|---|--|---|
| Alpha-fetoprotein (AFP) | Maternal blood or amniotic fluid | 16–18 wks of pregnancy | AFP is a screening test for neural tube defects and Down's syndrome. |
| Glucose tolerance test (GTT) | Maternal blood | End of second trimester or when risk of gestational diabetes is recognized | A 1-hr or a 3-hr GTT may be done to determine the presence of gestational diabetes. |
| Indirect Coombs test | Maternal blood | 28 wks gestation | In an Rh– mother, a positive indirect Coombs test could indicate the development of antibodies against the baby's blood. |
| Screening for group-B streptococcus | Vaginal and rectal swabs | 35–37 wks gestation | Presence of group-B streptococcus in the vagina is associated with higher incidences of neonatal morbidity and mortality. A positive swab will result in prophylactic, intravenous antibiotic administration to the pregnant woman. |
| Percutaneous umbilical blood sampling | Intrauterine umbilical cord blood | Second and third trimesters | This test allows for prenatal diagnosis of inherited blood disorders, karyotyping of the fetus, and other fetal problems. |
| Chorionic villi sampling | Placental structure | 8–10 wks | This sampling allows for evaluation of fetal chromosome makeup at an early date. |
| Amniocentesis | Amniotic fluid from the fetal sac through the maternal abdomen and uterus | After week 14 of pregnancy | Amniocentesis is used to identify genetic disorders. |

- With lightening, there will be greater pressure on the bladder and urinary frequency will occur.
- Because of the presence of the gravid uterus in the pelvis, there will be venous stasis affecting the lower extremities.

Braxton Hicks Contractions: Although Braxton Hicks contractions have been occurring throughout the pregnancy, they become more noticeable and occur more frequently as labor approaches.

- Often referred to as “false labor,” these contractions must be differentiated from “true labor” (see Table 6–10).
 - Many women will be seen in the hospital for “false labor” and may feel embarrassed when sent home. It is not unusual to have the woman return hours later in true labor.
- Bloody Show:* This refers to the loss of the mucous plug.
- Pink tinged secretions are expelled with the softening of the cervix in preparation for labor.

Table 6–10 Differences between False Labor and True Labor

| Sign | “False Labor” | “True Labor” |
|--|---|--|
| Contractions' regularity and frequency | Contractions are irregular and do not increase in frequency. | They are irregular in the beginning and then become more regular. The time between contractions shortens and contraction length increases while intensity heightens. |
| Location | They are felt in abdomen and groin. They may be uncomfortable and interfere with sleep. | They start in the back and extend to the abdomen. |
| Comfort measures | Walking usually lessens the discomfort. | Walking does not lessen the discomfort and may intensify the pain. |
| Differentiation | There is no change in cervix. | The cervix dilates and effaces. |

- Onset of labor usually begins within 24 hours of the passage of the bloody show.
- The amount is relatively small and not to be confused with vaginal bleeding or with the blood-tinged discharge that may follow a vaginal examination.

Burst of Energy: Considered to be part of the “nesting” phenomena, the pregnant woman will experience a burst of energy days before going into labor.

- It is often seen as a time when the woman will complete the nursery preparations and prepare the household for her absence during delivery and postpartum.
- Pregnant women who experience a “burst of energy” should be cautioned not to overdo. The woman would be wise to conserve much of this energy to release during the labor process.

Rupture of the membranes: It is not uncommon for the membranes to rupture prior to the onset of labor contractions. This is termed Spontaneous Rupture of the Membranes (SROM).

- If the woman is at term, labor contractions will usually begin within 24 hours.
- The pregnant woman may confuse SROM with urinary incontinence. There are several tests to determine if the vaginal discharge contains amniotic fluid:
 - The vaginal secretions can be tested with nitrazine paper. Since amniotic fluid is alkaline while most body fluids including urine are acidic, the presence of a blue or green result indicates amniotic fluid is present in the discharge.
 - A second method is to place a drop of discharge on a slide and allow it to dry. When viewed under a microscope, a fern appearance indicates the presence of amniotic fluid.
- If the presenting part is not engaged, the gush of fluid may cause the umbilical cord to rush into the vagina. As the presenting part engages, the umbilical cord may be compressed between the pelvis and the presenting part, obstructing blood flow from the placenta to the fetus. The first nursing action following rupture of the membranes should be to listen to FHTs. Immediate notification of the physician is required if there is any change in the FHTs.
- If the woman is at term when the membranes rupture, it is the goal of the medical team to deliver the fetus within 24 hours of the rupture. Delay in delivery may lead to the development of an infection.

THE FOUR Ps OF INTRAPARTUM

The nurse in the obstetrical unit will need a clear understanding of factors that influence labor and delivery. These factors are often referred to as “the four Ps of intrapartum”

which include the passenger, the passageway, the powers, and the psyche.

Passenger

Passenger refers to the fetus. Factors influencing the outcome of labor involving the passenger include the fetal lie, presentation, attitude, and position.

- Fetal lie—It compares the long axis of the fetus (the spinal column) to the long axis (spinal cord) of the mother.
 - Longitudinal lie: In this, the fetal spinal column is parallel to the maternal spinal column. The fetus in longitudinal lie may be either a cephalic or breech presentation.
 - Transverse lie: In this, the fetal spinal column is horizontal to the maternal spinal column. The fetus in transverse lie presents as a shoulder presentation. Vaginal delivery is impossible if this lie is maintained.
- Fetal presentation—It describes the part of the fetus that enters the maternal pelvis first. In a longitudinal lie, cephalic or breech presentation are the options. In a transverse lie, the fetal shoulder will enter the pelvis first.
 - Cephalic presentation describes an infant that presents itself head-first; it is the most common presentation.
 - Breech presentation describes an infant whose buttocks are the presenting part. Breech can further be divided into frank breech and complete breech:
 - Frank breech describes an infant whose hips are flexed and the knees are extended, placing the infant’s feet near the fetal head.
 - Complete breech describes an infant whose hips and knees are flexed. In addition to the buttocks being noted on vaginal examination, the feet may also be felt. If during the delivery process, the fetus extends one or both feet, the feet will precede the buttocks and the delivery will be described as a footling breech or double footling breech.
 - Shoulder presentation is when the fetus is lying across the maternal abdomen. The infant cannot be delivered in this position.
- Fetal attitude—It compares the relationship of fetal parts to each other.
 - Flexed: Most infants present in the flexed attitude. If the fetus is in a cephalic presentation, the flexed attitude makes the occiput of the fetal skull the presenting part. This provides the smallest diameter possible for delivery. It is the most common attitude of the fetus.
 - Extension: In the cephalic presentation, but with an extended attitude, the forehead will be the presenting part. The diameter of the skull will be greater than the occiput and vaginal delivery will be more difficult.
 - Hyperextended: This fetus has tilted its head back. In the cephalic presentation, the face becomes the presenting part. This presents a wide diameter of the skull. Vaginal delivery is very difficult. The baby will usually have noticeable bruising of the face following this delivery.

- **Fetal position**—It refers to the relationship between the presenting part of the fetus and the maternal pelvis. The maternal pelvis is divided into four quadrants described as left anterior (LA), right anterior (RA), left posterior (LP), and right posterior (RP). In the flexed fetus presenting in the vertex lie, the occiput becomes the presenting part and is described as O. In the hyperextended attitude, the chin or M (for mentum) is the presenting part. If the fetus is in breech position, the sacrum (S) is the presenting part. For a transverse fetus, the scapula (SC) is described as the presenting part. The position will be described with three letters: mother's left or right, fetal presentation, then maternal anterior or posterior. Thus, a designation of ROA indicates a fetus in vertex position, flexed (to put the crown of the head down) longitudinal lie. The fetal crown faces the mother's right anterior.

Passageway

Made up of the birth canal and the maternal pelvis, the passageway can influence the delivery in either a positive or a negative manner. During early prenatal visits, the physician will have determined the type and adequacy of the maternal pelvis. In evaluating the pelvis, the true pelvis or area between the ischial spines will be the smallest internal diameter that the baby must pass through. There are four basic pelvis types:

- **Gynecoid**—the typical female pelvis provides the widest diameter in the true pelvis making delivery easier.
- **Android**—about one-fourth of all women have this form of pelvis. It is similar to the male pelvis with a narrow internal diameter making vaginal delivery difficult or impossible.
- **Anthropoid**—another one-fourth of all women will have this oval-shaped pelvis.
- **Platypelloid**—relatively rare, this pelvis is described as flat.

During the later part of pregnancy, the physician will estimate whether *this* fetus can be delivered vaginally through this pelvis. If in doubt, an X-ray can confirm the adequacy of the pelvis or the presence of cephalopelvic disproportionment.

The birth canal is composed of the cervix, vagina, and introitus. The cervix will dilate and efface during the first stage of labor. The normally thick cervix thins (effaces) and dilates (opens) to allow the fetus to pass. When the mother is 100% effaced and 10 cm dilated, the woman enters the second stage of labor. In primiparas, the cervix effaces and then dilates. In the multipara woman, the cervix effaces and dilates together, shortening the first stage of labor.

Powers

Power involves voluntary and involuntary powers that expel the fetus.

- **Involuntary powers** are responsible for the dilation and effacement of the cervix. The fundus contracts causing the

cervix, normally about 3 cm long to be pulled up into the body of the uterus. As the cervix is pulled into the body of the uterus, the fetus is pushed down out of the uterus much like pushing your head through a turtleneck sweater. The contractions will be described in terms of frequency and duration, both of which increase as labor progresses.

- **Voluntary powers**, also called secondary powers, contribute to the delivery once the cervix is dilated or effaced. The conscious bearing down by the woman adds intraabdominal pressure to assist in expelling the fetus.

Psyche

The emotional state of the mother can affect the progress of labor. The woman who is able to relax with the contractions progresses faster than the woman who is fearful and resists the contractions, tightening nonlabor muscles. Many factors will affect the emotional state of the mother including the presence of a support person, childbirth preparation, and previous experiences. The nurse will work with the laboring woman to provide support and comfort measures. The environment should be controlled in terms of light, noise, and personnel. The nurse will need to provide information about the woman's labor progress to the laboring woman. During the latent period, the nurse can provide information on breathing that will assist the woman in managing her contractions better.

LABOR

Labor can be divided into four distinct stages.

First Stage of Labor

This stage begins with the onset of regular contractions and continues until the cervix is completely dilated and effaced. This is the longest stage of labor and can last for up to 20 hours in the primipara and still be considered normal. The first stage of labor is further broken down into three phases—latent, active, and transition (see Table 6–11).

Rupture of membranes

- On admission to the labor unit, the membranes may or may not be ruptured. The nurse can test for ruptured membranes by the following methods:
 - test the vaginal discharge with nitrazine paper. If the paper turns blue or green, the membranes are ruptured.
 - vaginal discharge can be spread on a slide and allowed to dry. When viewed under the microscope, a fern pattern will be observed.
- If not ruptured on admission, the membranes will rupture during labor. There is always the risk that the membrane rupture will cause the umbilical cord to precede the fetal presenting part and occlude the blood flow to the fetus. The first nursing activity following rupture of the membranes is always to take the FHTs.

Table 6–11 Phases of the First Stage of Labor

| Phases of the First Stage of Labor and Corresponding Cervical Dilation | Contractions and Fetal Descent | Client's Behavior | Nursing Interventions | Pain Control |
|--|--|--|--|---|
| <ul style="list-style-type: none"> Latent phase This phase extends from the onset of labor until the cervix is dilated to 3 cm. | <ul style="list-style-type: none"> Contractions are irregular, mild in degree, widely spaced, and lasting less than 45 sec. This is the longest phase of the first stage of labor. The mucous plug is lost. The fetal head may be floating. | <p>The client is</p> <ul style="list-style-type: none"> excited and talkative able to read and converse with others between contractions | <ul style="list-style-type: none"> Encourage the client to stay home as long as possible Suggest walking and diversional activities Admit to the labor unit and complete the paperwork Review breathing exercises Encourage to void q 2 hrs Change position frequently Take vital signs including FHT as per hospital routine, usually q 30 min during latent and active phases. The temperature can be taken every 4 hrs. Limit vaginal examinations to reduce the risk of contamination. | <p>Encourage the client to</p> <ul style="list-style-type: none"> relax effleurage walk follow breathing techniques |
| <ul style="list-style-type: none"> Active phase In this phase, there is 4–7-cm cervix dilation. | <ul style="list-style-type: none"> Contractions are regular. Their frequency increases to every 3–5 min. Duration of each contraction lasts 30–45 sec. The discharge increases slightly and consists of pink or bloody mucus. | <ul style="list-style-type: none"> Labor becomes more intense. The woman is concentrating on her contractions. She has a serious demeanor. She does not want to be left alone. She rests between contractions. | <ul style="list-style-type: none"> Continue monitoring P, R, BP, and FHT q 30 min. Encourage to void q 2 hrs. Encourage ambulation and position changes. Clear liquids orally. Assist with personal hygiene. | <ul style="list-style-type: none"> Ask client to follow breathing techniques Provide opioid analgesia Provide epidural analgesia |
| <ul style="list-style-type: none"> Transitional phase In this phase, there is 8 cm to complete cervix dilation | <ul style="list-style-type: none"> Contractions are strong. They occur 2–3 min apart, each lasting up to 90 sec. Discharge increases and is bloody. | <p>The client</p> <ul style="list-style-type: none"> is nauseated is irritable has limited ability to concentrate is concerned that she will lose control sleeps between contractions | <ul style="list-style-type: none"> The multipara may be moved to the delivery room. The primipara will continue in the labor room until dilation is complete. Vital signs are monitored every 15 min. Continue to encourage voiding to prevent a full bladder from slowing progress. Stay with the client. Prepare for birth. | <ul style="list-style-type: none"> Same as above |

- If membranes are ruptured for a prolonged period, there is a risk of an ascending infection. It is desirable to deliver the baby within 24 hours of rupture. If the membranes have been ruptured longer, monitor the woman's temperature closely. If attempts to hasten labor and delivery are unsuccessful, the physician may choose to perform a cesarean section.
- If the membranes do not rupture spontaneously, the physician may choose to rupture the membranes artificially. This is termed an amniotomy. An amniotomy may

also be performed to assist with the onset of labor or to speed its progress. The physician uses a small sterile device to reach into the vagina and break the membranes. The nurse will immediately take FHT before providing personal hygiene for the mother.

- When the membranes rupture, the fluid should be assessed for color and consistency. Normal amniotic fluid is straw-colored and may contain vernix caseosa. The normal volume is about 1000 ml at term. Excessive amniotic fluid, polyhydramnios, is associated with fetal abnormali-

ties including GI obstruction and anencephaly. Diminished amniotic fluid, oligohydramnios, is associated with renal anomalies in the fetus.

- If the amniotic fluid is greenish-brown in color, the fetus may have passed meconium in utero, a sign of fetal distress.

Fetal assessments during intrapartum

During labor, the FHTs can provide essential information about fetal well-being and the fetal response to labor. The FHTs can be monitored intermittently with a fetoscope or with a Doppler ultrasound transducer. If more detailed information about the fetus is important, a fetal heart monitor can be applied to allow for continuous electronic monitoring of the fetus and provide additional information about the maternal contractions.

- *External fetal monitoring:* Fetal monitoring can be performed externally using sensors or transducers. This method is noninvasive. These devices are secured to the mother's abdomen with belts and provide continuous tracings comparing the FHT to the maternal contraction. The sensor that monitors FHTs is placed directly only at the spot on the maternal abdomen where the FHTs are best heard. In the cephalic presentation, this is usually on the lower abdomen. This device may need to be reapplied during labor as the fetal position changes. The second sensor, measuring the contractions, is applied over the fundus.
- *Internal fetal monitoring:* For more accurate monitoring of the fetus and contractions, an internal fetal monitor may be placed. Prior to placing an internal monitor, the mother's membranes will need to be ruptured and the cervix dilated at least 2 cm. The internal monitor will consist of two devices. An intrauterine pressure catheter will be placed in the uterus to measure the internal uterine pressure of the maternal contractions. A fetal scalp electrode will be attached to the presenting part by means of a sharp wire that punctures the skin of the presenting part. This device is less affected by maternal movement than the external fetal monitoring device but because of its nature, promotes the introduction of bacteria.
 - Monitoring information to be noted include the baseline fetal heart rate. This information is acquired between uterine contractions. Normal FHT baseline is between 110–160 bpm.
 - Baseline variability can also be obtained through both external and internal monitoring. It is expected that there will be beat-to-beat variability as well as long-term variability during the course of labor. Loss of variability can be attributed to factors such as hypoxia, fetal anomalies, and narcotic administration.
 - Recurrent patterns in the FHTs include accelerations and decelerations. Accelerations (abrupt, short-term increases in the FHTs) are due to fetal movement and are usually considered a positive sign of fetal response.

Decelerations refer to the decreases in the FHTs and can be divided into three general classifications:

- Early decelerations are considered a normal response to pressure on the fetal head during contractions. These decelerations appear as a slightly delayed reverse mirror of the contraction. The heart rate drops slightly shortly after the beginning of the contraction and returns to baseline as the contraction ends.
- Late decelerations have a similar appearance as early decelerations except the fact that they are more delayed in their onset following the beginning of a contraction and return to baseline later, after the contraction ends. These decelerations are thought to be due to uretero-placental insufficiency and are a nonreassuring pattern.
- Variable decelerations are tracings showing the slowing of the fetal heart with no relation to the contraction. These decelerations are thought to be due to umbilical cord compression and are another nonreassuring pattern.

Anesthesia and analgesia for labor and delivery

Pain is a personal, subjective experience. Pain is a normal component of childbirth. Pain during labor can be attributed to pressure, stretching and distension of the pelvic organs and the birth canal as well as tissue ischemia of the uterine muscle as a result of the contraction. Many factors affect a woman's perception of labor pain and her response to it including cultural beliefs, childbirth preparation, anxiety, fetal position, and support system.

- Nonpharmacologic methods of pain relief are often based on the Gate Control method of pain relief. This theory explains that the pain message is carried to the brain by small diameter nerve fibers. Larger diameter nerve fibers carry other messages to the brain. In Gate Control, the "gate" allowing passage through the small diameter fibers is closed by sending messages through the larger diameter nerve fibers. Tactile stimulation is carried over these larger fibers so massage, either self-massage or massage by others, can be effective in reducing the pain messages that the brain receives.
 - Self-massage involves the technique called effleurage, a light, stroking touch done over the abdomen.
 - Counter pressure is particularly effective for back labor, when the fetal presenting part is in the posterior position.
 - Hydrotherapy also provides tactile stimulation. The laboring woman may find a shower or a warm bath relaxing.
 - Mental stimulation including imagery, soft music, and breathing techniques can be effective, reduce breath holding, and promote relaxation.
- Pharmacologic pain relief can be administered by many routes. Both analgesia and anesthesia may be used to assist the mother through the birth process. The analgesic can be systemic, regional, or local. With analgesic administration, there is always a concern that the fetus will be adversely affected during labor or after birth. In addition, improperly

used analgesics can slow or stop the progress of labor, especially during the latent period. Regional analgesics may hamper the woman's ability to push during the second stage of labor. On the other hand, a mother who is relaxed and comfortable during labor may progress at a more rapid rate as she allows her muscles to contract without resistance.

—Systemic analgesia and anesthesia

- Parenteral analgesia includes intravenous administration of opioids including fentanyl (Sublimaze), butorphanol (Stadol), and nalbuphine (Nubain). These drugs cross the placenta and should not be administered when delivery is imminent as it may cause respiratory depression in the newborn. The nurse should always have naloxone (Narcan) available in case opioid reversal is necessary. Promethazine (Phenergan) may be added as an adjunctive drug to the opioid serving as an antiemetic.
- General anesthesia is rarely used in obstetrics. It may be utilized when immediate cesarean delivery is required in emergency situations since it provides more immediate access to the uterus. Respiratory depression may develop in the mother and/or the fetus, and with some general anesthetics, uterine relaxation may predispose the woman to postpartum hemorrhage.

—Regional analgesia: It refers to temporary loss of sensation and usually involves nerve blocks. Typical drugs used for the blocks include lidocaine (Xylocaine), bupivacaine (Marcaine), and other “caines.” The advantage of regional analgesia is that the drug will have little or no effect on the fetus.

- Epidural blocks involve the threading of a catheter into the epidural space at the L5–S1 level and an anesthetic agent being injected. In addition to difficulty in moving lower extremities and potential urinary retention, the client will feel little urge to push.
- Spinal block has local anesthetic agents injected into the cerebral spinal fluid. Spinal blocks are used primarily for cesarean sections.

—Local analgesia: It is used during the second stage of labor to reduce the pain of delivery on the perineum and may be used for the episiotomy. The fetus will be minimally affected by local analgesia.

- Pudendal nerve block is used to relieve pain from the vulva and perineum. It does not relieve discomfort from labor contractions.

Second Stage of Labor

The second stage of labor begins with complete dilation and effacement and ends with the delivery of the fetus.

- The contractions are intense coming every 2–3 minutes and lasting up to 90 seconds. It is important that a rest period between contractions occur so that oxygenated blood can be delivered to the fetus.

- The woman will have the urge to bear down, increasing intra-abdominal pressure to help expel the fetus. Some women experience the urge to push prior to complete dilation and effacement. Other women may mistakenly believe that early pushing will shorten labor. The laboring client should use breathing techniques to resist the urge to push prior to complete dilation and effacement. Failure to resist can lead to a bruised fetus and maternal cervix.
- An episiotomy may be performed to prevent tearing of the perineum and to shorten the second stage of labor. An episiotomy is a surgical incision into the vagina and perineum to widen the birth outlet.

The cardinal movements of delivery

During labor and delivery, the fetus must move through the birth canal. By changing positions during the course of labor and delivery, the fetus attempts to maneuver through the birth canal. These steps occur in order and are

- engagement, descent, and flexion. These three movements occur almost simultaneously. The head flexes presenting the occiput, the fetus descends into the true pelvis, and engagement occurs.
- internal rotation. As the fetal head moves through the maternal pelvis, this rotation aligns the smallest diameter of the presenting part with the largest diameter of the maternal pelvis.
- extension. Once the head is through the pelvis, the fetus will extend his neck, and the head is delivered.
- external rotation. The next largest diameter of the fetus, the shoulder, is now in the pelvis. The fetus will turn again to slide the front shoulder out from the pelvis. With the fetal head outside the maternal body, observers can see this rotation.
- expulsion. As soon as the shoulders have passed the pelvis, the rest of the body will quickly slide through. This movement will happen quickly as the diameter of the body is much less than that which has already passed through the maternal pelvis.

Nursing care during the second stage of labor

The nurse's role of monitoring and supporting the woman continues in the second stage of labor. Vital signs, FHTs, and contraction assessments are monitored every 5 minutes. The client is positioned to promote delivery. Special birthing beds are used in many hospitals that allow a variety of positions for delivery. Positions that utilize gravity are beneficial. If the client will be placed in lithotomy position for delivery, it is important that both legs are placed in and removed from the stirrups simultaneously.

- The nurse and the client's support person will be assisting the laboring woman with her pushing technique. The nurse will need to provide simple, explicit instructions repeatedly as the woman's concentration is hampered. Breathing techniques will assist with the effectiveness of pushing and promote oxygenation.

- It is important that the laboring woman be kept informed of her progress and encouraged in her efforts. The support person may also need encouragement at this time.
- With delivery of the head, the nurse or physician will suction the oral cavity of the fetus.
- With full delivery, the physician or the infant's father will cut the umbilical cord.
- Until the cord is cut, the infant must be held at the level of the placenta to prevent a shift in the blood dynamics. The infant may be placed on the mother's abdomen at this time.
- Stimulation of infant respiration is a priority. A second priority is to warm the baby. The infant is wet and the room may be slightly cool (for the mother's and health care workers' comfort). Immediately wrap the baby in a warm towel and briskly rub. This will assist in drying and stimulate respiration at the same time.
- Allow the mother and father to see and touch their infant.
- The infant is usually placed in an over-bed warmer in mother's sight to continue the warming and stimulation. At this time, the nurse or the pediatrician will do a quick assessment, checking vital signs and looking for signs of distress, birth injuries, and birth defects. If the infant's condition allows, the baby should be returned to the parents as soon as possible.

Third Stage of Labor

The third stage of labor is termed “the stage of the placenta.” Beginning with the birth of the baby, it ends with the delivery of the placenta.

- Immediately after the birth of the baby, the uterus can be palpated just below the umbilicus as a round, firm mass.
- After a short rest, contractions begin again.
- The uterus changes to a discoid shape.
- Usually within 5 minutes of the delivery of the baby, the placenta will separate.
- Separation of the placenta can be recognized by the following symptoms:
 - The umbilical cord protruding from the vagina will lengthen.
 - There will be a sudden increase in vaginal bleeding.
- Traction should never be applied to the umbilical cord to hasten delivery as it may cause the uterus to invert, a condition termed uterine prolapse. This will constitute a medical emergency that may have fatal consequences for the mother.

The placenta can separate first from the center and then to the edges or from the edges to the center. The method of separation will determine the appearance of the placenta at delivery. If the separation began at the center, the placenta will present with the fetal side of the placenta first. The fetal membranes give the placenta a shiny appearance; hence, this delivery is termed “shiny” shultz. If the placental separation begins at the edge, the placenta tends to deliver with the

maternal side of the placenta first. This side is red and beefy in appearance and is termed a “dirty” duncan delivery. The physician will inspect the delivered placenta to determine its completeness. Retention of placenta pieces will inhibit normal involution and lead to postpartal hemorrhage.

Once the placenta is delivered, the episiotomy and any perineal lacerations will be repaired. Oxytocins are usually administered intravenously or intramuscularly to promote uterine contraction and decrease uterine bleeding.

The nurse will remove the client from the stirrups (if used) and the client will be transferred to a recovery bed. The fourth stage of labor is about to begin.

Fourth Stage of Labor

The immediate postpartal period is often termed “the fourth stage of labor.” The woman, her support person, and the baby (if conditions allow) will be placed in a recovery room. The room will provide a degree of privacy for the new family while allowing the nurse to monitor the condition of the mother and infant. Immediately on arrival into the recovery room, the mother's vital signs will be taken. Her fundus and lochia will be assessed. Pericare will be provided. The mother will be given a clean gown and will appreciate a warmed blanket as chills and shaking are common. The woman will need assurance that this is a normal occurrence.

The nurse will continue to assess vital signs, fundus location and consistency, and amount and characteristics of the lochia every 15 minutes for the first hour, then if findings are normal, changing to every 30 minutes the next hour, and then hourly for the remainder of the recovery period.

Between assessments, the room should be dimly lit to allow the infant to open his or her eyes. This will be a quiet time for the new family to begin bonding. The mother may initiate breast-feeding if desired. This is an excellent time for the initial attempt at breast-feeding as the infant is awake and alert. After a short period of time, the baby may be transferred to the nursery to allow for a more thorough assessment and initiation of nursery procedures. The mother may request food at this time or the parents may want to notify other family members by phone. Some new mothers may choose to sleep during this short recovery period.

CESAREAN DELIVERY

Cesarean section refers to the surgical delivery of the infant. It can be a planned or an unexpected event. There are many factors that may lead to a cesarean delivery including the following:

- maternal factors
 - cephalopelvic disproportionment: It is a condition where the fetal head cannot be delivered through the maternal pelvis due to size discrepancies.
 - active genital herpes: Vaginal delivery may spread the infection to the newborn.

- failed induction: This refers to the case when the attempt to induce labor is unsuccessful and delivery is necessary.
- previous cesarean sections: It is no longer an exclusive factor. Previous cesareans, which involved a classic incision, are still considered to require a repeat cesarean.
- fetal factors
 - multiple gestation
 - transverse fetal lie
 - fetal distress
 - breech presentations
 - fetal anomalies such as hydrocephalus
- placental factors
 - placenta previa
 - umbilical cord prolapse
 - premature separation of the placenta

Emergency or unexpected cesarean deliveries can be extremely stressful for the woman and her family. There is the concern for the well-being of the fetus. In addition, the woman may feel that she failed in her womanly role of fetal delivery. The

woman and her family will need to understand the reason for the cesarean delivery. They will need to be kept informed on the status of the fetus and the mother. The mother will need a chance in the postpartal period to reconcile her planned delivery to the actual event. This is usually accomplished by describing her delivery experience many times over the postpartal period. The nurse should assure the client that she did a good job in delivering her baby. In nonemergency cesarean deliveries, the father or support person may be allowed to accompany the woman, which will contribute to a more pleasant delivery experience. Regional or general anesthetics may be selected dependent upon the necessity of rapid access to the fetus.

Following a cesarean delivery, the mother will go to the recovery room (OB or surgical) and will be monitored during the recovery period. Like all postpartal women, the woman will need to have her vital signs, fundus, and lochia monitored along with her surgical incision. The abdomen will be very tender, so assessing the fundus is done gently and from the side but must still be monitored. Infants born by cesarean delivery are at greater risk for respiratory distress in the recovery period, so they may be immediately transferred to the newborn or high-risk nursery.

POSTPARTUM PERIOD

INVOLUTION

With the delivery of the fetus and placenta, the body of the woman begins the process of involution, returning to the nonpregnant state. All systems of the body are included in the involution process although the changes in the reproductive system are the greatest.

Nursing Assessments

Vital signs often may indicate the onset of postpartal complications:

- temperature above 100.4°F after the first 24 hours may indicate infection
- elevated pulse and blood pressure are associated with hemorrhage
- elevated blood pressure may indicate pregnancy-induced hypertension
- clients may develop orthostatic hypotension on arising after delivery

BUBBLE-HEB is a mnemonic used to remember the appropriate assessment of the postpartal client, where

- B = breast
- U = uterus
- B = bladder

- B = bowel
- L = lochia
- E = episiotomy
- H = Homan's Sign
- E = emotional status
- B = bonding

Nursing Interventions

Nursing interventions during the postpartum period are aimed at promoting the involution, providing comfort, and teaching the woman to care for herself and her infant.

Uterus

- Gentle fundal massage promotes contraction of the uterus. Overmassage can cause a boggy fundus.
- Oxytocins may be ordered to promote involution: oxytocin (Pitocin), methylergonovine maleate (Methergine), and ergonovine maleate (Ergotrate).
 - Methergine and ergonovine promote the contraction of the cervix as well as the fundus and are therefore never given during labor.

Bladder

- Promote emptying the bladder every 2 hours while awake

Table 6–12 Changes in the Various Structures/Systems in the Postpartum Period

| Structure/ System | Postpartal Activity | Variations from Normal |
|----------------------|--|--|
| Uterus | <p>There is a contraction of the uterine muscle resulting in descending level of the fundus</p> <ul style="list-style-type: none"> • Immediately after delivery of the placenta, the fundus will be located midway between the symphysis pubis and the umbilicus • By day 1 postpartum, the fundus will have risen back to the level of the umbilicus • The fundus will descend 1 fingerbreadth a day until it is no longer palpable behind the symphysis pubis <p>The contractions of the uterus will be felt by the new mother and are called “afterbirth pain.” These are felt more fully</p> <ul style="list-style-type: none"> • in the multipara • following delivery of a large baby or multiple fetuses • in the breast-feeding mother | <p>When the fundus is higher in the abdomen than expected, bleeding will increase. Nursing activities will be aimed at promoting uterine contraction</p> <ul style="list-style-type: none"> • The woman should be encouraged to void as a full bladder will prevent contraction of the uterus • While supporting the uterine body, the nurse will massage the fundus. Overmassage of the fundus can lead to a boggy fundus • Breast-feeding the baby will also promote uterine contraction <p>Retained placenta segments will prevent uterine contraction; the fundus will be described as “boggy” and bleeding will be heavier than expected</p> |
| Lochia | <p>The bloody discharge following delivery is termed lochia. Lochia consists of blood, shed decidua, white blood cells as well as other debris. The discharge follows a predictable pattern:</p> <ul style="list-style-type: none"> • Lochia rubra—dark red, bloody discharge with a musty, earthy smell occurs on days 1–3 postpartum • Lochia serosa—pink or brownish discharge that occurs on days 4–10 • Lochia alba—whitish discharge that persists typically for a couple of weeks but may persist for up to 6 wks <p>Lochia often pools in the uterus when the mother is in bed. The first few times out of bed, the mother may note a sudden “gush” of lochia when she gets up</p> <p>Menstruation usually resumes about the eighth week postpartum for the non—breast-feeding mother and 12 wks for the breast-feeding mother. This first cycle is usually anovulatory</p> | <ul style="list-style-type: none"> • Reverting to an earlier stage of lochial discharge can be a negative finding usually indicating the mother needs to reduce her activity level • Lochia with a foul smell can indicate uterine infection |
| Cervix | <p>By the end of the first week postpartum, the cervix will have closed so that only a fingertip can be admitted</p> | <p>Continuous oozing of bright red blood can indicate a cervical laceration</p> |
| Vagina | <p>The vagina reverts to the nonpregnant state by 2 wks</p> <p>For several weeks following delivery, the vagina will have decreased lubrication due to low estrogen levels. When intercourse resumes, the woman may want to use a water-soluble lubricant for comfort</p> | |
| Perineum | <p>Labia may be swollen</p> <p>Episiotomy remains intact</p> | <p>Hematoma may form in the labia during the postpartal period</p> <p>Episiotomy may separate or become infected</p> <p>Hemorrhoids may be present due to pushing during delivery</p> |
| Breasts | <p>Prior to the birth of the baby, the woman may be able to express a small amount of a colorless liquid. With delivery, the volume will increase slightly. Milk production is dependent on the release of prolactin from the pituitary gland</p> <ul style="list-style-type: none"> • The first milk is colostrum, which is rich in antibodies • By day 3, engorgement will occur where the breasts fill with milk. Breast milk is thin and appears bluish in color • By day 5–6, the let-down reflex will release milk when it is time to nurse the infant and the engorgement will diminish | <p>Cracks and fissures in the nipples are not uncommon in the breast-feeding mother, usually thought to be the result of an infant who latches incorrectly</p> <ul style="list-style-type: none"> • The nipples can be protected by assisting the infant to latch on correctly • Colostrum can be expressed and spread on the nipple as a protectant |

(continued on next page)

Table 6–12 (continued from previous page)

| Structure/System | Postpartal Activity | Variations from Normal |
|-----------------------|--|--|
| Breasts | <p>Early and regular stimulation of the breasts by nursing the infant will promote milk production and let-down which will ease engorgement</p> <p>For the non–breast-feeding mother, care should be taken to avoid breast stimulation, which will increase milk production and breast discomfort. Instructions for the non-lactating mother would include:</p> <ul style="list-style-type: none"> • Wear a tight, well-fitting bra; it will suppress milk production • Avoid stimulating the breast. Do not handle the nipples and do not express the milk that develops • Stand in the shower so that water does not stimulate the breasts • For discomfort, the non–breast-feeding mother may be given NSAIDS and ice packs. Medications which suppress lactation are not usually given | <ul style="list-style-type: none"> • The mother should wash her hands before handling the breasts and feeding the infant to reduce the risk of infection <p>Mastitis—It is the infection of the breast tissue</p> <ul style="list-style-type: none"> • Causative factors include crackled nipples and lowered maternal immune levels • Symptoms include a hard, reddened, engorged area of the breast, fever, and other systemic symptoms of infection • Treatment includes antibiotics and antipyretics. Heat may be used to help milk let-down and ice may be used for comfort <p>In most cases, breast-feeding will be continued despite the presence of mastitis as keeping the breast empty helps to prevent the growth of microorganisms</p> |
| Cardiovascular system | <p>High blood volume is no longer needed so fluid is eliminated by diuresis</p> <ul style="list-style-type: none"> • Blood pressure remains consistent with pregnancy • Heart rate is usually slow (50–70 bpm) as the workload of the body has decreased • Homan's sign (test for thrombophlebitis) should be negative • An elevated WBC count may be a normal finding due to labor preparations by the body | <ul style="list-style-type: none"> • For the client with cardiac disease, this period of diuresis places the client at risk for cardiac failure • PIH can occur up to 48 hrs after delivery • Tachycardia is associated with excessive blood loss • Because the platelet count was high as the body prepared for labor, the client may be at risk for thrombophlebitis |
| Abdomen | <p>Immediately after delivery, the skin will appear loose and flabby. Striae (stretch marks), which were red streaks during pregnancy, will fade to silver</p> | |
| Urinary bladder | <p>Diuresis will occur as the blood volume decreases to the nonpregnant state</p> <ul style="list-style-type: none"> • Urinary output in the first 24 hrs may exceed 2000 ml | <ul style="list-style-type: none"> • Decreased bladder sensation and bladder tone makes the woman susceptible to a UTI during the postpartal period |
| Metabolism | <p>The client will be hungry and thirsty after birth</p> <ul style="list-style-type: none"> • The breast-feeding woman will need to increase her diet by 500 kcal/d and should have a fluid intake of at least 2000 ml/d | |
| Bowel function | <ul style="list-style-type: none"> • Normal bowel function returns by 2–3 wks postpartum • The client with an episiotomy may fear the bowel movement • Stool softeners may be ordered | <ul style="list-style-type: none"> • No suppositories are given if client had a third- or fourth-degree laceration |

Clinical Alert

A full bladder will push the uterus up in the pelvis and interfere with contraction causing heavier lochia. Following labor and delivery, the woman may be less aware of a full bladder and needs to be reminded to void regularly.

Bowel

- Promote early ambulation
- Increase fluid and fiber in the diet

Comfort

- Episiotomy
 - Apply ice pack to perineum (20 minutes on/10 minutes off) × 24 hours.
 - Encourage sitz bath up to thrice a day beginning at 12 hours postpartum.
 - Pericare
- After voiding or bowel elimination, spray the perineum with warm water.
- Apply clean peri-pad from front to back.
 - Apply witch hazel or local anesthetics to the perineum.

- Teach the woman to contract her buttocks before sitting to reduce pressure on the perineum.
- After-birth pains and cesarean section incisional pain
 - Give ordered acetaminophen, NSAIDs, and opioids for pain control.
 - If mother is breast-feeding, encourage nursing the baby before taking opioids.

EMOTIONAL CHANGES—MATERNAL ADJUSTMENT

The typical emotional changes that postpartum client experiences can be divided into three sequential phases:

- taking in
 - occurs for the first 2 days postpartum
 - during this period, the mother is passive and preoccupied with her own needs
 - the woman needs to discuss the labor and delivery experience to assist in the integration of the planned experience with the reality of labor and delivery
 - nurses need to “mother” the mother so that she can move into the taking-hold phase
- taking hold
 - occurs in the second and third days postpartum
 - the mother is still concerned with her body functions
 - this is an excellent time for teaching about caring for herself and her infant
 - mood swings may be evident
- letting-go phase
 - beginning on about the fourth day of postpartum and proceeds through the postpartum period
 - the mother “lets go” of her old concept of herself to acquire the self-concept of being the mother of this infant
 - wants to be independent in caring for her infant

BONDING

- Bonding occurs most readily in the immediate postpartum period, but can also occur later.
- It is facilitated by close contact with the infant.

- It is facilitated by the infant opening his eyes and looking at the mother (dim the lights).
- Nursing assessments that indicate bonding is occurring include the following behaviors:
 - The mother begins exploring her infant with the fingertips, progress to the whole hand exploration, and finally enfolding the newborn in her arms.
 - She holds the infant face-to-face at a short distance from her face (*en face* position).
 - She speaks to the infant in a high-pitched soft tone.
- The father will also bond to the infant and should display interest in the infant.

POSTPARTUM BLUES

- This refers to a temporary mood depression that is fairly common in the early postpartum period.
- It is different from postpartum psychosis or postpartum depression, a serious emotional condition that occurs in some postpartum women.

CLIENT TEACHING

Prior to discharge from the maternity unit, the new mother will need information on how to take care of herself and her infant. Instructions should include:

- Maternal care
 - involution
 - breast care
 - resuming sexual relations
 - birth control
 - general health
- Newborn care
 - bathing and clothing
 - cord care
 - nutrition
 - breast-feeding
 - bottle feeding
 - immunizations and proper baby care
 - car safety

NEWBORN CARE

NEWBORN TRANSITION

The delivery of the newborn begins a period of transition for the infant. While in utero, the fetus has lived a parasitic lifestyle, totally dependent upon the maternal body for nutrients, oxygen, and even waste disposal. Suddenly with birth, the newborn must take over these functions. Health care

workers monitor this transition beginning with the Apgar score.

Apgar Score

The newborn is assigned an Apgar score by the physician or the nurse at the delivery. Apgar scoring is performed at 1 minute and 5 minutes after birth. The score describes the success or

difficulty with the transition. Five areas are scored and each area is scored as a 0, 1, or 2. The areas evaluated on the Apgar are

- A: activity (or muscle tone)
- P: pulse (or heart rate)
- G: grimace (reflex irritability)
- A: appearance (or skin color)
- R: respiratory effort

Since there are five areas evaluated and each area has a possible score of 0, 1, or 2, newborns can score anywhere from 0 to 10. The higher the score, the better the transition for the baby. Scores between 8 and 10 indicate a good extrauterine transition, while scores in the lower range indicate the newborn is struggling with the transition process and resuscitation efforts are needed.

Delivery Room Activities

As soon as the infant is delivered and the cord is clamped, he or she will be placed in an over-bed warmer. This device provides external heat while the infant is dried and evaluated. Two identification bands are placed on the infant with corresponding identification applied to the wrist of the mother and her significant other. In the over-bed warmer, an infant requiring resuscitation can receive the necessary treatment while avoiding the loss of body heat. An infant who has made a good transition can be monitored while the placenta is being delivered. This infant can then be wrapped in a warm blanket and given to the new mother for bonding. Some mothers choose to breast-feed the infant at this time. If the mother has received a minimum amount of analgesia, the infant will be awake, alert, and eager to feed. This period is termed the *first period of reactivity*.

Parent–Infant Bonding

Early parent–infant contact enhances the attachment process called bonding. Immediately after birth and the delivery of the placenta is a good time to promote bonding. The infant is awake and alert and the parents and infant can be provided time to become acquainted. Eye prophylaxis for the infant should be postponed until after this initial bonding period has occurred. The establishment of eye contact between parent and infant, a positive event promoting bonding, is enhanced by the *en face* position. The newborn's eyes are unaccustomed to bright lights and the infant will open his or her eyes more fully when the room is dimly lit. Private time should be provided to the new family. The new mother may choose to initiate breast-feeding, if she has not already, and the nurse will need to assist the new mother and baby in this activity. The new parent will initiate tactile contact with the fingertip touch but will progress to whole hand stroking followed by whole palm enclosing as the parent–baby relationship grows.

Eye Prophylaxis

Eye prophylaxis with an antimicrobial agent is required in all states in the United States to prevent the development of ophthalmia neonatorum. Ophthalmia neonatorum is an

infection of the eye caused by the gonorrheal organism transmitted to the infant during the birth process. If untreated, ophthalmia neonatorum can result in blindness. Treatment consists of the instillation of silver nitrate, erythromycin, or other antimicrobials as prescribed by hospital protocols. This treatment may be delayed for up to 1 hour following birth to allow for parent–infant interaction.

Newborn Nursery Admission

Practice Alert

Gloves are always worn when caring for a newborn until the first bath. This protects the health care worker from blood and body fluid exposure. The vernix, amniotic fluid, and bloody secretions are removed with the first bath.

On admission to the newborn nursery, all infants must have a complete physical assessment by the nurse. This assessment will continue to evaluate the child's transition as well as determine congenital problems and other conditions that can affect the infant's well-being. This assessment should be performed in a well-lit, distraction-free area. The baby will need to be observed without clothing so an external source of heat, such as an over-bed warmer, is necessary. The assessment should be organized and usually begins with the measurement of vital signs, height, and weight.

ASSESSMENT OF GESTATIONAL AGE

Ballard Score

The Ballard Score is an assessment tool that allows postnatal assessment of gestational age. This assessment is important to allow for monitoring for age-related problems. The Ballard Score should be performed within the first 24 hours after birth. It has two primary components: physical characteristics and neuromuscular maturation. The two areas together provide a maximum score of 50, which equates to a gestational age of 44 weeks+. The "New Ballard Score" has been updated to provide more accurate assessment of the very preterm infant.

PHYSICAL ASSESSMENT

General Appearance

Prior to the hands-on assessment, the nurse should do a general visual assessment noting, in particular, the respiratory effort. The infant who is struggling with respiration needs the assessment to be as invasion-free as possible to limit the stress on his body.

Table 6–13 Physical Assessment of a Newborn

| Assessment Area | Normal Findings | Findings to Report |
|---|--|--|
| Skin <ul style="list-style-type: none"> • Color • Normal skin variations | <ul style="list-style-type: none"> • The skin is either all pink or the body is pink with blue extremities (acrocyanosis). • Vernix caseosa (white cheesy covering of the skin) in varying amounts will be observed at birth. This material has a protective quality. It will be removed during the initial bath or by being rubbed onto clothing and blankets. It is not necessary to remove it forcefully. • Mongolian spot: A dark bluish discoloration seen on the buttocks of dark-skinned individuals. This spot will fade by the age of 2 yrs. • Milia: Obstructed sebaceous glands seen on the face, most commonly on the nose. These white cysts should be left alone. • Lanugo: Fine, downy hair seen on the less mature newborn. • Erythema toxicum (newborn rash): White or yellow pustules with a red base. These may be widespread or limited. The rash comes and goes quickly appearing shortly after birth and continuing until about 5 d of life. • Mottling: Often associated with chilling, the skin color will appear patchy. • Petechiae: Small hemorrhages most commonly due to the pressures of labor and delivery. • Ecccymoses: Bruises, usually from forceps. • Birthmarks: Birthmarks vary widely in appearance and location. • Telangiectatic nevi: More commonly known as “stork bites,” they appear as flat, pink or red spots on the eyelids, between the eyes, under the nares, and at the nape of the neck. They generally fade by the age of 2 yrs. | <ul style="list-style-type: none"> • Generalized or circumoral cyanosis, pallor, dusky red, or jaundiced at birth or shortly thereafter. • Skin lesions: May be caused by forceps or internal scalp monitors. These sites should be documented and watched for signs of infection. |
| Vital Signs <ul style="list-style-type: none"> • Temperature • Pulse • Respiration | <ul style="list-style-type: none"> • The initial method of assessing temperature may be with a rectal thermometer. In addition to providing a close approximation of core body temperature, this method assesses rectal patency. Normal rectal temperature is 97.7–99.7°F. • Axillary temperature ranges from 97.7–98.6°F. • Apical pulse rate is between 100 and 160. • Check peripheral pulses. • Normal respiration is 30–60/min. The diaphragm is the major muscle of respiration. For a short period after birth, crackles and other sounds of moisture may be heard in the chest as the amniotic fluid present in the lungs is absorbed by the body. | <ul style="list-style-type: none"> • Subnormal temperatures can result from excessive heat loss during the delivery or nursery experience and may result in cold stress. Cold stress can lead to respiratory distress, jaundice, metabolic acidosis, and hypoglycemia. • Unlike an older infant, newborns most frequently display elevated temperatures due to an overheated environment, excessive clothing, or dehydration. • Report bradycardia, tachycardia, irregularity, murmurs, and absent or peripheral pulses. • Report signs of respiratory distress, nasal flaring, grunting, gasping, and seesaw respirations. In addition, report apneic periods lasting longer than 15 sec, retractions, and bowel sounds heard in the chest. |
| Body Measurements <ul style="list-style-type: none"> • Length • Weight | <ul style="list-style-type: none"> • Measure from top of head to heel. Normal length is 19–21 in. (48–53 cm). • Normal weight is 2500–4000 g. The infant will lose approximately 10% of their body weight in the first 3 d of life and then start to gain. This weight loss is due to loss of maternal hormones, urination, and defecation. | <ul style="list-style-type: none"> • Variations under the normal range could indicate intrauterine growth retardate (IUGR), gestational age discrepancies, and chromosomal abnormalities. • Variations include small for gestational age (SGA) and large for gestational age (LGA). Both conditions can indicate predelivery conditions that might affect the newborn’s well-being. |

(continued on next page)

Table 6–13 (continued from previous page)

| Assessment Area | Normal Findings | Findings to Report |
|---|---|--|
| <ul style="list-style-type: none"> Blink Reflex Discharge Pupils Eyebrows | <ul style="list-style-type: none"> Present Normally there is no discharge from the eyes. When a light is shined into the pupil, a round red or brownish red reflection can be seen. This is termed as the red reflex and is a visualization of the retina. Two distinct eyebrows should be present. | <ul style="list-style-type: none"> The eyes may appear swollen and have a slight discharge. This is attributed to the eye prophylaxis and is termed chemical conjunctivitis. Absence of the red reflex could indicate congenital cataracts and should be reported to the physician. The presence of a single connected midline eyebrow can indicate certain chromosomal abnormalities. |
| Ears <ul style="list-style-type: none"> Placement Appearance | <ul style="list-style-type: none"> Draw an imaginary line from the inner canthus to the outer canthus of the eye and straight back toward the ear. The top of the auricle (helix) should be above this imaginary line. Observe for the normal shape of the auricle. The auricle should feel firm and return to its normal position when folded. This indicates a firm cartilage. Check for the presence of an ear canal in both ears. | <ul style="list-style-type: none"> Low-set ears are associated with renal disorders and mental retardation. Ear tags (these may be removed during the nursery stay). Extra skin usually located in front of the ear. Very soft cartilage in the auricle is associated with prematurity. Bruises are not uncommon around the ear, especially in forceps delivery. Be sure to look for bruises or scratches behind the ear. |
| Nose | <ul style="list-style-type: none"> The nose should be midline and free of discharge. Infants are obligate nasal breathers. If anything occludes the nares, the baby will stop breathing. The sneezing reflex is present and assists in clearing the airway. It does not indicate the newborn “is catching a cold.” | <ul style="list-style-type: none"> Snuffles (copious discharge) is associated with congenital syphilis. Choanal atresia is a membrane or bony development that occludes the nares. It can be unilateral or bilateral. If bilateral, when the infant falls asleep, breathing will cease. Maintain the mouth in the open position until the atresia can be surgically corrected. |
| Mouth <ul style="list-style-type: none"> Appearance Reflexes Tongue and gums Palate | <ul style="list-style-type: none"> It is pink in color. It has a symmetrical movement. Sucking and rooting reflexes are present at birth. A short lingual frenulum gives the appearance of being “tongue tied.” Palate is intact. Epstein’s pearls are small white cysts located on the hard palate of newborns. These disappear a few weeks after birth. | <ul style="list-style-type: none"> Transient circumoral cyanosis is not uncommon but may be associated with respiratory distress or hypothermia. Asymmetrical movement of the mouth is associated with facial paralysis often due to the placement of the forceps. This can be a permanent or temporary damage. The tongue may seem too large for the infant’s mouth and protrude. This is associated with selected chromosomal abnormalities including Down’s syndrome. On occasion, a newborn is born with a tooth in the lower gum line. This is usually not the deciduous tooth, but a third tooth for that position. It is often removed. Report cleft, unilateral, or bilateral, soft and hard palates. |
| Neck | <ul style="list-style-type: none"> Neck is short. | <ul style="list-style-type: none"> Webbed neck is associated with Turner’s syndrome. |
| Chest <ul style="list-style-type: none"> Appearance | <ul style="list-style-type: none"> Chest is round in appearance. | |

(continued on next page)

Table 6–13 (continued from previous page)

| Assessment Area | Normal Findings | Findings to Report |
|-----------------|---|---|
| Anus | <ul style="list-style-type: none"> Anus is intact. A rectal thermometer can be inserted with ease. Infant should pass meconium stool within 24 hrs of birth. | <ul style="list-style-type: none"> Report imperforate anus in which there is no connection between the anus and the rectum, varying from a membrane separation to a significant distance between the two. Failure to pass meconium usually indicates GI obstruction disorders including Hirschsprung's disease (lack of sympathetic nervous system connection to the intestines). |
| Extremities | <ul style="list-style-type: none"> Infant should move all extremities equally. There are 5 fingers and 5 toes on each hand and foot. Equal in number thigh skin folds and equal knee height is expected. No click is heard or felt when hips are abducted. | <ul style="list-style-type: none"> Failure to move one or more extremities could indicate birth injuries such as a fractured clavicle. Report supernumerary fingers or toes and webbed or fused fingers or toes. Unequal skin folds or knee heights can indicate a unilateral dislocated hip. Presence of a hip click also indicates dislocated hips. |
| Reflexes | <p>The expected reflexes are</p> <ul style="list-style-type: none"> moro rooting sucking/swallowing tonic neck grasp Babinski | <ul style="list-style-type: none"> Absence of any of the expected reflex should be evaluated. Immediately after birth, if the mother received narcotic analgesia, the baby may not respond fully. |

TRANSITION

The period after birth is one of great transition for the infant. In the uterus, all the needs of the infant are met by the mother through the placenta. With birth, the infant will need to make changes in many systems in order to sustain life.

Cardiac and Respiratory Transition Changes

With the loss of the placenta, the infant will need to change both the function of the circulatory and respiratory systems.

Cardiac system

Three fetal structures of the circulatory system are no longer needed and if retained may even be detrimental. These structures are the foramen ovale, ductus arteriosus, and ductus venosus.

- Foramen ovale* is an opening between the right and left atrium. This structure allows oxygenated blood entering the right atrium from the placenta to bypass the lungs and enter the body circulation by way of the left atrium. Because of the decrease in blood entering the right atrium from the inferior vena cava, the foramen ovale is structurally closed almost immediately after birth.
- Ductus arteriosus* is a connection between the aorta and the pulmonary artery. Because the lungs are nonfunctioning, the lungs need very little blood prior to delivery. The ductus arte-

rius allows the blood that entered the pulmonary artery from the right ventricle to bypass the lungs and enter the aorta. This structure closes functionally following birth as a result of the increased needs of the lungs. Structurally, the ductus may still be present for a period after birth and if respiratory distress occurs, may reopen. It is not uncommon in the preterm infant for a patent ductus arteriosus to be present.

- Ductus venosus* is a shortcut through the liver for the oxygenated blood. With the loss of the placenta, this structure closes functionally with birth.

Respiratory system

- In utero, the fetus will “practice” breathing with prer respiratory movements. These occur irregularly and the fetus does not “practice” throughout pregnancy.
- With birth, respiratory movements must occur and continue.
- Some immature infants may demonstrate short apneic periods when they “forget” to breathe.
- In monitoring the respirations of a newborn, the monitor is often set to allow for “apneic periods” of 15 seconds before alarming as this is not an uncommon finding.
- In utero, the lungs will contain amniotic fluid. This is sterile fluid and causes no problems at delivery.
- With birth and the onset of respirations, the fluid is absorbed. Initially, the nurse may hear moist respirations on auscultation, but it should quickly clear up.

Nursing Intervention Alert

To reduce oxygen demand when the infant shows signs of respiratory distress, minimize the physical manipulation of the infant. Placing the infant in Trendelenburg position will cause gravity to put intestinal pressure on the diaphragm, the major muscle of respiration for the infant, increasing respiratory effort. A semi-Fowler's position with the head in "sniffing" position will best promote respirations.

- If the infant passes meconium in utero, the amniotic fluid in the lungs may contain meconium. This condition is called meconium aspiration and can create severe respiratory difficulties for the infant.

Hematologic System

- In utero, due to low oxygen tension, the fetus has a high hemoglobin and hematocrit.
- With delivery, the high levels of blood cells are no longer needed so the infant will begin breaking down the excessive numbers of cells.
- With the destruction of blood cells, bilirubin is released. As it is released from the RBC, the bilirubin is fat soluble and not easily eliminated from the body.
- The liver will convert this fat-soluble bilirubin (indirect or unconjugated bilirubin) to direct or conjugated bilirubin, a water-soluble bilirubin that will be excreted in the urine.
- If the liver is unable to convert this bilirubin efficiently due to liver stress or excessive breakdown secondary to bruising or injury, the unconjugated bilirubin will accumulate in the body (hyperbilirubinemia). The baby will appear jaundiced.
- When excessive unconjugated bilirubin builds up in the body, it will interfere with nutrition to the brain and can lead to brain damage, a condition called kernicterus.
- Infants who are premature or immature, those with birth trauma, maternal–fetal blood incompatibilities, and those who suffer cold stress are more likely to have higher levels of unconjugated bilirubin.

Elimination System

- It is normal for the fetus to void in utero and this liquid adds volume to the amniotic fluid. A fetus that passes meconium in utero is showing symptoms of distress.
- The infant should void and pass meconium within 24 hours of birth.
- Although the liver is functioning at birth, it is immature and takes several days to become fully active. Stressors on the infant, such as prematurity, cold stress, and bleeding and bruising problems will all affect the liver functioning.

TEMPERATURE MAINTENANCE

- At birth, the infant will be wet allowing loss of body heat. Drying quickly is extremely important to prevent cold stress.
- A mature infant will be better prepared to maintain body heat than a preterm infant.
- The nurse is responsible for ensuring conditions that maintain the normal body temperature of the infant. This includes frequent monitoring as well as activities designed to reduce the loss of body heat.
- Cold stress, a condition when the infant loses body heat, is extremely stressful on the body and will affect glucose metabolism and functioning of all body systems.

NEWBORN NUTRITION

Bottle Feeding

- The first feeding is usually glucose water or sterile water. This feeding substance is less irritating if the feeding should enter the lungs.
- Subsequent formula feedings should be every 3–4 hours.
- Nighttime feedings may be offered by the nursery personnel to allow the mother to rest.
- Commercially prepared formula offers the best nutrition to the bottle-fed baby as the companies producing formula have mimicked breast milk.
- The milk should be fed at room temperature and never heated in the microwave.

Breast-Feeding

- The first breast-feeding may occur in the delivery or recovery room.
- Unless the mother has received medication, the infant will be alert and eager to nurse.
- Colostrum is the first breast secretion. It is thin and watery and contains significant antibodies for the baby.
- Breast milk arrives at around the third day of life. It is bluish in appearance and is an ideal food for the human baby.
- Because it is easily digested, breast-fed babies often are hungry more frequently, eating at least every three hours.
- The infant will usually empty the breast within 5 minutes of sucking. Sucking is a pleasurable experience for the baby and the baby may continue to nurse when the breasts are empty.
- Throughout the breast-feeding experience, the baby will nurse more frequently with each growth spurt.

Parent Teaching

One of the main roles of the nurse in the maternity unit is client teaching. In addition to teaching the mother how to

take care of herself, the nurse will provide instructions on infant care including bathing, warmth, holding, and immunizations.

- Nutrition: Infants should remain on formula or breast milk until 12 months of age for the best growth and devel-

opment. Sterilization of the bottles are not usually required if sanitary conditions are present.

- The breast-feeding mother should be taught that the infant is probably getting adequate nutrition if it voids 6–8 times daily.

OBSTETRICAL COMPLICATIONS

ANTEPARTUM

Ectopic Pregnancy

- In ectopic pregnancy, the fertilized ovum implants in areas other than the endometrial lining of the uterus. The four types of ectopic pregnancy are
 - abdominal: The abdomen is usually unable to sustain the growing embryo.
 - tubal: The fallopian tube is the most common site of ectopic pregnancy. Tubal ectopic pregnancy places the client at risk for tubal rupture, which can be a life-threatening situation.
 - myometrial: It is also called placenta accreta. It is not usually recognized until delivery but will usually require a hysterectomy to stop hemorrhage.
 - cervical: Such low implantations are associated with placenta previa.
- Such pregnancy is not usually successful as areas outside of the uterus cannot sustain a full-term pregnancy.

Etiology: It usually occurs when tubal blockage prevents the fertilized ovum from passing through the fallopian tubes.

Precipitating factors: Pelvic inflammatory disease (PID), previous tubal surgery or tubal pregnancy, endometriosis, and congenital anomalies of the fallopian tubes.

S&S: Dependent upon location.

- Usual signs and symptoms of pregnancy are seen early in gestation
- There is a sharp one-sided pain
- There is adnexal (area over ovary and tube) tenderness
- Vaginal bleeding may or may not be present. (Bleeding may be occurring in the abdomen)
- With tubal rupture, abdomen becomes hard and rigid and signs of circulatory collapse occur. If it is not recognized and treated immediately, maternal death will occur

Dx: Transvaginal ultrasound is used to check for uterine pregnancy

Rx: Surgical removal of the products of conception is the most common treatment. An alternative medical treatment

may be used if the tube has not ruptured. Methotrexate, a folic acid antagonist that inhibits DNA synthesis, may be administered IM to terminate the pregnancy in clients who desires future pregnancies

Nursing Process Elements

- Carefully assess all pregnant women to identify those with an ectopic pregnancy
- Provide emotional support for the woman undergoing either surgical or medical treatment for an ectopic pregnancy
- Provide emergency resuscitation including IV fluids and oxygen, and prepare for emergency surgery for the woman whose tube ruptures

Client teaching for self-care

- Methotrexate treatment will cause abdominal discomfort which must be differentiated from tubal rupture
- Teach client about pre- and postoperative self-care elements
- Refer client to a Fetal Demise Support Group

Hyperemesis Gravidarum

- Hyperemesis gravidarum refers to excessive vomiting during pregnancy.
- It can lead to electrolyte imbalances and dehydration.
- The resulting lack of nutrition may lead to fetal injury or death.
- Maternal death can also occur from the electrolyte imbalances and dehydration.

Etiology: It begins as morning sickness that progresses to severe vomiting. In addition to vomiting everything in the stomach, the woman may continue to retch even when the stomach is empty.

Precipitating factors: It is associated with higher levels of HCG including multiple pregnancies and molar pregnancies. It is seen more frequently in women with history of migraine headaches and motion sickness.

S&S:

- Dehydration with loss of skin turgor, diminished urine output, elevated hemoglobin, hematocrit, and BUN —can lead to hypovolemia, hypotension, and tachycardia
- Electrolyte imbalances including potassium loss which can cause cardiac arrhythmias
- Loss of hydrochloric acid which causes alkalosis
- Starvation which can cause protein and vitamin deficiencies

Dx: Based on above laboratory values and client history

Rx: Antiemetics and NPO are prescribed for 24–48 hours until retching has stopped and IV fluids until dehydration and electrolytes restored. Diet is returned slowly to full, but spicy and fatty foods are withheld. If hyperemesis is not controlled, the client may be placed on total parenteral nutrition (TPN)

**Nursing Process Elements**

- Monitor hydration status, skin turgor, urine output, and specific gravity of urine
- Monitor for signs of electrolyte imbalances
- Administer antiemetics and intravenous fluids as ordered
- If TPN is ordered, monitor for expected and untoward effects of treatment
- Provide emotional support
- Monitor weight

**Client teaching for self-care**

Instruct client to

- avoid fatty and spicy foods
- ingest liquids and solids separately

Hydatiform Mole

- Hydatiform mole is also called gestational trophoblastic disease or molar pregnancy.
- In molar pregnancy, conception occurs but in most cases, an embryo does not develop.
- The trophoblast proliferates and becomes filled with fluid-filled, grape-like clusters.
- Choriocarcinoma may develop from the trophoblastic tissue.

Etiology: In a complete mole, an empty ovum was fertilized making all chromosomal material coming from the father. In a partial mole, the embryo forms but dies prior to 9 weeks gestation. The embryo is found to have 69 chromosomes, the triploid number resulting from an ovum being fertilized by 2 sperms or by 1 sperm which had not undergone haploid division of chromosomes.

Precipitating factors: It occurs most often in the woman over 35 years of age, those with low protein intake, and those of Asian heritage.

S&S:

- Early pregnancy signs are present
- HCG levels are higher than expected
- Uterus grows more rapidly than expected
- Symptoms of pregnancy-induced hypertension (PIH) occurs in the second trimester
- Dark brown spotting occurs

Dx: Ultrasound diagnosis

Rx: Suction curettage is prescribed to remove the mole. HCG levels are monitored for 1 year after the termination of the pregnancy because of the risk of the development of choriocarcinoma

**Nursing Process Elements**

- Assess all first and second trimester women for signs of hydatiform mole
- Provide emotional support for the loss of the pregnancy
- Provide preoperative preparation for the curettage

**Client teaching for self-care**

- Instruct the client to use a reliable birth control method for 1 year after the curettage
- Provide instructions to avoid pregnancy so that the client can be monitored for the development of choriocarcinoma
- Refer the client to a Miscarriage Support Group

Abortion

- Abortion refers to the termination of pregnancy before the fetus is viable, usually before 20 weeks gestation.
- It may be elective (induced) or spontaneous.
- A spontaneous abortion in lay terms is called a miscarriage.
- The five types of spontaneous abortion are
 - threatened: There may be vaginal spotting and slight cramping but the cervix remains closed. It may stop spontaneously or progress to abortion.
 - imminent or inevitable: In this type, cervical dilation occurs and fetal loss is imminent.
 - complete: In complete abortion, entire products of conception are expelled.
 - incomplete: Although some of the products of conception are expelled, some remain in the uterus. A dilation and curettage are performed to empty the uterus.

—missed: In missed abortion, fetus dies in utero but is not expelled. Dilation and curettage are performed to remove the products of conception.

Etiology: Spontaneous abortions are natural events usually unrelated to the mother's activities.

Precipitating factors: Abortions are caused by fetal abnormalities due to a teratogenic agent or chromosomal abnormalities, implantation problems, hormonal insufficiencies, and uterine abnormalities.

S&S:

- Vaginal spotting
- Abdominal cramping

Dx: Differentiate the types of abortion, which determines treatment. Determine the viability of the fetus and the contents of the uterus with sonogram, HCG levels, and FHTs.

Rx:

- Threatened—avoid strenuous activities for 48 hours and intercourse for 2 weeks
- All other forms of abortion—dilation and curettage to remove the products of conception, if not fully expelled

Nursing Process Elements

- Preoperatively monitor blood pressure, pulse, and vaginal discharge frequently
- Retain all expelled tissue for examination
- Monitor FHTs if abortion is threatened
- Prepare for surgical procedure
- Obtain blood for type and cross match
- Provide emotional support

Client teaching for self-care

- Teach client that she was not responsible for miscarriage
- Refer client to Miscarriage Support Group

Incompetent Cervix

- Incompetent cervix refers to the premature dilation of the cervix.
- It usually occurs in the fourth or fifth month of gestation.
- It is a cause of repeated miscarriages.

Etiology: Cervix dilates due to the increasing pressure of uterine contents. It is not associated with uterine contractions.

Precipitating factors: The causal factors include cervical trauma, congenital anomalies of the cervix, and infection.

S&S:

- History of repeated miscarriages
- Painless second trimester cervical dilation

- Little to no vaginal bleeding
- Bulging membranes on vaginal examination

Dx: Serial ultrasounds demonstrate progressive effacement and dilation

Rx: Surgical suture insertion used to maintain closed cervix, performed early in pregnancy

- Shirodkar's operation (cerclage of the cervix)
- McDonald's procedure which uses sutures to reinforce the cervix
- Delivery may be by clipping the suture or cesarean delivery

Nursing Process Elements

- Carry out preoperative preparation
- Conduct postoperative monitoring of the woman, the uterus for contractions, and the fetus
- Provide emotional support

Preterm Labor

- Preterm labor is that which occurs after the twentieth week and prior to the thirty-seventh week of gestation.
- The risk for fetus is dependent upon gestational age; the earlier in gestation that labor occurs, the lesser will be the chances that the fetus will survive. Even if the infant survives, he or she is more likely to have resultant long-term sequelae including cerebral palsy, mental retardation, and visual problems.

Etiology: Unknown.

Precipitating factors: Numerous factors are associated with preterm labor including multiple gestations, incompetent cervix, abdominal trauma, urinary tract infections, low maternal weight, and substance abuse including cigarettes.

S&S:

- Persistent backache
- Vaginal spotting
- Feeling of pelvic pressure

Dx: Assessment of contractions by a trained practitioner, vaginal examination for cervical dilation and FHTs. Vaginal and urine cultures are often obtained to rule out infection

Rx: If the membranes have not ruptured, cervix is minimally dilated, and the fetus is not in distress, attempts will be made to halt labor. Bed rest is usually prescribed to reduce pressure on the cervix. Medications that may be administered include

- betamethasone (Celestone Soluspan)—given to mature fetal lungs. To be effective, the drug must be given 24 hours prior to delivery and
- tocolytics (medications to halt preterm labor)
 - beta-adrenergic agonists such as ritodrine (Yutopar) and terbutaline sulfate (Brethine) and
 - magnesium sulfate

Nursing Process Elements

- Obtain baseline hematocrit, serum glucose, sodium chloride, potassium, and pCO₂ levels
- Administer medications according to directions and physician's orders
- Monitor contractions, vaginal discharge, FHTs, and for negative effects of tocolytic drugs
- Administer betamethasone as ordered
- Provide emotional support

Client teaching for self-care

Once labor has been stopped, the woman will be discharged to be managed at home. Discharge teaching will include the following instructions:

- Take increased amounts of rest, varying from two to three extra rest periods a day to total bed rest; left-side lying is preferred
- Ensure proper medication administration, effects, and side effects. It is important to stress that medications must be taken on time
- Void every 2 hours to reduce pressure on the uterus
- Drink 8–12 glasses of water or juice per day. Avoid caffeine
- Avoid heavy lifting and strenuous activities
- Prohibit sexual activity
- Contact physician for cramping, increased pelvis pressure, low back pain, or unusual vaginal discharge. The clients are usually instructed to count contractions (even non-painful contractions) and report to physician if they are greater than five per hour

Pregnancy-Induced Hypertension (PIH)

- Pregnancy-induced hypertension is a condition of vessel spasm involving both large and small vessels.
- It was originally called toxemia of pregnancy.
- It usually occurs in the third trimester.
- This is a progressive disorder and is generally divided into two stages
 - preeclampsia: the period before seizures occur and
 - eclampsia: generalized seizure.
- HELLP Syndrome (hemolysis, elevated liver enzymes, and low platelet count) is associated with PIH and may cause
 - multiple organ failure and
 - high morbidity and mortality for client and fetus.
- With delivery, the condition resolves although seizures may occur for up to 48 hours after delivery.

Etiology: Unknown.

Precipitating factors: The client may be a primigravida, age under 20 or over 40, grand multipara (more than 5 pregnancies), or may have had multiple gestation.

S&S: Classic signs are hypertension, proteinuria, and edema.

- Hypertension
 - in preeclampsia, the readings are above 140/90
 - in eclampsia, the readings are 160/110
- Proteinuria
 - in preeclampsia, 1–2+
 - in eclampsia,—there is marked proteinuria, 3–4+
- Edema
 - in preeclampsia, weight gain is greater than 1 lb per week
 - in eclampsia, weight gain increases
- Oliguria
- Symptoms indicating the approach of eclampsia are
 - epigastric pain
 - visual or cerebral disturbances
 - pulmonary and cardiac involvement
 - hyperreflexia

Dx: Based on the presence of the classic three symptoms

Rx:

- Bed rest
- Diet high in protein, moderate sodium
- Antihypertensives
- Anticonvulsants

Nursing Process Elements

- Monitor blood pressure, pulse rate, and edema
- Monitor urine output, protein, and specific gravity
- Monitor daily weights
- Monitor FHTs and for signs of placental separation such as bleeding and uterine rigidity
- Assess lungs for pulmonary hypertension
- Monitor laboratory values including hematocrit, clotting factors, and liver enzymes
- Monitor for symptoms of approaching seizures such as severe headaches, hyperreflexia, and visual disturbances
- Be prepared if seizures should occur—have oxygen and suction available

Client teaching for self-care

- Mild preeclampsia may be managed at home. The client will be taught
 - bed rest, primarily on left side
 - to monitor weight, urine output, and urine protein
 - expected effects and untoward effects of medications
 - to monitor fetal movements and report decrease in movements

—to notify the physician immediately if signs of approaching symptoms or HELLP syndrome occur

Placenta Previa

- Placenta previa refers to the attachment of placenta in the lower uterine segment which
 - may occlude internal cervical os.
- During later weeks of pregnancy, as the uterus prepares for delivery and cervical dilation begins, placenta may be torn away from the endometrium. Painless bleeding occurs.
- There are three degrees of placenta previa:
 - complete: In this, the placenta covers the internal os. Successful delivery cannot occur by the vaginal route as placenta must separate before fetus can be delivered. Cesarean section delivery is required.
 - partial or marginal: In this, the placenta partially covers internal cervical os.
 - low lying: In this, the placenta is attached low in the uterus but not covering the cervical os.

Etiology: Unknown.

Precipitating factors: Previous history of placenta previa, multiparity, previous cesarean section(s), increasing maternal age, and cocaine use and smoking during pregnancy.

S&S:

- Painless vaginal bleeding occurring in the third trimester; bleeding is bright red

Dx: Ultrasound demonstrates location of placenta

Rx: Prior to term, bed rest with bathroom privileges, no vaginal examinations. Client usually has blood typed and cross-matched for transfusion. Delivery by cesarean section if complete placenta previa present. Low-lying and partial may attempt delivery under double set-up so that an emergency cesarean can be performed if fetal distress occurs

Nursing Process Elements

- Monitor pulse, blood pressure, and vaginal discharge
- Encourage bed rest with left side-lying position
- Monitor FHTs
- Provide emotional support

Client teaching for self-care

- Assist the family in planning bed rest at home to minimize activity
- Teach the client and family about the signs and symptoms that must be reported immediately

Abruptio Placenta

- Abruptio placenta refers to the premature separation of the normally implanted placenta.

- It is divided into three types:
 - marginal in which placenta separation occurs at the edge and blood escapes vaginally,
 - central in which placenta separates in the center with the margins attached and blood collects under the placenta so that there is no visible bleeding, and
 - complete in which there is total separation of the placenta with massive hemorrhage and loss of FHTs.
- There is an increased risk of developing disseminated intravascular coagulation (DIC), and diminished clotting factors, which increase the risk of hemorrhage.

Etiology: Unknown.

Precipitating factors: Hypertension and cocaine use during pregnancy, higher maternal age and parity, smoking, and abdominal trauma.

S&S:

- Sudden onset
- Dark bleeding or bleeding that may not be observed due to concealed bleed
- Severe abdominal pain
- Uterus is hard to touch
- FHTs may or may not be present
- Development of symptoms of shock and anemia dependent on the degree of separation

Dx: Based on symptoms. Usually an emergency situation

Rx: Dependent on the degree of separation and gestational age. Moderate to severe placental separation requires immediate cesarean section to salvage the fetus. Intravenous fluids are required to maintain blood volume. Client may require blood transfusions

Nursing Process Elements

- Start IV line and run fluid at ordered rate
- Draw blood for hemoglobin and hematocrit values, type, and crossmatch
- Monitor pulse, blood pressure, and FHTs (if present)
- Prepare client for immediate cesarean section
- Provide emotional support for client and family

Client teaching for self-care

Teach the client about

- signs and symptoms of placental separation
- risk factors, to promote a healthy pregnancy

Rh Incompatibility

- Rh incompatibility occurs when the pregnant woman is Rh⁻ while fetus is Rh⁺.
- Rh⁺ blood has a protein not found in Rh⁻ blood.

- Following exposure to Rh+ blood, the Rh− woman becomes sensitized and produces antibodies against the Rh+ protein.
- These antibodies can cross the placenta and attack the fetus.
- Maternal and fetal circulations are separate with minimal mixing of blood.
- Sensitization occurs when fetal blood enters the maternal circulation. This occurs primarily with delivery.
- Antibodies are produced after delivery and the woman is sensitized.
- With any subsequent pregnancy involving an Rh+ fetus, the small amount of blood that crosses the placenta will cause the pregnant woman to produce antibodies.
- These antibodies cross the placenta and attack the fetal blood.
- With the advent of Rh immune globulin (RhoGram or RhIgG), the incidence of fetal loss due to Rh incompatibility has decreased.

Etiology: The Rh− woman usually does not have problems with Rh incompatibility in the first pregnancy with an Rh+ fetus, but becomes sensitized in the following delivery and will have problems in all subsequent pregnancies with an Rh+ fetus.

Precipitating factors: The majority of the population has Rh+ blood. If a man with Rh+ blood fathers a child with a woman who is Rh−, the fetus could be Rh+.

S&S: Rh incompatibility problems are rarely seen now. If present, signs and symptoms would be

- antepartum
 - fetal hydrops: Fetus is severely anemic due to the destruction of the RBCs by the maternal antibodies. Severe edema and congestive heart failure will be present in the fetus. Fetal death is common
- after delivery
 - rapid onset of hyperbilirubinemia
 - continued anemia and congestive heart failure

Dx: Blood tests are done on the first prenatal visit to determine the mother's Rh

Rx: If mother is Rh−, screening for antibodies (Indirect Coomb's test) will be done at 28 weeks gestation. If the antibody titer is negative, the mother will receive Rh immune globulin. After delivery, if the father was Rh+ or paternal Rh status was unknown, the mother will receive additional Rh immune globulin. This occurs with every pregnancy that might include a Rh+ fetus. Rh immune globulin will also be given after abortions, ectopic pregnancies, chorionic villi sampling, and amniocentesis. Infant blood is screened for antibodies with the Direct Coomb's test

Nursing Process Elements

- Administer Rh immune globulin as ordered prenatally and within 72 hours of birth

Client teaching for self-care

- The mother needs to be taught about the condition and about the need for Rh immune globulin with every pregnancy of an Rh+ fetus or fetus of unknown Rh type

ABO Incompatibility

- The naturally occurring blood types are A, B, O, and AB. In considering blood types, consider the antigen in the blood (A or B) and the antibody (anti-A or anti-B) present.
 - Type A blood contains the A antigen and the anti-B antibody
 - Type B blood contains the B antigen and the anti-A antibody
 - Type AB blood contains the A and B antigens and no antibodies
 - Type O blood contains no antigens and both anti-A and anti-B antibodies
- ABO incompatibilities may occur in the first pregnancy or any subsequent pregnancies. It is not predictable as the mother who has one infant with an ABO incompatibility may not have problems with the next infant.
- It is usually a less severe problem than Rh incompatibility.

Etiology: Typically, it is caused when the mother is O and the baby either A or B. The maternal antibodies cross the placenta and attack the fetal blood.

S&S:

- Early development of jaundice in the infant

Dx: Direct Coomb's test on the infant blood

Rx: Phototherapy treatment

Nursing Process Elements

See hyperbilirubinemia

Client teaching for self-care

See hyperbilirubinemia

INTRAPARTUM

Dystocia

- Dystocia refers to difficult delivery.
- In dystocia, labor may be long and painful. Vaginal delivery may be impossible, requiring cesarean delivery.

Etiology: It may be caused due to the following factors:

- Fetal factors
 - difficult presentation: There is face or shoulder presentation or transverse lie.

—oversized fetus: The infant is of a diabetic mother or there is disparity in size of the mother and father.

- Maternal factors
 - small pelvis or other than gynecoid pelvis shape,
 - disparity in size of fetal head and maternal pelvis, cephalopelvic disproportionment (CPD),
 - full bladder,
 - low-lying placenta, and
 - emotional factors.

Precipitating factors: The client may be a very young primigravida or one with no prenatal care.

S&S:

- Failure to progress despite adequate time

Dx: Pelvimetry, ultrasound

Rx: May require a cesarean section

Nursing Process Elements

- Monitor labor progress
- Observe for nonreassuring pattern on fetal monitoring
- Provide emotional support
- Ensure physical and emotional preparation for surgery
- Provide postoperative care

Client teaching for self-care

- Potential CPD may be determined in early pregnancy. This pregnant woman can then be prepared emotionally and educationally for what to expect with a cesarean delivery
- The woman who experiences an emergency cesarean delivery will need an explanation of the cause, what happened, and emotional support

Prolapsed Cord

- In case of prolapsed cord, a loop of the umbilical cord precedes the presenting part into the birth canal and becomes compressed as the presenting part descends.
- It requires immediate intervention for a successful delivery.

Etiology: Prolapsed cord occurs most frequently when the membranes rupture prior to engagement of the presenting part.

Precipitating factors: Hydramnios (excessive amniotic fluid), multiple gestation, noncephalic presentation, small fetus, CPD, and placenta previa.

S&S:

- Fetal bradycardia
- Fetal monitoring demonstrates severe variable decelerations
- Umbilical cord is felt on vaginal examination

Dx: Based on fetal assessment and vaginal examination

Rx: Immediate cesarean delivery

Nursing Process Elements

- Keep all women in labor on bed rest until the presenting part has engaged (this reduces the chance that rupture of membranes will “wash” the cord ahead of the presenting part)
- Immediately upon rupture of the membranes, take the FHTs for one full minute
- If prolapsed cord is suspected
 - notify physician immediately
 - place the woman in Trendelenburg position
 - place a gloved hand in the vagina to elevate the presenting part off the cord
 - administer oxygen per mask to mother
 - if cord is protruding into room air, cover with a sterile saline moistened cloth to prevent drying
 - prepare the client for an emergency cesarean section
 - provide emotional support

Amniotic Fluid Emboli

- Amniotic fluid emboli is a nonpreventable cause of maternal mortality during delivery.
- It causes a sudden onset of respiratory distress and circulatory collapse.

Etiology: Amniotic fluid enters maternal circulation through a defect in the fetal membranes where it becomes an embolous when it reaches the lungs.

Precipitating factors: Associated with rapid delivery, oxytocin augmentation, abruptio placenta, and polyhydramnios.

S&S:

- Sudden onset of chest pain
- Cyanosis and dyspnea
- Tachycardia
- Hemorrhage
- Shock, coma, and death

Dx: Based upon symptoms

Rx: Immediate intervention is required to restore circulation. Cardiopulmonary resuscitation is started immediately, although it is not always successful. Prognosis is dependent upon the restoration of pulmonary circulation

Nursing Process Elements

- Carefully monitor all women in labor, especially those with precipitating factors
- Quick recognition and initiation of emergency interventions essential to the woman's survival
- Start intravenous fluids
- Provide oxygen

- Provide CPR as necessary
- Prepare for cesarean section if undelivered
- Prepare for blood transfusion and the insertion of a CVP line

Client teaching for self-care

- After successful resuscitation, the woman and her family will need to understand what has happened
- Emotional support should be provided for the woman and her family

POSTPARTUM

Postpartum Hemorrhage

- Postpartum hemorrhage can occur in the first 24 hours after delivery or up to 6 weeks after birth.
- There are numerous causes of hemorrhage including
 - uterine atony,
 - retained placenta,
 - hematomas of the pelvic region,
 - lacerations,
 - subinvolution, and
 - uterine inversion which is an unusual cause occurring at the time of delivery when the uterus prolapses through the cervix.

Etiology: It is caused by the failure of the uterus to contract to conserve maternal blood or loss of excessive blood during the postpartal period.

Precipitating factors: The factors responsible are overdistention of the uterus due to multiple gestation or polyhydramnios, rapid or prolonged labor, oxytocin augmentation, use of anesthesia, and grand multiparity. Uterine inversion is associated with traction on the umbilical cord prior to separation of the placenta at birth.

S&S:

- Excessive vaginal bleeding the amount of which varies dependent on the time of occurrence
- Decreasing blood pressure and increasing pulse
- Dropping hemoglobin and hematocrit
- Decreased urine output

Dx: Based on laboratory values and reports of vaginal discharge. Assessment of a boggy fundus could indicate subinvolution. Sonogram may demonstrate retained placental fragments

Rx: Dependent upon cause. Retained placenta will usually require dilation and curettage to manually remove the fragments. Oxytocins or Methylergonovine Maleate (Methergine) may be administered for subinvolution. Lacerations may require packing and/or suturing. Transfusions may be required if blood loss is extensive

Nursing Process Elements

- Assess vaginal discharge for color and amount. Question new mother about the frequency of pad changes and observe pads for the amount of blood
- Remind the new mother that after being in bed for a period of time and then arising, a gush of blood escaping the vagina is normal and due to pooling of blood in the uterus
- Assess fundus, provide bimanual massage—massage the fundus while supporting the cervix with the opposite hand
- Assess perineum for hematoma formation. Clients with developing hematomas will often complain of pain
- Have client void frequently as a full bladder will hamper uterine contractions
- Administer medications for uterine contraction as ordered
- Monitor vital signs
- Administer blood products as ordered

Client teaching for self-care

- Once the cause of the blood loss is determined and treated, the client may be discharged home. Prior to discharge, the nurse should teach the client about
 - the reason for the blood loss
 - foods that will promote blood formation
 - medications, including iron administration
 - the need for extra rest periods due to anemia

Postpartum Infection

- It is also called puerperal infection.
- It was once the major cause of maternal mortality.

Etiology: It is caused by introduction of an organism into the uterine or perineal tissues.

Precipitating factors: It is associated with prolonged rupture of the membranes (greater than 24 hours), postpartal hemorrhage, prolonged and difficult labor and delivery, internal fetal monitoring, frequent vaginal examinations, vacuum and forcep deliveries, and poor hygiene.

S&S:

- Temperature of 100.4°F or higher for 48 consecutive hours that do not include the first 24 hours after delivery, excluding the first 24 hours
- Pain
- Foul-smelling lochia

Dx: Based on signs and symptoms as well as laboratory findings

Rx: Appropriate antibiotic therapy

Nursing Process Elements

- Monitor vital signs
- Teach perineal care to promote cleanliness of area

- Administer antibiotics as ordered
- The client's infant may be isolated from other infants in the nursery
- The pediatrician should decide if the breast-feeding mother should nurse her infant as the antibiotics may be present in breast milk
- If breast-feeding is not recommended, the mother can pump her breasts and discard the milk. Once the antibiotic therapy has been completed, breast-feeding can be reinitiated

Client teaching for self-care

- Teach client good hygiene practices including frequent hand washing
- Discuss with the breast-feeding mother the issue of continuing nursing the infant while antibiotics are being administered. Assist client as necessary to maintain milk supply
- Instruct client to complete antibiotic therapy as ordered

Mastitis

- Mastitis is an infection of the breast tissue that occurs primarily in the lactating woman.
- It usually does not occur in the first week of lactation but may occur anytime during the remaining period of lactation.
- It is usually unilateral.

Etiology: The organism usually enters the breast tissue through cracks and fissures in the nipples. The source can be the infant's mouth or maternal hands.

Precipitating factors: One factor is that the infant latches incorrectly traumatizing the nipple. Other factors can include milk stasis, maternal fatigue, plastic-lined nursing pads which maintain moisture around the nipple, and incorrect infant-removal techniques.

S&S:

- Pain in the breasts
- Redness, heat, and swelling
- Fever
- Breast milk may diminish in quantity

Dx: Based on signs and symptoms, laboratory values, and breast-milk culture

Rx: Appropriate antibiotic therapy

Nursing Process Elements

- Observe the breast-feeding and assist the mother in positioning the infant correctly
- Encourage adequate rest and nutrition in the breast-feeding mother
- Encourage the mother to change infant positions while nursing to promote breast emptying

- Encourage the mother to wear a well-fitting, supportive bra
- Ice packs may promote comfort. Heat may be applied prior to nursing to promote let-down

Client teaching for self-care

- Teach the mother to wash her hands prior to handling the breasts
- Monitor the nipples for cracks and fissures
- Vitamin E ointment may be used on the nipples to maintain integrity. Colostrum and breast milk may also be applied to the nipple to promote integrity
- Teach the mother to allow the nipples to air dry after feeding
- Teach the mother about antibiotic administration including the need to complete the prescription. The pediatrician will determine the advisability of continued nursing while on the antibiotics

NEWBORN

Prematurity

- Prematurity refers to birth prior to 37 weeks gestation.
- The earlier in gestation that birth occurs, the less mature is the infant and the less likely to sustain extrauterine life.
- Prematurity affects all systems
 - Respiratory: The infant has inadequate surfactant, a substance that helps maintain lung expansion. Lung development is inadequate for transfer of oxygen and waste products to and from the blood. Its brain is too immature to maintain continuous respirations. Bronchopulmonary dysplasia (BPD) is a long-term lung injury that results from high oxygen concentration and positive pressure respirator use to sustain life.
 - Gastrointestinal: Suck and swallow reflexes of the infant are weak and ineffective. The immature digestive system is unable to digest and absorb nutrients. The basal metabolic rate is increased which means the nutrient requirement is higher per mass than more mature infant. The risk of NEC (necrotizing enterocolitis), a condition where the intestines may become ischemic and perforate secondary to diminished blood flow.
 - Renal: The kidneys are unable to concentrate urine. Kidneys are too immature to modify pH predisposing the infant to metabolic acidosis.
 - Integumentary: Its skin is thin and fragile and is easily damaged allowing bacteria to enter. There is inadequate fat for insulation making the infant prone to hypothermia.
 - Cardiac: The ductus arteriosus, a fetal structure, may remain open after birth due to low oxygen tension. The PDA increases the blood volume entering the lungs leading to pulmonary congestion and eventually to congestive heart failure.

—Nervous: The tissues of the skull are fragile and easily damaged. Premature infants are prone to intracranial hemorrhage, which can lead to brain damage, seizures, and the development of hydrocephalus.

—Skeletal: Bones are not as fully mineralized as full term infants making them more susceptible to injury during the birth process.

Etiology: It is the birth of the infant prior to 37 weeks gestation.

Precipitating factors: The associated factors are multiple gestations, poor maternal nutrition, maternal smoking, or infection.

S&S: Numerous assessment findings are present in the preterm including:

- Skin appears thin and transparent. Blood vessels are easily visible.
- Lanugo may be noted in greater quantity than on a full term infant.
- Plantar creases are absent or only on the anterior portion of the foot. This must be assessed within 12 hours of birth for accuracy.
- Position tends to be primarily one of extension versus flexion in the full term infant.
- Areolar tissue increases with gestation age.
- Ear becomes more firm as gestational age increases due to presence of cartilage.
- Head may be described as “hammer head” due to the prominence of the back skull.

Dx: Ballard and Dubowitz gestation age assessment tools can determine the gestation age of the infant as maternal EDC may be incorrect, the baby may appear larger or smaller than expected based on “due date”

Rx: Careful attention should be paid to meeting all the needs of the infant. Total parenteral nutrition or gavage feedings will probably be necessary. Warmth must be maintained externally. Respirations will need support with oxygen, surfactant therapy, and possibly positive pressure respirators

Nursing Process Elements

- Ensure careful and frequent monitoring of all systems. Labs will be drawn frequently to monitor blood values, gases and electrolytes
- Place the infant in an external heat source such as an isolette or over-the-bed warmer where the body temperature can be maintained while allowing close observation of the neonate
- Pay careful attention to nutritional needs. Measure abdominal circumference to monitor for NEC
- Monitor vital signs and pO₂
- Provide oxygen, positive pressure respirators, and medications to maintain lung function and acid-base balance
- Carefully handle the infant due to friable skin

- Protect from infection
- Provide emotional support for infant and his family

Client teaching for self-care

- Prior to discharge, the parents will need to be able to handle all the infant's needs including feeding, respiratory support, and maintenance of temperature
- These infants may be discharged with special equipment including apnea monitors, tracheotomies and gastrostomy tubes and feedings. The parents will need to be comfortable handling all this equipment
- Teach client about infant CPR
- Teach about the need to protect the infant from infections
- Instruct about the signs and symptoms to report to the physician
- Provide knowledge about the need for RSV vaccine (respiratory syncytival virus) during winter months as premature infants are especially susceptible to the organism

Hyperbilirubinemia

- Due to low oxygen tension in fetal blood, the fetus has a high hemoglobin and hematocrit. This condition is known as hyperbilirubinemia.
- At birth, oxygen tension increases and the extra RBCs are no longer needed.
- The infant begins breaking down the excessive RBCs.
- As RBCs are broken down, indirect bilirubin is released.
- Indirect bilirubin (unconjugated) is fat soluble.
- The liver converts indirect bilirubin to direct bilirubin (conjugated), which is water soluble and can be excreted in the urine.
- In the normal newborn, the direct bilirubin reaches its peak at about three days of life and then starts to decrease. This is termed physiologic jaundice.
- In a child with hyperbilirubinemia, the indirect bilirubin level may start climbing within hours of birth or the level of indirect bilirubin is excessive interfering with brain function.
- Normal indirect (unconjugated) bilirubin levels are below 1.4 mg/dl.

Etiology: Following birth, the liver is unable to convert indirect bilirubin to direct bilirubin adequately. The indirect bilirubin builds up in the blood and collects in fat-rich tissues including the skin and the lining of the brain. When the indirect bilirubin level reaches toxic range, the brain will be affected. This bilirubin encephalopathy is called kernicterus. Any condition that stresses the liver will delay the conjugation and increase the risk of hyperbilirubinemia.

Precipitating factors: Causes of hyperbilirubinemia include Rh and ABO incompatibility, prematurity and immaturity, any injury which increases blood cell destruction such as

bruising, petechiae, and hematomas, infant of a diabetic mother, cold stress, infection, and breast-feeding.

S&S:

- Yellow appearance to the skin—the skin discoloration begins on the face and spreads caudally. Sclera also appear yellow
- As kernicterus develops, additional symptoms may be seen, such as
 - poor feeding
 - high-pitched shrill cry
 - lethargy or irritability

Dx: Based on bilirubin levels

Rx: Phototherapy. Exchange transfusions are done only in the most extreme cases

Nursing Process Elements

- Provide phototherapy, which slowly converts the indirect bilirubin on the skin surface so that it can be excreted. It is important that the treatment be continuous. Removing the infant from the treatment for extended periods of time will slow the therapy
- Ensure that the child is nude except for genitalia covering
- Cover the eyes with occlusive pads
- Phototherapy converts on the exposed skin surface only; turn the infant frequently
- Use no lotions or oils on the infant's skin to prevent burning
- Provide extra water feedings
- Maintain body temperature within normal limits
- Provide diaper care frequently as the stools tend to be loose and irritating

Client teaching for self-care

- For the infant discharged prior to 3 days of life, the mother will need instructions on monitoring the skin color
 - Expose skin to the sunlight while maintaining body temperature. Care should be taken that the child does not receive a sunburn
 - Provide extra po water to aid in excretion

Infant of a Diabetic Mother

- Women with poorly controlled diabetes will have a fetus that developed in the presence of large amounts of glucose and will thus be large for gestational age (LGA).
- Women with a severe form of diabetes may have vascular deterioration, which leads to poor nutrition to the fetus. The fetus will be small for gestational age (SGA).
- Infants of diabetic mothers are usually immature in physiologic functions and will respond as an infant of a lesser gestational age.

- The placenta of an infant of a diabetic mother often begins to deteriorate prior to the ninth month of gestation causing preterm delivery and/or fetal death. Many physicians choose to deliver the infant prior to term to reduce this risk.
- Because of the size of the fetus, many infants of diabetic mothers are delivered by cesarean section.
- The fetus is accustomed to plentiful glucose in utero. At delivery, the glucose source is terminated abruptly. The infant pancreas may continue to produce insulin leading to hypoglycemia shortly after birth.
- Excessive glucose in utero has been shown to predispose the fetus to congenital defects.

Etiology: Glucose readily crosses the placenta. The fetal pancreas produces insulin and utilizes the glucose. Excessive glucose in the fetal cell is converted to glycogen and stored. Infants of diabetic mothers are often obese.

Precipitating factors: Any woman with a history of producing large babies (weighing over 9 lbs at birth) should be evaluated for diabetes.

S&S:

- LGA infant
- Development of hypoglycemia within hours of delivery
- Polycythemia
- Possible birth trauma due to size of the fetus
 - shoulder dystocia is common in vaginal deliveries
 - potential for fractured clavicle
- Symptoms of immaturity
 - difficulty maintaining body temperature
 - Hyperbilirubinemia
 - prone to respiratory distress syndrome

Dx: Based on Glucose Tolerance Test (GTT)

Rx: Close monitoring of diabetic condition throughout pregnancy, diet and insulin regulation of glucose, and close monitoring of fetus including stress and nonstress tests

Nursing Process Elements

- Assess gestational age using Dubowitz and Ballard on all infants
- Assess infants who are LGA or SGA for S&S of infant of diabetic mother
- Monitor blood glucose at birth and frequently. Provide early protein feedings
- Assist the IDM in maintaining body heat
- Observe for early onset of hyperbilirubinemia
- Assess for birth injuries and congenital defects

Client teaching for self-care

- Provide preventative teaching of pregnant diabetic to assist the mother in maintaining blood sugars as close to normal as possible

Cold Stress

- Loss of body heat is a major event for the newborn and can be life-threatening if not corrected.
- Nonshivering thermogenesis is the major source of heat production in the neonate and is based on brown-fat metabolism.
- Cold stress in the neonate will lead to other physiologic problems including hyperbilirubinemia, hypoglycemia, respiratory distress, and acidemia.

Etiology:

- The neonate loses body heat through evaporation, conduction, convection, and radiation
- The neonate attempts to maintain body heat through nonshivering thermogenesis

Precipitating factors: Premature and SGA infants have less brown-fat stores and thus are at greater risk for cold stress. LGA infants, although they have adequate fat stores, have immature neurologic functioning making them at greater risk for hypothermia.

S&S:

- Decreased skin temperature
- If cold stress has occurred, the neonate will have the following symptoms:
 - lethargy
 - poor feeding
 - hypoglycemia
 - pallor
 - apnea
 - hypotonia

Dx: Based on axillary or rectal temperatures

Rx: Restore body temperature. Intravenous fluids may be required to restore glucose levels

Nursing Process Elements

Prevention is preferable to treatment.

- Dry newborn immediately to reduce evaporative heat loss
- Use external heat source to maintain core body temperature after birth
- Maintain nursery temperature 1°C higher than neonate's temperature
- Locate bassinet away from outside windows
- Wrap snugly in blankets
- Encourage mother to maintain covering

If cold stress has occurred

- Use external heat source to return skin temperature to desired range
- Monitor temperature more frequently than routine
- Monitor blood glucose
- Assess the neonate for respiratory distress
- Assist the infant in taking formula to restore blood sugar. The infant will be a poor feeder and lethargic

Client teaching for self-care

- Teach mother about the need to keep the infant warm without overheating
- Infants usually need one layer of clothing above adult's needs
- Head is a major source of heat loss and should be covered when out of doors in winter

WORKSHEET

SHORT ANSWER QUESTIONS

1. Discuss how para, gravida, and TPAL are determined on an obstetric client.
2. Discuss the process of determining due dates using Nagele's rule.
3. Describe the initial prenatal obstetrician visit and the frequency of the subsequent visit.
4. Describe the probable, presumptive, and positive signs of pregnancy and the interpretations of these signs.

(continued)

5. Describe the warning signs that pregnant women should immediately report to the physician and their implications.
6. Describe the factors that initiate the onset of labor.
7. Define the four stages of labor.
8. Describe the mother's emotions and attitude during the three phases of labor.
9. Identify the five areas evaluated on the Apgar score and the possible point value of each area.
10. List the three fetal structures of normal circulation during the gestation and what each structure does.

MATCHING QUESTIONS

Match the following:

- | | |
|---------------------------|---|
| 1. ___ Lightning | a. A mnemonic to guide the nurse's assessment of the postpartum woman |
| 2. ___ Quickening | b. Explains the relationship between the fetal presenting part and the mother's pelvis |
| 3. ___ Crowning | c. An assessment performed on the mother to determine the presence of thrombophlebitis |
| 4. ___ Engagement | d. The presenting part is seen on the mother's perineum |
| 5. ___ Station | e. Evaluates the relationship of the fetal presenting part to the ischial spines of the mother's pelvis |
| 6. ___ Attitude | f. Compares the spinal cord of the fetus to the spinal cord of the mother |
| 7. ___ Lie | g. Fetal movement |
| 8. ___ Presentation | h. Swelling of the scalp if the head was the presenting part |
| 9. ___ Position | i. Determines which fetal part is entering the pelvis first for delivery |
| 10. ___ Striae | j. The filling of the breasts with milk |
| 11. ___ Engorgement | k. Stretch marks |
| 12. ___ Homan's sign | l. Bleeding into the periosteum of the skull |
| 13. ___ BUBBLE-HEB | m. The presenting part descends into the pelvis before the onset of labor |
| 14. ___ Caput succedaneum | n. In a cephalic presentation, the largest diameter of the head is at the smallest diameter of the pelvis |
| 15. ___ Cephalohematoma | o. The relationship of fetal parts to each other |

APPLICATION QUESTIONS

1. A woman visits her obstetrician for a pregnancy test that is positive. In taking her history, she reports that she has been pregnant four times before. She has two children at home, one of which was born at 32 weeks gestation. She lost a set of twins at 14 weeks and another baby at 12 weeks. What is her para, gravida, and TPAL?
 - a. G5, P4 (T1, P1, A2, L2)
 - b. G5, P2 (T1, P1, A3, L2)
 - c. G3, P2 (T1, P2, A2, L1)
 - d. G3, P4 (T2, P3, A3, L2)
2. The obstetrician asks the nurse to determine the due date for a pregnant client on her first prenatal visit. The client reports that her last menstrual period began on February 5, 2007 and ended on February 10, 2007. What is her due date?
 - a. November 5, 2007
 - b. November 12, 2007
 - c. November 10, 2007
 - d. November 17, 2007
3. A pregnant woman at 14 weeks gestation calls the obstetrician's office to report that she has noted some vaginal discharge. The discharge is clear and without odor. The office nurse would instruct the client to
 - a. wear a peri-pad to absorb the liquid, which is normal
 - b. douche with water to see if that improves the drainage
 - c. do nothing, as vaginal discharge in pregnancy is normal
 - d. report to the physician's office immediately for assessment
4. While attending childbirth education class, a primigravida asks when she should go to the hospital. The nurse's best response would be:
 - a. With the first contraction.
 - b. One hour after the onset of labor.
 - c. When she thinks her membranes have ruptured.
 - d. As soon as she is sure she is in true labor.
5. A nurse is teaching a class of childbirth education to four women in late pregnancy. The women make the following statements. Which statement would most likely indicate that lightening has occurred?
 - a. "I can feel my baby move."
 - b. "It's hard to sleep at night—I have to lie on my side."
 - c. "I feel like my lungs are being crowded by the baby."
 - d. "I have to void frequently like I did in the first trimester."
6. A woman arrives at the labor unit in labor. She is talkative and smiling between contractions. Prior to completing the vaginal examination, the nurse would suspect the woman is in what phase/stage of labor?
 - a. Latent phase
 - b. Active phase
 - c. Transition phase
 - d. Second stage
7. Monitoring the client during labor is the nurse's responsibility. If the mother is not hooked up to a fetal monitor, the nurse would assess FHT at the following times: (Select all that apply.)
 - a. on admission
 - b. after each contraction
 - c. immediately when the membranes rupture
 - d. each time the mother's vital signs are taken
 - e. as the mother enters each phase of labor
8. One minute after birth, the nurse performs an Apgar scoring on the newborn. The baby receives a score of 6. The mother asks what this score indicates. The nurse's response would be based on the knowledge that
 - a. the higher the score, the more intelligent the baby will be
 - b. low scores indicate a baby who has experienced birth trauma
 - c. a score of 6 suggests an infant that needs immediate transfer to the high-risk nursery
 - d. the score indicates how well or poorly an infant has transitioned from intrauterine to extrauterine life
9. A newborn is admitted to the newborn nursery. A new nurse will be caring for the infant. The charge nurse is explaining bloodborne precautions to the new nurse. The charge nurse would tell the new nurse to wear gloves for what activities? (Select all that apply.)
 - a. Admission bath
 - b. Daily bath
 - c. Meconium diaper change
 - d. Urine diaper change
 - e. Any contact with the infant

(continued)

10. There has been a rush of difficult deliveries at your hospital and the hospital nursery currently has babies with the following abnormalities. Which infant should be monitored for increased intracranial pressure?
 - a. Cephalohematoma
 - b. Caput succedaneum
 - c. Intracranial hemorrhage
 - d. Cerebral petechiae
11. The nurse is assessing a client on the second day postpartum. The nurse would intervene if the fundus was located
 - a. 2 fingerbreadth above the umbilicus
 - b. 1 fingerbreadth below the umbilicus
 - c. 2 fingerbreadths below the umbilicus
 - d. 3 fingerbreadths below the umbilicus
12. A new mother is planning to bottle feed her infant. Instructions have been given to the mother to prevent milk production. The nurse observes all the following activities by the mother. Which activity indicates a lack of understanding?
 - a. The mother is wearing a tight bra.
 - b. The mother does not try to express the milk.
 - c. The mother avoids handling or touching the nipples.
 - d. The mother takes a long, hot shower with water hitting the breasts.
13. The new mother calls the obstetrician's office at 8 days postpartum to state that her lochia had returned to red in appearance although the volume has not increased. The nurse would recommend the mother to
 - a. drink more milk
 - b. rest more frequently
 - c. avoid sexual activity
 - d. increase her iron intake
14. A woman is at the obstetrician's office for her second prenatal visit. She has numerous complaints including all of the following. Which would require reporting to the physician?
 - a. She has to void frequently.
 - b. She is tired and wants to sleep all the time.
 - c. She has a burning sensation when she urinates.
 - d. Although she has not vomited, she feels nauseated most of the time.
15. At 20 weeks gestation, a pregnant woman is diagnosed with polyhydramnios. Which assessment finding contributed to this diagnosis?
 - a. voids frequently
 - b. blood pressure is 148/86
 - c. quickening has not been noted
 - d. the fundus is two fingerbreadths above the umbilicus
16. Following admission to the newborn nursery, a newborn's rectal temperature is found to be 98.0°F. His pulse is 146 and respirations are 36. Lung assessments include adventitious sounds. Immediate nursing interventions should be directed at
 - a. warming the baby
 - b. promoting bonding with the parents
 - c. calming the infant to slow the heart rate
 - d. percussion and postural drainage to clear the lungs
17. A pregnant woman at term is being admitted to the labor room in early labor. During the admission process, the woman's membranes suddenly rupture. Priority nursing activities at this time would include
 - a. checking the fetal heart tones
 - b. vaginal examination to determine dilation and effacement
 - c. cleaning up the woman and making her comfortable
 - d. completing the admission process so that all paperwork is completed before delivery
18. A fetus of a woman in labor is found to have a breech presentation, longitudinal lie, and a flexed attitude. In listening for fetal heart tones, the nurse would listen on the mother's abdomen
 - a. below the umbilicus
 - b. at the umbilicus
 - c. above the umbilicus
 - d. lateral to the umbilicus
19. A teenager is admitted at term to the labor unit in early labor. She has not attended any childbirth education classes. Her mother is present as her support person. The best time to discuss breathing techniques with this teenager is
 - a. during the latent phase of labor
 - b. as she approaches transition stage
 - c. after delivery in anticipation of future pregnancies
 - d. as she approaches each labor stage that requires a different breathing technique
20. A single mother has delivered an infant boy. Which behavior by the mother indicates that bonding is proceeding on schedule?
 - a. The mother successfully breast-feeds the infant.
 - b. The mother asks questions about the baby's condition.

- c. The mother states: “I wanted a girl, but a boy will be OK too.”
- d. The mother progresses from touching the infant with her fingertips to whole hand touching.
21. The nurses in the delivery room reported a concern about the mother’s reaction to her newborn. Mother and infant are moved to the recovery room. Which activity by the recovery room nurse will promote mother–infant bonding?
- Dimming the overhead lights.
 - Allowing the father to stay with the family unit.
 - Administering morphine to ensure that the woman is pain free.
 - Limiting fundal assessments to allow the family unit time alone.
22. The nurse is discharging a breast-feeding mother and her infant from the hospital on the third day postdelivery. Discharge instructions relative to breast-feeding have been given by the nurse. Which statement by the mother indicates the correct information about breast-feeding?
- “Six to eight wet diapers indicate my baby is getting enough milk.”
 - “I need to limit my fluid intake so that I won’t dilute my breast milk.”
 - “I can feed formula from a bottle during the nights until my milk comes in.”
 - “I should weigh the baby before and after feeding to determine if I have enough milk.”
23. The nurse is checking the infants in the newborn nursery for hyperbilirubinemia. The nurse knows that the infants most likely to have hyperbilirubinemia are those who (Select all that apply.)
- are premature
 - are full term
 - have broken bones
 - have chromosomal disorders
 - have a large amount of bruising
24. A woman in late pregnancy is complaining of severe backaches. The nurse notes that the pregnant woman’s posture displays lordosis. To reduce the backaches, the nurse would suggest
- wearing a girdle to support the back muscles
 - wearing shoes with heels no higher than 1 inch
 - performing the pelvic tilt several times during the day
 - limiting the amount of walking that she does during the day
25. A teenager purchases a home pregnancy test. She later asks the nurse how these tests work. The nurse’s response is that the pregnancy tests are based on which hormone?
- Oxytocin
 - Estrogen
 - Progesterone
 - Human chorionic gonadotropin

ANSWERS & RATIONALES

SHORT ANSWER QUESTIONS

- Discuss how para, gravida, and TPAL are determined on an obstetric client.

Answer

Para and gravida describe the pregnancies. Gravida stands for pregnancies and is a simple count of every pregnancy including the current one. Para refers to pregnancies terminated after the age of viability (usually considered 20 weeks). Para does not consider the survival of the fetus or the number of fetuses delivered. TPAL describes the infants. T is for term infants (born at 38+ weeks), P is for premature (above 20 weeks gestation up to 38 weeks gestation), A is for abortions, babies lost before 20 weeks gestation (includes therapeutic abortions and miscarriages), and L is a total of the living children.

(continued)

Think Smart/Test Smart

The terms gravida and para refer to pregnancies while TPAL describes the babies.

2. Discuss the process of determining due dates using Nagele's rule.

Answer

Beginning with the first day of the woman's last menstrual period, count back 3 months and add 7 days.

3. Describe the initial prenatal obstetrician visit and the frequency of the subsequent visit.

Answer

A pelvic examination determines presumptive and probable signs of pregnancy. The para, gravida, and TPAL status is determined as well as the due date. Urine will be checked for sugar and protein. Blood will be drawn for blood typing, rubella titer, and hemoglobin and hematocrit. Initial instructions will be given to the pregnant woman about activities to promote health and situations to avoid. The woman will return once a month until the ninth month when she will see the obstetrician every week.

4. Describe the probable, presumptive, and positive signs of pregnancy and the interpretations of these signs.

Answer

Presumptive signs of pregnancy are subjective signs and can be caused by many other conditions including the desire to be pregnant. Probable signs are objective signs and are more closely related to the probability of pregnancy. These signs can have alternative causes and may be misinterpreted as pregnancy. Positive signs of pregnancy refer to the acknowledgment of the presence of the fetus and will have no alternative causes.

5. Describe the warning signs that pregnant women should immediately report to the physician and their implications.

Answer

- a. Vaginal discharge, which could indicate premature rupture of membranes.
- b. Vaginal bleeding—although some women will continue to have a small amount of bleeding at the time of the normal menstrual period. The doctor will need to determine if the mother is experiencing placenta previa or abruptio placenta.
- c. Abdominal pain—could indicate premature labor or abruptio placenta.
- d. Temperature above 101°F—could indicate infection.
- e. Vomiting, especially into the second trimester—could indicate hyperemesis.
- f. Severe headache, dizziness, and spots before the eyes—could indicate pregnancy-induced hypertension.
- g. Edema of the lower extremities—could indicate pregnancy-induced hypertension.
- h. Epigastric pain—could indicate pregnancy-induced hypertension.
- i. Burning on urination—could indicate UTI.
- j. Absence of fetal movement—could indicate fetal demise.

6. Describe the factors that initiate the onset of labor.

Answer

Although the cause of labor onset is not fully understood, theories include the beginning of deterioration of the placenta that results in decreasing hormones, stretching of the uterus to its capacity, some factor from the mature fetus initiating labor, and the presence of prostaglandin.

7. Define the four stages of labor.

Answer

First stage is from the onset of labor to complete dilation of the cervix. It can be further broken down into three phases: latent (early labor), active (the period of primary work), and transition (as the dilation and effacement is completed). Second stage is from complete dilation of the cervix to delivery of the fetus. Third stage is the stage of the placenta, extending from the birth of the fetus to the delivery of the placenta. Fourth stage is the beginning of the postpartal period usually lasting from 1–4 hours.

8. Describe the mother's emotions and attitude during the three phases of labor.

Answer

Latent—Happy, excited, and talkative. Good time for teaching.

Active—Busy, concentrating on the contractions, woman is more dependent on others, only talks between contractions.

Transition—May develop nausea and vomiting. Client fears she is losing control. Often irritable and sleeps between contractions.

9. Identify the five areas evaluated on the Apgar score and the possible point value of each area.

Answer

Color, heart rate, reflex irritability, muscle tone, and respiratory effort. Each area may receive a score of 0, 1, or 2. Total scores can range from 0–10.

10. List the three fetal structures of normal circulation during the gestation and what each structure does.

Answer

Foramen ovale—a hole between the right and left atrium that allows the blood to bypass the lungs.

Ductus arteriosus—a connection between the pulmonary artery and the aorta that allows blood to bypass the lungs.

Ductus venosus—a connection from the umbilical vein that bypasses the liver delivering blood to the inferior vena cava.

MATCHING ANSWERS

APPLICATION ANSWERS

1. A woman visits her obstetrician for a pregnancy test that is positive. In taking her history, she reports that she has been pregnant four times before. She has two children at home, one of which was born at 32 weeks gestation. She lost a set of twins at 14 weeks and another baby at 12 weeks. What is her para, gravida, and TPAL?
- G5, P4 (T1, P1, A2, L2)
 - G5, P2 (T1, P1, A3, L2)
 - G3, P2 (T1, P2, A2, L1)
 - G3, P4 (T2, P3, A3, L2)

Rationale

Correct answer: b.

Para and gravida refer to pregnancies and pregnancies terminated after the age of viability. The woman is now pregnant and has been pregnant four times before—G5. She has delivered twice after the age of viability—P2. TPAL looks at babies. She had 1 term infant, 1 preterm infant, 3 abortions (one at 12 weeks and two at 14 weeks), and has 2 living children.

2. The obstetrician asks the nurse to determine the due date for a pregnant client on her first prenatal visit. The client reports that her last menstrual period began on February 5, 2007 and ended on February 10, 2007. What is her due date?
- November 5, 2007
 - November 12, 2007
 - November 10, 2007
 - November 17, 2007

Rationale

Correct answer: c.

Count back 3 months from February and add 7 days.

3. A pregnant woman at 14 weeks gestation calls the obstetrician's office to report that she has noted some vaginal discharge. The discharge is clear and without odor. The office nurse would instruct the client to
- wear a peri-pad to absorb the liquid, which is normal
 - douche with water to see if that improves the drainage
 - do nothing, as vaginal discharge in pregnancy is normal
 - report to the physician's office immediately for assessment

Rationale

Correct answer: d.

Vaginal discharge should be evaluated to ensure that the membranes have not ruptured. Only a physician can determine if discharge is normal or abnormal.

4. While attending childbirth education class, a primigravida asks when she should go to the hospital. The nurse's best response would be:
- With the first contraction.
 - One hour after the onset of labor.
 - When she thinks her membranes have ruptured.
 - As soon as she is sure she is in true labor.

Rationale

Correct answer: d.

When the membranes rupture, labor should start. If it does not, ruptured membranes could increase the risk of infection. The woman would not go to the hospital with the first contraction. Women cannot always tell the difference between true and false labor. During first pregnancies, latent labor may last several hours and the woman would be more comfortable at home.

5. A nurse is teaching a childbirth education class to four women in late pregnancy. The women make the following statements. Which statement would most likely indicate that lightening has occurred?
- “I can feel my baby move.”
 - “It’s hard to sleep at night—I have to lie on my side.”
 - “I feel like my lungs are being crowded by the baby.”
 - “I have to void frequently like I did in the first trimester.”

Rationale

Correct answer: d.

When lightening occurs, the baby settles back into the pelvis putting pressure on the bladder. Response “a” refers to quickening. Women in late pregnancy have trouble sleeping. At about 36 weeks, the uterus reaches the level of the xiphoid process making breathing difficult.

6. A woman arrives at the labor unit in labor. She is talkative and smiling between contractions. Prior to completing the vaginal examination, the nurse would suspect the woman is in what phase/stage of labor?
- Latent phase
 - Active phase
 - Transition phase
 - Second stage

Rationale

Correct answer: a.

In latent phase, the woman is excited to finally be in labor, is able to walk around comfortably and will read or talk to family members between contractions. During the active phase, the woman is serious, no longer laughing and talking but working. In transition phase, the woman may suddenly complain of nausea and will be irritable. The second stage of labor is the delivery phase.

7. Monitoring the client during labor is the nurse’s responsibility. If the mother is not hooked up to a fetal monitor, the nurse would assess FHT at the following times: (Select all that apply)
- on admission
 - after each contraction
 - immediately when the membranes rupture
 - each time the mother’s vital signs are taken
 - as the mother enters each phase of labor

Rationale

Correct answers: a, c, and d.

An initial assessment is a component of every admission. When the membranes rupture, it is critical to assess FHT as the cord may prolapse. Hospitals will have a routine periodic assessment of vital signs, which will include the FHT, typically every 30 minutes during active labor and every 15 minutes during transition. If FHT were taken after each contraction, the nurse would accomplish nothing else.

8. One minute after birth, the nurse performs an Apgar scoring on the newborn. The baby receives a score of 6. The mother asks what this score indicates. The nurse’s response would be based on the knowledge that
- the higher the score, the more intelligent the baby will be
 - low scores indicate a baby who has experienced birth trauma
 - A score of 6 suggests an infant that needs immediate transfer to the high risk nursery
 - the score indicates how well or poorly an infant has transitioned from intrauterine to extrauterine life

Rationale

Correct answer: d.

The Apgar score is an indication of how well the infant has transitioned, the higher the score, the better the transition. It does not predict outcome or future events.

9. A newborn is admitted to the newborn nursery. A new nurse will be caring for the infant. The charge nurse is explaining bloodborne precautions to the new nurse. The charge nurse would tell the new nurse to wear gloves for what activities? (Select all that apply.)
- Admission bath
 - Daily bath
 - Meconium diaper change
 - Urine diaper change
 - Any contact with the infant

Rationale

Correct answers: a, c, and d.

Gloves are always worn when the nurse may be exposed to blood or body fluids. Since at birth, the baby is covered with vernix and amniotic fluid and maternal blood, gloves should be worn then, but subsequent baths do not require gloving.

10. There has been a rush of difficult deliveries at your hospital and the hospital nursery currently has babies

(continued)

with the following abnormalities. Which infant should be monitored for increased intracranial pressure?

- Cephalohematoma
- Caput succedaneum
- Intracranial hemorrhage
- Facial petechiae

Rationale

Correct answer: c.

Caput succedaneum is swelling of the scalp but puts no pressure inside the skull. Both cephalohematoma and facial petechiae are bleeding on the outside of the skull. Only intracranial hemorrhage would increase intracranial pressure.

- The nurse is assessing a client on the second day postpartum. The nurse would intervene if the fundus was located
 - 2 fingerbreadth above the umbilicus
 - 1 fingerbreadth below the umbilicus
 - 2 fingerbreadths below the umbilicus
 - 3 fingerbreadths below the umbilicus

Rationale

Correct answer: a.

The fundus should decrease 1 fingerbreadth per day. The woman who has the fundus 2–3 fingerbreadths below the umbilicus is progressing normally. One fingerbreadth is slightly above where we expect but the woman 2 fingerbreadths above the umbilicus is displaying subinvolution, might have a full bladder or uterine atony.

- A new mother is planning to bottle feed her infant. Instructions have been given to the mother to prevent milk production. The nurse observes all the following activities by the mother. Which activity indicates a lack of understanding?
 - The mother is wearing a tight bra.
 - The mother does not try to express the milk.
 - The mother avoids handling or touching the nipples.
 - The mother takes a long hot shower with water hitting the breasts.

Rationale

Correct answer: d.

This activity will stimulate milk production. The other activities will not.

- The new mother calls the obstetrician's office at 8 days postpartum to state that her lochia had returned

to red in appearance although the volume has not increased. The nurse would recommend the mother to

- drink more milk
- rest more frequently
- avoid sexual activity
- increase her iron intake

Rationale

Correct answer: b.

The change from lochia serosa back to lochia rubra usually occurs when the mother is becoming more active and is overdoing herself.

- A woman is at the obstetrician's office for her second prenatal visit. She has numerous complaints including all of the following. Which would require reporting to the physician?
 - She has to void frequently.
 - She is tired and wants to sleep all the time.
 - She has a burning sensation when she urinates.
 - Although she has not vomited, she feels nauseated most of the time.

Rationale

Correct answer: c.

All other findings are normal in early pregnancy. Burning on urination could indicate a urinary tract infection.

- At 20 weeks gestation, a pregnant woman is diagnosed with polyhydramnios. Which assessment finding contributed to this diagnosis?
 - voids frequently
 - blood pressure is 148/86
 - quickening has not been noted.
 - the fundus is two fingerbreadths above the umbilicus.

Rationale

Correct answer: d.

Polyhydramnios is excessive amniotic fluid. The extra amniotic fluid will push the fundus higher than normal. At 20 weeks, the fundus should be at the umbilicus.

- Following admission to the newborn nursery, a newborn's rectal temperature is found to be 98.0°F. His pulse is 146 and respirations are 36. Lung assessments include adventitious sounds. Immediate nursing interventions should be directed at
 - warming the baby
 - promoting bonding with the parents
 - calming the infant to slow the heart rate
 - percussion and postural drainage to clear the lungs

Rationale

Correct answer: a.

This baby's core body temperature is low. Cold stress will cause the baby to develop hypoglycemia. Bonding is important but warming the baby takes priority. Moisture in the lungs is common at admission to the nursery and the lungs will quickly absorb the moisture.

17. A pregnant woman at term is being admitted to the labor room in early labor. During the admission process, the woman's membranes suddenly rupture. Priority nursing activities at this time would include
- checking the fetal heart tones
 - vaginal examination to determine dilation and effacement
 - cleaning up the woman and making her comfortable
 - completing the admission process so that all paperwork is completed before delivery

Rationale

Correct answer: a.

There is a danger that the umbilical cord could prolapse if the membranes rupture prior to full engagement so the priority action is to check fetal heart tones.

18. A fetus of a woman in labor is found to have a breech presentation, longitudinal lie and a flexed attitude. In listening for fetal heart tones, the nurse would listen on the mother's abdomen
- below the umbilicus
 - at the umbilicus
 - above the umbilicus
 - lateral to the umbilicus

Rationale

Correct answer: c.

In a breech presentation, the fetal heart tones are heard above the umbilicus.

19. A teenager is admitted at term to the labor unit in early labor. She has not attended any childbirth education classes. Her mother is present as her support person. The best time to discuss breathing techniques with this teenager is
- during the latent phase of labor
 - as she approaches transition stage
 - after delivery in anticipation of future pregnancies
 - as she approaches each labor stage that requires a different breathing technique

Rationale

Correct answer: a.

During the latent phase, the teenager is alert and able to learn. When labor is active, it is hard for a woman to concentrate.

20. A single mother has delivered an infant boy. Which behavior by the mother indicates that bonding is proceeding on schedule?
- The mother successfully breast-feeds the infant.
 - The mother asks questions about the baby's condition.
 - The mother states: "I wanted a girl, but a boy will be OK too."
 - The mother progresses from touching the infant with her fingertips to whole hand touching.

Rationale

Correct answer: d.

A woman will explore the newborn first with fingertips, progress to whole hand and then to enclosing the infant in her arms. *En face* behaviors also indicate bonding is occurring.

21. The nurses in the delivery room reported a concern about the mother's reaction to her newborn. Mother and infant are moved to the recovery room. Which activity by the recovery room nurse will promote mother-infant bonding?
- Dimming the overhead lights.
 - Allowing the father to stay with the family unit.
 - Administering morphine to ensure that the woman is pain free.
 - Limiting fundal assessments to allow the family unit time alone.

Rationale

Correct answer: a.

Dimming the lights will cause the infant to open his eyes. Studies have shown that the baby looking back at the mother promotes the mother's interest in her child.

22. The nurse is discharging a breast-feeding mother and her infant from the hospital on the third day postdelivery. Discharge instructions relative to breast-feeding have been given by the nurse. Which statement by the mother indicates the correct information about breast-feeding?
- "Six to eight wet diapers indicate my baby is getting enough milk."
 - "I need to limit my fluid intake so that I won't dilute my breast milk."
 - "I can feed formula from a bottle during the nights until my milk comes in."
 - "I should weigh the baby before and after feeding to determine if I have enough milk."

Rationale

Correct answer: a.

Urine output is a good indicator of the supply of breast milk. A breast-feeding mother will need ample fluid

(continued)

intake to produce breast milk. Missing feedings will diminish the amount of breast milk. Home baby scales are usually not accurate enough to determine how much milk the baby is receiving.

23. The nurse is checking the infants in the newborn nursery for hyperbilirubinemia. The nurse knows that the infants most likely to have hyperbilirubinemia are those who (Select all that apply.)
- are premature
 - are full term
 - have broken bones
 - have chromosomal disorders
 - have a large amount of bruising

Rationale

Correct answers: a, c, and e.

Any condition that causes excessive bruising or affects the maturing of the liver will cause hyperbilirubinemia. In addition to those listed above, infants who are large for gestational age and those who suffer cold stress are more likely to have hyperbilirubinemia.

24. A woman in late pregnancy is complaining of severe backaches. The nurse notes that the pregnant woman's posture displays lordosis. To reduce the backaches, the nurse would suggest

- wearing a girdle to support the back muscles
- wearing shoes with heels no higher than 1 inch
- performing the pelvic tilt several times during the day
- limiting the amount of walking that she does during the day

Rationale

Correct answer: c.

Pelvic tilt exercises will strengthen the muscle supporting the pelvis necessary for posture. Wearing a girdle reduces the muscle support. Shoes should be flat. Walking is excellent exercise for the pregnant woman.

25. A teenager purchases a home pregnancy test. She later asks the nurse how these tests work. The nurse's response is that the pregnancy tests are based on which hormone?
- Oxytocin
 - Estrogen
 - Progesterone
 - Human chorionic gonadotropin

Rationale

Correct answer: d.

HCG is the hormone produced by the chorionic villi and then the placenta. It is the basis for most pregnancy tests.

Health Promotion and Maintenance—Part 2

Sub-category: None

Topics: Growth and Development

Aging Process

Development Stages and Transitions

Expected Body Image Changes

Family Systems

Human Sexuality

Family Planning

| | | | |
|-------------------|-----|--------------------------|-----|
| ▸ Aging Process | 152 | ▸ Family Systems | 157 |
| ▸ Body Image | 155 | ▸ Growth and Development | 131 |
| ▸ Family Planning | 158 | ▸ Human Sexuality | 157 |

GROWTH AND DEVELOPMENT

- Closely interrelated processes influenced by the inner forces of heredity and temperament and outer forces of family, peers, nutrition, life experiences, and environmental elements.
- In the child
 - There is a definite and predictable **sequence** of growth and development through which an individual normally proceeds (one crawls before he/she walk)
 - These patterns are universal, but individuals progress at their own **pace**
 - There are regular patterns in the **direction** of growth and development; cephalocaudal (head to toe) and proximodistal (center to periphery)
- In the aging adult
 - There is a decline of systems, both physical and sensory
 - There is a loss of fine motor skills

GROWTH

- Increase in body size—quantitative change
- Measurements are plotted on standardized growth charts and expressed as percentile of height, weight, head circumference, and body mass index (BMI) for age.

Assessment Alert

A child who is above the 95th or below the 5th percentile needs further evaluation.

DEVELOPMENT

- Increasing capacity to function at more advanced levels—qualitative change
- **Maturation:** the process of aging; increasing adaptability and competence in new situations allowing for relinquishing of existing behavior and the learning and integrating of new, more mature patterns of behavior
- **Critical or sensitive periods:** specific time period during which the environment has the greatest impact on the individual (i.e., if encouragement and stimulation to walk occurs at the critical period, walking will occur more easily than if at another time)

Think Smart/Test Smart

Prepare yourself to answer questions about growth and development from both a normal and an abnormal perspective. Study the milestones of growth and development; this is the normal perspective. Next, stones change to the abnormal perspective by putting “is not” or “does not” in front of each of the normal developmental milestones.

Examples of questions from a normal perspective are “At what age would the nurse expect a child to _____” or “When assessing a 3-month old, which finding would the nurse expect?” Questions like these ask that you identify what constitutes normal development at a specific point in the lifespan. Examples of questions from an abnormal perspective are “When assessing a 3-month old, which finding indicates a need for further investigation?” and “Which behavior on the part of a 6-month old, suggests that a developmental delay or disability may exist?”

DEVELOPMENTAL STAGES

- Stages are approximate age ranges incorporating specific developmental changes and tasks
- The success or failure of achieving developmental tasks within a stage affects the ability to complete the stage and move on to the next stage

- Prenatal period: conception to birth
 - Rapid growth, development of body systems, and total dependency on maternal health
- Infancy period: Neonatal and infancy period from birth to 12 months
 - Initial adjustment to extrauterine life and subsequent rapid motor, social, and cognitive development, when mother and child develop a strong attachment influencing future adjustment and relationships
- Early childhood: Toddler and preschool period from 1 to 6 years
 - Begins with the child’s first steps and a vocabulary of just a few words and extends until the child is physically and cognitively mature enough to start school. During these years, the child separates self from others, gains self-control, and develops social relationships outside of the home.
- Middle childhood: School-age period from 6 to 11 years
 - Child shifts away from family to the ever-increasing importance of peer relationships
 - Continual development and refinement of motor, language, and social skills
- Later childhood: 11–19 years preadolescent and adolescence
 - Rapid biological and psychosocial maturation accompanied by emotional turmoil and change
 - Begins at onset of puberty and extends until entry into the adult world
- Adulthood: Young adults from 20 to mid-to-late 30s, Middle adult from late 30s to mid-60s and older adult, 65 years and older
 - Young adulthood: crucial decisions made regarding career, marriage, and starting a family
 - Middle adulthood: life choices are reexamined and changes made if desired; time of giving back to the community and guiding the next generation
 - Older adulthood: time of adjustment to physical changes and losses and finding new ways to live and enjoy life

DEVELOPMENTAL TASKS

- Age related achievements, skills, or competencies normally occurring in a specific developmental stage
- The developmental tasks for each stage must be accomplished before progressing to the next stage
 - Physical tasks/motor development (e.g., learning to sit, crawl, walk)
 - Psychosocial tasks (e.g., learning trust, self-esteem)
 - Cognitive tasks (e.g., acquiring concepts of time and space, abstract thought)

DEVELOPMENTAL CRISIS

- Time when there is great difficulty in meeting the tasks of a specific developmental period

DEVELOPMENTAL AGE

- Achievement of specific developmental skills and tasks related to developmental stage

DEVELOPMENTAL THEORIES OF PERSONALITY, SOCIALIZATION, COGNITION, AND MORALS ARE:

- Freud's psychosexual theory of personality development
- Erikson's psychosocial theory of personality development
- Piaget's theory of cognitive development
- Kohlberg's theory of moral development

Freud's Psychosexual Theory of Personality Development

- Five stages each characterized by the inborn tendency of all individuals to reduce tension and seek pleasure (that which produces bodily pleasure is described as sexual)
- Each stage is associated with a particular conflict that must be resolved before the child can move successfully to the next stage
- Experiences during early stages determine an individual's adult adjustment patterns and personality traits
- Theory is grounded in the belief that two internal biologic forces, sexual and aggressive energies, drive psychological change in the child
- Motivation is to achieve pleasure and avoid pain created by these energies, which come into conflict with the reality of the world, thus facilitating maturational changes

Psychosocial Development (Erikson)

- Trust vs. mistrust (birth to 1 year)
- Infants whose needs for warmth, comfort, love, security, and food are met learn to trust. Infants whose needs are significantly delayed or unmet, learn to mistrust
- Erikson reasons that the quality of parent–infant interactions determines development of trust or mistrust

Nursing Intervention Alert

The nurse assesses the appropriateness and availability of experiences that will promote the development of trust.

Piaget's Theory of Cognitive Development

- Looks at age-related intellectual organization
- Defines cognitive acts as ways in which the mind organizes and adapts to the environment
- Four stages, each stage builds on accomplishments of the previous stage in a continuous, predictable, orderly process, however at an individualized rate

Kohlberg's Theory of Moral Development

- Focuses on the development of moral reasoning
- Attempts to explain how moral reasoning matures for an individual
- Children's moral development follows their cognitive development
- Moral development is a complicated process involving the acceptance of values and rules of society in a way that shapes behavior

DEVELOPMENTAL ASSESSMENT

- Essential component of the health assessment
- Developmental assessment tool: Denver Developmental Screening Test (DDST) revised, restandardized, and renamed the Denver II
- Denver II tool measures gross motor, fine motor, language, and personal-social development; does not measure intelligence
- Screening tests quickly and reliably identify infants and children whose developmental level falls below the expected norm and require further evaluation
- Means of recording present objective measurements for future reference

Assessment Alert

Caution: the tests are only as good as the examiner's expertise in administering them.

INFANCY PERIOD: BIRTH TO 12 OR 18 MONTHS

Newborn Infant or Neonate (birth to 1 month)

- **Apgar score:** Initial assessment of the newborn including heart rate, respiratory effort, muscle tone, reflex irritability and color at 1 and 5 minutes after birth. Each item is given a score of 0, 1, or 2. Total score of 0–3 is severe distress, 4–6 moderate distresses, and 7–10 good adjustment.

- **Weight:** Average birth weight = 2700–4000 grams (6–9 lbs).
—10% of birth weight is lost in first few days of life, primarily through fluid losses and regained by the 2nd week;
- **Length:** Average birth length = 48–53 cm. (19–21 inches).
- **Head:** Average neonatal head circumference is 33–35 cm (13–14 inches) about 2–3 cm (1 inch) larger than chest circumference.
—**Molding**, or overlapping of the soft skull bones, allows the fetal head to adjust to the diameter of maternal pelvis; the bones readjust within a few days producing a rounded appearance; molding may alter head circumference; head and chest circumference may be equal for first 1–2 days
—**Fontanels**; Anterior diamond shape; Posterior fontanel triangular shape; (between the unfused bones of the skull); Fontanels should be flat, soft, and firm; may bulge when crying. The posterior fontanel closes at 2–3 months; anterior fontanel closes at 12–18 months

Assessment Alert

Bulging or depressed fontanels when infant is quiet indicates a potential problem and requires further evaluation.

- Transitions to extrauterine life** include: physiologic onset of breathing, initiated by chemical and thermal stimuli; cough and sneeze to clear fluid present from intrauterine life; pressure changes in the heart and lungs; closure of fetal shunts; the foramen ovale; the ductus arteriosus; increased pulmonary blood flow
- Heart rate:** 120–160 beats per minute and irregular for the neonate; count apical pulse for one full minute
- Respiratory rate:** 30–60 breaths per minute and irregular; count for one full minute; neonates are abdominal breathers and obligate nose breathers

Assessment Alert

Signs of respiratory distress in newborn are: diminished breath sounds, periodic breathing with repeated apneic spells, wheezing, grunting, inspiratory stridor, persistent cyanosis.

- **Thermoregulation:** Newborns are subject to heat loss and stress from cold due to large body surface and thin subcutaneous fat; poor development of sweating and shivering

mechanisms; poor temperature regulation. To compensate the infant has brown adipose tissue or *brown fat* which has a greater capacity for heat production than regular adipose tissue to help in heat regulation. Also, the flexed position decreases the amount of surface area exposed to the environment.

• Elimination

- Meconium:** infant's first stool should pass within the first 24–48 hours
- Transitional stools** usually appear by 3rd day after initiation of feeding
- Milk stool** appears by 4th day, by 2nd week elimination pattern associated with the frequency and amount of feeding. Breast fed-pasty, yellow, odor of sour milk; formula fed light brown, firmer consistency, stronger odor.
- Urinary output** 200–300 ml by the end of the 1st week

• Neurological

- Assessment of reflexes** is an essential component of the neurological assessment, along with assessment of posture, muscle tone, head control, and movement

• Reflexes

- Blink** reflex in response to light or touch; **corneal** reflex in response to touch; **pupillary** reflex in response to light or touch; reflexes persist for life
- Gag** in response to stimulation of posterior pharynx by food or tube; causes infant to gag; reflex persists for life
- Startle** in response to sudden loud noise; causes abduction of the arms with flexion of the elbow; disappears by 4 months
- Moro** in response to sudden loud noise; infant extends then flexes arms and fingers; decreases at 3–4 months, disappears at 6 months
- Sucking** in response to touching infant's lips; strong and coordinated; disappears at 3–4 months
- Rooting** in response to touching or stroking cheek along side of mouth; causes infant to turn head toward that side and begin to suck; disappears at 3–4 months
- Babinski** in response to stroking outer sole of foot upward from heel and across ball of the foot causes toes to hyperextend and hallux, big toe to dorsiflex; disappears after 1 year

• Motor Development

- Movements** are sporadic, symmetrical, and involve all extremities
- Extremities flexes**, knees flexed under abdomen
- Turns head** from side to side when prone; briefly lifts head off bed
- Little head control**

• Sleep–wake pattern

- First hour of life** quiet, alert, eyes wide opened with vigorous sucking

- Next 2–3 days sleeps most of the time, recovering from birth
- Sleep periods vary from 20 minutes to 6 hours, little day or night variation
- Wake newborn to feed q4hours (recommended by most practitioners)
- **Sensory**
 - Focus on objects 8–10 inches away and can perceive forms
 - Preference for human face apparent
 - Auditory systems function at birth
- **Cognitive Development**
 - Newborn learns to turn to the nipple
 - Learns that crying results in parents' response
- **Psychosocial Development**
 - Interactions during routine care between newborn and parent lay foundation for deep attachment

Nursing Process Elements

Assessment Alert

Deviations in growth and development require further evaluation, examples: absent reflex, hypotonia, hypertonia, limp posture, extension of extremities.

- Maintain open airway
- Stabilize and maintain body temperature
- Protect from infection
- Promote parent–infant attachment
 - Early parent–infant interaction, close body contact, and breast-feeding encourages attachment.
 - In the first hour of life, the newborn is quiet, alert, eyes wide-open and vigorously sucking, making this an opportune time to promote parent–child attachment.
 - Bonding occurs when newborn and parent elicit reciprocal and complementary behavior.
 - Attentiveness and physical contact are behaviors indicating successful parent–infant bonding.

Assessment Alert

If newborn or mother experiences health complications after birth, attachment and bonding may be compromised.

Infant (1 month to 1 year)

- **Growth**
 - Infancy most rapid period of growth; especially during the first 6 months
 - Growth monitored by plotting on standardized growth chart
 - **Weight**
 - Gains 5–7 oz. per week for first 6 months (150–210 g)
 - Birth weight doubles at 5–6 months
 - Weight gain slows during the second 6 months
 - Gains 3–5 oz (85–150 g) weekly for next 6 months
 - Birth weight triples by 1 year
 - **Length**
 - Grows 2.5 cm (1 inch) per month for the first 6 months
 - Slows during the second 6 months
 - Grows 1.25 cm (½ inch) for second 6 months
 - Birth length increases by 50%, mainly in the trunk, by 1 year
 - **Head Growth**
 - Posterior fontanel closes
 - Increases by 1.5 cm (1/2 inch) per month for the first 6 months and by 1.25 cm per month during the second 6 months
 - **Chest Circumference**
 - Increases by 2–3 cm. for the first 6 months (1 inch less than head circumference)
 - Chest and head circumferences equal at 1 year
 - **Vital Signs**
 - Heart rate 80–130
 - Respiratory rate 30–50 up till 6 months; 20–30 till 2 years
 - B/P 90/50 on average
 - **Dentition**
 - Beginning signs of tooth eruption by 5–6 months
 - Chewing and biting 5–6 months
 - **Sensory**
 - Rudimentary fixation on light or objects; ability to follow light to midline; and differentiates light and dark at birth
 - Hearing and touch are well developed at birth
 - Rudimentary color vision begins at 2 months and improves throughout the first year
 - Able to fixate on moving object 8–10 inches away, 45 degrees range at 1 month
- Follows objects 180 degrees at 3 months
- Beginning hand eye coordination at 4 months
 - Can fixate on very small objects at 7 months
 - Begins to develop depth perception 7–9 months
 - Able to discriminate simple geometric forms at 12 months

- Able to follow rapidly moving objects at 12 months
- Locates sound by turning head to side, looking in same direction at 3 months

- **Sleep**

- Most newborn infants sleep when not eating, being changed or bathed
- Most infants sleep 9–11 hours a night by 3–4 months
- Total daily sleep is approximately 15 hours
- Nighttime sleep hours and amount and length of naps vary among infants

Most infants take routine morning and afternoon naps by 12 months

- **Gross Motor Developmental Milestones**

- Lifts head 90 degrees when prone, sits with support at 3 months
- Good head control at 5 months
- Rolls completely over, good head control in sitting position, crawls on abdomen with arms at 6 months
- Attains sitting position independently, creeps on all four extremities, pulls self to standing position at 9 months
- Walks holding on to furniture cruising at 11 months
- Stands alone, takes one to two steps at 12 months
- Walks alone at 15 months

- **Fine Motor Developmental Milestones**

- Grasps and briefly holds objects and takes them to mouth at 3 months
- Uses palm grasp with fingers encircling object, transfers cube from hand to hand at 6 months
- Crude thumb-finger pincer grasp, bangs hand held cubes together at 9 months
- Places tiny object, such as raisin into container, makes marks with crayon at 12 months
- Builds tower of two cubes, scribbles with crayon at 15 months

Assessment Alert

Head lag at 6 months requires further neurological evaluation.

An infant who does not pull up to a standing position by 11 or 12 months needs evaluation for dysplasia of the hip.

- **Cognitive Development (Piaget)**

- Sensorimotor (birth to 2 years)**
- Learning takes place through the child's developing sensory and motor skills

Assessment Alert

Infants need opportunities to develop and use their senses.

Visual, sensory, and tactile stimulation are as necessary as food for healthy development.

Nurses evaluate adequacy of these opportunities.

- The child progresses from reflexive activity to purposeful acts
- Initially the infant focuses on own body; discovers own body parts at 2–4 months; gradually shifts attention to objects in the environment
- Learning by simple repetitive behaviors: repeating pleasing actions; learning that sucking gives pleasure, leads to generalized sucking of fingers, rattle
- Prolonging interesting actions for reasons that result; grasping and holding becomes shaking, banging, and pulling. Shaking makes one noise, shaking more or less makes a different noise
- Imitates simple acts and noises
- Beginning understanding of object permanence, searches for dropped objects
 - Can find partially hidden object at 6 months
 - Briefly searches for dropped object; begins to understand object permanence 7–9 months
 - Develops sense of object permanence at 10 months
 - Searches for objects where seen last, even if not hidden at 12 months

- **Language Development**

- Vocalization is distinct from crying at 2 months
- Vocalizes to show pleasure; squeals at 3 months
- Laughs at 4 months
- Begins to imitate sounds at 6 months
- One syllable utterances *ma*, *da*, *mu*, *hi* at 6 months
- Chained syllables *baba*, *dada* at 7 months
- Dada*, *mama* with meaning at 10 months
- Five word vocabulary at 12 months

Assessment Alert

Language Developmental Milestone is: First words with meaning “dada,” “mama” around 10 months.

- **Psychosocial Development (Erikson)**
 - Trust vs. Mistrust (birth to 1 year)**
 - Infants whose needs for warmth, comfort, love, security, and food are met learn to trust. Infants whose needs are significantly delayed or unmet, learn to mistrust
 - Erikson reasons that the quality of parent–infant interactions determines development of trust or mistrust
- **Psychosocial Behaviors**
 - Parents and infants develop a strong bond that grows into deep attachment as the parent cares for the newborn
 - Stares at parents' face when parent talks to infant at 1 month
 - Smiles socially at 2 months
 - Recognizes familiar faces at 3 months
 - Demands attention, enjoys social interaction with people at 4 months
 - May show aggressiveness by occasional biting
 - Plays peekaboo and pat-a-cake at 11 months
- **Fears**
 - Begins to express fear; anticipates fear of mutilation, animal noises, the dark
 - Stranger anxiety** begins at around 6 months and intensifies in the following months, consistent stranger anxiety at 8 months
- **Psychosexual Development (Freud)**
 - Oral stage (birth to 1 year)**
 - Actions center on oral activities. The infant sucks, tastes, bites, chews, swallows, and vocalizes for pleasure

Nursing Process Elements

- **Communication with Infant**
 - Talking softly, singing, rocking, cuddling

Assessment Alert

Assess the appropriateness and availability of experiences that will promote the development of trust.

- **Nursing Care of the Hospitalized Infant**
 - Encourage parent to stay and provide care for infant; hospitalized infants experiencing repeated bodily intrusions, multiple caregivers, and separation from the parent are at risk for difficulty with establishing boundaries and building trust
 - Diminish stranger anxiety by limiting the number of caregivers who have contact with the infant

Nursing Intervention Alert

Parents of infants that are ill, have congenital defects, or who are hearing or visually impaired will need extra support and teaching on how to compensate and minimize developmental delay for those children. Nurses play an instrumental role in teaching, modeling interactions, and care for the compromised infant.

Preparing The Infant For Procedures

- Speak softly and handle gently, but firmly, have calm, unhurried approach
- Keep infant in view of parent; if possible have parent hold infant; upright position tolerated best; encourage parent to cuddle infant after procedure; if parent not available place familiar stuffed animal near infant
- **Diminish stranger anxiety**; have primary nurse perform or assist with procedure; limit number of strangers entering room during procedure
- **Sensorimotor** considerations; use sensory soothing measures; firm gentle handling and stroking; hugging and cuddling; soothing, calming, quiet voice
- Analgesics as needed
- Do not perform painful procedures in crib
- Expect older infants to resist; restrain safely if needed

Parent teaching

- **Caring for the infant:**
 - Care of umbilicus and circumcision
 - Support of thermoregulation in neonate
 - Prevention of diaper rash, skin care
 - Care of the teeth
 - Clean teeth with damp cloth
 - Frozen teething ring to reduce inflammation and manage pain
 - Tylenol may be given for teething pain disrupting sleep and feeding
 - Topical baby Ora Jel, benzocaine, may be used if instructions followed carefully
 - Prevent dental carries by avoiding having infant falling asleep with bottle, causing milk to linger, avoid apple juice bottles for older infants before sleep
 - Fluoride supplement at 6 months and up for breast or formula fed, if water supply not adequately fluorinated
 - Stress management/prevention of abuse/**shaken baby syndrome**

Nursing Intervention Alert

Alert parents to major causes of injury and death: aspiration of foreign objects, suffocation, falls, poisoning, burns, motor vehicular injuries, and teach prevention.

- **Safety:**

- Use federally approved infant car seat, teach proper installation facing rear, place in back seat, not in a seat with an air bag. Infants up to 9 kg (20 lb) and younger than 1 year should face rear
- Check bathing water temperature/formula temperature
- Ensure crib mattress fits snugly; no pillow or comforter in the crib
- Position supine or supported on side for sleep until infant can turn over because prone position may increase sudden infant death syndrome (SIDS). SIDS—sudden unexpected unexplained death of a seemingly healthy infant
- Only use pacifier with one-piece construction and loop handle
- Do not warm frozen breast milk in the microwave causing uneven warming and risk for burns; defrost in refrigerator, then run under warm water
- Never leave infant on raised, unguarded surface (may roll)
- Restrain in infant seat
- Remove bib before putting infant in crib
- Inspect toys for small removable parts

- **Older infant:**

- Keep phone number of poison control center posted near telephones or programmed in speed dial
- Be sure paint on furniture does not contain lead
- Teach danger of latex balloons
- Restrain in high chair
- Keep crib away from windows or other furniture

- **Child proofing the environment:**

- Install gates to block stairways
- Place safety plugs in electrical outlets
- Remove hanging electrical wires; remove tablecloths
- Use cabinet locks; use child protective caps
- Place cleaning solutions and medications out of reach
- Never leave child alone in bathtub

- **Infant nutrition:**

- Breast milk is a complete and healthful diet for the first 6 months; importance of breast-feeding mother being well nourished

- Support choice to use commercial iron fortified formula if breast-feeding not desirable to mother or not a feasible option; recommend mixing powdered formula with bottled water, if water supply has lead or other impurities

- No additional fluids needed during first 4–6 months, will fill infant up, not allowing for adequate nutritional calories

- Cows milk, imitation milks are **not acceptable**

- Breast milk or formula primary source of nutrition in second 6 months as well

- Gradual introduction of solid foods during second 6 months; starting with cereals, fruits, vegetables, and meats

- Finger foods: Teething crackers; zwieback can be given at 6 months, fresh fruit, at 8–9 months (not grapes); many table foods by 12 months

- Do not feed nuts, food with pits, hot dogs, or any foods that could block the airway or have risk of choking

- Honey not given in first year, a source of botulism

- Supplements include: vitamin D, iron by 4–6 months (fetal iron stores are depleted), vitamin B₁₂ may be needed if mother's intake is inadequate

- Fluoride beginning at 6 months

- **Play, stimulation and toys (Birth to 6 months):**

- Importance of talking to infant at close range, singing to infant using soft tone, cuddling, caressing (enhance attachment), and rocking infant

- Place nude on soft surface and gently massage body and exercise extremities (swimming motion)

- Provide musical toys; rattles; soft cuddly stuffed toys; squeeze toys; toys with black and white designs and bright colors; hang musical mobiles within 8–10 inches from infant's face

- Place infant in front of unbreakable mirrors

- Use an infant seat; infant swing; cradle gym; and take for walks in stroller

- Allow infant to splash in tub

- Place on floor to encourage rolling over, crawling, and sitting, starting at 4 months and continue throughout infancy

- Encourage parent to teach language: Teach to repeat sounds infant makes, laugh when infant laughs, call by name, pick up infant, say “up”

- **Play, stimulation and toys (6–12 months):**

- Play hide and seek, peekaboo, hiding face in towel, pat-a-cake, bang a drum, give ball of yarn to pull apart, “catch running water,” swimming in shallow baby pool or bathtub, play ball; rolling to child, take to place where can see animals, other children, people

- Put toys out of reach and encourage to get them

- Play with large toys with movable parts, noisemakers, stacking toys, blocks, pots, pans, push and pull toys, large puzzles with few pieces
- Read to infant: nursery rhymes, books with various textures, books with large bright pictures; encourage infant to turn pages
- Demonstrate building 2-block tower, stacking toys, placing objects into container
- **Discipline:**
 - Consistently and promptly meeting infant's needs builds trust; does not “spoil” infant
 - Setting limits is appropriate and will be required in establishing nighttime routine
 - Corporal punishment is unacceptable

TODDLER (1–3 YEARS)

- Time of intense activity, exploration of the environment and discovery.
 - Developmental tasks: acquisition of language and the ability to communicate verbally, learning socially acceptable behavior, coping with separation from parent, coping with delayed gratification, and controlling bodily functions
 - Transition into toddlerhood begins when the child walks independently and extends until the toddler walks and runs with ease
 - Development of motor skills allows the child to participate in dressing and feeding
 - Sphincter control allows for toilet training
- 

Assessment Alert

Parents report extreme frustration with setting limits and promoting independence at the same time. Be alert to risk for child abuse. Parenting classes are very helpful for support, valuable information, and socialization for the parent with other parents with similar challenges.
- **Physical Growth**
 - Growth** rate slows down during toddler years
 - Weight** average weight gain is 4–6 lbs. per year; (1.8–2.7 kg). The average weight of a 2-year old is 27 lbs (12.2 kg)
 - Height** average toddler grows 3 inches (7.5 cm) per year; average 2-year old is 34 inches (86.5 cm)
 - Head** circumference equals chest circumference for ages 1–2—Anterior fontanel closes at 18 months
 - Chest circumference** exceeds head circumference after age 2
 - **Vital Signs**—cardiopulmonary system stabilizes
 - Heart rate slows to approximately 110
 - Respiratory rate slows to 25
 - B/P average 90/50
 - **Dentition**
 - Primary dentition completed (20 deciduous teeth) by 2½ years
 - **Sensory**
 - Visual acuity: Binocular vision is fully developed; depth perception continues to develop
 - Hearing, touch, taste, and smell become more refined and increasingly coordinated with each other
 - **Elimination and Toilet Training**
 - Gaining sphincter control
 - Readiness for toilet training; stays dry for 2 hours; regular bowel movements; wants to have soiled diaper changed without delay; motor readiness
 - Urinary output 500–1000 ml/day
 - **Sleep**
 - An average of 12 hours a day
 - Most toddlers nap once a day until age 3 or 4
 - Sleep problems related to fears of separation
 - Bedtime rituals, and objects that represent security such as stuffed animals and special blanket are helpful
 - **Gross Motor Development**
 - Locomotion is the major gross motor development
 - Walks independently by age 12–15 months, uses wide stance, protuberant abdomen, and hands out to the side for balance
 - Walks up stairs, holding on to wall at first, both feet on the same step before continuing and when masters going up, is ready for the upright mode for going down the stairs by 2–2½ years
 - Jumps with both feet at 2½ years
- 

Assessment Alert

Walking independently is a developmental milestone.
- **Fine Motor Development**
 - Can build towers by 2 years
 - Draws lines at 2 years
 - Ability to help with dressing/undressing at 18 months; can dress himself at 24 months
 - Draws stick figures by 3 years

- **Safety**
 - Many safety concerns in toddlerhood related to increasing motor development and the toddlers' exploration of the environment
- **Cognitive Development (Piaget)**
 - Continued **sensorimotor stage** and beginning **preoperational thought**
 - Actions become intentional and coordinated
 - Tries new actions to see what happens and holds thought for later action
 - Object permanence**, retains image of person or object out of sight and senses self as separate from others, signals the transition to **preoperational thought (2–7 years)**, which is divided into **preconceptual** and **intuitive thought**
 - Predominant characteristic of preoperational thought is **egocentrism**, which is the inability to recognize that others have a different point of view than their own; events and objects are understood in terms of their relationship to and the effect on the child
 - Thinking is concrete and tangible, children can only reason with what they see or experience (perceptual thinking)
 - Preconceptual (2–4 years)** uses symbols, language, and play for representing ideas as well as recalling the past
 - Intuitive thought (4–7 years)** next section
 - Transductive reasoning: Associates one event with a simultaneous event
- **Language**
 - Language development continues; speech becomes understandable
 - Gestures precede and then accompany language during toddlerhood
 - Points to object and names, e.g., ball, body parts
 - Comprehension much greater than number of words used
 - One-word sentences at 1 year “up”
 - Begins to use short 3-word sentences by 18–24 months “go bye bye”
 - Uses pronouns “I”, “you” at 24 months
 - Uses first name by 24 months and first and last name by 30 months
 - Simple sentences; beginning to use grammatical rules at 3 years
 - Asks questions, “What’s that? Who’s that?” “Why”
 - “That’s mine,” demonstrates desire for independence and control
 - Favorite word is “no”
- **Moral Development (Kohlberg)**
 - Preconventional stage
 - Moral development is closely associated with cognitive abilities and is only beginning

—Does not understand concepts of right and wrong but learns to understand that some behaviors elicit positive feedback and other behaviors elicit negative feedback

- **Psychosocial Development (Erikson)**
 - Autonomy vs. shame and doubt (1–3 years)
 - Toddlers have an ever-increasing ability to control their bodies themselves, and the environment and need to express themselves and gain independence in areas where they are capable of assuming control. Empathetic guidance and support from parents allows for achievement of successful self-control without loss of self-esteem, thus avoiding shame and doubt
- **Psychosocial Behaviors**
 - Increasing independence, ritualism, and negativism are hallmarks of toddlerhood
 - Ritualism: provides comfort and a sense of reliability; has favorite toys, dolls or blanket, bedtime rituals
 - Negativism: strongly expressed emotions “no”
 - Temper tantrums; attention seeking behavior; teach to ignore
 - Possessiveness; beginning awareness of ownership “mine”
 - After stranger anxiety peaks start learning to tolerate separation from parent; transitional items such as special blanket during separation (nap)
 - Sibling rivalry common when there is a new baby
 - Differentiating self from others

Assessment Alert

Behaviors and emotions of toddlerhood can be exasperating for parents:

Assess for the possibility of child abuse; signs of neglect, or mistreatment; provide parenting classes for teaching, reassurance, and support.

- **Discipline**
 - Establish consistency in discipline
 - Behavior is bad, not the child
 - Ensure privacy, not shame inducing
 - Time out, 1 minute per year of age
- **Fears**
 - Loss of parents; separation anxiety
 - Stranger anxiety
 - Loud noises, e.g., vacuum cleaner
 - Going to sleep
 - Large animals

- **Play**
 - Play is the work of the child
 - Parallel play at 18 months, toddlers play alongside other toddlers
- **Psychosexual Development (Freud)**
 - Anal** stage (12 months to 3 years)
 - Sphincter muscles develop and pleasure is centered on the anal region, the child gains pleasure from the elimination and retention of feces. The child is asked to withhold pleasure to meet parental expectations with toilet training.

Nursing Process Elements

- **Communicating with the Toddler**
 - Use simple, short sentences
 - Use concrete explanations
 - Be sure nonverbal messages are consistent with spoken words and actions; do not smile while doing something painful; the child will think you enjoy hurting them
 - Keep in mind the toddler understand words literally: “A little stick in the arm” they are imagining a twig from a tree in their arm
 - Provide art supplies and encourage expression through drawing
 - Play is a form of communication for the child; dolls are good for child to express family relationships
- **Nursing Care of the Hospitalized Toddler**
 - Encourage parent to stay with child; rooming in
 - Promote sense of autonomy by providing opportunities for choices; encouraging self-care as is able
 - Involve the child in his care
 - Maintain rituals and routine that child is accustomed to
 - Provide the child with transitional objects (representation of the parent) from home, e.g., favorite doll, blanket
 - Provide opportunities for play
 - Prepare parents for regression to previous level of behavior, which is a primary defense mechanism used in response to stressful events
 - Stages of separation anxiety in the toddler:
 - Protest:** prolonged crying for parent, rejects others, attempts to find parent, clings to parent when present
 - Despair:** disinterested in environment and play, decreased appetite, passive
 - Detachment or denial:** superficial adjustment, cheerful, shows interest, but remains detached
 - Toddler has no concept of death; primary reaction is separation and loss

Preparing the Toddler for Procedures

- Encourage parent involvement as much as possible
- Communicate using gestures and behaviors; keep language simple; select words carefully, understands words literally (do not say “take B/P,” say “check B/P”)
- Prepare toddler almost immediately before procedure; keep teaching short 5–10 minutes
- Give toddlers information relevant to them only; how will this procedure affect them; what will they feel, see, hear, and taste (sensory aspects of procedure); the **ego-centric** toddler is not interested in the experience of another
- Promote autonomy by providing opportunities for choices and encouraging the child to “help” as much as possible, holding bandages, tape etc.
- Allow toddler to touch and play with equipment that will come in contact with them; or use nurse’s play kit
- Use play with dolls and puppets to demonstrate procedures; avoid favorite doll, child believes doll has feelings
- Use distraction; favorite toy; singing a song; blowing bubbles
- Keep frightening objects out of view; young children believe objects have life like qualities and can harm them (animism)
- Tell child it is ok to yell, cry or whatever to express discomfort verbally
- Expect treatments to be resisted and temper tantrums; use firm consistent approach; restrain safely if must
- Reward good behavior

Parent teaching

- **The toddler years:**
 - Teach importance of attending parenting classes for information, support, and socialization
 - Teach regarding common behaviors and thought processes in toddlerhood: desire to control, negativism, temper tantrums, ritualistic behavior, magical thinking
 - Explain that unsuccessful attempts at control often result in negativism and temper tantrums; temper tantrums are attention seeking behavior
 - Explain importance of ritualistic behavior and that it serves to master skills and decrease anxiety
 - Explain how magical thinking (the child’s belief that his own feelings and wishes affect events) leads to feelings of guilt; e.g., if child wishes that sibling would die and by chance sibling is hospitalized for illness, the toddler will feel intense guilt
 - Teach to encourage independence but at the same time setting limits and giving guidance
 - Teach on use of transitional objects, e.g., favorite blanket during separations

- **Care of teeth:**
 - Teach toddler to clean teeth with soft toothbrush and water (dislikes toothpaste), then floss
 - Do not use fluoridated toothpaste because it is dangerous if swallowed
 - Continue with fluoride supplementation, if water supply not adequate
 - Begin regular dental checkups
- **Nutrition:**
 - As growth periods slow, appetite diminishes and the toddler has periods of physiologic anorexia; small amounts of meat and vegetables are of greater nutritional value to the toddler than large servings of bread or potatoes
 - Do not overwhelm the toddler with large portions
 - Limit cow's milk to a maximum of 24 oz. a day; cow's milk is a poor source of iron and interferes with iron absorption, leading to iron deficiency anemia
 - Serve toddler using favorite dish, cup, and utensils (might refuse well-liked food if served in different dishes)
 - Serve toddler single foods instead of mixtures (such as stews); will often refuse two foods that are just touching each other
 - Serve a variety of nutritious foods, repeating them often so that they will be recognized by the toddler
- **Elimination and toilet training:**
 - Do not initiate toilet training during acutely stressful period, e.g., birth of a new baby, divorce
 - Reward desired outcomes

Nursing Intervention Alert

Guide and teach parents' signs of readiness for toilet training: motor readiness; stays dry for 2 hours; regular bowel movements, wants to have soiled diaper changed without delay.

Teach parents: need for patience and consistency; reward desired outcomes; avoid initiating toilet training during acutely stressful period, e.g., birth of new baby, divorce.

- **Safety: child proofing the environment, with increasing motor development:**
 - Place gates to block stairways
 - Place screens and bars on all open windows; safety locks on cabinets
 - Keep all toxic and dangerous items locked and out of child's reach: medications, cleaning products, knives, firearms, matches, plastic bags
 - Use of safety outlets

- Remove all small objects with potential for aspiration; teach regarding danger in playing with and blowing up balloons
- Move small kitchen appliances far back on the counter
- Use tablecloth with caution because toddler will pull on it.
- Teach parents dangers associated with outdoor play and prevention by not allowing child to play unsupervised; running after ball into traffic, playing in pile of leaves behind parked car; too close to the curb
- Practice water safety, never leave child unattended even just for a moment, near pool, kiddie pool, bathtub, toilet
- Use of federally approved car seat for size/weight (high incidence of deaths from MVA due to not using car seat or improper use)
- **Fears:**
 - Provide emotional support, simple explanations, and controlled desensitization
- **Play, stimulation and toys:**
 - Imitation is one of the most common forms of play
 - Toddlers change toys frequently due to their short attention span
 - Toddlers enjoy activities that provide mobility: riding toys, wagons, pull toys
 - Toddlers enjoy activities for fine motor development: finger painting, large piece puzzles, interlocking blocks

Parent teaching: moral development

- Teach parent that moral development is facilitated when parents use appropriate discipline measures:
 - Take advantage of every opportunity to praise appropriate behavior
 - Explain to the child simply why certain behaviors are unacceptable
 - Use distraction with the child to avoid inappropriate behavior

PRESCHOOL (3–5 YEARS)

- Refinement of all skills in preparation for formal education
- More effective communication and less negativity
- **Physical Growth**
 - Slower growth rate continues with continued refinement and coordination of fine and gross motor skills
 - Running, skipping, hopping, drawing
 - Height** increases 2½–3 inches a year (6.75–7.5 cm)
 - Birth length doubles at 4 years
 - Weight** increases on average 5 lbs a year (2.3 kg)
- **Vital Signs**
 - Slight decrease in heart rate 70–110 and respiratory rate 20–30

- **Dentition**
 - 20 deciduous teeth by age 3
- **Nutrition**
 - Nutritional requirements similar to toddler
 - Continues to reject mixed dishes
 - 5-year old is aware of table manners, willing to try some new foods
- **Elimination**
 - For the most part independent with using toilet by end of preschool period, some children still have “accidents”
- **Sleep**
 - Sleeps 11–13 hours; may take afternoon nap till age 5
 - Extends bedtime rituals to delay sleep, 30 minutes or longer
 - Nighttime awakening and nightmares are not uncommon
 - Security object and night-light helpful
- **Gross Motor Development**
 - Coordination continues to improve; child is increasingly agile and graceful; good posture
 - Can learn to skate and swim
 - Rides tricycle; walks up stairs using alternate feet; stands on one foot for a few seconds by 3 years
 - Walks down stairs using alternate feet; hops on one foot by 4 years
 - Throws and catches a ball; skips using alternate feet; hops on alternate feet; jumps rope by 5 years
- **Fine Motor Development**
 - Preschooler developing self-care abilities: can use a toothbrush, lace shoes
 - Drawing increasing in sophistication; draws circles, may add facial features by 3 years
 - Laces shoes; copies a square; traces a diamond by 4 years
 - Hand dominance is established by 5 years
 - Ties shoelaces; handles scissors well; prints letters and numbers; manages fork and spoon by 5 years
- **Cognitive Development (Piaget)**
 - Preoperational period continues: Intuitive thought (ages 4–7)**
 - Child exhibits intuitive thought process; aware that something is right but cannot say why
 - Thought process increasing in complexity, able to classify, increasing social interactions, and beginning awareness of cause and effect. Uses words appropriately but lacks real knowledge of their meaning
 - Beginning understanding of time at 3 years; greater understanding of time related to sequence of daily events at 4 years; using time oriented words with increasing understanding at 5 years
 - Uses own name and address by 5 years
 - Understands words literally; bad means bad person
 - The preschooler has **magical thinking**; thoughts are all powerful; if bad thought coincides with wished for event, e.g., wishes sibling were dead and sibling subsequently falls ill, the preschooler will experience extreme guilt
 - Begins to question and compare what parents think at 5 years
 - School readiness (attention span, easy separation from parent) around 5 years
- **Language Development**
 - 3- and 4-word sentences at 3–4 years; using 4- and 5-word sentences by 4–5 years, termed telegraphic speech
 - The 3-year-old child asks many questions, talks constantly, uses pronouns correctly, plurals, and past tense of verbs, names objects and people they know, with a vocabulary of 900 words
 - The 4- and 5-year-old children use many more parts of speech, such as adjectives, prepositions, verbs; pattern of asking questions peaks and tells exaggerated stories
 - By the end of 5 years most children use all parts of speech correctly, have increased ability to describe things based on various properties, and have a vocabulary of over 2000 words
- **Moral Development (Kohlberg)**
 - Preconventional stage continues
 - Increasing ability to identify behaviors that elicit rewards or punishments and then labels these behaviors as right or wrong
 - Moral standards are those of others and does behaviors to receive rewards and avoid punishment
- **Psychosocial Development (Erikson)**
 - Initiative vs. guilt (3–6 years)**
 - Curiosity and developing initiative leads to active exploration of the environment
 - Activities are attempted that might break the rules, impinge on the rights of others, or be beyond their capabilities, often resulting in unsuccessful outcomes and conflicts
 - Appropriate resolution of unsuccessful outcomes and conflict, will have a tremendous impact on whether the child feels good about himself/herself and moves forward, or is made to feel guilty by an overpunitive parent
 - Parents need to strike a balance between encouraging independence and setting limits. The child needs guidance on what he should and should not be doing
 - Successful completion of the earlier stages requires a loving family environment, allowing the child to engage in relationships beyond the family unit

- **Psychosocial Behaviors**
 - Pervasive negativism and ritualism of toddlerhood diminishes gradually
 - Egocentric in thought and behavior at 3 years; less egocentrism at 4 years; begins to tolerate other's perspective at 5 years
 - Increased ability to separate comfortably from parents for short periods at 3 years, with increasing comfort for longer separations as getting closer to school age
 - Less jealous of younger sibling at 3 years, (than toddler); sibling rivalry for older and younger siblings at 4 years
 - Attempts to please parents and conform at 3 years; rebels if parents expect too much, “runs away from home” at 4 years; gets along better with parents at 5 years, seeks parents out for reassurance
- **Fears**
 - Greatest number of imagined and real fears: dark, alone at bedtime, large dogs, ghosts, thunderstorms
 - Body mutilation, pain, and people associated with painful experiences
- **Play**
 - Play is the work of the child
 - Associative play: children in a group, engaged in similar activities without rigid organization or rules
- **Psychosexual Development (Freud)**
 - Phallic** or **Oedipal** stage (3–6 years)
 - Genitals are central; children recognize and are curious about the differences between the sexes. The boy becomes interested in the penis, and the girl becomes aware of the absence thereof. Exploration and imagination come into play and the child fantasizes about the parent as the first love.
 - The developing superego (conscience) temporarily pushes these wishes aside as the resolution to this stage

Nursing Process Elements

- **Communicating with the Preschool Child**
 - Very similar to toddler
 - Use concrete explanations
 - Be sure nonverbal messages are consistent with spoken words and actions; do not smile while doing something painful; the child will think you enjoy hurting them
 - Keep in mind the preschooler understands words literally: “A little stick in the arm,” he is imagining a twig from a tree in his arm
 - Use nonthreatening words, say medicine under the skin, instead of shot
 - Provide art supplies and encourage expression through drawing
 - Plays with dolls and puppets to act out feelings

- **Nursing Care of the Hospitalized Preschool Child**
 - Provide experiences and opportunities the child can master, to minimize regression (dependency), which is the child's primary defense mechanism in stressful situations. Success facilitates return to previously achieved more independent level of functioning
 - Fears of bodily harm are now greater than fears of separation including: fear of the simplest intrusive procedure such as needles, fear of mutilation and castration, and pain
 - Preschooler sees death as temporary and reversible, like going to sleep; may view death as punishment, fears the separation and abandonment
 - Use adhesive bandages after giving injection or any opening to the skin; is afraid “insides will fall out”
 - Encourage independence; provide opportunities for decision making; encourage self-care; praise and give rewards for accomplishments
 - Protect from guilt; explain no one is to blame for illness
 - Use puppets, dolls, nurse play kits, to demonstrate and act out and demonstrate procedures

Preparing the Preschool Child for Procedures

- Encourage parent to remain with child as much as possible
- Prepare preschool age shortly before procedure; 10–15 minute teaching sessions
- Encourage questions and praise suggestions
- Reassure preschooler that he or she is not responsible for illness and procedures are never a form of punishment; the child views illness as a punishment due to magical thinking
- Use puppets and dolls to demonstrate procedures; point out on drawing or doll where procedure is performed, emphasize that no other body part will be involved
- Play out experience (therapeutic play); play with equipment; use nurse kits
- Use noninvasive equipment when possible; tympanic temps and oral meds; allow child to wear underpants with gown; preschool child has fear of mutilation, castration, bodily injury; (stage of psychosexual conflict)
- Use adhesive bandages and Band-aids after injections, blood work, or any intrusive procedure with a break in the integrity of the skin. The preschooler believes an opening in the skin will allow the “insides of their body to leak out”
- Explain procedures using simple appropriate language for child's age; remember preschooler takes words literally; when you say “a little stick in the arm” the child is imagining a twig from a tree in their arm
- Use nonthreatening words; say I'm going to check your blood pressure instead of take your blood pressure; check how warm you are

- Provide opportunities for choices; opportunities to help out: hold gauze, remove bandage, tear tape, as the child strives for independence
- Allow child to maintain control as much as possible, own clothing, self-care, simple decision making
- Keep unfamiliar equipment out of view until it is needed because like in the toddler, the preschool child believes objects can perform without human direction and can jump up or bite at them on their own
- Tell child when procedure is completed, praise cooperation and give rewards

Parent/client teaching

- **The preschool years:**
 - Teach importance of attending parenting classes for information, support, and socialization
 - Teach regarding common behaviors and thought processes: child commonly has more fears in preschool than any other time. Fear of the dark, being left alone at bedtime, large dogs, other animals, ghosts, body mutilation and pain
 - Magical and animistic (inanimate objects taking on human attributes) thinking of toddlerhood continues and contributes to illogical fears
- **Care of the teeth:**
 - Teach child proper use of toothbrush and to brush twice a day
 - Supervise brushing and floss for child
 - Maintain routine dental care q6–12 m depending on presence or absence of caries
 - Obtain prompt evaluation by dentist in the event of trauma to teeth (common occurrence)
- **Elimination:**
 - Teach child proper hand washing and to flush
- **Safety:**
 - Preschoolers should be taught safety measures, as they can understand and will listen to precautions
 - Use belt positioned booster seat when child outgrows car seat (40–80 lbs); adult seat belts do not properly fit
 - Instruct on: pedestrian and street safety skills, proper use of playground equipment, fire safety, and pool and water safety
 - Preschooler is curious about fire, so matches, fire arms, must be keep out of reach
- **Socialization:**
 - Needs interactions with peers; benefits from social systems beyond parents, siblings, grandparents, and teachers
- **Discipline:**
 - Fair, but firm and consistent

- Explain why behavior is inappropriate
- Short time out to regain control and lessen intense feelings; 1 minute per year, 3-year-old child; 3 minutes time out

- **Fears:**

- Play out fears with dolls
- Night-light
- Exposure to feared objects in controlled setting; desensitization

- **Play, stimulation and toys:**

- Encourage activities and toys for physical development: jumping, running, climbing, tricycles, wagons, sand boxes
- Choose activities for fine motor development: building blocks, puzzles, coloring, and painting
- Most characteristic and enjoyable preschool activities and toys are for imitative, imaginative, and dramatic play; playing house, dress up, dolls, doll house, doing housekeeping chores, playing store, cars and trucks, doctor and nurse kits provide for hours of self-expression
- Reassure parents that **imaginary playmates** are a normal healthy and useful part of the preschoolers play. It is okay to set a place at the table for the “friend” but do not allow the child to avoid responsibility by blaming something such as the mess in the room on the “friend”
- Reading is an excellent activity that parent and child can do together (mutual activity)
- Control time and content of TV or videos also teach parent that children enjoy and learn from educational programming and when watched together with parent becomes an interactive activity
- Involve in household chores: picking up toys, clothing

SCHOOL-AGE (6–12 YEARS) ALSO KNOWN AS SCHOOL YEARS

- The transition from an informal playgroup or preschool to the structured formal education of the first grade marks the transition of the school years
- The school-aged child must learn to cope with new rules and expectations
- Continues to acquire new skills as well as continued refinement of skills in all areas of development
- **Physical Growth**
 - Growth** from beginning of school-age years until preadolescence is gradual, steady pace, and slower than as compared with earlier years
 - Weight** gain is from 4.5 to 6.5 lbs per year (2–3 kg)
 - Height** increases an average of 2 inches per year (5 cm)

—Later middle years: diminishing fat and change in distribution pattern, slimmer appearance

—**Head circumference:** decrease in head circumference in relation to height; decrease in waist circumference in relation to height; and an increase in leg length in relation to height (indicators of physical maturity)

—**Body systems** becoming more mature: including the GI system, less stomach upsets, immune system, more competent in localizing an infection and producing an antibody–antigen response improves and strength increases substantially

—Independence in self-care is achieved

- **Dentition**

—Primary teeth lost and replaced by permanent teeth during school-age period

- **Sensory**

—Vision reaches maturity

- **Elimination**

—By age 6, most children have full bowel and bladder control

—Nocturnal enuresis (bed wetting) occurs in 15% of 6-year olds, 3% of 12-year olds

Assessment Alert

Problems with soiling should be referred to primary health provider.

- **Sleep**

—Typically require 9½ hours a night, (slowed growth rate) will require more sleep during adolescence

—Bedtime should be firmly established on school nights

—8–11-year-old children often resist going to bed; child may be unaware of fatigue, if they are allowed to stay up, they will be tired the next day

—Quiet activity before bedtime such as reading, listening to soft music facilitates sleep and establishes a positive bedtime pattern

- **Gross Motor Development**

—Increasingly active

—Steadier on their feet; more graceful; longer legs; lower center of gravity; improved posture; slimmer look; movement more fluid by 8–9 years

—Increasing strength and physical capabilities; however, muscles still functionally immature with risk of muscular damage due to overuse

—Bones continue to ossify (not mature yet) and yield to pressure

- **Fine Motor Development**

—Continual increasing dexterity

—Draws, prints, cuts, pastes, can sew by 6 years if needle is threaded

—Cursive writing 8–9 years

- **Cognitive Development (Piaget)**

—**Concrete operations** (7–11 years)

—Thought becoming increasingly logical and coherent

—Problem solving is systematic and concrete; based on tasks in the here and now (not in abstraction)

—Less egocentricity, seeing things from more than one perspective and enabling concentration on more than one aspect of a situation

—Masters concept of **conservation:** permanence of mass and volume, even if its shape or appearance changes; concept of reversibility, if $2 + 3 = 5$, $5 - 3 = 2$, $5 - 2 = 3$

—**Classification** becomes more complex, understanding that the same element can exist in more than one class at a time

- **Cognitive Skills**

—Concept of numbers by 6 years

—Knows right and left hand by 6 years

—Tells time by 6 years; develops understanding of more abstract time

—Understands places in relation to space—geography 8–9 years

- **Language Development**

—Realization that words have arbitrary rather than absolute meanings and that words can have more than one meaning

—Learns how to read; increasing ease during school-age years

- **Moral Development (Kohlberg)**

—Preconventional stage continues

—Instrumental relativist orientation: the child recognizes that there is more than one correct view; conforms to obtain rewards; becomes more flexible with time

- **Psychosocial Development (Erikson)**

—**Industry vs. inferiority** (6–12 years)

—The child needs to engage in tasks at which he can be successful and to acquire competence in his abilities. When success is recognized, he feels a sense of worth. If faced with failure, a sense of unworthiness ensues.

—A sense of accomplishment also involves the ability to cooperate with others to accomplish goals; peer approval is a strong motivating power; feelings of inferiority develop if he feels he cannot measure up to the expectations of others, resulting in withdrawal from school and peers

- **Psychosocial Behaviors**

- Needs to engage in tasks that can be carried through to completion
- More independence and increased ability to cooperate and share with others starting at 6 years
- Rules and rituals have great importance
- Conformity evidenced in mannerisms, clothing styles, and speech patterns
- Considering others' points of view
- Develops modesty at 8–9 years
- Better behaved and easy to get along with at home at 8–9 years
- Family increasingly important and meaningful at 10–12 years

- **Socialization**

- Increasing importance and identification with peer groups; most important socializing agent; most important in gaining independence from parents
- Prefers playing with groups of same sex 7–9 years; continues playing with groups of same sex, with increasing interest in the opposite sex 10–12 years
- Talks about friends constantly; may have best friend 10–12 years,

- **Fears**

- Most fears of earlier childhood resolving
- May hide fears; does not want to be a “baby”
- Fears include: intimidating teachers; not succeeding in school; something bad happening to parents

- **Play, Activities and Games**

- Play competitive during school-age period
- Play is a means to acquiring mastery over themselves, others, and the environment
- May cheat to win
- Activities that aid in growth and development include: team games, athletic activities, clubs, reading, music and art, complex board games and puzzles, sophisticated collections

- **Dishonest Behavior: cheating, lying, stealing**

- Lying:** may be exaggerated storytelling to impress others; difficulty differentiating between reality and fantasy; parents need to teach what is real and what is make believe
- Might lie to escape punishment; older children may lie to meet expectations set by others; most children recognize that lying is wrong and outgrow it
- Cheating:** ages 5–6, cheat to win, do not want to lose a contest; do not understand that it is wrong; resolves as the child matures
- Stealing:** ages 5–8, limited understanding of property rights; when caught they “are sorry” and “they didn’t mean to do it” but will do it again

- Children do not take responsibility for these behaviors till the end of middle childhood. Have the child pay back the money or return the stolen object and teach the child respect for the property of others

Nursing Intervention Alert

Teach parents the importance of modeling honest behavior and being conscious of setting a good example for children.

If stealing continues it can be an indication that something is seriously wrong, or lacking in the child’s life, such as love and the child steals to fill the void; further help is needed.

- **Psychosexual Development (Freud)**

- Latency period** (6–12 years)
- Time of tranquility between oedipal stage of early childhood and eroticism of adolescence. Children experience relationships with same sex peers following indifference of earlier years and preceding opposite sex fascination in adolescence
- Sexual urges are submerged in the unconscious and energy is channeled into enthusiastic play and extensive learning

Nursing Process Elements

- **Communicating with the School-aged child**

- School-aged children want explanations and reasons for everything; functional information; what something is used for, how is it used, why is it used
- Give simple, concrete, accurate explanations
- Encourage questions
- Drawing for expression
- Older school-aged children can use writing for expression

- **Caring for the Hospitalized School-aged child**

- School-aged child believes outside forces are cause of illness
- Monitor behavior and mood; primary defense mechanism in stressful situation is reaction formation (acts brave but is really frightened)
- The nurse can help the child understand his illness and assume responsibility for his general health due to the child’s increased sophistication in cognition and psychosocial development
- Encourage child to talk about fears; common fears in school-aged children are fear of bodily injury, pain, illness, disability, and death

—Begins to see death as irreversible; may interpret it as destructive, scary, and/or violent

Preparing the School-aged Child for Procedures

- School-aged children want explanations for everything that will take place, how it will be done; where and why
- Give simple, concrete, accurate explanations and demonstrations; use diagrams and models
- Encourage questions and discussion before and after procedure; encourage verbalization of concerns (very concerned about threat or injury to their body)
- School-aged children are able to plan in advance for procedures; can tolerate longer teaching sessions, 20 minutes at a time or longer
- Encourage taking notes during teaching sessions
- Assign tasks the child can accomplish; encourage responsibility and participation collecting specimens, keeping records, handing practitioner equipment, removing bandages
- Provide opportunities for decision making, (e.g., preferred site, time of day to do procedure)
- Assist the child in taking control over the situation; teach relaxation techniques, suggest deep breathing

Client and parent teaching

- **The school age years:**
 - Teach parent importance of fostering a sense of industry in the child by encouraging and helping him or her to achieve success in school, sports, other activities
 - Teach parent importance of developing independence in the child, e.g., provide opportunities for child to make choices
 - Counsel parents about safety measures for latchkey children including: a list of emergency phone numbers, instruct child to tell callers that parent cannot come to the phone instead of saying they are not home, teach child basic first aid and safety

Nursing Intervention Alert

As children will be spending more and more of their time away from home, they will be confronted with many choices; food choices, activities, they may be offered cigarettes etc.

- Teach children about health, safety, nutrition, and exercise
- Teach older school-aged children about drugs, alcohol, cigarettes, STDs

- **Nutrition:**
 - Caloric needs are less than preschool years in relation to body size
 - What a healthy well balanced diet is; the food pyramid
 - Help child differentiate nutritious food from junk food
- **Gross motor development:**
 - Use backpack for books, distribute weight more evenly than tote bag
- **Safety:**
 - Proper use of seat belt while passenger in a vehicle
 - Safe pedestrian behavior
 - Use helmet for bicycle riding
 - How to swim; water safety; depth of water needed for diving
 - Potential burn hazards (matches, gasoline, firecrackers, cigarette lighters, bon fires, chemistry sets)
 - Procedures/proper behavior in the event of a fire
 - Hazards in regards to taking nonprescription drugs such as aspirin, antihistamines
 - Teach child about alcohol and drug abuse, cigarette smoking, and tobacco use. Teach child to say “no” if offered drugs or alcohol
- **Discipline:**
 - Set reasonable limits, keep rules reasonable
 - Provide explanations as to why behavior is inappropriate
 - Disciplinary technique should help control behavior
 - Withholding privileges is effective and fair
 - Include child in process of determining appropriate disciplinary measures
- **Play, activities and games:**
 - Importance of monitoring Internet use due to sexual predators, violence

PREADOLESCENT OR PREPUBERTAL 10–13 YEARS AND ADOLESCENCE 13 TO APPROXIMATELY 18

- Adolescence is the period of development during which the individual makes the transition from childhood to adulthood, with physiological and psychological maturation accompanied by turmoil and change
- **Physical Growth**
 - Reproduction becomes possible, referred to as puberty
 - Body mass increases to adult size
 - Fast period of growth
 - Girls mature earlier than boys
 - Girls: growth spurt begins between 9.5 and 14.5 years, height increase approximately 3 inches a year; slows at menarche; stops approximately at age 16, or 2–2.5 years after menarche

- Girls have fat deposited in thighs, hips, and breasts; pelvis broadens
- Boys: growth spurt starts between 10.5 and 16; height increases 4 inches a year; slows in late teens, between ages 18 and 20
- Boys become leaner with broader chest and have increased muscle mass
- Secondary sex characteristics
- Very conscious of changes in body
- **Vital Signs** approach adult norms
- **Sexual Development: Girls**
 - Thelarche: appearance of breast buds, between 9 and 13.5
 - Adrenarche: growth of pubic hair, 2–6 months afterward
 - Menarche: initial menstruation, approximately 2 years after the first signs of puberty
- **Sexual Development: Boys**
 - Testicular enlargement, between 9.5 and 14 years of age
 - Growth of pubic hair
 - Penile enlargement
 - Axillary hair
 - Facial hair
 - Voice changes
- **Nutrition**
 - Nutritional requirements peak during years of maximum growth; 10–12 in girls; 2 years later in boys
 - Females have increased risk for eating disorders; ongoing nursing assessment needed
- **Sleep**
 - During the time of growth spurts, increased activity, and overexertion the body requires more sleep
 - The tendency to stay up late necessitates sleeping late whenever possible
- **Gross motor/Fine motor development**
 - Gross motor at adult level; fine motor nearing adult level
- **Safety**
 - Feelings of immortality contribute to taking risks
 - Peer pressure significantly influences risk-taking behaviors; speeding to show off; doing drugs to be part of the gang; not cool to wear helmet
 - Prone to motor vehicle accidents due to: reckless driving, speeding, driving under the influence of drugs or alcohol, failure to use seat belt; risk for diving and swimming accidents; bicycle and motorcycle accidents; sports injuries; misuse of firearms
- **Cognitive Development (Piaget)**
 - Formal Operations (11 years to adulthood)**
 - Abstract thinking develops; uses abstract symbols, scientific reasoning, and formal logic; develops, constructs and tests hypotheses, and reflects on theoretical and philosophical matters
- **Language Development**
 - Language development practically complete; vocabulary continually expanding
- **Moral Development (Kohlberg)**
 - Transition to the **Conventional stage** between ages 10 and 13, in which the early adolescent seeks good relationships; wants approval of family; increased desire to please others; wants to be considered good by those persons whose opinions matter
 - The middle adolescent has a society maintaining orientation: obedience to law and order in society; social order; respect for authority
 - In the **Postconventional stage**, the later adolescent solves moral dilemmas by using an internalized set of moral principles that provide him with the resources to evaluate each situation
 - There is social contract orientation: the concern with basic individual rights and following the laws of society; he recognizes the possibility of changing laws to improve society
 - Universal ethical principle orientation: the last phase of the Postconventional stage and of the theory. Internal decisions of conscience define what is “right” based on abstract principles, like the Golden Rule, without clear rationale or universal principles. Kohlberg later termed this stage theoretical, as few people actually reasoned at this level
- **Psychosocial Development (Erikson)**
 - Identity vs. Role Confusion (12–18 years)**
 - Adolescence is marked by many struggles and challenges. There are major decisions to be made, such as career choice and whether to marry. Identity development and separation from family are essential to successful resolution of this stage
- **Transition to Puberty**
 - Young adolescents become very preoccupied with the rapid changes in their bodies and must make adjustments to handle them
 - Boys must confront the sexual feelings and desires that accompany puberty
 - Girls must deal with the appearance of secondary sex characteristics and menstruation
 - Not every adolescent enters puberty at the same time, and there can be considerable inner conflict as each teenager worries about if he is normal
- **Socialization**
 - Freedom from family domination is necessary to achieve full maturity
 - Adolescents attempt to define their own identity, independent of their parents

- Social relationships serve as important functions in the maturation of identity
- Relationships with parents change from protection-dependency to mutual affection and equality
- Peer groups have a strong influence on teenagers' behavior and self-evaluation. Belonging to a group is of utmost importance
- Best friends provide support for each other and are an important stepping-stone toward development of intimate relationships in the future
- Increased interest in the opposite sex
- Sexual activity in older teens is high, reasons being to obtain pleasurable sensations, to satisfy curiosity and sexual drives, for affection, or to conform to peer pressure. By age 17, more than 50% of teenagers have had sexual intercourse
- Certain individuals become aware of same-sex attraction during the adolescent years, and the challenges that they face need to be addressed so that they can grow up mentally and physically healthy
- Leisure-time activities move from being family centered to peer centered, and teenagers learn to juggle their time to accommodate school, fun, and work
- **Discipline**
 - Firm, reasonable limit setting appropriate
 - Realistic rules regarding curfew, jobs, homework, and meals are needed
 - Criticism or derogatory remarks should be minimized
 - Positive behavior and accomplishments should be recognized
- **Fears/stressors**
 - Homosexual feelings
 - Not being normal or not developing normally
 - Not belonging or not being accepted by group; being mocked by peers
- **Recreation**
 - Sports, sports events and sports gear, computer and video games, musical events and disc/MP3 players, collectibles
- **Psychosexual Development (Freud)**
 - Genital** stage (Puberty through Adulthood)
 - With maturation of reproductive system and sex hormones, earlier sexual urges reemerge
 - Energies are invested into becoming emotionally independent, forming friendships, and finding adult sexual partner
- Anticipate shifts in mood and identity
- Give undivided attention, listen, encourage open honest communication
- Try not to interrupt; be courteous, calm, and open-minded
- Try not to overreact
- Avoid disapproval, judging, criticizing, or giving advice; be nonjudgmental
- If taking a stand, make sure that the issue is important; remain open-minded and consider options, then make expectations clear.
- Ask adolescent to clarify meaning of expressions if not clearly understood due to teen culture
- Nonverbal means of communication can be expressed with spontaneous drawing, directed drawing, spontaneous play, directed play, (providing medical equipment or doll house for focused reasons) writing down thoughts and feelings, keeping a diary
- **Caring for the Hospitalized Adolescent**
 - An adolescent's concerns during hospitalization include separation from peers, restricted independence, alterations in body image, and illness as punishment
 - Potential reactions to hospitalization, therefore, include uncooperativeness, self-assertion, anger, and withdrawal. Defense mechanisms include denial and displacement (shifting focus from undesired objects or feelings to more acceptable ones)
 - Adolescents may have numerous questions, psychosomatic complaints, and may question the adequacy of care
 - Fear of mutilation and sexual changes should be addressed by providing counseling related to issues of puberty and health
 - Older children and early adolescents view death as final and irreversible; may become interested in biological death and funerals
 - A later adolescent begins to exhibit a mature understanding of death; may have difficulty coping with death of significant others
 - Relate to an adolescent on his own level, respect his privacy, allow him to wear his own clothes and to decorate his room, and promote peer contact, by providing a telephone if possible, and allowing visits and calls

Nursing Process Elements

- **Communicating with the Adolescent**

- Facilitate trust; talk to adolescent without parent

Preparing the Adolescent for Procedures

- Facilitate trust; talk to adolescent without parent
- Respect privacy and ensure confidentiality
- Have parent wait outside if adolescent prefers
- Encourage questions and verbalization of concerns
- Encourage participation

Client teaching

- **Adolescence:**
 - Teach parent importance of positive reinforcement and limiting negativity and criticism
 - Teach parent to be realistic when establishing family rules, e.g., curfew
 - Teach parent that adolescents engage in risk-taking behaviors due to intense peer pressure and feelings of immortality
 - Teach parent to encourage and empower child to stand up to peer pressure regarding risk-taking behaviors such as using drugs, cigarette smoking, and driving under the influence of alcohol
 - Teach parent importance of talking to adolescent about techniques to prevent physical, emotional, and sexual abuse; talking to adolescent about safe sex, contraception, and STDs
- **Nutrition:**
 - Adolescent caloric and protein requirements are higher now than at any other time in life; calcium and protein needed for skeletal and muscle growth
 - Common deficiencies include iron, folate, and zinc (menstruation effects iron requirements)
 - Dangers of poor eating habits, obesity, anorexia nervosa, and bulimia
- **Safety and health promotion:**
 - Encourage discussions regarding standing up to peer pressure, drugs, alcohol, cigarette smoking, anger management and problem solving to avoid use of guns
 - Prevention of physical, emotional, and sexual abuse
 - Safe sex, contraception, STDs
 - Encourage taking first aid course

**Assessment Alert**

Be alert for risk factors for suicide: depression, substance abuse, history of a previous attempt (serious risk); any talk of suicide (must be taken seriously).

**Nursing Intervention Alert**

Adolescents who express suicidal thoughts with a specific plan need close observation and professional psychiatric evaluation. Prevent access to guns, razors, prescription, or over-the-counter drugs. Have adolescent sign a contract not to attempt suicide for agreed upon amount of time.

YOUNG ADULT (20 TO MID- TO LATE 30s)

- Challenges and rewards of young adulthood include: starting and raising a family, starting and advancing in a career, economic stability or instability, caring for aging parents
- **Physical Development**
 - Completed by age 20, exception is the pregnant and lactating woman
 - Natural process of maturation
 - Lifestyle assessment: diet, exercise, cigarette smoking, alcohol consumption etc., to identify risks for chronic disease or accidents (routine component of physical examination)
- **Cognitive Development**
 - Rational thinking steadily increases, educational, occupational, and life experiences dramatically increase conceptual and problem-solving skills
- **Moral Development (Kohlberg)**
 - Postconventional stage, last stage identified, continues through adulthood
- **Psychosocial Development (Erikson)**
 - Intimacy vs. Isolation (young adult)**
 - A strong sense of personal identity allows one to enjoy adult freedoms and responsibilities as well as love and care for another. When the individual is ready to share their life with another, this task is complete. Otherwise, isolation follows.
- **Other developmental tasks for the young adult**
 - Unfinished tasks from previous stages should be revisited
 - Separate from family of origin
 - Decide whether to marry, begin a family, or remain single
 - Identifying occupation that matches own qualities, abilities, and life goals
- **Sexual Development**
 - Freud's last stage of psychosexual development, Genital, covers puberty through adulthood, with no special considerations for the maturing adult
 - The young adult usually has the emotional maturity to complement the physical ability

MIDDLE ADULT (LATE 30s TO MID-60s)

- Transition into middle age occurs when changes in reproductive and physical abilities become apparent
- This may very well be a time of continuing transitions as individuals reexamine their life goals, life partner, and career

- Major life changes are often made to meet the person's needs, known as “midlife crisis”
- Have an abstract and realistic concept of death

Nursing Intervention Alert

Nursing support, insightful counseling, and appropriate referrals promote resolution of midlife crisis with optimum outcome.

- **Physical Development**
 - Beginning outward signs of aging such as: hair graying, balding in men (may begin earlier) wrinkles, thickening of the waist
 - Decreasing visual acuity for many, Glaucoma not uncommon, some decreased hearing
 - Menopause in women, Climacteric in men
 - Lifestyle assessment: including diet, exercise, cigarette smoking, alcohol consumption etc. to identify risks for chronic disease or accidents; continues throughout adulthood
- **Cognitive Development**
 - Rational thinking continues to increase
 - Decline in cognition is rare
- **Psychosocial Development (Erikson)**
 - Generativity vs. Stagnation (middle adult)**
 - The adult can now focus on raising the next generation, caring for others, and avoiding self-absorption and stagnation
- **Psychosocial Changes**
 - Empty nest syndrome: Children moving away from home
 - Reaching maturity: When an individual reaches physiological, psychological, cognitive maturation; feels comfortable with their abilities, accomplishments, and knowledge gained over the years; learns to accept and live with unsolvable problems, shortcomings, and own limitations; accepts constructive criticism, open to recommendations from others, yet not overly influenced or intimidated by others; and is accountable and accepts responsibility for his actions
- **Sexual**
 - After departure of children from the home, many couples find increased marital and sexual satisfaction

OLDER ADULT (65 YEARS AND OLDER)

- **Physical Development**
 - Changes in functioning and appearance
 - Changes in strength and endurance
 - Sensory changes
 - Accepting self as an aging person
- **Cognitive Development**
 - Active learning
 - May be adjusting to actual declining memory or concern about possible declining memory in the future
- **Psychosocial Development (Erikson)**
 - Ego-Integrity vs. Despair (older adult)**
 - Aging creates many losses with high risk of despair. Searching for meaning in life and meeting these challenges creates further opportunities for growth and integrity. Nurses can contribute to the valuing of older persons
- **Other Developmental Tasks of the Older Adult**
 - Adjusting to many losses including: death of spouse, siblings, and friends
 - Adjusting to loss of working role, loss of income
 - Adjusting to loss of home, might need to move to less expensive, easier access, senior housing
 - Adjusting to loss of caregiver role, if requires caregiving from children
 - Adjusting to changing and redefined relationships with adult children
 - Learning new ways in which to find quality of life
- **Adjusting to Retirement**
 - A dramatic role change is coping with the loss of work outside the home
 - Nursing evaluation and intervention is geared toward helping the individual pursue new interests and hobbies, get involved in volunteer activities, continue their education, and may be start a new business career that fits their new lifestyle
 - Adjustment to living on a fixed income goes along with retirement

AGING PROCESS

- Number of older adults is increasing exponentially compared to any other age group, with the most dramatic increase in adults 85 years and older
- **Older adults** are divided into four groups:
 - young-old, ages 64–74 years
 - middle-old, ages 75–84 years

—old-old, ages 85–99

—centurions, age 100 and over

- Most body systems show progressive deteriorative changes to a greater or lesser degree with aging
- Extent and rate of change varies from individual to individual with lifestyle, stressors, and environmental conditions directly affecting the degree of change (decline) that is experienced
- These changes increase the older adults' vulnerability to multiple clinical conditions and disease

Clinical Alert

The response to stress and illness in the older adult is slowed, and less effective, and so a longer period is generally required for readjustment and return to baseline.

Assessment Alert

Classic signs and symptoms of diseases may be absent or atypical in the older adult.

Confusion, restlessness, and altered mental status are common symptoms and often the **only** symptoms with acute illness. For example, a UTI may present with confusion, loss of appetite, and fatigue, instead of the expected fever, dysuria, frequency, or urgency. An MI may present without chest pain.

- Normal aging changes are called **primary changes** and disease related changes are referred to as **secondary changes**

Assessment Alert

Distinguishing between primary (normative) aging changes and secondary (disease related) changes is integral to the nursing assessment of the older adult.

PRIMARY AGING CHANGES

• Integumentary

Decreased elasticity; loss of subcutaneous fat; decreased sebaceous secretions ► wrinkles, sagging, dry thin fragile skin ► risk for skin breakdown

Decreased vascular supply to nails ► thick brittle nails ► hard to cut

Loss of melanin ► graying of hair

• Musculoskeletal

Decreased muscle fibers; muscle mass; cartilage deterioration ► decreased strength and agility ► risk for impaired mobility

Shrinkage of vertebral discs and narrowing of intervertebral space ► shortening of trunk

• Respiratory

Reduced chest wall compliance; respiratory muscles atrophied ► reduced vital capacity; increased residual volume
Decreased alveoli ► possible shortness of breath on exertion

Decreased ciliary action ► reduced cough reflex ► risk for stasis of secretions ► increased susceptibility to infection

• Cardiovascular

Endocardial thickening; thickened, more rigid heart valves ► decreased force of contraction ► risk for decreased cardiac output

Decreased elasticity of arteries ► increased resistance to blood flow; mild increase in systolic B/P; cold extremities

• Thermoregulation

Diminished subcutaneous tissue ► increased susceptibility to hypothermia

Decreased efficiency of vasoconstriction ► diminished febrile responses to infections

Decreased efficiency of sweating ► diminished acclimation to heat

• Urinary

Decreased blood flow to the kidneys; decreased glomerular filtration rate; decreased number of functioning nephrons ► decreased renal function; increased serum creatinine and blood urea nitrogen; decreased creatinine clearance ► increased risk of infection; incontinence; and medication toxicity

Clinical Alert

The decline in renal function results in inefficient excretion of active drug, allowing toxic drug levels to accumulate, placing the older adult at risk for **drug toxicity**.

Perineal muscle weakness in women > risk for urinary incontinence

Benign prostatic hypertrophy (BPH) > risk for urgency and frequency and risk for urinary incontinence

Assessment Alert

Urinary incontinence is a concern of many older adults. Rule out UTI, impaction, teach Kegel exercises.

• Gastrointestinal

Decreased saliva, gastric acid, and digestive enzyme ► dry mouth; indigestion; risk for impaired absorption of nutrients and medications

Decreased peristalsis ► delayed gastric emptying ► risk for constipation

Assessment Alert

Gastrointestinal changes contribute to risk for malnutrition.

• Neurological

Decreased neurons; dendrites; decreased size of brain ► delayed reaction ► may need more time needed for cognitive processes

Decline in coordination of brain interactions ► causing a slowing of reaction time ► increased risk for accidents

Decreased nerve endings ► decreased sensation ► risk for burns

Pain, temperature, taste and touch are all dulled to some extent with aging

Pain perception diminished ► risk for injury

Taste buds atrophy and lose sensitivity ► nutritional risk

Altered sleep stages and sleep patterns (increased difficulty falling asleep and staying asleep, and sleep may be less restful)

seem to occur as part of normal aging

• Vision

Reduced lens elasticity ► presbyopia

Increased lens density ► difficulty seeing in dim light ► risk for injury

Lens beginning to yellow ► colors perceived differently

• Hearing

Nerve degeneration to inner ear ► high frequency tone loss; auditory reaction time increased ► risk for impaired communication

Tympanic membrane ► atrophied, thickened ► many will experience some hearing loss ► risk for impaired communication

Assessment Alert

Impaired hearing might be more pronounced due to cerumen impaction. Inspect the inner ear and irrigate if warranted.

Nursing Intervention Alert

Sensory changes in vision and hearing lead to impaired communication and significantly increase the risk for isolation and loneliness.

• Reproductive System

Hormone production diminished ► vaginal dryness ► dyspareunia ► increased risk of vaginal infection

Decreased testosterone levels; decreased testicular volume; decreased sperm count ► possible change in libido

—Impotence is a **secondary change** that may be related to medications, alcohol, diabetes, anxiety or other situations or conditions.

Clinical Alert

Many myths exist about sexuality and aging. If in good health, sexual desire and a satisfying sex life can extend well into the eighties and beyond.

• Endocrine

—**Primary change**

Decreased basal metabolic rate ► decreased temperature

FUNCTIONAL ASSESSMENT (SELF-CARE ABILITY)

Functional health and independence is described in terms of the ability to perform **Activities of Daily Living (ADLs) and Instrumental Activities of Daily Living (IADLs)**

- ADLs include bathing, dressing, toileting, and eating
- IADLs include more complex activities such as shopping, managing finances, housekeeping, cooking, managing medications, and the ability to use the telephone

Assessment Alert

Change in functional status may be the only clinical indicator of acute illness, such as a subtle change in ambulation status.

BODY IMAGE

- Mental picture of one's own body
- Not necessarily consistent with a person's actual body structure or appearance
- Includes attitudes and emotions one has toward one's own body, perception of one's value and abilities, and the self in relation to others
- Gradually develops, evolves, and changes as a result of growth and development and the unique experiences from within the self, others, and realities of the world (cultural and societal values)
- Strongly influenced by perceptions of others' views, approval of others
- Actual or perceived change from the norm is cause for concern

BODY IMAGE DEVELOPMENT

Infancy

- Tasks in infancy contributing to body image:
 - Positive messages about body conveyed from caregiver to infant through meeting physical needs, pleasant and nurturing interactions, kissing and caressing which result in feelings of comfort, satisfaction, and internalization of positive messages about self
 - Interest in mirror image
 - Begins to differentiate between self and others

Toddler

- Tasks and practices contributing to body image:
 - Learns names of body parts and increasing usefulness of body parts
 - Looks in the mirror and makes verbal references about himself: "me big"
 - Recognition of gender differences by age 2, gender identity by age 3
 - Beginning comprehension of words used to describe physical appearance such as "big boy" or "pretty" influences view of his own body; positive body image is fostered by using positive language and avoiding labels such as "chubby thighs"

- Increasing independence and separation from others
- Learns control of body
- Respect for the body contributes to positive body image; refer to body parts, especially those related to elimination and reproduction, by their correct names
- Awareness of body
 - Body integrity and boundaries are poorly understood and intrusive experiences are threatening
 - Toddler does not differentiate between nonviable body parts (such as feces) and essential body parts; reason toddler might be upset with flushing the toilet

Preschool

- Tasks and practices contributing to body image:
 - Significant advances in body image development
 - Increasing language comprehension, preschoolers learn that individuals have desirable and undesirable appearances "pretty" "ugly"
 - Reflect the opinions of others regarding their own appearance
 - Recognize differences in skin color and racial identity and are vulnerable to prejudices
 - Compare their size with their peers at age 5
- Awareness of body
 - Poorly defined body boundaries
 - Little knowledge of internal anatomy
 - Intrusive experiences are frightening, especially those that disrupt skin integrity; believes if the skin is "broken" the "insides can leak out," bandages "keep everything inside"
 - Sexual identity developing; sex role imitation, dressing up like mommy or daddy
 - Modesty and fear of mutilation often a concern

School-age

- Tasks and practices contributing to body image:
 - Body image strongly influenced not only by primary caregivers, but by increasing number of teachers and peers

- Awareness of body
 - Relatively accurate and positive perception of the physical self; likes self less as gets older
 - Acutely aware of own body and bodies of peers and adults
 - Head very important to child's perceived image of self with the hair and eye color used to describe themselves
 - Increasing awareness of deviations from the norm; physical impairments in hearing, vision or birthmarks assume great importance; if accompanied by unkind comments contribute to feelings of inferiority
 - Important to teach school-aged child about bodily functions using correct information and terminology

Early Adolescence

- Secondary sex characteristics and rapid change in physical appearance heighten self-consciousness and concerns regarding body image
- Lost familiar body and feel uncomfortable with new body
- Either hide or advertise
- Continually comparing self with peers; most comfortable when just like peers
- Perceived or actual defects or deviations are threatening to the idealized image
- Time spent in front of the mirror to see what they look like to others
- Hormonal changes during adolescence influence body image
- Girls perceive increase in weight and changes in fat distribution as evidence of obesity and start fad dieting
- When there is a lag in physical maturation, girls feel out of place, left out;
- Boys feel weak and small compared with their more muscular peers, can no longer compete

Nursing Process Elements

- Compare adolescent's physical maturation with that of parents' and siblings' maturation, when extremes in growth are noted
- Start estrogen therapy before menarche to control height in extreme cases of tall stature if psychosocially indicated; begin growth hormone therapy in extreme cases of short stature if psychosocially indicated
- Listen to distressed adolescents, reassure them that they are normal, focus on positive aspects of personality and body
- Anticipate difficult behaviors or mood swings and support as needed
- Assess impact of physical changes and accompanying mood swings on family

- Teach client and family that hormonal changes are primary cause of changes in behaviors and will pass as body adjusts

Assessment Alert

Early maturing boys and girls as well as late maturing boys have higher rates of risk taking behaviors than their peers.

Middle to Later Adolescence

- Rapid changes diminish, energies concentrated on making the body more attractive
- Needs the "perfect" body and the "right" clothes and hairstyle
- Practices facial expressions and postures and hair styles and agonizes over a pimple
- Later adolescents have a more secure body image
- Body image established during adolescence is retained throughout life

Young Adult

- Stable positive feelings about self
- **Pregnancy**
 - Feel big, awkward, may feel unattractive
 - Increase in breast size
 - Begins to show during second trimester
 - Feelings of well-being when baby moves, kicks, or heartbeat heard
 - Desire for sexual activity may be influenced by body image

Middle Adult

- Accepts inevitable changes in appearance, such as graying of the hair, wrinkles, diminishing visual acuity
- Healthy lifestyle, i.e., physical exercise, balanced diet, and adequate sleep, contribute to a favorable body image

Older Adult

- How the older adult presents self impacts body image
- Changes in appearance threatening to body image: sagging skin, spotty skin pigmentation, loss of muscle tone, fat redistribution, shorter stature, hearing aid
- Changes in function threatening to body image: loss of sensation in a body part, incontinence, dependence on others for hygiene and grooming
- Increased difficulty in maintaining body image during illness

Nursing Process Elements

- Assess body image:
 - What aspects of your appearance do you like?
 - Are there any aspects of your appearance that you would like to change?
 - If yes, describe the changes you would like to make.

- Long list of dislikes is problematic and requires intervention
- Encourage verbalization of feelings of client and family regarding changes in body
- Assist in fostering a sense of integrity and avoiding despair (Erikson)
- Assist with grooming and hygiene
- Assess impact on primary caregivers
- Suggest caregiver support groups

FAMILY SYSTEMS

CONCEPTS RELATED TO FAMILY FUNCTION

- Family is what the individual client says it is.
- Does not depend on legal or biological ties
- Types of families include nuclear, extended, single parent, blended, skip-generation, homosexual couples, cohabiting partners, multiadult, communal groups with children
- Families change and grow and can be described as going through developmental stages, each of which has tasks which need to be completed before the family can move successfully to the next stage, e.g., family with young children must successfully accept new members into the system; older family must accept shifting of generational roles
- Patterns of relationships in families determine roles and power within families: the resultant structure affects ability to cope and respond to stress
- Very rigid or very flexible structures can impede effective coping: very rigid by not allowing tasks to be assumed by others and very flexible because there are not clear and stable roles and so disintegration can occur in times of crisis
- Family function refers to the processes the family uses to achieve its goals, e.g., communication, goal setting, conflict resolution, use of resources including a social network, nurturing
- Psychological needs of family members must be met or dysfunctional family function results
- Clear, open communication supports effective family function including coping and conflict resolution
- Health promotion and disease prevention is determined strongly by family beliefs, values, and practices which in

turn are significantly influenced by educational and economic level as well as cultural background

Nursing Process Elements

- When assessing a client within the context of family, the extent to which the family meets the individual's basic physical and psychological needs must be determined
- When the family is the client, family processes and relationships are the foci of assessment
- Assessment starts with finding out who constitutes the family, the client's attitude toward them, and the degree to which they can be involved
- Existing and potential internal and external resources and supports must be identified
- Collaboration with family members, which requires mutual respect and trust, is essential—all need to understand and agree on the plan of care
- Families need a sense of control; facilitate this by providing options not “musts” whenever possible and by asking for ideas or suggestions
- Help families identify their strengths and see how they will positively impact current coping
- Provide preparation and support for family caregiving: without this the risk of declining health in both the caregiver and receiver increases as does the risk of dysfunctional relationships and abuse
- Encourage caregivers and receivers to make decisions together; this gives the care receiver a sense of control, decreases risk of overprotective care, and promotes a positive feeling about caregiving

HUMAN SEXUALITY

- Feelings and attitudes about sex vary widely; sexual physiology has common features.
- **The Sexual Response Cycle** has four stages:

—**Excitement:** occurs with physical and psychological stimulation that causes parasympathetic nerve stimulation leading to arterial dilatation and venous constriction in the genital area. This increased blood supply leads to vasocongestion and increasing muscular tension. In women, the vasocongestion causes the clitoris to increase in size and lubricating fluid to be secreted. The vagina widens and increases in length. The nipples become erect. In men, penile erection occurs, the scrotum thickens, and the testes elevate. In both sexes, there is an increase in heart rate, respiratory rate, and blood pressure.

—**Plateau:** in women, the clitoris is drawn forward and retracts under the clitoral prepuce; the lower part of the vagina becomes extremely congested, and there is increased nipple elevation. In men, the vasocongestion leads to distension of the penis.

—**Orgasm:** as the shortest stage in the cycle, orgasm is usually experienced as intense pleasure affecting the whole body as the body suddenly discharges accumulated sexual tension. A vigorous contraction of muscles in the pelvic area expels blood and fluid from the area of congestion. In men, muscle contractions surrounding the seminal vessels and prostate project semen into the proximal urethra. The contractions are followed by propulsive ejaculatory contractions, occurring at the same time as the woman, which forces semen from the penis.

—**Resolution:** the period in which the external and internal genital organs return to an unaroused state. For men, a refractory period occurs during which further orgasm is impossible. Women do not go through this refractory period, so it is possible for woman to have additional orgasms immediately after the first. The resolution period usually takes 30 minutes for both men and women.

FAMILY PLANNING

Reproductive life planning, or family planning, includes all the decisions an individual or couple make about having children: whether and when to have children, how many children to have, and how they are spaced as well as counseling on contraception or on how to increase their fertility.

Contraception—natural and artificial methods used to prevent a pregnancy

Natural Family Planning—methods of conception regulation based on awareness of signs and symptoms of fertility during a menstrual cycle; do not involve introduction of chemicals or foreign material into the body

- **Abstinence** (celibacy)—only completely effective means of preventing pregnancy
- **Calendar (Rhythm) Method**—requires abstinence from coitus on the days of a menstrual cycle when the woman is most likely to conceive (3 or 4 days before until 3 or 4 days after ovulation); formulated after six menstrual cycles, the woman calculates her safe days by subtracting 18 from the shortest cycle documented representing her first fertile day; she subtracts 11 from her longest cycle which represents her last fertile day thereby giving her a window of fertility to initiate or prevent a pregnancy

Client teaching for self-care

- Keep a diary of six menstrual cycles in order to calculate “safe days”
- Avoid coitus or use a contraceptive such as vaginal foam during these days
- Calendar method has an ideal failure rate of 9%

- **Basal Body Temperature Method**—basal body temperature (BBT), which falls about 0.5 degrees just before the day of ovulation and at the time of ovulation rises a full degree, is monitored to determine when ovulation has occurred so that activity to produce a pregnancy can occur or she can refrain from having sex for 3 days to prevent pregnancy

Client teaching for self-care

- Take temperature each morning immediately after waking, before undertaking any activity, eating, or drinking
- Use a special BBT thermometer or a tympanic thermometer
- Record temperature each morning for at least 1 month
- Problems with this method arise because many factors can affect the BBT, e.g., temperature rise due to illness can be mistaken as the signal of ovulation; changes in daily schedule, such as starting an exercise program, can affect the BBT
- Women who work nights should take temperature after awakening from their longer sleep period, no matter what time of day
- Ideal failure rate is 9%
- **Cervical Mucus (Billings) Method**—this method used to predict ovulation is based on the properties of cervical mucus; before ovulation each month, the cervical mucus is thick and does not stretch when pulled; just before ovulation the mucous secretion increases and with ovulation, the mucous becomes copious, thin, watery,

transparent, slippery, and stretches before the strand breaks; all the days the mucous is copious, or at least 3 days after the peak day, the woman is considered fertile

Client teaching for self-care

- Assess vaginal secretions daily or the change in cervical secretions can be missed
- Feel of vaginal secretions after intercourse is unreliable because seminal fluid has a watery, postovulatory consistency and can be confused with ovulatory mucus
- Ideal failure rate for this method is 3%

CHEMICAL BARRIERS

- **Oral Contraceptives (The Pill)**—composed of varying amounts of synthetic estrogen and/or progesterone; the estrogen acts to suppress follicle-stimulating hormone (FSH) and LH, thereby suppressing stimulation; progesterone acts to cause a decrease in the permeability of cervical mucus which limits sperm motility and access to ova
- **Mini-Pill**—contains progesterone only; does not allow the endometrium to develop fully, so implantation will not take place

Client teaching for self-care

- Must be prescribed by a physician, nurse practitioner, or nurse midwife after a physical examination and a Pap smear
- Contraindications to oral contraceptive use:
 - breast-feeding and less than 6 weeks postpartum
 - age 35 years or older and smoking 15 or more cigarettes a day
 - multiple risk factors for arterial cardiovascular disease such as older age, cigarette smoking, diabetes, hypertension
 - current or history of deep vein thrombosis or pulmonary embolism
 - complicated valvular heart disease
 - current or history of ischemic heart disease
 - history of stroke
 - major surgery that requires prolonged immobilization
 - history of migraines with focal neurologic symptoms
 - current breast cancer
 - diabetes with neuropathy, retinopathy, vascular disease, or diabetes of more than 20 years duration
 - severe cirrhosis
 - liver tumors

—Major side effects are nausea, weight gain, headache, breast tenderness, breakthrough bleeding, monilial yeast infections, mild hypertension, depression

—Must take pills consistently and conscientiously; not a good method for those who are forgetful and/or non-compliant with regimens

—Women without risk factors may continue to use low-dose oral contraceptives until they reach menopause

—After stopping oral contraceptives, pregnancy may not be possible for 1 or 2 months, sometimes as long as 6–8 months, because the pituitary gland requires a recovery period before it begins gonadotropin stimulation again

—Ideal failure rate is under 1%

- **Implant Contraceptives (Norplant)**—low-dose progesterone-only device consisting of six soft Silastic capsules that are implanted under the skin of a woman's upper arm; the implant releases hormone over 5 years inhibiting ovulation

Client teaching for self-care

—Major advantage of this method of birth control is that it offers an effective and realistic alternative to oral contraceptives and their estrogen-related side effects

—Sexual enjoyment is not inhibited as may be the case with other contraceptive methods

—Implants can be used while breast-feeding without an effect on milk production

—Implants can be used safely in adolescents

—Return to fertility is rapid (1–3 months after removal)

—Failure rate is less than 1%

- **IM Injection (Depo-Provera)**—long-acting progestin inhibits ovulation for 3 months, reliable and convenient

—Long-term reliability without the estrogen-related side effects of oral contraceptives

—No visible signs that a birth control method is being used

—Can be used during breast-feeding because it contains no progesterone

—Must return to the health care provider every 4–12 weeks for another injection

—Return to fertility is often delayed by 6–12 months

—Almost 100% effective

- **Intrauterine Device (Progestasert)**—a small plastic device, usually t-shaped, inserted into the uterine cavity; prevents conception by causing a local inflammatory reaction which is toxic to spermatozoa and blastocytes; the Progestasert releases progestin for 1 year and has to be replaced

**Client teaching for self-care**

- Advantages over other methods; only one insertion is necessary; only one expense; the device does not require daily attention; does not interfere with sexual enjoyment
- Appropriate for women who are at risk for complications associated with oral contraceptives or who wish to avoid some of the systemic hormonal side effects
- Can be used while breast-feeding
- Check after each menstrual flow that the IUD string is in place
- Must have yearly pelvic examination
- Failure rate can be as low as 0.1–1.5%
- **Vaginal Ring**—a silicone ring that surrounds the cervix and continually releases a combination of estrogen and progesterone; it is left in place for 3 weeks and then removed for 1 week to allow for menstruation

**Client teaching for self-care**

- Hormones released are absorbed directly by the mucous membrane of the vagina, thereby avoiding passing through the liver which is an advantage for those with liver disease
- Fertility returns immediately after removal of the ring
- Failure rate is 1%
- **Estrogen/Progesterone Patch**—transdermal patch that slowly and continuously releases a combination of estrogen and progesterone; applied once a week for 3 weeks; the 4th week is patch-free to allow for menstruation

**Client teaching for self-care**

- Efficiency of transdermal patches is the same as for oral contraceptives
- Can be concealed
- Mild breast discomfort and irritation at the application site may occur
- Remove and replace a loose patch immediately with a new one; if loose less than 24 hours, no backup contraception is required; if loose or missing for over 24 hours, a new patch is applied and a new 4-week cycle is started; a backup method of contraception should be used for the 1st week of the new cycle
- **Spermicides**—available over the counter as foams, gels, inserts (sponges), and on condoms

MECHANICAL BARRIERS

- **Diaphragm**—consists of a round, flexible spring (50–90 mm wide) covered with a domelike latex rubber cup; a

spermicide is used to coat the concave side of the diaphragm before it is inserted deep into the vagina

**Client teaching for self-care**

- Do not use if allergic to latex
- Always empty bladder before insertion
- Increases risk of UTIs
- Inspect diaphragm for holes or tears by holding it up to a light source, or fill it with water and check for a leak
- Can be inserted up to 6 hours prior to intercourse
- Must be left in place for at least 6 hours after intercourse to be effective
- Wash the diaphragm with soap and water after use and dry thoroughly
- Place the diaphragm back into its storage case
- Have the diaphragm refitted for a weight loss or gain of 15 lbs. or after childbirth
- Failure rate is 20%
- **Cervical cap**—much smaller than the diaphragm, fits snugly over the cervix; used with a spermicide

**Client teaching for self-care**

- Do not use if allergic to latex
- Wait 30 minutes after insertion before engaging in sexual intercourse to be sure that a seal has formed between the rim and the cervix
- Leave in place for a minimum of 6 hours after sexual intercourse; can be left for up to 48 hours without additional spermicide being added
- Do not use during menses due to the potential for toxic shock syndrome; use an alternate method such as condoms during this time
- Inspect prior to insertion for cracks, holes, or tears
- Wash after use with soap and water, dry thoroughly, and store in its container
- Failure rate is 17%
- **Female condom**—cylinder of polyurethane enclosed at one end by a closed ring that covers the cervix and at the other end by an open ring that covers the perineum; expensive for frequent use and cumbersome

**Client teaching for self-care**

- Noisy during sex act
- For single use only
- Can be inserted up to 8 hours before intercourse
- Can be purchased over the counter
- Avoid wearing rings to prevent tears; long fingernails can also cause tears

- Protects against STIs
- Failure rate is 21%

- **Male condom**—latex rubber or synthetic sheath that is placed over the erect penis before coitus begins

Client teaching for self-care

- Do not use if either partner has a latex allergy
- Widely available at low cost
- Physiologically safe
- Decreases sensation for men
- Interferes with sexual spontaneity
- Protects against STIs
- Failure rate is 14%

EMERGENCY POSTCOITAL CONTRACEPTION

- **“Morning-After Pills”**—high-level estrogen pills that interfere with the production of progesterone, prohibiting implantation
 - Yuzpe regimen consists of the administration of two fixed-dose combination pills, taken within 72 hours of unprotected intercourse followed by two additional pills 12 hours later
 - “plan B” regimen is a progestin-only based where two pills containing high doses of levonorgestrel are taken (one pill immediately and one 12 hours later)

Client teaching for self-care

- Last chance to prevent a pregnancy: reduces risk of pregnancy for a single act of unprotected sex by almost 80%

- Sooner ECs (pills) are taken, the more effective they are
- Do not interrupt an established pregnancy
- Is a risk of ectopic pregnancy if ECs fail
- Side effects include nausea, vomiting, abdominal pain, fatigue, headache

- **Post-coital Intrauterine Device**—insertion of a copper-bearing IUD within 5 days of unprotected intercourse; the mechanism of action is unknown but is thought to interfere with fertilization

ABORTION is the interruption of pregnancy (induced or elective Ab) or expulsion of the product of conception (spontaneous Ab) before the fetus is viable; several types of abortion

- **Elective Termination of Pregnancy (Induced Abortion)**—procedure performed to deliberately end a pregnancy before fetal viability usually done in the case of an unwanted pregnancy; several methods employed (D&C, D&E, menstrual extraction, prostaglandin or saline induction, or administration of mifepristone and misoprostol)

SURGICAL METHODS OF FAMILY LIFE PLANNING (SEE CHAPTER 18 FOR NURSING CARE)

- **Tubal Ligation**—female sterilization; minor surgical procedure in which fallopian tubes are occluded by cautery, clamping, or blocking preventing passage of both sperm and ova; considered permanent
- **Vasectomy**—male sterilization; small incision is made on each side of the scrotum and vas deferens is cut and tied, cauterized, or plugged, blocking the passage of spermatozoa; considered permanent; failure rate of less than 1%

WORKSHEET

FILL IN THE BLANKS

Fill in the blank with the correct term.

Definitions related to Growth and Development

1. Control of the head proceeding to control over the torso and legs is known as _____ development.
2. Development progressing from the center of the body to the extremities is called _____ development.
3. Development progressing from mastery of simple operations to complex ones is called _____ development.

(continued)

Fill in the blank with the appropriate number.

Milestones in Infancy

1. Good head control at _____ months
2. Attains sitting position independently at _____ months
3. Cruising at _____ months
4. Walks alone by _____ months
5. Grasp reflex fades and can actively hold rattle at _____ months
6. Crude pincer grasp at _____ months
7. First words with meaning _____ months
8. Builds 2-block tower at _____ months

Fill in the blank with the correct type of play.

1. Play alongside another, not with another is called _____
2. Cooperative play is called _____
3. Play is primarily _____ in infancy
4. Play is advancing to _____ play in toddlerhood
5. Play is advancing to _____ in the preschool child

TRUE & FALSE QUESTIONS

Concept of Death

- | | | |
|---|-------|-------|
| 1. The toddler has no concept of death. | _____ | _____ |
| | T | F |
| 2. The preschool child views death as temporary and reversible. | _____ | _____ |
| | T | F |
| 3. The younger school-aged child begins to see death as reversible. | _____ | _____ |
| | T | F |
| 4. The older school-aged child views death as final and irreversible. | _____ | _____ |
| | T | F |
| 5. The adolescent begins to exhibit mature understanding of death. | _____ | _____ |
| | T | F |

FILL IN THE BLANKS

Separation Anxiety

1. Separation anxiety is a major stress for the hospitalized child during which years?

2. Describe behavior exhibited for all 3 stages of separation anxiety:

Protest: _____

Despair: _____

Detachment (denial): _____

3. Which of the 3 stages of separation anxiety is seen in prolonged separation?

Erikson's Theory of Psychosocial Development/Complete the list of developmental tasks and identify its stage

| Developmental Task | | | Stage of Development |
|--------------------|-----|----------|----------------------|
| Autonomy | Vs. | | |
| Trust | Vs. | Mistrust | Infancy |
| Industry | Vs. | | |
| Identity | Vs. | | |
| Initiative | Vs. | | |
| Intimacy | Vs. | | |
| Ego Integrity | Vs. | | |
| Generativity | Vs. | | |

Freud's Psychosexual Theory of Personality Development/Fill in the blanks.

| Conflict | Description | Developmental Stage |
|--------------------|-------------------------|---------------------|
| Oral | | |
| | | Toddler |
| Phallic or Oedipal | | |
| | Time of tranquility | |
| Genital | Sexual emerges reemerge | |

(continued)

Piaget's Theory of Cognitive Development/Fill in the blanks

| Stage | Age | Characteristics/Description |
|-------|----------|--|
| 1. | 1–2 yrs | Learning takes place through developing sensory and motor skill |
| 2. | 2–4 yrs | Preconceptual. Object permanence is transition to preoperational thought. Egocentrism, concrete, tangible |
| | 4–7 yrs | Aware something is right, cannot say why Intuitive thought. Simple classification |
| 3. | 7–11 yrs | Logical, systematic, concrete, based on tasks in the here and now, start seeing things from more than one perspective, <i>masters conservation, complex classification</i> |
| 4. | 11–adult | Abstract thinking, scientific reasoning, reflect on theoretical matters |

APPLICATION QUESTIONS

- Which of the following principles of growth and development is being addressed when the nurse teaches the parent that the infant will develop control of the head before control of the torso and legs?
 - cephalocaudal
 - proximodistal
 - mass to specific
 - simple to complex
- Which is a sign of socialization that would be anticipated in a 6-month-old infant?
 - social smile
 - shows emotions such as jealousy
 - begins to fear strangers
 - smiles at mirror image
- Which finding in an infant requires further evaluation?
 - has a strong grasp at 1 month
 - head lag at 6 months
 - sits unsupported at 8 months
 - pulls self to stand at 9 months
- Which statement by a mother indicates the need for further teaching regarding infant nutrition?
 - "I will feed the baby only commercially prepared infant formula for the first 6 months."
 - "I will start skim milk and give an iron supplement at 6 months"
 - "It is important for the mother to be well nourished when breast-feeding"
 - "Solid foods are gradually introduced at around 5 or 6 months"
- Which toy could appropriately be recommended for a 4-month-old infant?
 - unbreakable mirror in a soft black and white frame
 - large brightly colored balloon
 - 5" doll with removable clothing and shoes
 - push-pull toy
- When assessing a 5-month-old infant, which weight parameter indicates healthy growth?
 - 10 lbs or more
 - 15 lbs or more
 - doubles birth weight
 - triples birth weight
- At which age do beginning signs of tooth eruption appear?
 - 2–3 months
 - 3–4 months
 - 5–6 months
 - 8–9 months
- When discussing psychosocial development with a new parent group, the nurse presents Erikson's theory and identifies which task as the psychosocial task of infancy?
 - trust versus mistrust
 - oral versus anal
 - sensation versus mobilization
 - initiative versus guilt

9. Which is the best description of the function of the Denver II developmental assessment tool?
 - a. measures fine and gross motor development and intelligence and is a means of recording measurements
 - b. objectively measures cognitive development
 - c. measures gross and fine motor, language and personal-social development and is a means of recording objective measurements
 - d. measures psychosocial and cognitive development
10. When asked by a child's parent about Freud's theory of psychosexual development, which response by the nurse would be most accurate?
 - a. Each stage of development is characterized by the inborn tendency of all individuals to reduce tension and seek pleasure and is associated with a particular conflict that must be resolved before moving on to the next stage
 - b. Experiences during early childhood determine a child's pleasure-seeking behaviors but have little impact on later relationship and adjustment patterns
 - c. Freud identified 8 stages of psychosocial conflicts and tasks that the individual strives to master from infancy through adulthood
 - d. During the Latency stage of development patterns of pleasure, reward and guilt become established.
11. When assessing of an 11-month old, which the following developmental milestone achievements would the nurse expect to find as being the most recently achieved?
 - a. Rolls completely over from back to abdomen
 - b. Attains sitting position independently
 - c. Walks holding on to furniture, cruising
 - d. Develops crude thumb-finger pincer grasp
12. Which is the first stage of Piaget's theory of cognitive development?
 - a. sensorimotor stage
 - b. oral stage
 - c. preoperational
 - d. development of trust
13. During the routine well check-up visit of an 18-month old, the mother asks the nurse the reason for her son's protruding abdomen. Which is a correct response for the nurse to give?
 - a. Increased food intake at this age causes distention
 - b. Underdeveloped abdominal muscles bulge
 - c. Growth of the liver causes temporary protrusion
 - d. It is uncommon in toddlers and requires further assessment
14. The nurse teaches the parent about readiness for toilet training. Which event indicates that the time is not yet right for toilet training?
 - a. Wakes up dry from a nap
 - b. Stays dry for 2 hours
 - c. Wants to have soiled diaper changed promptly
 - d. Moves with family to new home with bathroom adjacent to bedroom
15. When discussing development with parents of a young child's play group, which would the nurse correctly identify as the psychosocial development task of the preschool child?
 - a. Initiative versus guilt
 - b. Autonomy versus shame and doubt
 - c. Industry versus inferiority
 - d. Identity versus role confusion
16. A preschooler is admitted to the hospital the day before scheduled surgery. Which of the following actions will best help reduce the child's anxiety in this situation?
 - a. have parent wait outside the room as child settles in
 - b. begin preoperative teaching immediately; 30 minute session
 - c. explain procedure in detail
 - d. give the child dolls, puppets, and medical equipment to play out experience
17. According to Freud, which is the psychosexual stage of development of the preschooler?
 - a. Phallic or oedipal stage
 - b. Latency period
 - c. Anal stage
 - d. Genital stage
18. Which type of thought process is uncharacteristic of the 3-year-old child?
 - a. Literal word interpretation
 - b. Magical thinking
 - c. Animistic thinking (inanimate objects take on human attributes)
 - d. Intuitive thought
19. When assessing a preschooler, which description by the child of his or her parents would be considered typical?
 - a. Persons who are in charge
 - b. Persons who can do no wrong, practically perfect
 - c. Old and rigid
 - d. Necessary evil

(continued)

Think Smart/Test Smart

Note that the question asks for the uncharacteristic thought process. This means the one that would not be usual or expected in a 3-year old.

20. When exploring a 6-year old's concept of death, what would the nurse expect the child's perception to be?
- Death is punishment
 - Death is a temporary state of sleep
 - Death can be reversed
 - Death probably lasts forever
21. Which behavior indicates that an adolescent is using formal thought?
- Uses abstract arguments for making a point
 - Solves problems based on the here and now
 - Uses language correctly without clear understanding of the meaning of words
 - Is increasingly logical in thinking patterns
22. Which is the psychosocial task of the middle adult years?
- raising the next generation
 - striving for identity
 - sharing life with another
 - searching for meaning in life
23. Which assessment finding related to the pulmonary function of an 89-year-old man who has come to the clinic for his annual checkup, would the nurse interpret as reflecting a normal age-related change?
- an increase in functional alveoli
 - reduction of residual volume
 - a decrease in vital capacity
 - blood gases that show mild acidosis
24. Which is a normal sign of aging that may appear during assessment of the renal system of an 82-year old?
- concentrated urine
 - microscopic hematuria
 - occasional incontinence
 - decreased glomerular filtration rate
25. An older gentleman who likes to eat tells the nurse that he has to use more salt than usual to make his food taste good. A possible explanation for this might be
- he has decreased sensitivity of his taste buds
 - he needs more sodium to ensure good kidney function
 - he is compensating for lost fluids
 - he is confused due to his advancing age

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

Definitions related to Growth and Development

- Control of the head proceeding to control over the torso and legs known is called cephalocaudal (head to tail) development.
- Development progressing from the center of the body to the extremities is called proximodistal development.
- Development progressing from mastery of simple operations to complex ones is called mass-to-specific development.

Milestones in Infancy

1. Good head control at 5–6 months
2. Attains sitting position independently at 9 months
3. Cruising at 11 months
4. Walks alone by 15 months
5. Grasp reflex fades and can actively hold rattle at 3 months
6. Crude pincer grasp at 9 months
7. First words with meaning 10 months
8. Builds 2-block tower at 12 months

Types of play

Although children engage in all types of play in each stage of development, the child adding new type of play to his repertoire

1. Play alongside another, not with another is called parallel play
2. Cooperative or interactive play is called associative play
3. Play is primarily solitary in infancy
4. Play is advancing to parallel play in toddlerhood
5. Play is advancing to associative in the preschool child

TRUE & FALSE ANSWERS*Concept of Death*

1. The toddler has no concept of death. *True*
2. The preschool child views death as temporary and reversible. *True*
3. The younger school-aged child begins to see death as reversible. *False*
4. The older school-aged child views death as final and irreversible. *True*
5. The adolescent begins to exhibit mature understanding of death. *True*

ANSWERS FOR FILL IN THE BLANKS

Separation Anxiety

1. Separation anxiety is a major stress for the hospitalized child during which years?

Middle infancy through preschool years

2. Describe behavior exhibited for all 3 stages of separation anxiety:

Protest: cries for parent, inconsolable, attacks others, attempts to find parents, clings

Despair: disinterested in the play or food, shows passivity, depression

Detachment (denial): superficial adjustment, apparent interest, remains detached

3. Which of the 3 stages of separation anxiety is seen in prolonged separation?

Detachment

Erikson's Theory of Psychosocial Development/Complete the list of developmental tasks and identify its stage

| Developmental Task | | | Stage of Development |
|--------------------|-----|-----------------|----------------------|
| Autonomy | Vs. | Shame and doubt | Toddler |
| Trust | Vs. | Mistrust | Infancy |
| Industry | Vs. | Inferiority | School-age |
| Identity | Vs. | Role diffusion | Adolescence |
| Initiative | Vs. | Guilt | Preschool |
| Intimacy | Vs. | Isolation | Young adulthood |
| Ego Integrity | Vs. | Despair | Older adulthood |
| Generativity | Vs. | Stagnation | Middle adulthood |

Freud's Psychosexual Theory of Personality Development/Fill in the blanks

| Conflict | Description | Developmental Stage |
|--------------------|--|-----------------------|
| Oral stage | Pleasure source centered on oral activities | Infancy |
| Anal stage | Interest centered on anal region; sphincter muscles develop | Toddler |
| Phallic or Oedipal | Genitals interesting and sensitive; recognize differences in the sexes; penis envy | Preschool |
| Latency period | Time of tranquility | School-age |
| Genital | Sexual emerges reemerge | Adolescence–adulthood |

Piaget's Theory of Cognitive Development/Fill in the blanks

| Stage | Age | Characteristics/Description |
|------------------------|----------|--|
| 1. Sensorimotor | 1–2 yrs | Learning takes place through developing sensory and motor skill |
| 2. Preoperational | 2–4 yrs | Preconceptual. Object permanence is transition to preoperational thought. Egocentrism, concrete, tangible |
| | 4–7 yrs | Aware something is right, cannot say why Intuitive thought. Simple classification |
| 3. Concrete operations | 7–11 yrs | Logical, systematic, concrete, based on tasks in the here and now, start seeing things from more than one perspective, <i>masters conservation, complex classification</i> |
| 4. Formal operations | 11–adult | Abstract thinking, scientific reasoning, reflect on theoretical matters |

APPLICATION ANSWERS

1. Which of the following principles of growth and development is being addressed when the nurse teaches the parent that the infant will develop control of the head before control of the torso and legs?
- cephalocaudal
 - proximodistal
 - mass to specific
 - simple to complex

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

- proximodistal, midline to periphery.
 - mass to specific (differentiation), simple operations precede complex ones.
 - same as choice c.
2. Which is a sign of socialization that would be anticipated in a 6-month-old infant?
- social smile
 - shows emotions such as jealousy
 - begins to fear strangers
 - smiles at mirror image

Rationale

Correct answer: c.

- stranger anxiety begins around 6 months

Incorrect answers: a, b, and d.

- social smile at 2 months.
- shows jealousy at 12 months.
- smiles at mirror image at 5 months.

3. Which finding in an infant requires further evaluation?
- has a strong grasp at 1 month
 - head lag at 6 months
 - sits unsupported at 8 months
 - pulls self to stand at 9 months

Rationale

Correct answer: b.

- head lag at 6 months is an unfavorable developmental sign requiring further evaluation.
- a, c, and d are correct statements.

4. Which statement by a mother indicates the need for further teaching regarding infant nutrition?
- "I will feed the baby only commercially prepared infant formula for the first 6 months"
 - "I will start skim milk and give an iron supplement at 6 months"
 - "It is important for the mother to be well nourished when breast-feeding"
 - "Solid foods are gradually introduced at around 5 or 6 months"

Rationale

Correct answer: b.

No cow's milk during first year, poor digestibility, lack of components needed for growth, no skim products either; infant needs fat for proper growth.

- a, c, and d are true statements.

(continued)

5. Which toy could appropriately be recommended for a 4-month-old infant?
- unbreakable mirror in a soft black and white frame
 - large brightly colored balloon
 - 5" doll with removable clothing and shoes
 - push-pull toy

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

- balloons are dangerous, they can be aspirated
- removable shoes of 5" doll are too small, can choke
- pull-push toy for older infants when they can stand

6. When assessing a 5-month-old infant, which weight parameter indicates healthy growth?
- 10 lbs or more
 - 15 lbs or more
 - doubles birth weight
 - triples birth weight

Rationale

Correct answer: c.

- doubles birth weight at 5–6 months.

Incorrect answers: a, b, and d.

- full-term infant should be over 10 lbs, but c is more accurate.
- if birth weight is 6 or 7 lbs, will be less than 15 lbs.
- triples birth weight at 1 year

7. At which age do beginning signs of tooth eruption appear?
- 2–3 months
 - 3–4 months
 - 5–6 months
 - 8–9 months

Rationale

Correct answer: c.

- tooth eruption 5–6 months

Incorrect answers: a, b, and d.

8. When discussing psychosocial development with a new parent group, the nurse presents Erikson's theory and identifies which task as the psychosocial task of infancy?
- trust versus mistrust
 - oral versus anal
 - sensation versus mobilization
 - initiative versus guilt

Rationale

Correct answer: a.

- trust versus mistrust is the psychosocial task in infancy.

Incorrect answers: b, c, and d.

- preschool
- and c are terms from Freud and Piaget.

9. Which is the best description of the function of the Denver II developmental assessment tool?
- measures fine and gross motor development and intelligence and is a means of recording measurements
 - objectively measures cognitive development
 - measures gross and fine motor, language and personal-social development and is a means of recording objective measurements
 - measures psychosocial and cognitive development

Rationale

Correct answer: c.

- denver II measures all items listed in c.

Incorrect answers: a, b, and d.

- intelligence is not measured.
- measures language.
- inaccurate.

10. When asked by a child's parent about Freud's theory of psychosexual development, which response by the nurse would be most accurate?
- Each stage of development is characterized by the inborn tendency of all individuals to reduce tension and seek pleasure and is associated with a particular conflict that must be resolved before moving on to the next stage
 - Experiences during early childhood determine a child's pleasure-seeking behaviors but have little impact on later relationship and adjustment patterns
 - Freud identified 8 stages of psychosocial conflicts and tasks that the individual strives to master from infancy through adulthood
 - During the Latency stage of development patterns of pleasure, reward and guilt become established.

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

- Experiences during early childhood effect later adjustments and relationships.
- Erikson identified 8 stages of psychosocial conflicts from infancy through adulthood.
- During Latency (6–12 years), sexual urges are submerged into the unconscious and channeled into productive activities.

11. When assessing an 11-month old, which of the following developmental milestone achievements would the nurse expect to find as being the most recently achieved?
- Rolls completely over from back to abdomen
 - Attains sitting position independently
 - Walks holding on to furniture, cruising
 - Develops crude thumb-finger pincer grasp

Rationale

Correct answer: c.

- c. cruises at 11 months.

Incorrect answers: a, b, and d.

- a. Rolls over back to abdomen at 6 months.
- b. Attains sitting position independently at 8–9 months.
- d. Develops crude thumb-finger pincer grasp at 9 months.

12. Which is the first stage of Piaget's theory of cognitive development?

- a. sensorimotor stage
- b. oral stage
- c. preoperational
- d. development of trust

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

- b. oral stage is stage 1 of Freud's theory.
- c. preoperational is the thought process for 1–2 years in Piaget's sensorimotor stage.
- d. development of trust is Erikson's first stage of psychosocial development.

13. During the routine well check-up visit of an 18-month old, the mother asks the nurse the reason for her son's protruding abdomen. Which is a correct response for the nurse to give?

- a. Increased food intake at this age causes distention
- b. Underdeveloped abdominal muscles bulge
- c. Growth of the liver causes temporary protrusion
- d. It is uncommon in toddlers and requires further assessment

Rationale

Correct answer: b.

- b. Undeveloped abdominal musculature gives the toddler the characteristic protruding abdomen.

Incorrect answers: a, c, and d.

- a. During toddlerhood, food intake decreases.
- c. Development of the liver does not cause the abdomen to protrude.
- d. Protruding abdomen is common in toddlers.

14. The nurse teaches the parent about readiness for toilet training. Which event indicates that the time is not yet right for toilet training?

- a. Wakes up dry from a nap
- b. Stays dry for 2 hours
- c. Wants to have soiled diaper changed promptly
- d. Moves with family to new home with bathroom adjacent to bedroom

Rationale

Correct answer: d.

- d. Moving is stressful and toilet training should not be initiated during stressful period.

Incorrect answers: a, b, and c.

- a, b, and c are all signs of readiness for toilet training.

15. When discussing development with parents of a young child's play group, which would the nurse correctly identify as the psychosocial development task of the preschool child?

- a. Initiative versus guilt
- b. Autonomy versus shame and doubt
- c. Industry versus inferiority
- d. Identity versus role confusion

Rationale

Correct answer: a.

Incorrect answers: b, c, and d.

- b. Is developmental task of toddlerhood.
- c. Is task of school-aged child.
- d. Is task of adolescence.

16. A preschooler is admitted to the hospital the day before scheduled surgery. Which of the following actions will best help reduce the child's anxiety in this situation?

- a. have parent wait outside the room as child settles in
- b. begin preoperative teaching immediately; 30 minute session
- c. explain procedure in detail
- d. give the child dolls, puppets, and medical equipment to play out experience

Rationale

Correct answer: d.

Incorrect answers: a, b, and c.

- a. parent should stay with the child.
- b. Preoperative teaching is done shortly before the procedure; sessions should be no longer than 20 minutes.
- c. no reason for detailed explanations, will only further frighten the child.

17. According to Freud, which is the psychosexual stage of development of the preschooler?

- a. Phallic or oedipal stage
- b. Latency period
- c. Anal stage
- d. Genital stage

(continued)

Rationale

Correct answer: a.

- a. Phallic or oedipal stage, where genitals are central

Incorrect answers: b, c, and d.

- b. Latency is school-age
- c. Anal is toddlerhood
- d. Genital is adolescent through adulthood

18. Which type of thought process is uncharacteristic of the 3-year-old child?

- a. Literal word interpretation
- b. Magical thinking
- c. Animistic thinking (inanimate objects take on human attributes)
- d. Intuitive thought

Rationale

Correct answer: d.

- d. Intuitive thought (ages 4–7) is the 2nd phase of Piaget's preoperational period, increasing complexity in thought process and beginning ability to classify.

Incorrect answers: a, b, and c.

- a, b, and c, are all characteristics of the 3-year-old child, and continue through preschool period.

19. When assessing a preschooler, which description by the child of his or her parents would be considered typical?

- a. Persons who are in charge
- b. Persons who can do no wrong, practically perfect
- c. Old and rigid
- d. Necessary evil

Rationale

Correct answer: b.

- b. The preschooler sees parents as omnipotent, and enjoys and benefits from their guidance.

Incorrect answers: a, c, and d.

- a. May be, but not adequate
- c. Rigid, not a bad trait for the preschooler who likes order. Old is meaningless.
- d. Maybe in adolescence

20. When exploring a 6-year old's concept of death, what would the nurse expect the child's perception to be?

- a. Death is punishment
- b. Death is a temporary state of sleep
- c. Death can be reversed
- d. Death probably lasts forever

Rationale

Correct answer: d.

- d. The 6-year old begins to see death as irreversible.

Incorrect answers: a, b, and c.

- a. Adolescent has mature understanding of death.
- b and c. Preschool child sees death as reversible

21. Which behavior indicates that an adolescent is using formal thought?

- a. Uses abstract arguments for making a point
- b. Solves problems based on the here and now
- c. Uses language correctly without clear understanding of the meaning of words
- d. Is increasingly logical in thinking patterns

Rationale

Correct answer: a.

- a. Adolescent using abstract thought.

Incorrect answers: b, c, and d.

- b and d are stages of concrete operations, in school-aged child.
- c. Preoperational stage using words appropriately, without clear understanding of their meaning

22. Which is the psychosocial task of the middle adult years?

- a. raising the next generation
- b. striving for identity
- c. sharing life with another
- d. searching for meaning in life

Rationale

Correct answer: a.

- a. generativity versus stagnation.

Incorrect answers: b, c, and d

- b. is seen in adolescence, identity versus role diffusion.
- c. seen in young adulthood, intimacy versus isolation.
- d. seen in the older adult, ego integrity versus despair.

23. Which assessment finding related to the pulmonary function of an 89-year-old man who has come to the clinic for his annual checkup, would the nurse interpret as reflecting a normal age-related change?

- a. an increase in functional alveoli
- b. reduction of residual volume
- c. a decrease in vital capacity
- d. blood gases that show mild acidosis

Rationale

Correct answer: c.

- c. a decrease in vital capacity. Loss of elastic forces in the lung leads to an increase in residual volume and a decrease in vital capacity.

Incorrect answers: a, b, d.

None of the other options are age-related changes related to pulmonary function

24. Which is a normal sign of aging that may appear during assessment of the renal system of an 82-year old?
- concentrated urine
 - microscopic hematuria
 - occasional incontinence
 - decreased glomerular filtration rate

Rationale

Correct answer: d.

Changes in the renal tubules cause a dramatic decrease in the glomerular filtration rate.

Incorrect answers: a, b, c.

None of the other options are normal age related changes.

25. An older gentleman who likes to eat tells the nurse that he has to use more salt than usual to make his food taste good. A possible explanation for this might be

- he has decreased sensitivity of his taste buds
- he needs more sodium to ensure good kidney function
- he is compensating for lost fluids.
- he is confused due to his advancing age

Rationale

Correct answer: a.

- the taste buds begin to atrophy at age 40 and after age 60 there is an insensitivity to taste qualities. There are also studies that indicate that there are changes in the salt threshold in some elderly individuals.

Incorrect answers: b, c, d.

None of the other options would be correct or plausible explanations of the client's increased preference for salt.

| ▸ Health Promotion Programs | 178 | ▸ Principles of Teaching/Learning | 193 |

HEALTH AND WELLNESS

HEALTH

- World Health Organization (WHO, 1948): “health is a state of complete physical, mental, and social well-being, not merely the absence of disease”; holistic definition
- ANA social policy statement (1980): “dynamic state of being in which the developmental and behavioral potential of an individual is realized to the fullest extent possible”; adds concept of moving toward optimal function
- Perception of what is health varies from individual to individual depending on his/her age, knowledge, expectations of self, and sociocultural background

WELLNESS

- Movement toward integration of human functioning; maximizing of potential; self-responsibility for health;

increased self-awareness and satisfaction; wholeness of mind, body, and spirit.

- Seven aspects identified by Anspaugh, Hamrick, and Rosato are physical, social, emotional, intellectual, spiritual, occupational, and environmental.

Health Models

- Clinical Model—absence of S&S of disease indicates health; clients believing in this model are motivated toward healthy behaviors by a desire not to have a diagnosed disease
- Role Performance Model—health is the ability to perform normal societal roles, i.e., work; with this model, motivation for healthy behaviors is motivated by desire to be able to fulfill obligations at home, work, and in the community
- Adaptive Model—disease is a failure of the client’s ability to adapt and treatment is aimed at restoring ability to adapt; the easier one can cope with changes in the internal

or external environment, the better is the state of health; motivated toward healthy behaviors by desire to alter self as situations change

- Eudaemonistic Model—health is the realization or actualization of potential; illness prevents this actualization; clients are motivated for health by joy and self-fulfillment.

Health Belief Models

- Health Belief Models identify factors that contribute to perceived state of health or risk of disease and hence there is probability of a client participating in an appropriate action plan for health.
- These are primarily concerned with clients' likelihood of engaging in health-protecting behaviors (preventative actions).

Factors Affecting Health

- Biologic factors—genetic makeup, age, sex, and developmental level
- Education
- Social network
- Health care—availability, accessibility, and cost
- Personal habits
- Economic status
- Family and cultural beliefs
- Physical environment—climate, noise, air, water supply, light, and exposure to toxic substances

HEALTH SCREENING

- The purpose of health screening is to identify risk factors or undiagnosed disease to allow for early intervention.
- Targeted screening—selected screening tests are based on person's age, gender, underlying health condition, or family history.
- Dangers of health screening are
 - false positive results, which lead to more tests that may involve risk of complications, cost money, and cause anxiety;
 - false negative results, which give false reassurance and may keep a person from seeing a physician.

SCREENING RECOMMENDATIONS FOR SPECIFIC AGE GROUPS

Neonate/infant

- Height/weight
- Growth and development (e.g., head circumference, Denver Developmental Screening Test)
- Urinalysis
- Hematocrit or hemoglobin
- Phenylketonuria (PKU) test (test for a genetically determined enzyme deficiency that causes mental retardation if not treated; testing mandated by state law shortly after birth)
- Blood lead level at 9–12 months

Initial purified protein derivative (PPD) at 12 months Toddler/preschooler

- Vision
- Hearing
- Growth and development (head circumference to age 2, DDST, speech and language)
- Height/weight
- Tuberculosis
- Blood pressure starting at 3 years
- Initial dental referral at 3 years
- Hematocrit or hemoglobin
- Cholesterol
- Lead
- Tuberculosis

School age children

- Vision
- Hearing
- Blood pressure
- Scoliosis
- Height/weight
- Tuberculosis (PPD)
- Dental
- Urinalysis

Adolescents and young adults

- Sexually transmitted diseases

- Papanicolaou smear
 - Breast self-examination (Table 8-1)
 - Testicular self-examination (Table 8-2)
 - Blood pressure
 - Vision
 - Hearing
 - Height/weight
 - Dental
 - Mental health (eating disorders, depression, schizophrenia)
 - Tuberculosis (PPD)
 - Urinalysis
 - Hematocrit or hemoglobin
- Early adult
- Physical examination: females without symptoms every 1–3 years; males without symptoms every 5 years
 - Dental checkups: every 6 months
 - Pap smear for cervical cancer
 - Self-breast exam
 - Clinical breast exam
 - Baseline mammogram at 35 years
 - Testicular self-exam
- Middle adult
- Physical examination: annual for females; every 2–3 years for males
 - Dental checkups: every 6 months
 - Screening every 1–2 years for glaucoma starting at age 45 if family history of the disease
 - Pap smear for cervical cancer
 - Breast self-exam
 - Screen for heart disease
 - Colonoscopy
 - Pelvic exam for uterine cancer
 - Screen for prostate cancer
 - Testicular self-exam
 - HIV testing up to age 65
- Over age 50
- Eye exam every 2–4 years, every 1–2 years over age 65
 - Hearing test every 10 years
 - Dental exam 1–2 times per year
 - Blood pressure check at least every 2 years
 - Cholesterol check every 5 years
 - Diabetes screen every 3 years; every 1–3 years over age 65
 - Annual skin exam (Table 8-3)
 - Colorectal cancer screening: fecal occult blood test annually; sigmoidoscopy every 5 years; colonoscopy every 10 years
 - Mammogram every 1–2 years
 - Pelvic exam every 1–3 years (less often over 65 and if negative findings on previous screenings)
 - Pap smear every 1–3 years
 - Bone mineral density test at least once by age 65

Table 8–1 Client Teaching: Self Breast Examination

There are three parts to a self breast examination:

- Palpation of each breast while lying down so the breast tissue is spread more thinly over the chest wall.
- Inspection of the breast in a mirror with good lighting while standing with the arms in different positions
- Palpation of each axilla while sitting or standing with arms loosely at the side of the body.

Begin with palpation of the right breast

- Lying on the back, place the right arm up and behind your head.
- Use the pads of the middle three fingers of your left hand to palpate for nodules or changes in consistency.
- Move the finger pads in a circular motion feeling first with gentle then with increasing pressure so changes at all levels of the tissue can be felt.
- Progress in vertical lines going from your clavicle (collar bone) to the bottom of your ribs and from the middle of your side to your sternum (breastbone) in the middle of your chest being certain not to miss any areas.
- Remember a firm ridge felt at the bottom of each breast where it attaches to the chest wall is normal.

Repeat for the left breast.

Proceed to inspection of the breasts.

- Stand in front of a mirror and look for changes in the breast such as dimpling of the skin, prominent blood vessels, asymmetry, changes in size, pulling or deviation of the nipple inward or to one side, or nipple scaliness or discharge.
- Do this with hands on hips pressing down, arms loosely at sides, and with arms held up over the head.

Lastly, palpate each axilla.

Table 8–2 Client Teaching: Self Testicular Examination

-
- Perform once per month.
 - Best done after a warm bath or shower because the scrotal skin is relaxed making it easier to feel the testes and find any lumps or changes in their size, shape or consistency.
 - Examine the right and left testicle individually using both hands for each one.
 - Place the index and middle finger of each hand on top of the testicle and the thumbs underneath; roll the testicle between the finger pads.
 - Keep in mind that the epididymis may feel like a small bump on the upper or middle outer aspect of each testicle; this is normal.
 - See your health care provider and report any unusual findings without delay.
-

HEALTH PROMOTION

- Health promotion is comprised of activities designed to develop human resources and behaviors that maintain or enhance well-being; enabling people to maximize physical, mental, and emotional potential through increased awareness, attitude change, and recognition of alternatives related to healthy lifestyle choices.
- The focus of health promotion is on changing personal behaviors and the environment.
- Current U.S. national health promotion and disease prevention objectives are identified in Healthy People 2010, Understanding and Improving Health, a publication of the Public Health Service of the US Department of Health and Human Services (See Table 8-4).

HEALTH PROTECTION

- Disease prevention or avoidance of health threats
- Interventions to prevent illness are as follows:
 - Primary prevention: these are the actions that focus on the prevention of health problems, e.g., health education programs.
 - Secondary prevention: these are the actions that focus on the early diagnosis and prompt treatment

Table 8–3 Client Teaching: Self Skin Examination

-
- Need a full length mirror, a hand held mirror, and a good light
 - Systematically inspect **all** skin areas for new lesions, lesions that don't heal, and changes in existing lesions.
 - Remember that signs of malignant change in moles are asymmetry, irregular border, altered color, surface or sensation, and size greater than a diameter of 6 mm.
 - Stand naked in front of the full length mirror and inspect the entire front of the body from head to toe.
 - Turn so your right side is facing the mirror, raise your right arm over your head, and inspect all skin on the right side of the body.
 - Repeat for the left side.
 - Standing with your back to the full length mirror, use the hand held mirror to inspect the skin on the back of the body including the back of the neck and behind the ears.
 - Sit down and examine the inner aspects of the legs, between the toes and the soles of the feet.
 - Inspect the skin between the fingers.
 - Use a comb to part the hair and inspect the scalp.
 - See your health care provider without delay for any unusual findings.
-

of health problems, e.g., control/treatment of early disease.

—Tertiary prevention: these are the actions to minimize the effects of permanent, irreversible disease, or disability through interventions designed to prevent complications and deterioration.

PENDER'S HEALTH PROMOTION MODEL

This model analyzes the factors that influence person's behavior and lifestyle change as he/she seeks to improve well-being and maximize human potential. These factors can be classified into

- cognitive-perceptual factors—perceive importance of health;
- modifying factors—demographics, environment;
- factors that influence the likelihood of engaging in health promotion activities, i.e., internal and external cues to action such as mass media campaigns, reminders from doctors, newspaper and media ads.

HEALTH PROMOTION PROGRAMS

- Focus may be individual, family, or population (community)
- Types of health promotion/disease prevention activities
 - Information dissemination
 - Basic program to change attitudes, beliefs, and behaviors
 - Designed to raise level of awareness and knowledge to support client's ability to improve personal living conditions, make informed decisions about personal,

family, and community health practices; and access health services appropriately

- Uses health fairs, mass media, brochures, etc to inform clients about needed lifestyle changes and methods of enhancing quality of life

—Health risk appraisal and wellness assessment: designed to provide motivation to change, i.e., reduce risk behaviors and adopt healthy behaviors

Table 8–4 Healthy People 2010

| <ul style="list-style-type: none"> • National health objectives • Overarching goals <ul style="list-style-type: none"> —Increasing the quality and longevity of life —Eliminating disparities in health among different populations • Enabling goals <ul style="list-style-type: none"> —Promote health behaviors —Protect health —Provide access to quality health care —Strengthen community prevention • Defines public health priorities and 467 specific, measurable objectives aimed at improving health, which are grouped into 28 focus areas <ul style="list-style-type: none"> —Access to quality health services —Arthritis, osteoporosis, and chronic back conditions —Cancer —Chronic kidney disease —Diabetes —Disability and secondary conditions —Educational and community-based programs —Environmental health —Family planning —Food safety —Health communication —Heart disease and stroke —HIV —Immunization and infectious diseases | <ul style="list-style-type: none"> —Injury and violence prevention —Maternal, infant, and child health —Medical product safety —Mental health and mental disorders —Nutrition and overweight —Occupational safety and health —Oral health —Physical activity and fitness —Public health infrastructure —Respiratory diseases —Sexually transmitted diseases —Substance abuse —Tobacco use —Vision and hearing • Leading health indicators that reflect the major health issues that the nation needs to address <ul style="list-style-type: none"> —Physical activity —Overweight and obesity —Tobacco use —Substance abuse —Responsible sexual behavior —Mental health —Injury and violence —Environmental quality —Immunization —Access to health care |
|--|--|

From Healthy People 2010; Understanding and Improving Health, 2nd ed., by US Department of Health and Human Services, 2000, Washington, DC; US Government Printing Office.

- Lifestyle and behavior change
 - Assist clients to take responsibility for health and make needed changes
 - Take extended periods of time
- Environmental control and safety programs such as those related to nuclear power plants, air and water pollution, and use of pesticides
- Environmental restructuring
 - focuses on physical, social, and economic environment;
 - aims to increase available options and support use of health-promoting behaviors;
 - supports other types of programs.
- Basic types of program by sponsorship/locale
 - Community programs such as screening or immunization programs offered by the health department; fire safety or CPR programs offered by the fire department or bicycle or auto safety programs offered by the police department
 - Programs offered by health care agencies such as those on testicular and self-breast examination by the American Cancer Society, or stop smoking, stress management offered by hospitals, or cardiac fitness offered by the American Heart Association
 - School-based programs such as those related to nutrition, dental hygiene, drug and alcohol abuse, sexual behavior, and child abuse

- Work site programs such as accident prevention, hearing protection, fitness, and nutrition
- Programs offered at senior citizen and retirement centers such as safe driving classes, vision screening, and blood pressure screening

Nursing Process Elements

- Assessment
 - In-depth assessment of client's health status is the foundation for health promotion
 - Health history and physical examination
 - Physical fitness assessment: muscle endurance, flexibility, body composition, and cardiorespiratory endurance
 - Lifestyle assessment: personal habits such as physical activity, use of safety precautions, eating habits, smoking, alcohol, and drug use
 - Health risk assessment
 - Spiritual assessment
 - Review of life stress, health beliefs, and social support systems
- Work with the client to develop a Health Promotion Plan using the steps identified by Pender
 - Identify most important health goals (These are broad goals such as reduce blood pressure to within recommended range)

Table 8–5 Stage Model of Health Behavior Change (Data from Prochaska et al., 1994.)

- Precontemplation—client does not see self as having problem; therefore needs no change; see others as having the problem and needing change
- Contemplation—client acknowledges problem and talks about change but is not ready to commit to action
- Preparation—person makes real plans to change; may have begun small changes
- Action—client implements strategies to change behavior; stage of greatest commitment of time and energy
- Maintenance—client integrates new behaviors into lifestyle warding off temptation to return to previous unhealthy behaviors and relapsing to the precontemplation or contemplation stage
- Termination—stage in which problem is no longer a temptation or threat; some behaviors may never be able to be terminated; they always require maintenance

—Identify behavioral or health outcomes related to each (These are specific indicators related to achievement of the goal, i.e., changes that are needed to achieve the goal such as lose weight; stop smoking; exercise regularly; decrease stress)

—Develop a plan for changes in behavior: options need to be examined and client assisted in selecting changes

that are most acceptable based on personal values and preferences as well as expectations for success

—Reinforce benefits of change: having the client reiterate the benefits promotes ownership and commitment

—Consider interpersonal and environmental factors that both facilitate and inhibit the proposed changes: identify how facilitators can be used to reinforce the planned change and how barriers can be overcome

—Determine a time frame for instituting the planned behaviors; make sure it's realistic and schedule short-term goals, rewards, and reinforcement if possible

—Commit to behavior-change goals—often verbal but increasingly in the form of a written contract

- Use nursing strategies to promote implementation of a Health Promotion Plan

—Ensuring support to the client in regard to the behavior change; nurse may directly provide or facilitate receipt of support from others—social support network must be knowledgeable about client's needs and goals so nurse may meet with them at client's request

—Counseling to answer questions, review goals and activities; reinforce progress—in-person individual counseling; individual telephone counseling; group counseling, which also offers opportunity to learn from others

Table 8–6 Health Promotion for Specific Age Groups

| Age Group | Health Concerns/Primary Prevention | Injury Prevention/High-Risk Behaviors |
|------------------|---|--|
| Infants | Low birth weight Congenital disorders Influenza SIDs Pneumonia | Accidents |
| Children | Nutrition Activity and exercise Sleep and rest Dangers of drugs and alcohol | Home safety, fire safety, firearm safety, safety of latchkey children Play safety: bicycles, skateboards and in-line skating, and water safety Lead poisoning Child abuse |
| Adolescents | Yearly health checkup Immunizations Unwanted pregnancy Health education | Unintentional injuries Homicide Substance abuse STIs Suicide |
| Early adulthood | Accidents, suicide, hypertension, substance abuse, STDs, domestic abuse, malignancies | Motor vehicle safety, sun protection, occupational safety, safe sex, smoking, stress, periodontal disease |
| Middle adulthood | Accidents, cancer, heart disease, obesity, alcoholism, mental health disorders | Motor vehicle safety, sun protection occupational safety, safe sex, smoking, stress, periodontal disease |
| Late adulthood | Accidents, arthritis, heart disease, pulmonary disease, pharmaceutical misuse, alcoholism, dementia, elder abuse, pneumonia, influenza, loss and depression | Risk of falls, inadequate caloric and/or roughage intake, inadequate exercise |

- Teaching—must be based on client's need
- Facilitating modeling—helps the client identify a model that the client respects and can identify with in terms of

factors such as age and background, to observe for ideas about behaviors and coping strategies; the client is not supposed to mimic the model

IMMUNIZATIONS

Immunizations provide protection from infectious disease by inducing a state of immunity.

TYPES OF IMMUNITY

- Active immunity: client makes antibodies that provide immunity.
- Passive immunity: client is given antibodies made by another human or animal to induce immunity.
- Naturally acquired active: body makes antibodies because of actual infection; immunity is lifelong.
- Naturally acquired passive: antibodies are produced by a mother and passed through the placenta and colostrum to the fetus/baby; immunity lasts 6–12 months.
- Artificially acquired active: vaccines or toxoids containing antigens are given to cause the person's body to produce antibodies; must be reinforced with periodic boosters.
- Artificially acquired passive: immune serum (serum-containing antibody) is injected in order to produce immunity; immunity is of short duration.

TYPES OF IMMUNIZATIONS

- Live Attenuated Vaccine
 - Pathogen is treated with heat or chemicals to reduce its virulence, but the organism is not killed.
 - Examples are MMR, varicella, rubella, and LAIV Influenza.
- Inactivated Vaccine
 - Bacterial endotoxins are treated with heat or formalin to yield a nontoxic, inactivated agent that is still antigenic.
 - Killed viral organisms or parts thereof are used in the vaccine to produce immunity.
 - Examples are IPV, DTaP, HBV, TIV influenza, and Hib.
- Immunoglobulins—blood and Immunity
 - Immunoglobulins provide passive immunity without stimulating an immune response.
 - Solutions that contain antibodies from large pools of human blood plasma are introduced into the body.
 - Immunoglobulins are used primarily for maintenance of immunity in immunodeficient people, and for passive immunity against hepatitis A and measles.
 - Specific Immunoglobulins contain high antibody titers of a specific antigen, e.g., Tetanus Ig, varicella-zoster Ig, and hepatitis B Ig.

Think Smart/Test Smart

As you study the information on immunizations, remember to keep clear in your mind that there are three sets of immunization guidelines: standard guidelines for children and adolescents, guidelines for children and adolescents that have not had immunizations in accord with the standard guidelines and therefore are behind, and guidelines for adults. Be sure to note “exceptions to the rule” such as live vaccines are contraindicated for immunosuppressed children except for MMR, which is given to children with HIV.

—Antibodies received by the fetus in utero through the placenta and by the newborn who is breastfed provide the infant with immunity for the first few weeks of life against most bacterial, viral, and fungal infections.

Recommended Vaccinations for Children and Adolescents

- Diphtheria, tetanus, pertussis (whooping cough) (DTaP)—five shot series from age 2 months to 6 years, and a booster shot at age 11–12 years
- Haemophilus influenzae type B (Hib)—prevention against bacterial meningitis, pneumonia, and sepsis. Four shot series between ages 2 and 15 months
- Hepatitis B—three doses from birth to 18 months
- Measles, mumps, rubella (MMR)—two shots between ages 1 and 6
- Pneumococcal (PCA)—vaccination prevents fatal blood infections, pneumonia, and many ear infections. Four shots from 2–18 months
- Inactivated polio virus (IPV)—Four shots between 2 months and 6 years
- Varicella (Var)—One shot given between ages 1 and 6
- Hepatitis A (HepA)—two doses 6 months apart, at 1 year and at 18 months

See the following Recommended Childhood and Adolescent Immunization Schedule 2006 and the Recommended Immunization Schedule for Children and Adolescents Who Start Late or Who Are More Than 1 Month Behind 2006. For recommended adult immunizations, see Table 8-7.

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2005, for children through age 18 years. Any dose not administered at the recommended age should be administered at any subsequent visit when indicated and feasible. ■■■■ Indicates age groups that warrant special effort to administer those vaccines not previously administered. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever

any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective ACIP statement for detailed recommendations. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at www.vaers.hhs.gov or by telephone, 800-822-7967.

■ Range of recommended ages ■ Catch-up immunization ■ 11-12 year old assessment

- Hepatitis B vaccine (HepB).** *AT BIRTH:* All newborns should receive monovalent HepB soon after birth and before hospital discharge. **Infants born to mothers who are HBsAg-positive** should receive HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. **Infants born to mothers whose HBsAg status is unknown** should receive HepB within 12 hours of birth. The mother should have blood drawn as soon as possible to determine her HBsAg status; if HBsAg-positive, the infant should receive HBIG as soon as possible (no later than age 1 week). **For infants born to HBsAg-negative mothers,** the birth dose can be delayed in rare circumstances but only if a physician's order to withhold the vaccine and a copy of the mother's original HBsAg-negative laboratory report are documented in the infant's medical record. *FOLLOWING THE BIRTHDOSE:* The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1-2 months. The final dose should be administered at age ≥24 weeks. It is permissible to administer 4 doses of HepB (e.g., when combination vaccines are given after the birth dose); however, if monovalent HepB is used, a dose at age 4 months is not needed. **Infants born to HBsAg-positive mothers** should be tested for HBsAg and antibody to HBsAg after completion of the HepB series, at age 9-18 months (generally at the next well-child visit after completion of the vaccine series).
- Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).** The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose and the child is unlikely to return at age 15-18 months. The final dose in the series should be given at age ≥4 years. **Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap - adolescent preparation)** is recommended at age 11-12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a Td booster dose. Adolescents 13-18 years who missed the 11-12-year Td/Tdap booster dose should also receive a single dose of Tdap if they have completed the recommended childhood DTP/DTaP vaccination series. Subsequent **tetanus and diphtheria toxoids (Td)** are recommended every 10 years.
- Haemophilus influenzae type b conjugate vaccine (Hib).** Three Hib conjugate vaccines are licensed for infant use. If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required. DTaP/Hib combination products should not be used for primary immunization in infants at ages 2, 4 or 6 months but can be used as boosters after any Hib vaccine. The final dose in the series should be administered at age ≥12 months.
- Measles, mumps, and rubella vaccine (MMR).** The second dose of MMR is recommended routinely at age 4-6 years but may be administered during any visit, provided at least 4 weeks have elapsed since the first dose and both doses are administered beginning at or after age 12 months. Those who have not previously received the second dose should complete the schedule by age 11-12 years.

- Varicella vaccine.** Varicella vaccine is recommended at any visit at or after age 12 months for susceptible children (i.e., those who lack a reliable history of chickenpox). Susceptible persons aged ≥13 years should receive 2 doses administered at least 4 weeks apart.
- Meningococcal vaccine (MCV4).** Meningococcal conjugate vaccine (MCV4) should be given to all children at the 11-12 year old visit as well as to unvaccinated adolescents at high school entry (15 years of age). Other adolescents who wish to decrease their risk for meningococcal disease may also be vaccinated. All college freshmen living in dormitories should also be vaccinated, preferably with MCV4, although **meningococcal polysaccharide vaccine (MPSV4)** is an acceptable alternative. Vaccination against invasive meningococcal disease is recommended for children and adolescents aged ≥2 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high risk groups (see *MMWR* 2005;54 [RR-7]:1-21); use MPSV4 for children aged 2-10 years and MCV4 for older children, although MPSV4 is an acceptable alternative.
- Pneumococcal vaccine.** The heptavalent **pneumococcal conjugate vaccine (PCV)** is recommended for all children aged 2-23 months and for certain children aged 24-59 months. The final dose in the series should be given at age ≥12 months. **Pneumococcal polysaccharide vaccine (PPV)** is recommended in addition to PCV for certain high-risk groups. See *MMWR* 2000; 49(RR-9):1-35.
- Influenza vaccine.** Influenza vaccine is recommended annually for children aged ≥6 months with certain risk factors (including, but not limited to, asthma, cardiac disease, sickle cell disease, human immunodeficiency virus [HIV], diabetes, and conditions that can compromise respiratory function or handling of respiratory secretions or that can increase the risk for aspiration), healthcare workers, and other persons (including household members) in close contact with persons in groups at high risk (see *MMWR* 2005;54[RR-8]:1-55). In addition, healthy children aged 6-23 months and close contacts of healthy children aged 0-5 months are recommended to receive influenza vaccine because children in this age group are at substantially increased risk for influenza-related hospitalizations. For healthy persons aged 5-49 years, the intranasally administered, live, attenuated influenza vaccine (LAIV) is an acceptable alternative to the intramuscular trivalent inactivated influenza vaccine (TIV). See *MMWR* 2005;54(RR-8):1-55. Children receiving TIV should be administered a dosage appropriate for their age (0.25 mL if aged 6-35 months or 0.5 mL if aged ≥3 years). Children aged ≤8 years who are receiving influenza vaccine for the first time should receive 2 doses (separated by at least 4 weeks for TIV and at least 6 weeks for LAIV).
- Hepatitis A vaccine (HepA).** HepA is recommended for all children at 1 year of age (i.e., 12-23 months). The 2 doses in the series should be administered at least 6 months apart. States, counties, and communities with existing HepA vaccination programs for children 2-18 years of age are encouraged to maintain these programs. In these areas, new efforts focused on routine vaccination of 1-year-old children should enhance, not replace, ongoing programs directed at a broader population of children. HepA is also recommended for certain high risk groups (see *MMWR* 1999; 48[RR-12]:1-37).

Recommended Immunization Schedule for Children and Adolescents Who Start Late or Who Are More Than 1 Month Behind

UNITED STATES • 2006

The tables below give catch-up schedules and minimum intervals between doses for children who have delayed immunizations. There is no need to restart a vaccine series regardless of the time that has elapsed between doses. Use the chart appropriate for the child's age.

| CATCH-UP SCHEDULE FOR CHILDREN AGED 4 MONTHS THROUGH 6 YEARS | | | | | |
|--|------------------------|--|--|--|---|
| Vaccine | Minimum Age for Dose 1 | Minimum Interval Between Doses | | | |
| | | Dose 1 to Dose 2 | Dose 2 to Dose 3 | Dose 3 to Dose 4 | Dose 4 to Dose 5 |
| Diphtheria, Tetanus, Pertussis | 6 wks | 4 weeks | 4 weeks | 6 months | 6 months ¹ |
| Inactivated Poliovirus | 6 wks | 4 weeks | 4 weeks | 4 weeks ² | |
| Hepatitis B ³ | Birth | 4 weeks | 8 weeks (and 16 weeks after first dose) | | |
| Measles, Mumps, Rubella | 12 mo | 4 weeks ⁴ | | | |
| Varicella | 12 mo | | | | |
| <i>Haemophilus influenzae</i> type b ⁵ | 6 wks | 4 weeks if first dose given at age <12 months 8 weeks (as final dose) if first dose given at age 12-14 months No further doses needed if first dose given at age ≥15 months | 4 weeks ⁶ if current age <12 months 8 weeks (as final dose)⁶ if current age ≥12 months and second dose given at age <15 months No further doses needed if previous dose given at age ≥15 mo | 8 weeks (as final dose) This dose only necessary for children aged 12 months-5 years who received 3 doses before age 12 months | |
| Pneumococcal ⁷ | 6 wks | 4 weeks if first dose given at age <12 months and current age <24 months 8 weeks (as final dose) if first dose given at age ≥12 months or current age 24-59 months No further doses needed for healthy children if first dose given at age ≥24 months | 4 weeks if current age <12 months 8 weeks (as final dose) if current age ≥12 months No further doses needed for healthy children if previous dose given at age ≥24 months | 8 weeks (as final dose) This dose only necessary for children aged 12 months-5 years who received 3 doses before age 12 months |  |

| CATCH-UP SCHEDULE FOR CHILDREN AGED 7 YEARS THROUGH 18 YEARS | | | |
|--|--------------------------------|---|---|
| Vaccine | Minimum Interval Between Doses | | |
| | Dose 1 to Dose 2 | Dose 2 to Dose 3 | Dose 3 to Booster Dose |
| Tetanus, Diphtheria ⁸ | 4 weeks | 6 months | 6 months if first dose given at age <12 months and current age <11 years; otherwise 5 years |
| Inactivated Poliovirus ⁹ | 4 weeks | 4 weeks | IPV ^{2,9} |
| Hepatitis B | 4 weeks | 8 weeks (and 16 weeks after first dose) | |
| Measles, Mumps, Rubella | 4 weeks | | |
| Varicella ¹⁰ | 4 weeks | | |

1. **DTaP.** The fifth dose is not necessary if the fourth dose was administered after the fourth birthday.
2. **IPV.** For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if third dose was administered at age ≥4 years. If both OPV and IPV were administered as part of a series, a total of 4 doses should be given, regardless of the child's current age.
3. **HepB.** Administer the 3-dose series to all children and adolescents <19 years of age if they were not previously vaccinated.
4. **MMR.** The second dose of MMR is recommended routinely at age 4-6 years but may be administered earlier if desired.
5. **Hib.** Vaccine is not generally recommended for children aged ≥5 years.
6. **Hib.** If current age <12 months and the first 2 doses were PRP-OMP (PedvaxHIB[®] or ComVax[®] [Merck]), the third (and final) dose should be administered at age 12-15 months and at least 8 weeks after the second dose.
7. **PCV.** Vaccine is not generally recommended for children aged ≥5 years.
8. **Td.** Adolescent tetanus, diphtheria, and pertussis vaccine (Tdap) may be substituted for any dose in a primary catch-up series or as a booster if age appropriate for Tdap. A five-year interval from the last Td dose is encouraged when Tdap is used as a booster dose. See ACIP recommendations for further information.
9. **IPV.** Vaccine is not generally recommended for persons aged ≥18 years.
10. **Varicella.** Administer the 2-dose series to all susceptible adolescents aged ≥13 years.

Report adverse reactions to vaccines through the federal Vaccine Adverse Event Reporting System. For information on reporting reactions following immunization, please visit www.vaers.hhs.gov or call the 24-hour national toll-free information line 800-822-7967. Report suspected cases of vaccine-preventable diseases to your state or local health department.

For additional information about vaccines, including precautions and contraindications for immunization and vaccine shortages, please visit the National Immunization Program Website at www.cdc.gov/nip or contact 800-CDC-INFO (800-232-4636) (In English, En Español — 24/7)

Administration

- Be familiar with manufacturer's recommendation for proper storage and reconstitution of the vaccine.
- Check expiration dates.
- Excellent intramuscular injection technique must be used to avoid local reactions to the injection.
- When two or more vaccinations need to be given, the order of injections is arbitrary. They may be given sequentially or simultaneously by two people.
- Doses of live vaccines should be separated by a minimum of 30 days, but more than one live vaccine may be given on the same day.

Table 8–7 Adult Immunizations

| Vaccine Name and Route | For Whom Vaccination Is Recommended | Schedule for Vaccine Administration (Any Vaccine Can Be Given with Another) | Contraindications and Precautions (Mild Illness Is Not a Contraindication) |
|--|--|--|---|
| Influenza | <ul style="list-style-type: none"> • Persons aged 50 yrs and older. | | Contraindication Previous anaphylactic reaction to this vaccine, to any of its components, or to eggs. |
| Trivalent inactivated influenza vaccine (TIV) <i>Give IM</i> | <ul style="list-style-type: none"> • Persons with medical problems (e.g., heart disease, lung disease, diabetes, renal dysfunction, hemoglobinopathy, immunosuppression) and/or people living in chronic-care facilities. • Persons with any condition that compromises respiratory function or the handling of respiratory secretions or that can increase the risk of aspiration (e.g., cognitive dysfunction, spinal cord injury, seizure disorder, or other neuromuscular disorder). • Persons working or living with at-risk people. • Women who will be pregnant during the influenza season (December–March). • All health care workers and other persons who provide direct care to at-risk people. • Household contacts and out-of-home caregivers of children aged 0–59 mo. • Travelers at risk for complications of influenza who go to areas where influenza activity exists or who may be among people from areas of the world where there is current influenza activity (e.g., on organized tours). • Persons who provide essential community services. • Students or other persons in institutional settings (e.g., dormitory residents). • Anyone wishing to reduce the likelihood of becoming ill with influenza. | <ul style="list-style-type: none"> • Given every year in the fall or winter. • October and November are the ideal months to give TIV. • LAIV may be given as early as August. • Continue to give TIV and LAIV through the influenza season from December through March (including when influenza activity is present in the community) and at other times when the risk of influenza exists. | Precautions <ul style="list-style-type: none"> • Moderate or severe acute illness. • History of Guillain-Barré syndrome within 6 wks of previous TIV. |
| Influenza Live attenuated influenza vaccine (LAIV) <i>Give intranasally</i> | <ul style="list-style-type: none"> • Healthy, nonpregnant persons aged 49 yrs and younger who meet any of the conditions listed below: <ul style="list-style-type: none"> —Working or living with at-risk people as listed in the section above —Health care workers or other persons who provide direct care to at-risk people (except persons in close contact with severely immunosuppressed persons). —Household contacts and out-of-home caregivers of children ages 0–59 mo. | | Contraindications <ul style="list-style-type: none"> • Previous anaphylactic reaction to this vaccine, to any of its components, or to eggs • Pregnancy, asthma, reactive airway disease, or other chronic disorder of the pulmonary or cardiovascular system; an underlying medical condition, including metabolic disease such as diabetes, renal dysfunction, and hemoglobinopathy; a known or suspected immune deficiency disease or receiving immunosuppressive therapy; history of Guillain-Barré syndrome. <p style="text-align: right;"><i>(continued on next page)</i></p> |

Table 8–7 (continued from previous page)

| Vaccine Name and Route | For Whom Vaccination Is Recommended | Schedule for Vaccine Administration (Any Vaccine Can Be Given with Another) | Contraindications and Precautions (Mild Illness Is Not a Contraindication) |
|--|--|--|---|
| | <ul style="list-style-type: none"> —Travelers who may be among people from areas of the world where there is current influenza activity (e.g., on organized tours). —Persons who provide essential community services. —Students or other persons in institutional settings (e.g., dormitory residents). —Anyone wishing to reduce the likelihood of becoming ill with influenza. | | <p>Precaution Moderate or severe acute illness.</p> |
| <p>Pneumococcal poly-saccharide vaccine (PPV)</p> <p><i>Give IM or SC</i></p> | <ul style="list-style-type: none"> • Persons aged 65 yrs and older. • Persons who have chronic illness or other risk factors, including chronic cardiac or pulmonary disease, chronic liver disease, alcoholism, diabetes, CSF leak, as well as people living in special environments or social settings (including Alaska Natives and certain American Indian populations). Those at highest risk of fatal pneumococcal infection are persons with anatomic asplenia, functional asplenia, or sickle cell disease; immunocompromised persons including those with HIV infection, leukemia, lymphoma, Hodgkin’s disease, multiple myeloma, generalized malignancy, chronic renal failure, or nephrotic syndrome; persons receiving immunosuppressive chemotherapy (including corticosteroids); those who received an organ or bone marrow transplant; and candidates for or recipients of cochlear implants. | <ul style="list-style-type: none"> • Routinely given as a one-time dose; administer if previous vaccination history is unknown. • One-time revaccination is recommended 5 yrs later for persons at highest risk of fatal pneumococcal infection or rapid antibody loss (e.g., renal disease) and for persons age 65 yrs and older if the 1st dose was given prior to age 65 and 5 yrs or more have elapsed since the prior dose. | <p>Contraindication Previous anaphylactic reaction to this vaccine or to any of its components.</p> <p>Precaution Moderate or severe acute illness.</p> |
| <p>Hepatitis B (HepB)</p> <p><i>Give IM</i></p> <p>Brands may be used interchangeably.</p> | <ul style="list-style-type: none"> • All adolescents; any adult wishing to obtain immunity. • High-risk persons, including household contacts and sex partners of HBsAg-positive persons; injecting drug users; heterosexuals with more than one sex partner in 6 months; men who have sex with men; persons with recently diagnosed STDs; patients receiving hemodialysis and patients with renal disease that may result in dialysis; recipients of certain blood products; health care workers and public safety workers who are exposed to blood; clients and staff of institutions for the developmentally disabled; inmates of long-term correctional facilities; and certain international travelers. • Persons with chronic liver disease. | <ul style="list-style-type: none"> • Three doses are needed on a 0, 1, 6 mo schedule. • Alternative timing options for vaccination include 0, 2, 4 mo and 0, 1, 4 mo. • There must be 4 wks between doses #1 and #2, and 8 wks between doses #2 and #3. Overall, there must be at least 16 wks between doses #1 and #3. • Schedule for those who have fallen behind: If the series is delayed between doses, DO NOT start the series over. Continue from where you left off. | <p>Contraindication Previous anaphylactic reaction to this vaccine or to any of its components.</p> <p>Precaution Moderate or severe acute illness.</p> |

(continued on next page)

Table 8–7 (continued from previous page)

| Vaccine Name and Route | For Whom Vaccination Is Recommended | Schedule for Vaccine Administration (Any Vaccine Can Be Given with Another) | Contraindications and Precautions (Mild Illness Is Not a Contraindication) |
|--|---|--|--|
| | <p>Note: Provide serologic screening for immigrants from endemic areas. When HBsAg-positive persons are identified, offer appropriate disease management. In addition, screen their sex partners and household members, and give the first dose of vaccine at the same visit. If found susceptible, complete the vaccine series.</p> | | |
| <p>Hepatitis A (HepA) <i>Give IM</i> Brands may be used interchangeably.</p> | <ul style="list-style-type: none"> Persons who travel or work anywhere except the United States, western Europe, New Zealand, Australia, Canada, and Japan. Persons with chronic liver disease, including persons with hepatitis B and C; injecting and noninjecting drug users; men who have sex with men; people with clotting-factor disorders; persons who work with hepatitis A virus in experimental lab settings (not routine medical laboratories); and food handlers when health authorities or private employers determine vaccination to be cost effective. Anyone wishing to obtain immunity to hepatitis A. <p>Note: Prevaccination testing is likely to be cost-effective for persons older than age 40 yrs, as well as for younger persons in certain groups with a high prevalence of hepatitis A virus infection.</p> | <p>For Twinrix® (hepatitis A and B combination vaccine [GSK]), three doses are needed on a 0, 1, 6 mo schedule. Recipients must be of age 18 yrs or older.</p> <ul style="list-style-type: none"> Two doses are needed. The minimum interval between doses #1 and #2 is 6 mo. If dose #2 is delayed, do not repeat dose #1. Just give dose #2. | <p>Contraindication</p> <p>Previous anaphylactic reaction to this vaccine or to any of its components.</p> <p>Precautions</p> <ul style="list-style-type: none"> Moderate or severe acute illness. Safety during pregnancy has not been determined, so benefits must be weighed against potential risk. |
| <p>Td, DTaP (Tetanus, diphtheria, pertussis) <i>Give IM</i></p> | <ul style="list-style-type: none"> All adults who lack a history of a primary series consisting of at least three doses of tetanus- and diphtheria-containing vaccine. A booster dose of tetanus- and diphtheria-containing toxoid may be needed for wound management as early as 5 yrs after receiving a previous dose, so consult ACIP recommendations.* Using tetanus toxoid (TT) instead of Td or DTaP is not recommended. In pregnancy, when indicated, give Td or DTaP in 2nd or 3rd trimester. If not administered during pregnancy, give DTaP in immediate postpartum period. <p>For DTaP (tetanus- and diphtheria-toxoids with acellular pertussis vaccine) only:</p> | <ul style="list-style-type: none"> For persons who are unvaccinated or behind, complete the primary series with Td (spaced at 0, 1–2 mo, 6–12 mo intervals). One dose of DTaP may be used for any dose if aged 19–64 yrs. Give Td booster every 10 yrs after the primary series has been completed. For adults aged 19–64 yrs, a one-time dose of DTaP is recommended to replace the next Td. Intervals of 2 yrs or less between Td and DTaP may be used if needed. | <p>Contraindications</p> <ul style="list-style-type: none"> Previous anaphylactic reaction to this vaccine or to any of its components. For DTaP only, history of encephalopathy within 7 days following DTP/DTaP. <p>Precautions</p> <ul style="list-style-type: none"> Moderate or severe acute illness. Guillain-Barré syndrome within 6 wks of receiving a previous dose of tetanus toxoid-containing vaccine. Unstable neurologic condition. Note: Use of Td or DTaP is not contraindicated in pregnancy. At the provider's discretion, either vaccine may be administered during the 2nd or 3rd trimester. |

Table 8-7 (continued from previous page)

| Vaccine Name and Route | For Whom Vaccination Is Recommended | Schedule for Vaccine Administration (Any Vaccine Can Be Given with Another) | Contraindications and Precautions (Mild Illness Is Not a Contraindication) |
|--|--|--|---|
| | <ul style="list-style-type: none"> All adults younger than age 65 yrs who have not received DTaP. Health care workers who work in hospitals or ambulatory care settings and have direct patient contact and who have not received DTaP. Adults in contact with infants younger than age 12 month (e.g., parents, grandparents younger than age 65 yrs, child care providers, health care workers) who have not received a dose of DTaP. | <p>Note: The two DTaP products are licensed for different age groups: Adacel (sanofi) for use in persons aged 11–64 yrs and Boostrix (GSK) for use in persons aged 10–18 yrs.</p> | |
| Polio (IPV) <i>Give IM or SC</i> | <p>Not routinely recommended for persons aged 18 yrs and older.</p> <p>Note: Adults living in the United States who never received or completed a primary series of polio vaccine need not be vaccinated unless they intend to travel to areas where exposure to wild-type virus is likely (i.e., India, Pakistan, Afghanistan, and certain countries in Africa). Previously vaccinated adults can receive one booster dose if traveling to polio endemic areas.</p> | <ul style="list-style-type: none"> Refer to ACIP recommendations regarding unique situations, schedules, and dosing information. | <p>Contraindication</p> <p>Previous anaphylactic or neurologic reaction to this vaccine or to any of its components.</p> <p>Precautions</p> <ul style="list-style-type: none"> Moderate or severe acute illness. Pregnancy |
| Varicella (Var) (Chickenpox) <i>Give SC</i> | <p>All adults without evidence of immunity. Immunity is defined as any one of the following:</p> <ul style="list-style-type: none"> a history of two doses of Var. born in the United States before 1980. history of varicella disease or herpes zoster based on health care provider diagnosis. laboratory evidence of immunity or laboratory confirmation of disease. | <ul style="list-style-type: none"> Two doses are needed. Dose #2 is given 4–8 wks after dose #1. If Var and either MMR, LAIV, and/or yellow fever vaccine are not given on the same day, space them at least 28 days apart. If the second dose is delayed, do not repeat dose #1. Just give dose #2. | <p>Contraindications</p> <ul style="list-style-type: none"> Previous anaphylactic reaction to this vaccine or to any of its components. Pregnancy or possibility of pregnancy within 4 wks. Persons immunocompromised because of malignancies and primary or acquired cellular immunodeficiency including HIV/AIDS. (see <i>MMWR</i> 1999, Vol. 48, No. RR-6.) <p>Note: For those on high-dose immunosuppressive therapy, consult ACIP recommendations regarding delay time.*</p> <p>Precautions</p> <ul style="list-style-type: none"> If blood, plasma, and/or immunoglobulin (Ig or VZIG) were given in past 11mo, see ACIP statement <i>General Recommendations on Immunization</i> regarding time to wait before vaccinating. Moderate or severe acute illness. |
| Meningococcal conjugate vaccine (MCV4) <i>Give IM</i> | <ul style="list-style-type: none"> College freshmen living in dormitories. Adolescents and adults with anatomic or functional asplenia or with terminal complement component deficiencies. | <ul style="list-style-type: none"> One dose is needed. If previous vaccine was MPSV4, revaccinate after 5yrs if risk continues. | <p>Contraindication</p> <p>Previous anaphylactic or neurologic reaction to this vaccine or to any of its components, including diphtheria toxoid (for MCV4).</p> |

(continued on next page)

Table 8–7 (continued from previous page)

| Vaccine Name and Route | For Whom Vaccination Is Recommended | Schedule for Vaccine Administration (Any Vaccine Can Be Given with Another) | Contraindications and Precautions (Mild Illness Is Not a Contraindication) |
|---|--|---|--|
| Polysaccharide vaccine (MPSV4) Give SC | <ul style="list-style-type: none"> Persons who travel to or reside in countries in which meningococcal disease is hyperendemic or epidemic (e.g., the “meningitis belt” of sub-Saharan Africa). Microbiologists who are routinely exposed to isolates of <i>N. meningitidis</i>. | <ul style="list-style-type: none"> Revaccination after MCV4 is not recommended. MCV4 is preferred over MPSV4 for persons age 55 yrs and younger, although MPSV4 is an acceptable alternative. | Precautions <ul style="list-style-type: none"> Moderate or severe acute illness. For MCV4 only, history of Guillain-Barré syndrome. |
| MMR (measles, mumps, rubella) Give SC | <ul style="list-style-type: none"> Persons born in 1957 or later (especially those born outside the United States.) should receive at least one dose of MMR if there is no serologic proof of immunity or documentation of a dose given on or after the first birthday. Persons in high-risk groups, such as health care workers, students entering college and other post-high school educational institutions, and international travelers, should receive a total of two doses. Persons born before 1957 are usually considered immune, but proof of immunity (serology or vaccination) may be desirable for health care workers. Women of childbearing age who do not have acceptable evidence of rubella immunity or vaccination. | <ul style="list-style-type: none"> One or two doses are needed. If dose #2 is recommended, give it no sooner than 4 wks after dose #1. If MMR and either Var, LAIV, and/or yellow fever vaccine are not given on the same day, space them at least 28 d apart. If a pregnant woman is found to be rubella susceptible, administer MMR postpartum. | Contraindications <ul style="list-style-type: none"> Previous anaphylactic reaction to this vaccine or to any of its components. Pregnancy or possibility of pregnancy within 4 wks. Persons immunocompromised because of cancer, leukemia, lymphoma, immunosuppressive drug therapy, including high-dose steroids or radiation therapy. Note: HIV positivity is NOT a contraindication to MMR except for those who are severely immunocompromised. Precautions <ul style="list-style-type: none"> If blood, plasma, and/or immunoglobulin were given in past 11 mo, see ACIP statement <i>General Recommendations on Immunization*</i> regarding time to wait before vaccinating. Moderate or severe acute illness. History of thrombocytopenia or thrombocytopenic purpura. Note: If PPD (tuberculosis skin test) and MMR are both needed but not given on same day, delay PPD for 4–6 wks after MMR. |
| Human-papillomavirus (HPV) Give IM | All previously unvaccinated women through age 26 yrs. | <ul style="list-style-type: none"> Three doses are needed. Dose #2 is given 4–8 wks after dose #1, and dose #3 is given 6 mo after dose #1 (at least 12 wks after dose #2). | Contraindication Previous anaphylactic reaction to this vaccine or to any of its components. Precaution data on vaccination in pregnancy are limited; therefore, vaccination during pregnancy should be delayed until after completion of the pregnancy. |
| Zoster (shingles) (Zos) Give SC | A herpes zoster (shingles) vaccine was licensed in May 2006 for use in persons aged 60 yrs and older. ACIP recommendations for its use are pending. Refer to the package insert for details on its use. | | |

*For specific ACIP recommendations, refer to the official ACIP statements published in MMWR. To obtain copies of these statements, call the CDC-INFO Contact Center at (800) 232-4636; visit CDC's Web site at www.cdc.gov/nip/publications/ACIP-list.htm; or visit the Immunization Action Coalition (IAC) Web site at www.immunize.org/acip.

This table is revised periodically. Visit IAC's website at www.immunize.org/adultrules to make sure you have the most current version. IAC thanks William Atkinson, MD, MPH, from CDC's National Center for Immunization and Respiratory Diseases for his assistance. For more information, contact IAC at 1573 Selby Avenue, St. Paul, MN 55104, (651) 647-9009, or E-mail: admin@immunize.org.

Item #P2011 (9/06).

Immunization Action Coalition 1573 Selby Avenue St. Paul MN 55104. E-mail: admin@immunize.org; Web: <http://www.immunize.org/>

- Procedures should be in place to deal with allergic/anaphylactic reactions to the vaccine.

Interventions

- To minimize local reactions:
 - use a needle with adequate length to inject the antigen deep in the muscle mass;
 - inject into the vastus lateralis or ventrogluteal muscle in infants; the deltoid muscle may be used in children over 18 months old or for infants receiving the HBV vaccine;
 - clear the needle after injecting the vaccine by using an air bubble.
- To minimize pain:
 - apply topical EMLA (eutectic mixture of local anesthetic) to the injection site and after injecting, cover the site with an occlusive dressing for 2.5 hours.
 - apply an EMLA patch, which requires no dressing.
 - Spray a vapocoolant (ethyl chloride or Fluori-Methane) directly on the skin or on a cotton ball, which is placed on the skin 15 seconds before injecting.
 - use a distraction, such as telling the child to “take a deep breath and blow and blow and blow until I tell you to stop.”

Contraindications to Administering Vaccine

- All vaccines
 - Anaphylactic reaction or allergy to the vaccine or any of its components
 - Moderate or severe illness with or without a fever
 - Avoid giving live virus immunizations to children with an impaired immune system (except MMR for children with HIV), to children living with an immunosuppressed person, during pregnancy, and in women who may become pregnant within 3 months
 - Postpone giving live virus vaccines to children who have received passive immunity from blood transfusions or immunoglobulins, for 3–7 months
- DTaP
 - Severe adverse reactions from a previous DTaP immunization
 - Encephalopathy within 7 days of administration of previous dose of DTaP
 - Wait for at least 90 days after receiving immunoglobulins
 - Anaphylactic reaction or allergy to neomycin, streptomycin, or polymyxin B
- MMR
 - Pregnancy
 - Known altered immunocompetency (hematologic and solid tumors, congenital immunodeficiency, long-term immunosuppressive therapy) except HIV
 - Allergy to eggs and neomycin

- HBV
 - Anaphylactic reaction or allergy to common baker's yeast
- Var
 - Immunocompromised individuals (e.g., HIV, acute lymphocytic leukemia)
 - Pregnancy
- PCV
 - Allergy to vaccine components or anaphylactic response to previous dose
 - Acute, moderate, or severe illness with or without fever
- Influenza
 - Acute febrile illness
 - Egg hypersensitivity
- Hepatitis A (HAVRIX or VAQTA)
 - Sensitivity to alum or phenoxyethanol
- Haemophilus Influenza type B
 - No contraindications; quite safe

Precautions – Weigh Risks and Benefits Before Administering Vaccine

- DPaT –
 - Fever greater than 40.5°C (105°F) within 48 hours of vaccination with a prior dose of DTaP
 - Collapse or shock-like state within 48 hours of prior dose of DTaP
 - Seizures within 3 days of prior dose of DTaP
 - Persistent, inconsolable crying lasting 3 hours within 48 hours of prior dose of DTaP
 - Pregnancy
- IPV
 - Pregnancy
- MMR
 - Recent immunoglobulin administration.
 - MMR and immunoglobulin products should not be given simultaneously; if they must be given at the same time, give at different sites and revaccinate or test for seroconversion in 3 months.
 - If immunoglobulin is given first, MMR should not be given for 3–6 months, depending on the dose. If MMR is given first, immunoglobulin should not be given for 2 weeks.
 - Thrombocytopenia.

Side Effects/Allergic and Adverse Reactions

- DTaP
 - Usually occur within a few hours or days of administration, and are usually limited to local tenderness, erythema, and swelling at the injection site, low-grade fever; behavioral changes, and mild anorexia
 - Reactions are usually less severe when the deltoid site is used versus the vastus lateralis site

- Severe adverse reactions include anaphylaxis, shock or collapse, fever greater than 102°F, and persistent crying
- IPV, Salk
 - Site tenderness and irritability
- Hib
 - Low-grade fever and mild local reactions at the injection site; usually resolve rapidly.
 - Fever above 101.3°F may rarely occur.
- MMR
 - Unfavorable reactions and vaccine related disorders can occur for 30–60 days
 - Are usually mild; in older children and adults, reactions to rubella may be more troublesome. Include rash, itching, low-grade fever, and arthralgia
 - Studies have found no association between MMR and autism

Client teaching for self-care

- Parents need to be informed about vaccine safety, and benefits and risks associated with their administration
 - Lack of knowledge and unfounded fears may needlessly expose a child to the dangers of life-threatening diseases
 - Each child should have an accurate immunization record, kept by both the parents and physician. Parents should be made aware of when vaccinations are due to be given
 - Adolescents need to maintain their level of immunization by receiving booster shots when necessary
- Children at high risk should receive any of the following nonmandated vaccines, as necessary:
 - Nonmandated vaccines
 - Meningococcal Polysaccharide Vaccine (MPSV4)—preferred for children of ages 2–10
 - Meningococcal Conjugate Vaccine (MCV4)—preferred for older children
 - For prevention of meningococcal disease, which can lead to high fever, deafness, and death
 - Recommended for children of 2 years and older with terminal complement deficiencies and anatomic or functional asplenia, incoming college students who will live in dormitories, and military recruits
 - Safety during pregnancy has not been established
 - Lyme Disease Vaccine
 - Recommended for those living in lyme endemic areas and for those infected with lyme disease, ages 15–70
 - Has been demonstrated to be safe for children 4–18 years old
 - Influenza Virus Vaccine
 - Recommended for
 - children older than 6 months who have a chronic illness (cardiac or respiratory disorder, renal disease, diabetes mellitus), sickle cell disease, HIV, and children on long-term aspirin therapy;
 - adults who are elderly and frail;
 - health care professionals;
 - persons (family members, caregivers) who are in close contact with those at high risk.

LIFESTYLE CHOICES

- Healthy lifestyle is the choice of living behaviors, which maximize health and decrease risk of illness and death.
- Lifestyle choices are based on family experience with its ethnic, cultural, religious, and socioeconomic beliefs.
- Major risk factors related to illness and death are related to the Healthy People 2010 leading health indicators: age, heredity, diet, stress, exercise, smoking, alcohol use, environmental factors such as pollution, poverty, occupational hazards, unprotected sex, drunk driving, failure to wear seat belts in automobiles, helmets when riding motorcycles or bikes, helmets and knee and elbow protective gear when in-line skating.

GUIDELINES FOR HEALTHY LIVING

- *Eat a balanced diet* (see nutrition in Chapter 13 for further information including serving size and number)
- Select foods and number of daily servings of the five food groups based on the MYPyramid food guidance system produced by the US Department of Agriculture (MYPyramid.gov), which focuses on a balance between food eaten and energy expended in physical activity and recommends limited fat, sugar, and salt.
- Eat a variety of grains daily, at least half of which are whole grains, which provide complex carbohydrates. Approximately 60% of daily calories should be from carbohydrates and 80% of these from complex carbohydrates.
- Eat a variety of fruits and vegetables daily; they are rich in vitamins C and A, complex carbohydrates, and fiber. Daily diet should contain 20–30 g of fiber.
- Prepare, cook, serve, and store foods so they remain safe to eat.
- Select a diet that is low in saturated fat and cholesterol and moderate in total fat. Daily intake of cholesterol should be

less than 300 mg and fat intake 30% or less of total calories with not more than 10% from saturated fats.

- Select foods and beverages to moderate sugar intake.
- Choose and prepare foods with less salt. Limit daily intake to slightly less than one teaspoon per day.
- Use alcohol only in moderation: not more than two small glasses of wine, two cans of beer, or two drinks with not more than 1 ½ oz of alcohol per day each.
- Drink 5–8 glasses of water each day.

- *Maintain a healthy weight*

- Obesity is a chronic disease.
- Research has demonstrated relationships between obesity and coronary artery disease, hypertension, stroke, diabetes, arthritis, and selected cancers.
- Obesity and overweight is an increasing problem in the United States particularly in the Hispanic population.
- Ongoing balance between caloric intake and energy expended is the goal of weight control programs.

Assessment Alert

Best measure of weight is the BMI because it applies to men and women regardless of frame size or muscle mass.

BMI does not work for pregnant women, competitive athletes, or frail elderly.

- Loss of 1 lb of fat per week requires a 500-calorie deficit per day.
- Daily caloric requirement for men is about 2200 calories and for sedentary women and older adults about 1600 calories.
- Dieting with a marked reduction in daily calories results in an initial significant weight loss mainly due to water loss; more weight typically is then not lost for 7–10 days.
- Group support or a weight loss partner helps clients stick to the needed diet
- Diet teaching is most effective when the whole family or social group is involved especially if the client is not the cook.
- Drinking two or three glasses of water before each meal results in a feeling of fullness, which suppresses appetite.

- *Exercise regularly*

- Benefits of exercise
 - Improves cardiovascular fitness
 - Helps control weight
 - Creates a sense of well-being
 - Increases or maintains strength and endurance
 - Increases or maintains flexibility

- Maintains bone mass
- Increases glucose tolerance; helps prevent Type II diabetes
- Increases proportion of HDLs
- Reduces concentration of triglycerides
- Reduces risk of coronary artery disease
- Helps prevent hypertension

- Types of exercise

- Aerobic: rhythmic, continuous use of large muscle groups, e.g., swimming, dancing, and walking
- Anaerobic: bursts of energy expended at intervals, e.g., weight lifting

- Muscular strength

- Ability to contract at or near maximum for a short period of time
- Best improved by activities that overload or gradually increase the resistance (load or weight) that muscles must move
- Three types of overload-based exercise are
 - isometric: muscles contract against an immovable object because resistance is so great; can be dangerous for people with hypertension; not generally used in strength training.
 - isotonic resistive: repetitively use muscles to move or lift specific fixed resistances or weights, e.g., weight lifting, resistance exercise machines; most common type of exercise done to build strength.
 - isokinetic: resistance moves only at a preset speed regardless of force applied so muscles are consistently overloaded throughout the range of motion; require expensive machines.

Strength training helps minimize the progression of osteoporosis and helps older adults maintain muscle mass and strength.

- Muscular endurance

- Ability to perform at submaximal levels for a long period of time
- Improved by activities requiring repeated muscular contractions of less than maximal degree, e.g., sweeping, raking, or pushing a lawn mower

- Flexibility

- Ability of joints to move with ease through their range of motion
- Maintained by stretching
- Static stretching: slow stretch held at the most extended point for 10–30 seconds
- Ballistic stretching: repetitive, bouncing, quick, and forceful stretches

- Guidelines for cardiorespiratory fitness exercise training (American Academy of Sports Medicine)

- Mode of activity: any continuous physical activity using large muscle groups; may be rhythmic and aerobic
- Frequency: three to five times per week

- Intensity: (amount of effort put into an activity) moderate
- Duration: 30–60 minutes
- Higher levels of frequency, intensity, and duration can be set for specific clients

Nursing Process Elements (exercise)

Determine client's current pattern of activity and exercise. Determine client's understanding of the need for exercise to maintain/attain optimum health

Client teaching for self-care

- Consult physician if over age 45 or with risk factors for cardiovascular disease before beginning an exercise program
- Warm up with stretching before aerobic exercise and allow for a cool-down period at the end to let the heart gradually return to normal rate; this helps prevent hypotension and syncope
- Wear proper clothing
- Use any equipment correctly
- Avoid exercising in extremes of temperature
- Suggestions to help clients adhere to an exercise program:
 - Select a simple, not a complex, exercise routine
 - Exercise with a friend or group
 - Have a scheduled time to exercise that fits with daily lifestyle
 - Start small and increase gradually
 - Incorporate music into exercise routine
- *Avoid smoking*
 - Tobacco smoking is the number one cause of preventable death in the United States (40,000 deaths per year)
 - Tobacco-related causes of death include lung cancer; COPD; bladder, renal, pancreatic, and female reproductive cancers; CAD, hypertension, PVD, and cerebrovascular disease
 - Second-hand smoke causes 3000 deaths per year from lung cancer and numerous fetal problems
 - Nicotine is an addiction. It causes release of epinephrine resulting in tachycardia, peripheral vasoconstriction, elevation of blood pressure, and a feeling of euphoria
 - Withdrawal effects include irritability, anger, anxiety, restlessness, hunger, decreased concentration, and cravings
 - Snuffing tobacco or smoking cigars or pipes is associated with cancer of the lip, tongue, mouth, larynx, and esophagus
 - Approaches to smoking cessation include 12-step support programs, psychotherapy, hypnosis, aversion therapy, acupuncture, and nicotine replacement by means of gums, patches, nasal sprays, or pills, which is designed to alleviate withdrawal symptoms.

Nursing Process Elements (smoking)

- Use the “four A” approach with clients who are smokers.
 - Ask about the client's smoking habit
 - Advise client to stop smoking
 - Assist client to develop a specific plan to stop smoking
 - Arrange follow-up and support

Client teaching for self-care

- During the first week of smoking cessation, stay away from places and activities where people smoke
- Try chewing regular gum, sucking hard candy, using imagery or engaging in deep breathing, or other relaxation routine to control cravings
- Do not smoke if using nicotine replacement therapy because of the risk of overdose: headache, abdominal pain, N&V, and in some cases severe hypotension and its sequelae
- Most at risk for deleterious effects of overdose are clients with heart problems
- *Act responsibly in regard to sexual activity to prevent STIs and unwanted pregnancies*
 - STIs are epidemic among young adults and teenagers
 - STIs tend to have more serious effects in women
 - STIs are associated in pregnant women with spontaneous abortion, prematurity, low birth weight, and congenital infection
 - Engage only in “safer” sex
- *Limit sun exposure*
 - UVA and UVB rays are both harmful to the skin; they cause premature aging with wrinkling and are directly related to the development of skin cancer.
 - Different skin types vary in sensitivity to the skin; sunscreens with an SPF of 15 are appropriate for all types.

Nursing Process Elements (sun exposure)

Assess client's skin type.

Assess client's lifestyle for degree of sun exposure.

Client teaching for self-care

- Use sunscreen with a sun protection factor of 15 every day applying it at least 30 minutes before sun exposure
- Wear a hat and long-sleeved clothing when out in sun to shield from rays
- Avoid being out in the sun between 10 a.m. and 3 p.m. when ultraviolet rays are most intense
- Reapply sunscreen (even water resistant) after swimming, strenuous exercise, or prolonged sunbathing
- Avoid tanning lamps and commercial tanning booths

Assessment Alert

Photosensitivity rashes associated with medications have an abrupt onset and are bright red, symmetrical, and widespread. Medications that are associated with photosensitivity include certain tetracyclines, sulfas, antihypertensives, diuretics, oral hypoglycemics, psychotropic drugs, and NSAIDs.

- Avoid other risky behaviors: do not travel in an automobile without a seat belt; do not ride a motorcycle without proper training and a helmet; do not take infants and children in automobiles without proper car seats/seatbelts; do not in-line skate without a helmet and elbow and knee protectors; do not ride a bicycle without a helmet; do not abuse drugs or alcohol (see Chapter 12); do not remain in an environment with respiratory irritants without a protective mask or other device; do not remain in areas with loud sound without ear plugs; never dive in shallow water
- Research has linked dietary factors to the development of diseases such as heart disease, diabetes, and certain cancers

PRINCIPLES OF TEACHING/LEARNING

- Learning
 - Acquisition of a new or changed behavior by an individual
- Factors influencing learning are
 - motivation,
 - readiness to learn,
 - cognitive ability,
 - sensory ability,
 - environment,
 - physical status,
 - comfort level, and
 - culture.
- Strategies to promote learning:
 - Provide comfortable environment: free of distraction, private, nonjudgmental, and comfortable temperature
 - Involve client and family in developing teaching plan
 - Build on existing knowledge
 - Use short-term goals
 - Actively involve client
 - Use multiple strategies
 - Provide positive reinforcement
 - Evaluate learning through return demonstration, observing subsequent behavior, written test, return explanation, and self-report
 - Make client physically comfortable: pain free, empty bladder
- Areas of client teaching:
 - About health problem
 - About prescribed medications: name, dose, route, frequency, directions for taking (e.g., with water, food, on an empty stomach, do not take with foods, OTC, or prescribed medications), common side effects and how to manage them, adverse effects to be reported to health care provider, and expected effect
 - About follow-up care: when and how reports of lab tests will be received, date and times of next visit, needed follow up lab tests intervals, how to make appointment
 - Prevention and health promotion: screening guidelines, healthy lifestyle guidelines (each system—cigarette smoking, alcohol)
 - Preoperative teaching
 - Therapeutic interventions
 - Community services/support groups applicable to condition

WORKSHEET

Mark each health-related activity as an example of primary, secondary, or tertiary prevention.

1. Screening for hearing deficits
2. Teaching about dangers of high-fat diets
3. Recreation program for children of working mothers
4. Use of neonatal intensive care units
5. Immunization of the elderly against pneumonia
6. Clinical breast examinations
7. Health fair exhibit about dangers of water pollution
8. Physical therapy for an accident victim
9. Colonoscopy to screen for bowel cancer
10. Removal of asbestos tile from buildings

Mark each factor listed below as a leading health indicator from Healthy People 2010 or not. Do this by writing Healthy People 2010 beside those that are and No by the side of those that are not.

1. Physical activity
2. Accident mortality
3. Overweight and obesity
4. Tobacco use
5. Cancer screening
6. Chronic disease morbidity
7. Substance abuse
8. Responsible sexual behavior
9. Mental health
10. Incidence of infectious disease
11. Injury and violence
12. Environmental quality

13. Deaths from heart disease

14. Immunization

15. Access to health care

Underline the types of health screening recommended for a school-aged child.

1. Lead

2. Vision

3. Hearing

4. HIV

5. Mental health

6. Blood pressure

7. Scoliosis

8. Height/weight

9. Bone density

10. Tuberculosis (PPD)

11. Dental

12. Urinalysis

13. Hematocrit or hemoglobin

14. Physical abuse

15. Blood sugar

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. What are the five stages of health behavior changes as described by Prochaska et al.?

(continued)

2. In-depth assessment of client's health status is the foundation for _____.
3. The purpose of _____ is to identify risk factors or undiagnosed disease to allow for early intervention.
4. The most basic type of health promotion program is one that disseminates information to _____.
5. In a healthy diet at least _____ of the daily intake of grains should be whole grains.
6. How many 8-oz glasses of water should an adult drink per day? _____.
7. BMI as a measure of weight cannot be used for clients who are _____, _____, or _____.
8. Most sedentary women and older adults need about _____ cal/d whereas men need about _____ cal/d.
9. Rhythmic, continuous exercise using large muscle groups is _____.
10. The two overarching goals of Healthy People 2010 are to _____ and to _____.

APPLICATION QUESTIONS

1. Why can infants born without an immune system survive for the first few months of their lives with no apparent problems?
 - a. Limited antibodies are produced by bacteria in the infant's colon.
 - b. The exposure to pathogens during this time is limited.
 - c. Antibodies are passively received from the mother through the placenta and breast milk.
 - d. The fetal thymus produced a limited number of antibodies during the eighth and ninth months of pregnancy.
2. The nurse explains to the mother of a child who has received a tetanus toxoid injection, that this vaccination confers which type of immunity?
 - a. Lifelong active natural immunity
 - b. Lifelong passive immunity
 - c. Long lasting active immunity
 - d. Temporary passive natural immunity
3. Why are live virus vaccines contraindicated for children receiving corticosteroid, antineoplastic, or irradiation therapy? These children
 - a. Are be susceptible to infection because of their depressed immune response
 - b. Have had the disease already or may have been immunized against it
 - c. Are be unlikely to need this protection since they probably have a shortened lifespan
 - d. Have an allergy to rabbit serum, which is used as is for these vaccines
4. The nurse is asked which immunizations a child, currently up-to-date on all primary immunizations, should receive before starting kindergarten. He is currently up to date on all the primary immunizations. Which boosters should the mother be told the child needs?
 - a. IPV, Hep-B, and Td
 - b. DTaP, Hep-B, and Td
 - c. MMR, DTaP, and Hib
 - d. DTaP, IPV, and MMR
5. The nurse is reviewing the immunization history of an 11-month-old baby boy. Which diseases should the nurse expect the child to already have been immunized against?
 - a. Polio, pertussis, tetanus, and diphtheria
 - b. Pertussis, tetanus, polio, and measles

- c. Measles, mumps, rubella, and tuberculosis
 - d. Rubella, polio, measles, tuberculosis, and pertussis
6. Which is an example of primary prevention?
 - a. Testing neonates for sickle cell anemia
 - b. Admitting clients to an intensive care unit
 - c. Screening clients for osteoporosis
 - d. Speaking to community groups about radon exposure in the home
 7. Which is an example of secondary prevention?
 - a. Physical therapy for a stroke client
 - b. Immunization of children against measles
 - c. Teaching about birth control
 - d. Screening for hypertension
 8. Which is an example of tertiary prevention?
 - a. Occupational therapy for a client with spinal cord injury
 - b. PPD testing for tuberculosis
 - c. After school programs for at-risk youth
 - d. Vision checks
 9. A client comes to the clinic complaining of a rash that suddenly appeared while she was sunbathing earlier in the day. Assessment shows that the rash is bright red, covers wide symmetrical areas of the body, and has no accompanying local or systemic symptoms. Which question would be most important for the nurse to ask?
 - a. Did you use a new brand of sunscreen?
 - b. Did you wash with perfumed soap before sunbathing?
 - c. What medications do you take?
 - d. Have you eaten any new foods in the last 24 hours?
 10. The mother of an infant is questioning the nurse about the health care needed by her child. She expresses concern because of the number of people in her family with high blood pressure and asks when her baby's blood pressure will be checked. Which is the appropriate response for the nurse to give?
 - a. age 1
 - b. age 3
 - c. age 6
 - d. age 12
 11. Which health model does a person subscribe to when his or her motivation to engage in healthy behaviors is the desire to avoid illness?
 - a. Clinical
 - b. Adaptive
 - c. Role Performance
 - d. Eudaemonistic
 12. For which age groups would the nurse most appropriately plan to include a discussion of suicide as part of a health promotion program?
 - a. Children and teenagers
 - b. Teenagers and young adults
 - c. Young and middle adults
 - d. Middle and older adults
 13. Which client could the nurse administer an MMR vaccine to?
 - a. A child with HIV
 - b. A woman who is trying to get pregnant.
 - c. A child whose father had a kidney transplant.
 - d. A 7-month pregnant woman
 14. Which statement made by a client who is starting a smoking cessation program using a combination of nicotine replacement and hypnosis indicates the need for further teaching?
 - a. "I will try to use deep breathing and imagery to control cravings."
 - b. "I will suck hard candy when I get an urge for a cigarette."
 - c. "I will smoke just half a cigarette if I really feel out of control."
 - d. "I will stay away from places where people smoke during the next week."
 15. Which direction regarding self-testicular examination is appropriate for a nurse to give a 20-year-old male client?
 - a. Do not examine your testicles for at least 12 hours after intercourse.
 - b. Examine both testicles simultaneously so one can be compared to the other.
 - c. Keep in mind there may normally be what feels like a small bump on the upper or middle outer side of the testis.
 - d. If one testicle appears larger than the other, see your physician immediately.
 16. Which statement made by a client about self-breast examination indicates the need for health teaching?
 - a. "I palpate my breast carefully each month while standing in front of a mirror so I can see any changes in the contour or appearance of the skin."
 - b. "I use the finger pads of the three middle fingers of each hand to palpate my breasts."
 - c. "I use an up-and-down pattern of palpation on my breast and go all the way up until I reach my collar bone."

(continued)

- d. "I press lightly, then with medium pressure, and then with firm pressure on each area of my breast as I examine it."
17. A client who has been told that her total cholesterol is too high and that a cholesterol-lowering drug is being prescribed for her says that different people normally have different cholesterol levels and that everyone doesn't need pills and she is not going to take the ordered medication. According to the Stage Model of health behavior change, which stage is she in?
- Precontemplation
 - Contemplation
 - Preparation
 - Termination
18. How does the nurse begin to develop a Health Promotion Plan with a client?
- Involve a significant other
 - Identify priority health goals
 - Reinforce benefits of a change in health behaviors
 - Obtain a commitment to a healthy lifestyle
19. Which are strategies that the nurse may employ to aid a client in implementing a Health Promotion Plan? Mark all that apply.
- Group counseling
 - Telephone counseling
 - Modeling
 - Ensuring social support
 - Teaching
20. Which statement best indicates that a client who needs to begin an exercise program to improve cardiorespiratory fitness is in the preparation stage of the Stage Model of health behavior change?
- "I never really liked exercise but maybe I could get to like it."
 - "I think maybe I really do need to exercise; I get awfully short of breath going upstairs."
 - "I asked my friend if she would be interested in going to an exercise class with me."
 - "I asked my sister and she agrees exercise isn't always a good thing."
21. A mother states she will not allow her child to receive immunizations which contain live or attenuated organisms. Which immunizations could the child not receive?
- MMR
 - HBV
 - Varicella
 - DTaP
 - TIV influenza
 - IPV
22. A client asks about receiving the hepatitis A vaccine because of upcoming travel to an underdeveloped country where the disease is endemic. The client particularly wants to know how many injections are needed and at what interval. Which is a correct response for the nurse to give?
- 2 injections @ 3 months apart
 - 2 injections @ 6–18 months apart
 - 3 injections @ 1 month apart
 - 3 injections @ 3 months apart
23. What purpose does clearing the needle by injecting an air bubble after administration of an immunization serve?
- Decrease risk of an anaphylactic reaction
 - Decrease pain during injection
 - Minimize local reaction
 - Ensure proper dose
24. Which information should be given to a 52-year-old client who is planning to start a cardiorespiratory exercise program?
- Consult your physician to obtain an exercise prescription
 - Include only anaerobic activities
 - Stretch at the completion of each exercise session
 - Work up gradually to a maximum of 90 minutes five times per week.

ANSWERS & RATIONALES

Mark each health-related activity as an example of primary, secondary, or tertiary prevention.

- Screening for hearing deficits *Secondary*
- Teaching about dangers of high-fat diets *Primary*

3. Recreation program for children of working mothers *Primary*
4. Use of neonatal intensive care units *Tertiary*
5. Immunization of the elderly against pneumonia *Primary*
6. Clinical breast examinations *Secondary*
7. Health fair exhibit about dangers of water pollution *Primary*
8. Physical therapy for an accident victim *Tertiary*
9. Colonoscopy to screen for bowel cancer *Secondary*
10. Removal of asbestos tile from buildings *Primary*

Mark each factor listed below as a leading health indicator from Healthy People 2010 or not. Do this by writing Healthy People 2010 beside those that are and No by the side of those that are not.

1. Physical activity *Healthy People 2010*
2. Accident mortality
3. Overweight and obesity *Healthy People 2010*
4. Tobacco use *Healthy People 2010*
5. Cancer screening
6. Chronic disease morbidity
7. Substance abuse *Healthy People 2010*
8. Responsible sexual behavior *Healthy People 2010*
9. Mental health *Healthy People 2010*
10. Incidence of infectious disease
11. Injury and violence *Healthy People 2010*
12. Environmental quality *Healthy People 2010*
13. Deaths from heart disease
14. Immunization *Healthy People 2010*
15. Access to health care *Healthy People 2010*

Underline the types of health screening recommended for a school-aged child.

1. Lead
2. Vision

(continued)

3. Hearing
4. HIV
5. Mental health
6. Blood pressure
7. Scoliosis
8. Height/weight
9. Bone density
10. Tuberculosis (PPD)
11. Dental
12. Urinalysis
13. Hematocrit or hemoglobin
14. Physical abuse
15. Blood sugar

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. What are the five stages of health behavior changes as described by Prochaska et al.?
_____ Precontemplation _____
_____ Contemplation _____
_____ Preparation _____
_____ Action _____
_____ Maintenance _____
_____ Termination _____
2. In-depth assessment of client's health status is the foundation for _____ health promotion _____.
3. The purpose of _____ health screening _____ is to identify risk factors or undiagnosed disease to allow for early intervention.
4. The most basic type of health promotion program is one that disseminates information to _____ raise level of awareness and knowledge _____.
5. In a healthy diet, at least _____ half _____ of the daily intake of grains should be whole grains.
6. How many 8-oz glasses of water should an adult drink per day? ____ 5–8 ____.

7. BMI as a measure of weight cannot be used for clients who are _____ pregnant _____, _____ competitive athletes _____, or _____ frail elderly _____.
8. Most sedentary women and older adults need about _____ 1600 _____ cal/d. whereas men need about _____ 2200 _____ cal/d.
9. Rhythmic, continuous exercise using large muscle groups is _____ aerobic _____ exercise.
10. The two overarching goals of Healthy People 2010 are to _____ increase the quality and longevity of life _____ and to _____ eliminate disparities in health among different populations _____.

APPLICATION ANSWERS

1. Why can infants born without an immune system survive for the first few months of their lives with no apparent problems?
 - a. Limited antibodies are produced by bacteria in the infant's colon.
 - b. The exposure to pathogens during this time is limited.
 - c. Antibodies are passively received from the mother through the placenta and breast milk.
 - d. The fetal thymus produced a limited number of antibodies during the eighth and ninth months of pregnancy.

Rationale

Correct answer: c.

Antibodies received by the fetus in utero through the placenta and by the breast-fed newborn via the mother's milk provide the infant with immunity against most bacterial, viral, and fungal infections for the first few weeks after birth. Thereafter, as the titer of maternal antibodies drops and the infant is not replacing them with his own antibodies, infection can and will occur

2. The nurse explains to the mother of a child who has received a tetanus toxoid injection that this vaccination confers which type of immunity?
 - a. Lifelong active natural immunity
 - b. Lifelong passive immunity
 - c. Long lasting active immunity
 - d. Temporary passive natural immunity

Rationale

Correct answer: c.

The tetanus toxoid vaccine has modified toxins that stimulate the body to produce antibodies against tetanus that last for up to 10 years, at which time a booster shot will be necessary. Only having the actual disease can provide lifelong natural immunity.

3. Why are live virus vaccines contraindicated for children receiving corticosteroid, antineoplastic, or irradiation therapy? These children
 - a. Are be susceptible to infection because of their depressed immune response
 - b. Have had the disease already or may have been immunized against it
 - c. Are be unlikely to need this protection since they probably have a shortened life span
 - d. Have an allergy to rabbit serum, which is used as is for these vaccines

Rationale

Correct answer: a.

Corticosteroids, antineoplastic drugs, and radiation all depress the immune system, either by slowing the immune response or by killing off fast dividing cells, including lymphatic tissue and bone marrow, where antibodies are produced, and the body might not be able to fend off an attack by live virus injected into the system. It is therefore contraindicated

4. The nurse is asked which immunizations a child, currently up-to-date on all primary immunizations, should receive before starting kindergarten. He is currently up-to-date on all the primary immunizations. Which boosters should the mother be told the child needs?
 - a. IPV, Hep-B, and Td
 - b. DTaP, Hep-B, and Td
 - c. MMR, DTaP, and Hib
 - d. DTaP, IPV, and MMR

Rationale

Correct answer: d.

Only DTaP, IPV, and MMR require booster shots for preschool children. HepB does not require a booster, and a Td booster is given at age 7–10, depending on when the vaccine was first given. Hib booster is given at age 12–15 months.

(continued)

5. The nurse is reviewing the immunization history of an 11-month-old baby boy. Which diseases should the nurse expect the child to already have been immunized against?
- Polio, pertussis, tetanus, and diphtheria
 - Pertussis, tetanus, polio, and measles
 - Measles, mumps, rubella, and tuberculosis
 - Rubella, polio, measles, tuberculosis, and pertussis

Rationale

Correct answer: a.

DTaP and IVP are given at 2, 4, and 6 months. MMR is not administered till age 12 months.

6. Which is an example of primary prevention?
- Testing neonates for sickle cell anemia
 - Admitting clients to an intensive care unit
 - Screening clients for osteoporosis
 - Speaking to community groups about radon exposure in the home

Rationale

Correct answer: d.

Primary prevention is speaking to community groups about radon exposure in the home. Testing for sickle cell anemia is an example of secondary prevention, using intensive care unit is an example of tertiary prevention, screening for osteoporosis is an example of secondary prevention.

7. Which is an example of secondary prevention?
- Physical therapy for a stroke client
 - Immunization of children against measles
 - Teaching about birth control
 - Screening for hypertension

Rationale

Correct answer: d.

Screening for hypertension is an example of secondary prevention. Physical therapy for a client with a stroke is an example of tertiary prevention. Immunization against measles is an example of primary prevention. Teaching about birth control is also primary prevention.

8. Which is an example of tertiary prevention?
- Occupational therapy for a client with spinal cord injury
 - PPD testing for tuberculosis
 - After school programs for at-risk youth
 - Vision checks

Rationale

Correct answer: a.

Occupational therapy for a client with a spinal cord injury is an example of tertiary prevention. PPD testing for tuberculosis is an example of secondary prevention. After school programs for at-risk youth is second-

ary and checking for visual problems is secondary prevention.

9. A client comes to the clinic complaining of a rash that suddenly appeared while she was sunbathing earlier in the day. Assessment shows that the rash is bright red, covers wide symmetrical areas of the body, and has no accompanying local or systemic symptoms. Which question would be most important for the nurse to ask?
- Did you use a new brand of sunscreen?
 - Did you wash with perfumed soap before sunbathing?
 - What medications do you take?
 - Have you eaten any new foods in the last 24 hours?

Rationale

Correct answer: c.

Photosensitivity rashes associated with medications have an abrupt onset and are bright red, symmetrical, and widespread. Medications that are associated with photosensitivity include certain tetracyclines, sulfas, antihypertensives, diuretics, oral hypoglycemics, psychotropic drugs, and NSAIDs.

10. The mother of an infant is questioning the nurse about the health care needed by her child. She expresses concern because of the number of people in her family with high blood pressure and asks when her baby's blood pressure will be checked. Which is the appropriate response for the nurse to give?
- age 1
 - age 3
 - age 6
 - age 12

Rationale

Correct answer: b.

The American Academy of Pediatrics recommends that blood pressure screening start at age 3 and be a part of every physical checkup thereafter.

11. Which health model does a person subscribe to when his or her motivation to engage in healthy behaviors is the desire to avoid illness?
- Clinical
 - Adaptive
 - Role performance
 - Eudaemonistic

Rationale

Correct answer: a.

With the Clinical Model of health, motivation to engage in healthy behaviors is motivated by a desire to not have a diagnosed disease. In the Adaptive Model, motivation is

based on a desire to alter self. In the Role Performance Model, motivation for healthy behavior derives from a desire to be able to fulfill responsibilities at work, in the home, and in the community. In the Eudaemonistic model, motivation for health comes from joy and self-fulfillment.

12. For which age groups would the nurse most appropriately plan to include a discussion of suicide as part of a health promotion program?
- Children and teenagers
 - Teenagers and young adults
 - Young and middle adults
 - Middle and older adults

Rationale

Correct answer: b.

Suicide is a major risk among teenagers and young adults and needs to be addressed in health promotion programs. Primary areas of concern for children are fire safety, firearm safety and home safety; for middle adults, accidents are a major concern; and among older adults, the risk of falling is major.

13. Which client could the nurse administer an MMR vaccine to?
- A child with HIV
 - A woman who is trying to get pregnant.
 - A child whose father had a kidney transplant two months ago.
 - A 7-month pregnant woman

Rationale

Correct answer: a.

The only live virus vaccine that is given to a child with HIV is the MMR. Live virus vaccines of which MMR is one are contraindicated for women who are pregnant or may become pregnant within 3 months, and for children living with an immunosuppressed person.

14. Which statement made by a client who is starting a smoking cessation program using a combination of nicotine replacement and hypnosis indicates the need for further teaching?
- “I will try to use deep breathing and imagery to control cravings.”
 - “I will suck hard candy when I get an urge for a cigarette.”
 - “I will smoke just half a cigarette if I really feel out of control.”
 - “I will stay away from places where people smoke during the next week.”

Rationale

Correct answer: c.

Smoking while using nicotine replacement therapy is dangerous because of the possibility of nicotine over-

dose. It is most dangerous for those with cardiovascular problems and can lead to severe hypotension and prostration.

14. Which direction regarding self-testicular examination is appropriate for a nurse to give a 20-year-old male client?
- Do not examine your testicles for at least 12 hours after intercourse.
 - Examine both testicles simultaneously so one can be compared to the other.
 - Keep in mind there may normally be what feels like a small bump on the upper or middle outer side of the testis.
 - If one testicle appears larger than the other, see your physician immediately.

Rationale

Correct answer: c.

The epididymis can feel like a small bump on the middle or upper, outer side of each testis. Intercourse is unrelated to testicular examination; testicles are best examined after a warm bath or shower when the scrotum is relaxed. Each testicle is examined separately using both hands. One testicle is normally larger than the other.

16. Which statement made by a client about self-breast examination indicates the need for health teaching?
- “I palpate my breast carefully each month while standing in front of a mirror so I can see any changes in the contour or appearance of the skin.”
 - “I use the finger pads of the three middle fingers of each hand to palpate my breasts.”
 - “I use an up-and-down pattern of palpation on my breast and go all the way up until I reach my collar bone.”
 - “I press lightly, then with medium pressure, and then with firm pressure on each area of my breast as I examine it.”

Rationale

Correct answer: a.

The breast should be palpated while the client is lying down so that the breast tissue is spread over the chest wall making it as thin as possible and therefore making any abnormalities easier to feel. After palpating the breast lying down, the client stands in front of a mirror with the hands pressing down on the hips and observes for any changes in contour, size, dimpling, skin changes, or nipple changes.

17. A client who has been told that her total cholesterol is too high and that a cholesterol-lowering drug is being prescribed for her says that different people normally have different cholesterol levels and that everyone doesn't need pills and she is not going to take the

(continued)

ordered medication. According to the Stage Model of health behavior change, which stage is she in?

- Precontemplation
- Contemplation
- Preparation
- Termination

Rationale

Correct answer: a.

Precontemplation is the stage when persons deny they have a problem and therefore do not need to change. Contemplation is the stage in which the client admits to a problem and talks about it but is not ready to do anything about it yet. Preparation is the stage in which clients make real plans to change and may even have begun to make small changes. Termination is the stage at which the behavior is incorporated into the lifestyle and returning to prior unhealthy behaviors is no longer a temptation or threat.

18. How does the nurse begin to develop a Health Promotion Plan with a client?
- Involve a significant other
 - Identify priority health goals
 - Reinforce benefits of a change in health behaviors
 - Obtain a commitment to a healthy lifestyle

Rationale

Correct answer: b.

Joint development of a Health Promotion Plan begins with identifying priority health goals. Involving a significant other can facilitate adherence to the plan but it is not the first step. Reinforcing the benefits of change is also important but it comes after needed changes are identified. The final step is obtaining commitment to the behavior-change goals – not to the broad concept of a healthy lifestyle.

19. Which are strategies that the nurse may employ to aid a client in implementing a Health Promotion Plan? Mark all that apply.
- Group counseling
 - Telephone counseling
 - Modeling
 - Ensuring social support
 - Teaching

Rationale

Correct answers: a, b, c, d, and e.

All of these are strategies, which can facilitate adherence to a Health Promotion Plan.

20. Which statement best indicates that a client who needs to begin an exercise program to improve cardiorespiratory fitness is in the preparation stage of the Stage Model of health behavior change?

- “I never really liked exercise but maybe I could get to like it.”
- “I think maybe I really do need to exercise; I get awfully short of breath going upstairs.”
- “I asked my friend if she would be interested in going to an exercise class with me.”
- “I asked my sister and she agrees exercise isn’t always a good thing.”

Rationale

Correct answer: c.

In the preparation stage, the client makes a real plan to change. Asking a friend if she would go with her is part of such a plan. Answers a and b are representative of the contemplation stage in which the client acknowledges a problem but is not yet willing to commit to change. Answer d is more representative of the precontemplation stage in which the client denies having a problem.

21. A mother states she will not allow her child to receive immunizations which contain live or attenuated organisms. Which immunizations could the child not receive?
- x MMR
 - HBV
 - x Varicella
 - DTaP
 - TIV influenza
 - IPV

Rationale

Correct answers: a and c.

Measles, mumps and rubella, and varicella contained live viruses which have been treated with heat or chemicals to decrease their virulence; they have not been killed. Hepatitis B virus vaccine, diphtheria, pertussis and tetanus, TIV influenza, and IPV contain inactivated or killed pathogens.

22. A client asks about receiving the hepatitis A vaccine because of upcoming travel to an underdeveloped country where the disease is endemic. The client particularly wants to know how many injections are needed and at what interval. Which is a correct response for the nurse to give?
- 2 injections @ 3 months apart
 - 2 injections @ 6–18 months apart
 - 3 injections @ 1 month apart
 - 3 injections @ 3 months apart

Rationale

Correct answer: b.

Hepatitis A vaccine is given in two injections at 6–18 months apart.

23. What purpose does clearing the needle by injecting an air bubble after administration of an immunization serve?

- a. Decrease risk of an anaphylactic reaction
- b. Decrease pain during injection
- c. Minimize local reaction
- d. Ensure proper dose

Rationale

Correct answer: c.

Clearing the needle with an air bubble prevents leakage of vaccine back out through the needle tract and into surrounding tissue thereby minimizing local reaction. It does not decrease risk of anaphylaxis or decrease pain. It is not used to ensure proper dose.

24. Which information should be given to a 52-year-old client who is planning to start a cardiorespiratory exercise program?

- a. Consult your physician to obtain an exercise prescription
- b. Include only anaerobic activities
- c. Stretch at the completion of each exercise session
- d. Work up gradually to a maximum of 90 minutes five times per week

Rationale

Correct answer: a.

Clients over age 45 and those with risk factors for cardiac disease should consult a physician to determine the appropriate amount of exercise before beginning a program. Aerobic exercise involving continuous use of large muscle groups is effective in building cardiorespiratory reserve. Stretching should be done at the beginning of aerobic exercise and a cool down period at the end. Clients should start gradually but the recommended duration of exercise is 30–60 minutes three to five times per week.

Health Promotion and Maintenance— Part 4

Sub-category: None

Topic: Techniques of Physical Assessment

| | | | |
|---------------------------------|-----|---|-----|
| ▸ Biological Science Foundation | 207 | ▸ Psychomotor Skills Used in Assessment | 210 |
| ▸ Mental Status | 223 | ▸ Techniques of Physical Assessment | 207 |

TECHNIQUES OF PHYSICAL ASSESSMENT

BIOLOGICAL SCIENCE FOUNDATION

- The basic sciences inform the techniques of physical assessment.
- Physical assessment techniques reveal information about underlying structures.

Etiology: Physical assessment is guided by symptoms reported by the client as well as the nurse's understanding of human anatomy, physiology, and pathophysiology. Physical assessment techniques provide important information to determine the etiology of client's complaints.

Precipitating factors: If present, may require examination of additional body systems.

The scientific principles of physical assessment techniques by system are

- skin:
 - structure
 - epidermis: keratin, melanocytes; appendages, hair, sebaceous glands, sweat glands, and nails

- dermis: collagen and elastic tissue; location of epidermal appendages, nerves, sensory receptors, blood vessels, and lymphatics
- subcutaneous tissue: adipose tissue for energy, insulation, and cushioning; mobility allows skin to slide over underlying structures

—function

- protection from penetration and invasion
- temperature regulation
- sensory perception
- identification
- communication
- wound repair
- absorption and excretions
- production of vitamin D

- head:

—structure

- skull: cranium and facial bones

- cranium: frontal, parietal, occipital, temporal connected by coronal, sagittal, and lambdoid sutures
- face: 14 bones connected by sutures excluding the mandibular temporal joint
- muscles: temporalis and masseter
- lymph nodes: preauricular, postauricular, and occipital
- children: anterior and posterior fontanel
- function
 - protection of brain and sensory organs and expressions
- neck:
 - structure
 - bones: cervical spine, hyoid, clavicle, and manubrium
 - muscles: sternocleidomastoid, trapezius, and the anterior and posterior triangles
 - arteries: internal, external, and common carotid
 - veins: internal and external jugular
 - lymph nodes: jugulodigastric, superficial cervical, posterior cervical, deep cervical, and supraclavicular
 - other: thyroid cartilage, cricoid cartilage, thyroid gland, and trachea
 - function
 - head mobility and passage between head (brain) and body
- eyes:
 - structure
 - visible: upper eyelid, palpebral fissure, lateral canthus, medial canthus, caruncle, pupil, iris, sclera, limbus, lower eyelid, and conjunctiva
 - muscles: medial rectus, superior oblique, superior rectus, lateral rectus, inferior rectus, and inferior oblique
 - lacrimal system: lacrimal gland, inferior and superior lacrimal puncta, lacrimal sac, and nasolacrimal duct
 - outer: sclera and cornea
 - middle: choroids, pupil, lens, and anterior chamber
 - inner: retina, macula, optic disk, and optic nerve
 - function
 - central and peripheral vision
- ears:
 - structure
 - external: helix, antihelix, tragus, antitragus, lobule, mastoid process, and external auditory canal
 - middle: tympanic membrane, malleus, incus, stapes, and eustachian tubes
 - inner: bony labyrinth, vestibule, semicircular canals, and cochlea
 - function
 - hearing and equilibrium
- nose:
 - structure
 - external: bridge, tip, nares, columella, vestibule, and ala.
 - nasal cavity: superior, middle, and inferior turbinates; septum; olfactory.
 - nerve: maxillary, frontal, and ethmoid and sphenoid sinuses.
 - function
 - sense of smell and warm and filter external air flowing into lungs.
- mouth/throat:
 - structure
 - hard and soft palates, tongue, pharynx, tonsil, frenulum, and teeth
 - glands: salivary, parotid, submandibular, sublingual, and submental.
 - function
 - chew and begin digestion of food, enhance smell, swallowing, speech, and respiratory pathway.
- breasts:
 - structure
 - located over pectoralis major and serratus anterior muscles, Tail of Spence extends into axilla.
 - central nipple consisting of erectile tissue and pigmented
 - nipples surrounded by darker areola with hair follicles and Montgomery tubercles; 12–25 glandular lobes contain alveoli that produce milk and transport it to the nipple. Men lack the milk-producing alveoli.
 - Cooper's ligaments provide support for each breast.
 - lymph nodes: pectoral, brachial, subscapular, midaxillary, internal mammary (women only), and superficial lymphatic.
 - function
 - milk production and self-image
- respiratory:
 - structure
 - upper airway: nasopharynx, oropharynx, laryngopharynx, and larynx
 - lower airway: trachea, bronchial tubes, bronchi, bronchioles, alveolar ducts, and alveoli.
 - right lung has upper, middle, and lower lobes; left lung with upper and lower only; both wrapped in visceral pleura.
 - parietal pleura lines thorax and sends pain signals with inflammation
 - pleural fluid between parietal and visceral pleurae allows for expansion and contraction.
 - bones: ribs, manubrium, sternum, and xiphoid process.

- muscles: diaphragm, external intercostal muscles, trapezius, sternocleidomastoid, and scalenes.
- blood vessels: pulmonary artery from right ventricle brings deoxygenated blood to alveolar capillaries where oxygen and carbon dioxide exchange occurs; oxygenated blood returns via pulmonary veins to left atrium.
- function
 - acid—base balance, oxygenation
- cardiac:
 - structure
 - four chambers: right and left atria and right and left ventricle
 - heart wall: myocardium, endocardium, epicardium; surrounded by pericardium with parietal and visceral layers, pericardial space and fluid
 - blood vessels: inferior and superior vena cava and coronary sinus to right atrium; pulmonary artery to lungs; pulmonary vein from lungs to heart; aorta from heart to body
 - valves: mitral, tricuspid (atrioventricular), aortic, pulmonary (semilunar)
 - nerve conduction: sinoatrial node, atrioventricular node, bundle of His, Purkinje fibers
 - function
 - circulates blood cells, removes wastes, and provides oxygen and nutrients
- peripheral vascular:
 - structure
 - major blood vessels: arteries, arterioles, capillaries, venules, and veins
 - pulses: temporal, carotid, brachial, radial, ulnar, femoral, popliteal, posterior tibial, and dorsalis pedis
 - function
 - circulates blood cells to periphery and temperature regulation
- gastrointestinal:
 - structure
 - hollow tube from mouth to anus; smooth muscle; pharynx, esophagus, stomach, small intestine, and large intestine
 - organs aid in digestion: liver, pancreas, and gallbladder
 - blood supply: through abdominal aorta to common iliac arteries; back to heart through gastric and splenic veins to portal vein to hepatic vein to inferior vena cava
 - functions
 - digests and absorbs nutrients, water, and electrolytes and eliminates wastes
- genitourinary:
 - structure
 - urinary tract: kidneys, nephrons, ureters, bladder, urethra, and antidiuretic hormone (ADH)
 - functions: forms urine, maintains homeostasis, removes wastes, regulates acid—base, fluid, and electrolyte balance
 - female genitalia
 - external: vulva, mons pubis, labia majora, labia minora, clitoris, vestibule, vaginal introitus, urethral orifice, Skene's and Bartholin's glands, and perineum
 - internal: vagina, uterus, ovaries, and fallopian tubes
 - male genitalia: urethra, penis, scrotum, testicles, epididymis, vas deferens, seminal vesicles, prostate gland, and inguinal canal and ring
 - functions
 - intercourse, reproduction, and secondary sex characteristics
- musculoskeletal:
 - structure
 - muscles, tendons, ligaments, bones, cartilage, joints, bursae visceral, and skeletal and cardiac muscle types
 - long, short, flat, irregular, and sesamoid bone types
 - axial versus appendicular skeleton
 - immovable and synovial joints
 - functions
 - shape, movement, protection of organs, support, RBC production, mineral salt storage, and cushioning
- neurological:
 - structure
 - central nervous system: brain and spinal cord
 - brain: cerebrum, brain stem, cerebellum, meninges, and cerebrospinal fluid
 - dermatomes
 - peripheral nervous system: peripheral and cranial nerves
 - autonomic nervous system: sympathetic and parasympathetic
 - functions
 - controls and regulates systems, interprets motor and sensory stimuli, maintains equilibrium, and provides enervation to visceral organs

Assessment Alert

Although each body system is discussed separately, all body systems interact for proper functioning of the human body. Therefore, if there is a disorder in one system, more systems will eventually be affected. The acuity and chronic nature of the illness will determine how quickly the disorder is manifested in multiple systems.

Examples of assessment tools:

- Equipment such as stethoscope, otoscope, ophthalmoscope, sphygmomanometer, reflex hammer, and tuning fork
- Examiner's senses: smell, touch, vision, and hearing
- Special testing such as rebound tenderness or Apley's compression test

Examples of assessment questions:

Ask the client

- For more information about the complaint: onset, location, duration, severity, quality, associated symptoms, precipitating symptoms, and interventions that decrease the symptoms and situations in which the symptoms worsen.
- To localize the symptom by pointing to the location on his/her body.
- About all body systems. Often, a client does not understand the link between a symptom and a condition. In a complete review of systems, more information about associated symptoms or illnesses may be collected.
- About his/her perception of the problem. This may reveal an opportunity to reinforce a correct association between a symptom and an action or disease process or correct an erroneous association between a symptom and an action or disease process.
- To clarify information that is confusing or contradictory. For example, a client may have a cough and explain that this is due to foot pain. A further explanation is needed to determine the link, if it exists, between cough and foot pain.
- To correct any misperceptions in a summary of the complaint given by the nurse.

Rx: The etiology of a client complaint provides the basis for treatment. An accurate and thorough physical examination by the nurse helps to discern which treatments are most beneficial for each individual client.

Nursing care:

- The basic sciences inform the actions and interventions available for clients.
- Specific interventions for a specific client are guided by both the client's complaints and the objective physical findings.
- Assess all client complaints in intervals appropriate to the acuity of the problem.

**Assessment Alert**

Beware of complaints that may be referred from one organ/tissue to a different location on the body. For example, knee pain may be due to a disorder in the hip and not the knee itself.

**Client teaching for self-care**

- Teaching about the underlying illness processes helps clients and families understand disease manifestations, progression, and treatment.
- Teaching should be geared toward the needs of the client and family. They should be encouraged to ask questions and repeat their understanding of the education provided by the nurse.
- Assessment of the client/family's education level, age, language, and readiness for learning are essential for effective client/family teaching about illness.
- Specific questions about prognosis, further treatment and expectations should be referred to the health care team responsible for the client's treatment goals. A discussion involving the broader health care team decreases the risk of miscommunication and seemingly contradictory information.

**Clinical Alert**

Avoid assessing the client according to what seems to be the most plausible explanation of his/her complaints. A focused, yet thorough examination will prevent loss of relevant assessment data and lead to effective and efficient interventions.

PSYCHOMOTOR SKILLS USED IN ASSESSMENT

The basic techniques of physical assessment are interviewing, inspection, palpation, percussion, and auscultation.

- Interviewing techniques
 - Use verbal and nonverbal clues to guide discussion
 - Ask open-ended questions to hear the client's story in detail
 - Use nonjudgmental comments
 - Repeat statements to ensure understanding and encourage clients to continue
 - Summarize information and have the client verify the summary
 - Clarify contradictory and vague points
 - Obtain assistance from other appropriate health care providers/resources when needed
- Observation
 - Use vision to compare contours for symmetry, movement, pulsations, and deformities

- Magnifying devices, such as an otoscope, allow for visualization of areas which otherwise would not be visible
- Includes observing behavior and whether it is consistent with the situation
- Begins from the first meeting with the client and continues until the nurse or client leaves the examination site.
- Palpation
 - Second skill used in assessment excluding examination of the abdomen.
 - Finger pads are sensitive to contour, texture, consistency, movement, and pulsations.
 - Point of maximal impulse is located using the palm of the hand.
 - Dorsal surface of the hand is sensitive to temperature.
 - Gentle touch is used to elicit tenderness and/or identify superficial lesions or structures.
 - Deep touch is used to identify lesions or tenderness deep within tissue.
 - Touch is also used to evaluate organs such as the liver, kidneys, and spleen.
- Percussion
 - Tapping on the finger of a hand placed over a person's skin.
 - Percussion “note” is used to determine if the area under the tapped finger is solid or air-filled.
 - Requires considerable practice to elicit an audible, clear percussion note, and to hear the difference in percussion notes.
 - Flat: over the thigh
 - Dull: over the liver
 - Resonant: over healthy lungs
 - Hyperresonance: over hyperinflated lungs
 - Tympanic: over the gastric air bubble or puffed-out cheek
- Auscultation
 - Use of a stethoscope to hear sounds within a structure
 - The last step in physical assessment, excluding the abdomen where it is the second step
 - Listen for
 - abnormal heart sounds such as murmurs;
 - abnormal vascular sounds such as a bruit;
 - bronchial, bronchovesicular, and vesicular breath sounds;
 - bowel sounds.
- Physical assessment begins with inspection, then palpation, percussion, and auscultation excluding examination of the abdomen.

Assessment Alert

For the abdomen, inspection is followed by auscultation and percussion, then palpation. This sequence is necessary to prevent alteration of peristalsis and/or bowel sounds. To prevent muscle tensing that can interfere with palpation, ask client to take slow, deep breaths through the mouth. Have client void before percussing lower abdomen

Client teaching for self-care

- Explain the procedures or techniques used in physical assessment to the client.
- During the physical examination, step-by-step instructions prepare the client and result in increased cooperation.
- Determine which body systems may be tender for the client before starting the physical examination.
- Ensure privacy and comfort for the client.

Clinical Alert

Always evaluate a tender area last. The exam may be altered or halted if the tender area is examined first.

Requirements for a Good Physical Examination

- Systematic approach
- Privacy but with good exposure of body parts
- Good lighting
- Proper equipment
- Comfortable room temperature
- Appropriate positioning of the client
- Bilateral comparison of body parts to identify variations
- Use of standard precautions

Choosing Appropriate Equipment and Technique

- The assessment techniques of interviewing, observation, palpation, percussion, and auscultation may need to be modified for the age and/or capabilities of the client.
- Equipment may also need to be modified such as the use of a larger BP cuff for larger clients or a smaller pediatric stethoscope for a child.

- The general, underlying physical assessment principles remain the same:
 - observe the client from the moment he/she is visible;
 - learn about the client's concerns and history through interviewing techniques;
 - use palpation, percussion, and auscultation to gather further information about the physical condition of the client.

Variations in Physical Assessment Equipment and Techniques

- Infants
 - Use smaller equipment such as a pediatric stethoscope.
 - Infants generally will lie on an examining table during the exam.
 - Restrain PRN firmly by immobilizing joint above and joint below area to be examined. To restrain head, extend arms above head and press toward midline.
 - The otoscopic exam is the most traumatic and left until the end of the exam.
 - Ears are pulled back and down to visualize the tympanic membrane.
 - Use noises to distract the infant or to draw attention to a certain area. For example, if neck mobility is being examined, snapping fingers to one side of the head and then the other side will encourage the infant to turn the head side to side.
 - Red reflex of the eyes is important to elicit, but further ophthalmologic examination may not be possible.
 - Speak to the parents/guardians, but also speak directly to the infant. The infant may not be able to understand the words yet, but direct attention to the infant sets the stage for building rapport in the future.
 - Ask the parent/guardian about pregnancy, labor, and delivery, feeding amounts and times, sleep, urinary and fecal excretion.
 - The parent/guardian may help to stabilize a body part for injections.
 - Ask the parent/guardian if they have any further questions or concerns.
- Toddlers
 - Continue to use smaller equipment as for the infant.
 - Ask the toddler and parent/guardian whether the toddler would like to sit on the parent's/guardian's lap or on the examining table. Depending on the exact age, the toddler may feel safer in a parent's/guardian's lap; if not in lap, keep caretaker in view.
 - Ask the toddler and parent/guardian about day care, interests, food preferences, sleep, toileting, and safety practices.
 - Perform parts of exam likely to cause crying last; otoscopic exam remains traumatic and is completed at the end.
 - Ears are pulled back and down to visualize the tympanic membrane.
 - Use noises, phrases, toys to distract or attract attention to a certain area.
 - Red reflex of the eyes is important to elicit.
 - Speak to the toddler and parent/guardian directly. Continue to build rapport with the toddler.
 - Ask the toddler as well as the parent/guardian about any concerns or questions.
 - Give clear, firm directions in age-appropriate language.
- Preschool children
 - Continue to use smaller equipment
 - Sits on the examining table
 - May want to examine/explore equipment
 - Ask about school or day care, food preferences, toileting, safety, sleep, friends, interests, and hobbies
 - Repeat questions to the parent/guardian
 - May examine the child systematically from head to toe
 - Pull ear back and up to visualize the tympanic membrane
 - Red reflex of the eyes is important, but further examination may be possible
 - Ask the child as well as the parent/guardian about concerns or questions
- School-aged children
 - Continue to use smaller equipment according to the size of the child
 - Sits on the examining table
 - Ask about school, friends, activities, food preferences, toileting, sleep, and safety
 - Repeat questions to the parent/guardian
 - Systematically examine the child from head to toe
 - Pull ear back and up to visualize the tympanic membrane
 - Perform full eye exam
 - Ask the child as well as the parent/guardian about concerns or questions
- Adolescents
 - Use adult-sized equipment unless the adolescent is small/petite for their age
 - Sits on examining table
 - Ask about school, friends, activities, nutrition, sleep, safety, sexual development, and goals
 - Ask about the use of drugs and alcohol, risky behaviors
 - Repeat questions to parent/guardian
 - Question the adolescent alone at some point. Politely ask the parent/guardian to go to the waiting room
 - Full examination, although genital exam is traumatic and left to the end
 - Ask the adolescent as well as the parent/guardian about concerns or questions

- Older adult
 - Adjust voice, if needed, and speak clearly so that the client hears and understands
 - May not be able to get onto the examining table. If not, examination may be completed seated and standing.
 - Adjust exam to possible body positions; help with positioning and change position slowly; may need rest periods.
 - Elderly clients chill easily so draping is important.
 - Ask client about support system, activities, nutritional intake, water intake, bowel pattern, voiding pattern, sensory deficits, safety, and future plans
 - Ask client about concerns or questions
 - Head to toe systematic examination
 - Include supportive friends and family in interventions/care plans with client's permission
- Disabled clients
 - Adjustments to equipment and techniques according to specific disability
 - Often gentle approach and quiet manner will relax client
 - Physical development will continue although outward appearance may resemble younger/older client
 - Discuss condition and care plans with client and/or supportive caregivers

Assessment Alert

Adolescents may not admit to risky behaviors in front of parents/guardians. Interviewing adolescents alone is important. The information divulged between client and examiner is confidential unless deemed to be immediately harmful to the client or other person.

Examples of assessment questions:

Ask the client

- If he/she is comfortable?
- What other accommodations he/she might need?
- To listen to directions and explanations.
- Whether he/she can sit on the examining table?
- If he/she have any concerns or questions?

Nursing care:

- Nursing care differs according to age and/or disability.
- Nursing care is based on client's needs according to age and/or disability.
- Nursing care may require significant adaptation to meet the needs of a disabled client.

Assessment Alert

Be alert to S&S of physical and emotional abuse. It can occur at any age.

Client teaching for self-care

- The client's needs will be met through creative interventions.
- The client, his/her support system, and the nurse are all involved in meeting the client's health care needs.
- The client is entitled to a private interview with the nurse at any age.
- Information that threatens the safety of the client or those around him/her will be reported to the appropriate agencies.

Clinical Alert

The nurse is ethically and legally compelled to act upon S&S that indicate a client's safety has been compromised. Reporting such S&S to appropriate community agencies is in the best interests of the client.

Includes subjective information (what the client said) and objective information (what the examiner observed).

- The health history is subjective information. It includes
 - the chief complaint;
 - history of the present illness;
 - past history;
 - family history;
 - personal and social history; and
 - review of systems.
- The physical exam is objective information. It includes a general observation, vital signs, and the following systems:
 - skin;
 - head, eyes, ears, nose, and throat;
 - neck;
 - thorax and lungs;
 - breasts and lymph nodes;
 - cardiovascular;
 - abdomen;
 - peripheral vascular;
 - musculoskeletal; and
 - neurological

Comprehensive Health History

- Chief complaint is the reason for the visit.
- History of the present illness
 - It provides more information about the chief complaint.
 - The client explains onset, character, location, duration, severity, alleviating factors, aggravating factors, and perception of the symptom.
- Past history
 - Childhood and adult illnesses
 - Immunizations
 - Screening tests such as tuberculin test, mammogram, Pap smear, stools for occult blood, and lipid panel
 - Medications and allergies
- Family history
 - Age and health or cause of death
 - Immediate relatives: parents, grandparents, siblings, children, and grandchildren
 - Review family history of cardiac disease: hypertension, stroke, seizures, migraines, psychiatric illness, cancer, diabetes, thyroid disease, renal disease, substance abuse, and allergies
- Personal and social history
 - Education level
 - Occupation and financial situation
 - Interests and hobbies
 - Safety: both seatbelts, smoke detectors as well as feeling safe where they live, who they live with and where they work
 - Household members, significant others, and children
 - Diet and exercise: medications may be affected by diet. Iron, for example, is best absorbed with acidic substances like orange juice. Levothyroxine, a thyroid replacement hormone, is not absorbed well when taken with iron or calcium. Bananas have much potassium and a person with renal failure who is on a potassium-restricted diet should not eat potassium-rich foods like bananas.
 - Religion and spirituality
 - Sources of stress
- Review of systems: under each system, ask questions regarding
 - general: usual weight, recent weight change, fatigue, weakness, and fever
 - skin: rashes, lumps, sores, itching, dryness, color change, and changes in hair or nails
 - head: trauma, headache, dizziness, and light-headedness
 - eyes: vision changes, redness, spots, double vision, blurred vision, tearing, last eye exam, glaucoma, and pain
 - ears: decreased hearing, trauma, discharge, pain, tinnitus, and vertigo
 - nose: discharge, colds, stuffiness, allergies, itchiness, nose bleeds, and sinus infections
 - throat: pharyngitis, teeth, gums, dentures, bleeding, sores, dryness, hoarseness, and last dental exam
 - neck: lumps, swollen glands, goiter, stiffness, and pain
 - breasts: pain, discharge, lumps, and self-examination practices
 - respiratory: shortness of breath, wheezing, cough, sputum, hemoptysis, dyspnea, last chest X-ray, asthma, bronchitis, emphysema, pneumonia, tuberculosis, smoking, exposure to environmental chemicals, medications used to treat nasal congestion, cough, dyspnea, or other respiratory symptoms
 - cardiovascular: palpitations, murmurs, chest pain or pressure, dyspnea, orthopnea, high BP, heart trouble, rheumatic fever, edema, and last EKG
 - gastrointestinal: burping, cramping, diarrhea, constipation, last bowel movement, color and size of stools, hemorrhoids, pain, food intolerance, flatus, jaundice, gall-bladder problems, and hepatitis
 - urinary: frequency of urination, dysuria, polyuria, nocturia, urgency, burning on urination, hematuria, infections, kidney stones, incontinence; for males, reduced force of stream, hesitancy, or dribbling
 - genital:
 - male: hernias, discharge from penis, sores, testicular pain or pressure, sexually transmitted diseases, sexual habits, birth control methods, and exposure to HIV
 - female: age at menarche, last menstrual period, last gyn exam, pelvic pain or pressure, change in menstrual periods, spotting, premenstrual symptoms, discharge, itching sores, lumps, sexually transmitted diseases, exposure to HIV, birth control method, number of pregnancies, number and type of deliveries and abortions, complications during pregnancy, sexual habits, and exposure to diethylstilbestrol (DES) if born before 1971
 - peripheral vascular: leg pain or cramps, varicose veins, and clots
 - musculoskeletal: bone or joint pain, stiffness, arthritis, gout, backache, swelling, weakness, limited mobility, and trauma
 - neurologic: fainting, blackouts, seizures, weakness, paralysis, numbness, tingling, and tremors

Assessment Alert

For all symptoms reported by the client, obtain information about time and type of onset; course; severity, precipitating and relieving factors; and associated S&S.

- hematologic: anemia, bruising, bleeding, and transfusions
- endocrine: thyroid problems, diabetes, heat or cold intolerance, sweating, thirst, hunger, and polyuria
- psychiatric: anxiety, nervousness, depression, tension, memory change, and tendency to suicide

Assessment Alert

For clients who cannot report their history, interviewing family and significant others may provide pertinent information about the client's health history.

Complete Physical Examination

- General survey: observe general state of health, height, build, sexual development, weight, posture, motor activity, gait, dress, hygiene, grooming, odors, facial expressions, manner, affect, reactions, speech, awareness, and level of consciousness

Assessment Alert

Hearing and/or vision loss can cause an inaccurate assessment of orientation; make sure client is using assistive devices. Response time to questions slows with age. Confusion is not a normal age change—if present, determine if rapid or gradual onset.

- Vital signs: measure temperature, pulse, respirations, BP, height, and weight
 - Oral temperature contraindicated if client is confused, disoriented, comatose, and unable to keep the mouth closed; has chills, history of seizures, recent oral surgery, oxygen by face mask or has smoked, chewed gum, or ingested hot or cold substances within the last 15 minutes.
 - Rectal temperature contraindicated if client cannot follow directions; stay still or has recent rectal surgery, hemorrhoids, or an inability to assume an appropriate position.
 - Apical pulse (midclavicular line at fifth intercostal space) taken in children less than 2 years and clients with an arrhythmia or on cardiac medication. Baseline pulse is obtained at least 10 minutes after activity.

- Pulse is affected by factors that stimulate either the sympathetic nervous system (caffeine, stress, fever, pain, emotion) or the parasympathetic (vomiting, suctioning).
- Baseline BP is taken at least 30 minutes after smoking, exercising, or ingesting caffeine. Other BPs allow 5-minutes rest; have arm at level of heart; no constriction of upper arm and do not take on side with mastectomy, IV, or hemodialysis access site.
- Abnormal findings:
 - >10 mm difference in BP between right and left arm
 - >25 mm difference in systolic or >10 mm diastolic BP between sitting, lying, and standing positions
- Fever occurs less often in geriatric clients but hypothermia occurs more often.

See Chapter 17 for normal BP, pulse, and respiratory rates for various age groups.

Assessment Alert

An unintentional weight loss of 5% or greater in a month, 7.5% or greater in 3 months, or 10% or more in 6 months in older person is a cause of serious concern.

- Skin
 - Assess color, lesions, edema, moisture, temperature, texture, and turgor
 - Color: assess general color as well as local or patchy variations (see Table 9–1.). In dark-skinned individuals, observe in areas of least pigmentation such as under the tongue, buccal membranes, or sclera.
 - Lesions: observe and describe the size (measure in metric), shape, distribution, pattern, color, margins of lesions (regular, irregular, clearly demarcated), raised or flat
 - Edema: palpate with finger pads; note location; determine if pitting or non—pitting; if pitting note 1+ (2-mm depression), 2+ (4 mm), 3+ (6 mm), and 4+ (8 mm)
 - Moisture: check for moistness or dryness using pads of fingers
 - Temperature: use back of hand to determine hot, warm, cool or cold
 - Texture: use pads of fingers to determine if smooth or rough
 - Turgor: pinch and lift a skin fold over the sternum or clavicle and note time until skin returns to original position. Normal is 5 seconds; tenting of more than 5 seconds in these areas is indicative of dehydration

Table 9–1 Assessment of Skin Color

| Color Variation | Where to Observe | Clinical Notes | Interpretation |
|---------------------------------|--|---|---|
| Pallor | Nail beds, lips, oral mucous membranes, palpebral Conjunctiva | Appears as dull ash or gray in black skin and dull yellow-brown in brown skin | Marked pallor occurs with syncope, shock, and anemia |
| Central cyanosis | Lips, buccal mucosa, tongue | Noticeable only when severe in dark skin | Anxiety, cold exposure, heart, lung, or blood disorder |
| Peripheral cyanosis Jaundice | Nail beds, skin of arms or legs Sclera, lips, hard palate, skin | Noticeable only when severe in dark skin Outer sclera of dark-skinned individuals may normally have a yellow tinge; jaundice involves whole sclera up to iris. | Liver disease, hemolysis of RBCs (yellow tinge to skin only, especially exposed areas occurs with uremia) |
| Erythema | All areas of skin and mucous membrane | Redness cannot be seen in dark skin; therefore, must palpate for heat as a sign of inflammation | Local inflammation, fever, blushing, alcohol intake, cold exposure |
| Bronze (brown) | Skin, palmar creases, nipples, genitalia | | Addison's disease, pregnancy (face, nipples and genitalia only) |

Think Smart/Test Smart

Remember the parameters of skin assessment by thinking of CLEM and the 3 Ts (color, lesions, edema, moisture, temperature, texture, and turgor).

• Head

- Observe for symmetry and evidence of trauma
- Hair distribution: male or female
- Amount: sparse, balding, or thick
- Texture: fine, coarse, brittle, or soft
- Palpate for tenderness and lesions
- Palpate the temporomandibular joint: in front of the ear where the temporal and mandibular bones articulate. Ask the client to open his/her mouth, move the jaw front, back and side to side. Palpate for crepitus, observe for pain or locking.
- Palpate the masseter and temporal muscles: palpate superiorly from the temporomandibular joint as you ask the client to clench his/her teeth. Palpate for tone, tenderness, and any lesions.

• Eyes

- Observe position, alignment, symmetry, extraocular movements, and visual fields
- Observe eye for tearing, discharge, presence of lesions, and condition of brows and lashes
- Palpate upper and lower lids and lacrimal glands and ducts for tenderness

—Inspect sclera and conjunctiva for color and vascular patterns and lesions

- Separate lids with thumb and index finger and ask client to look up, down, and to the sides.
- Use thumb to evert lower lid while client looks up to inspect palpebral conjunctiva

—Estimate distance vision and near visual acuity

- Have the client read a clock or similar at a distance
- Have client read a newspaper or similar at 14 inches from face

—Check clarity of cornea

- Shine light from side into each eye; note smoothness and cloudiness

—Inspect pupil

- Note size (in mm), shape, and symmetry

—Elicit red reflex

- Ask the client to look over your shoulder/in the distance; shine a light into each pupil and look for a red reflection. Abnormal results occur with cataracts when either there is no red reflex or a white reflection rather than red.

—Test pupillary response to light

- Ask client to look into distance; shine a bright light on one pupil bringing the light in from the side. Observe for constriction of the pupil into which the light is shone (direct response) and simultaneous constriction of other pupil (consensual response). Repeat on the other side.

- Test accommodation
 - Hold a finger or pen 4–6 inches from client’s nose. Ask client to look into distance and then look quickly at finger/pen. Observe for inward movement of both eyes and pupillary constriction.
 - Normal findings are recorded as PERRLA (pupils equal, round, and reactive to light and accommodation).
- Test extraocular movements
 - Directly in front of the client, ask her/him to follow your pen/finger with eyes only, not head.
 - Draw a large letter “H” and observe each eye move in eight directions: up, down, lateral, medial, upper outer, upper inner, lower outer, and lower inner.
- Ears
 - Inspect auricles and tragus for symmetry, color, and lesions
 - Palpate the auricles and tragus for tenderness
 - Inspect auditory canal; the canal should be smooth and pink without foreign bodies
 - Inspect tympanic membrane, malleus, incus, stapes, umbo; using an otoscope, pull the ear up and back. The tympanic membrane appears pearly gray with a cone of light at 5 o’clock (left ear) or 7 o’clock (right ear). The cone of light is a triangular area with the base pointing toward the nose. The umbo may be seen as a central light area; the manubrium of the malleus runs superiorly from the umbo, the incus lies to one side of the manubrium, on the opposite side of the cone of light
 - Perform the whisper test: cover one ear and whisper a two syllable word on the side not covered. The client should be able to tell you what was whispered. Repeat on the other side.
 - If hearing is diminished, perform
 - Weber: place a vibrating tuning fork (512 Hz) on top of the head. Ask the client if he/she can hear the sound and if it is louder in one ear over the other. Normal is equal in both the ears.
 - Rinne: place a vibrating tuning fork (1024 Hz) behind the ear on the mastoid bone. Ask the client to tell you when he/she can no longer hear the sound. Move the tuning fork in front of the client’s same ear and ask the client if he/she can hear the sound again. Since air conduction is longer than bone conduction, the client should hear the sound again when the tuning fork is placed in front of the ear.
 - Abnormal results: conductive loss is indicated by lateralization of sound to the affected ear with the Weber and inability to hear the sound in the affected ear with the Rinne. Sensorineural loss is indicated by lateralization of sound to the healthy ear and inability to hear the sound in the ear on the Rinne.
- Nose
 - Inspect and palpate external nose.
 - Erythema and edema of nostril area may indicate allergy.
 - Using a light source and a broad, short speculum, observe internal nasal mucosa, septum, and turbinates.
 - Look for color of the mucous membrane, presence of drainage, and condition and position of the septum.
 - Erythema is seen with infection; paleness of the turbinates with allergy.
 - Watery drainage occurs with allergy; purulent with nasal or sinus infection
 - Perforations of the septum occur with chronic cocaine snorting
 - Deviated septum may be from trauma
 - Palpate frontal and maxillary sinuses for tenderness; this may indicate sinusitis.
 - Test bilateral nasal patency: ask the client to block one nostril and breathe in through the other nostril; repeat on the other side.
 - Test sense of smell: ask the client to identify common scents such as cinnamon, vanilla, or coffee by blocking one nostril and breathing in with the other; repeat on the other side using a different scent.
- Mouth
 - Inspect lips, oral mucosa, gums, and teeth
 - Use a tongue blade and a good light to inspect all areas including under the tongue and under dental plates
 - wearing gloves, grasp the tip of the tongue in a gauze pad and pull it left and right to inspect the sides
 - note the condition of teeth
 - palpate lips, oral mucosa, gums, teeth, and tongue for tenderness
 - test tongue protrusion: ask the client to stick out his/her tongue, move side to side
 - Observe for lateral deviation and fasciculations
- Throat
 - Inspect hard and soft palates and pharynx.
 - Inspect tonsils: grade 1 for tonsils less than one-quarter of the way between the anterior pillars and uvula, grade 2 for tonsils one-quarter to one-half the distance between the anterior pillars and uvula, grade 3 for tonsils one-half to three-quarters of the distance between the anterior pillars and uvula, grade 4 for touching tonsils.
 - Test elevation of uvula: ask the client to open his/her mouth and say “ah.” Observe elevation of the uvula. Deviation to either side is abnormal.
 - Test gag reflex: use a tongue blade to gently touch the posterior one-third of the tongue to elicit the gag reflex.

- Neck

- Inspect for midline alignment of neck and trachea. Pleural effusion and pneumothorax causes trachea to shift to the unaffected side. Atelectasis causes shift to the affected side.

- Inspect for symmetry.

- Inspect for pulsations, especially on either side of the neck.

- Inspect for visible lymph nodes.

- Inspect for thyroid gland enlargement: thickening of the neck at the base.

- Palpate for tenderness and lymph nodes: preauricular, postauricular, occipital, tonsillar, submandibular, submental, posterior cervical, anterior cervical, deep cervical and supraclavicular. Have the client shrug his/her shoulders while palpating for supraclavicular nodes.

- Palpate for tracheal alignment.

- Palpate thyroid gland: deviate the trachea to one side and while the client swallows, palpate for the lobe of the thyroid gland on the side to which the trachea was moved. Repeat on the other side.

- Palpate carotid arteries for amplitude and rate of pulsations.

- Auscultate carotid arteries for bruits.

- Breasts

- Inspect female breasts with arms relaxed, elevated, and pressing against the hips.

- Palpate the breasts for lumps in a systematic pattern usually circular or linear. All lumps require further assessment.

- Palpate the anterior, deep, and posterior axillary nodes and epitrochlear nodes along the humerus.

Assessment Alert

Do not omit palpation of the Tail of Spence that extends from the breast into the axilla. The majority of cancerous breast lesions are found in this area

- Thorax and lungs: anterior and posterior

- Sit the client up to examine the chest.

- Be alert for difficulty breathing, shortness of breath, e.g., stopping to breathe in middle of sentences when speaking, hoarseness, and cough.

- Observe for abnormalities in rate or rhythm of breathing (e.g., tachypnea, bradypnea, shallow).

- Ask about use of inhalants, oxygen, and aerosols.

- Inspect the size and shape of the chest.

- Anteroposterior diameter should be less than the transverse diameter (Normal ratio ranges from 1:2 to 5:7.).

- Barrel chest: AP diameter equals the transverse; occurs with emphysema.

- Pigeon chest: common deformity in which AP diameter is greater than the transverse.

- Inspect and palpate muscles and ribs .

- Intercostal retraction may occur with asthma.

- Intercostal bulging can occur with pneumothorax.

- Palpate the chest for tactile fremitus.

- Ask the client to say 99 as you palpate three different levels of the chest for vibration due to the sound waves passing through open bronchi to the chest wall.

- Tactile fremitus is decreased in atelectasis, emphysema, asthma, pleural effusion, and absent with pneumothorax; increased or normal with bronchitis, increased with bronchiectasis and over tumor mass.

- Palpate for equal respiratory excursion.

- Place thumbs over the spinal processes of the 10th rib and lay hands, palm down and fingers spread, on the posterolateral chest; press palms inward so there is a thin layer of skin between the thumbs; ask client to take a deep breath; observe your thumbs for amount and symmetry of movement as the client inhales.

- Asymmetrical expansion with movement on the affected side decreased with pneumonectomy, pneumothorax, pneumonia, pleural effusion, and atelectasis.

- Bilateral symmetrically decreased expansion is seen in emphysema.

- Percuss the chest to determine the nature of the underlying tissue.

- Dullness indicates solid or fluid-filled tissue; resonance over air-filled tissue; and tympany over tissue that is hyperinflated with air.

- Atelectasis, lobar pneumonia, and pleural effusion cause a dull percussion note; dull over tumor mass.

- Chronic asthma and pneumothorax cause hyperresonance.

- Determine diaphragmatic excursion.

- Ask client to exhale and hold, then percuss from a point of resonance over the lung down toward the diaphragm until dullness is heard; mark this point.

- Ask client to inhale and hold and repeat the above procedure.

- Measure distance between two marks.

- Normal is 3–6 cm.

- Bilaterally decreased in emphysema.

- Unilaterally (affected side) decreased with pleural effusion or pneumothorax.

- Absent in atelectasis.

—Auscultate breath sounds.

- Use diaphragm of stethoscope to listen to 10 areas on the back; 8 on the anterior chest.
- Move stethoscope from side to side then down to allow comparison.
- When the stethoscope is placed at each location, ask the client to take a deep breath; observe for signs of hyperventilation and pause if needed.
- Three types of normal breath sounds are bronchial, bronchovesicular, and vesicular.
 - Tracheal: heard over the trachea; loud, high-pitched; expiration longer than inspiration.
 - Bronchovesicular: heard anteriorly on either side of the sternum and posteriorly between scapula; medium pitch; inspiration equals expiration.
 - Vesicular: heard over all normal lung tissue except in area of major bronchi; soft, gentle, low-pitch sound; inspiration is longer than expiration.
- Four types of abnormal or adventitious sounds:
 - Wheezes: high-pitched and continuous musical sounds
 - Gurgles: low-pitched and continuous musical sounds
 - Crackles: short, discrete, and crackling sounds
 - Friction rub: loud, dry, and creaking sound
 - If adventitious sounds are heard, note location, timing (if on inspiration or expiration), and if cleared by coughing, deep breathing, or change in position
 - Wheezes result from markedly narrowed bronchi; do not clear with coughing, may be inspiratory or expiratory; expiratory wheeze common in asthma
 - Gurgles result from fluid or mucus in large airways; may clear with coughing; more evident on expiration
 - Crackles result from sudden reinflation of groups of alveoli as in CHF and atelectasis; may or may not change with coughing; may be inspiratory or expiratory
 - Friction rub: inflammation of the pleura with resultant rubbing of the parietal against the visceral pleura; most marked on inspiration; does not clear with coughing

• Cardiovascular

—Inspect and palpate the precordium: look for heaves, thrills, and pulsations anterior to the heart.

—Locate the point of maximal impulse (PMI): palpate the fifth right intercostal space, midclavicular line. Someone with left ventricular hypertrophy will have a PMI displaced toward the axilla.

—Auscultate heart sounds in the following areas:

- Aortic: second right intercostal space, where the closure of the aortic valve is heard well (S2)

- Pulmonic: second left intercostal space, where the closure of the pulmonic valve is heard well (S2)
- Erb's point: third left intercostal space, midclavicular line, where anatomically S1 and S2 are heard well
- Tricuspid: fourth left intercostal space, sternal border, where closure of the tricuspid valve is heard well (S1)
- Mitral: fifth left intercostal space, midclavicular line, where closure of the mitral valve is heard well (S1)

—Note any abnormal heart sounds or murmurs.

- S3: during systole, blood moving from atria to ventricles, indicates moderate to severe congestive heart failure.
- S4: during diastole, atria contract as ventricles almost filled, indicates decreased compliance of ventricles.
- Murmurs are caused by regurgitation of incompetent valves or narrow openings caused by stenotic valves.
- Common diastolic murmurs: aortic regurgitation and mitral stenosis.
- Common systolic murmurs: aortic stenosis, mitral regurgitation, mitral valve prolapse.

—Measure jugular venous pressure in relation to the sternal angle.

- With the client's head elevated to approximately 45 degrees, find the jugular venous pulsations in the neck (venous pulsations change with breathing and movement, arterial do not).
- Using a straight edge, run a line from the sternal angle (junction of the manubrium and sternum) to the base the neck.
- Measure from the sternal angle to the highest level of pulsations. Normal is 3 cm. Higher pressures indicate increased venous pressure in the body. Low or absent values may indicate dehydration.

• Abdomen

—Inspect the abdomen for symmetry and lesions.

—Inspect for pulsations: the aorta is above the umbilicus and slightly to the left. Localize pulsations between fingers to measure the size of the abdominal aorta.

—Peristaltic waves: more easily seen in slender individuals in the lower half of the abdomen.

—Auscultate bowel sounds in all four quadrants: bowel sounds are “absent” when none are heard in 5 minutes; normal bowel sounds are 5–25 tinkles per minute; hyperactive bowel sounds in one quadrant, followed by hypoactive in the next quadrant may indicate an impending obstruction; later, bowel sounds decrease before the obstruction as well.

—Auscultate the aorta for bruits.

—Percuss the abdomen: in all four quadrants. The percussion sounds vary between tympany and dullness. Tympany is heard over the gastric air bubble and dullness is heard over organs.

- Determine location and size of liver.
 - Percussion method: percuss downwards from the fourth right intercostal space midclavicular line until dullness is heard; this is the superior border of the liver. Percuss up from below the right costal margin midclavicular line until dullness is heard; this is the inferior border of the liver. Measure the distance between the borders. The normal size of the liver is 6–12 cm in the right midclavicular line.
 - Scratch test: place the diaphragm of the stethoscope over where the client's liver should be. Begin scratching downwards from the fourth right intercostal space midclavicular line. The superior border of the liver has been reached when the auscultated sound becomes much louder. Scratch up from below the right costal margin midclavicular line; the inferior border of the liver has been reached when the auscultated sound becomes much louder. Measure the distance between the borders.
- Determine the location of the spleen: the spleen should be well hidden under the left costal margin. Percuss in the anterior axillary line, 10th intercostal space. Dullness indicates the inferior border of the spleen. Extension of dullness below the left costal margin indicates splenomegaly.
- Percuss for costovertebral angle (CVA) tenderness: the CVA is formed by the posterior edge of the ribs and the spinal column. Place a hand on this area and with the other hand in the form of a fist, strike the hand. Repeat on the other side. Positive CVA tenderness occurs when pain is elicited with percussion. This could be an indication of renal infections such as glomerulonephritis, pyelonephritis, etc.
- Lightly palpate the abdomen for superficial masses, tenderness: light palpation is up to 0.5 inches deep.
- Deeply palpate the abdomen: up to 2 inches deep.
- Palpate the liver: with the client recumbent, place your left hand posteriorly to lift the right rib cage. Ask the client to take a deep breath and position the edge of the right hand at the right costal margin. Ask the client to exhale and deeply palpate with the edge of the right hand under the costal margin while lifting the rib cage. The liver edge may be felt returning to its normal position as the client exhales. Perform palpation only after percussing the borders of the liver. Adjust hand position for hepatomegaly.
- Palpate the spleen: while standing at the recumbent client's right side, hook the left hand under the left rib cage. Using the edge of the right hand, ask the client to inhale deeply and begin to palpate deeply under the left costal margin. Ask the client to exhale. Palpate the spleen only after determining size and location by percussion. Do not palpate the spleen when it is enlarged as it is easily ruptured.
- Kidneys: attempt to capture the kidneys between both hands. Position one hand behind the client at the CVA.
 - Place the other hand in the corresponding upper quadrant and attempt to capture a kidney between both hands. Repeat on the other side.
- Aorta: place fingers on the area of pulsation previously detected by inspection. Palpate for rhythm and amplitude.
- Palpate the inguinal nodes and femoral pulses: these are palpated in the groin along the crease formed by the thigh and hips. Normally, inguinal nodes are nonpalpable. Femoral pulses may be difficult to palpate. Check blood flow by assessing the lower extremities and checking capillary refill in the toes.
- Peripheral vascular
 - Inspect the lower extremities for skin discoloration, varicose veins, edema; peripheral vascular disease is indicated by brown discoloration of the lower extremities, hair loss, achiness, edema, worsens with standing; peripheral arterial disease is indicated by cool extremities, hair loss, numbness, paresthesias, dry and scaly skin, and weak pulses.
 - Palpate the popliteal, dorsalis pedis, and posterior tibialis pulses; popliteal pulse is found deep in the popliteal space behind the knee; dorsalis pedis is found on the top of the foot, proximal to the first digit, lightly palpated; posterior tibialis is found behind the medial malleolus grade pulses: 0 absent, 1+ weak/thready, 2+ normal, 3+ increased, 4+ bounding.
 - Palpate for edema, tenderness grade edema: 0 absent, 1+ impression disappears <10 sec, 2+ impression lasts 10–15 seconds, 3+ up to 1 minute, 4+ 2–5 minutes.
- Musculoskeletal: including the spine
 - For all muscles and joints
 - Inspect for muscular symmetry, size, tone, and shape
 - Compare bilateral muscles for strength, symmetry, equality, and resistance
 - Grading muscle strength
 - 0 = no contraction
 - 1 = contraction, but no movement
 - 2 = contraction and movement, but not fully against gravity
 - 3 = full movement against gravity
 - 4 = partial movement against resistance
 - 5 = full movement against resistance
 - Palpate joints for tenderness and alignment
 - Test range of motion of joints
 - Cervical spine
 - Inspect head alignment and muscle and skin fold symmetry
 - Palpate for tone, symmetry, tenderness, and spasm
 - Spasm may feel like hardened, tender areas in the neck

- Assess range of motion (ROM)
 - Flexion: touch chin to chest
 - Extension: look up to the ceiling
 - Lateral bending: touch each ear to shoulder
 - Rotation: turn the head to look over each shoulder
- Assess muscle strength: ROM with resistance
 - Trapezius: shrug shoulders and do not let the examiner push them down
 - Sternocleidomastoid: repeat lateral bending and rotation while the examiner applies a hand to resist the movement
- Thoracic and lumbar spine
 - Inspect alignment, straightness, and curves
 - Inspect for lordosis: hyperextension of lumbar spine
 - Inspect for kyphosis: thoracic spine hump
 - Inspect for scoliosis: standing look for curvature of the spine, flexed look for one side of the spine higher than the other
 - Palpate the vertebral column and paravertebral muscles for tenderness
 - Assess ROM
 - Flexion: bend forward as far as possible
 - Hyperextension: bend backward as far as possible
 - Lateral bending: bend side to side
 - Rotation: turn side to side
 - Muscle strength of thoracic and lumbar spine is not routinely tested
- Shoulders
 - Inspect size, shape, symmetry, and contour
 - Inspect for nerve damage to scapula: ask the client to push against the wall while observing the scapula. There is nerve damage if the scapula “wings” or dislocates laterally.
 - Palpate joint capsule and muscles
 - Assess ROM
 - Flexion: bring arms forward
 - Hyperextension: bring arms back
 - Abduction: bring arm laterally away from the body
 - Adduction: bring arm across the body
 - Internal rotation: place both arms behind the back
 - External rotation: place both arms behind the head
 - Assess muscle strength of shoulder girdle: repeat flexion, hyperextension, abduction, and adduction with pressure applied near the shoulder on each side.
- Elbows
 - Inspect contour
 - Inspect carrying angle: with the client standing, a line drawn from the shoulder and the relaxed position of the arm forms an angle of approximately 15 degrees
- Inspect for subcutaneous nodules
- Palpate for tenderness, swelling, and thickening
- Assess ROM
 - Flexion: bend the elbow and bring arm up to the body
 - Extension: extend the arm straight
 - Pronation: with arm extended, twist the hand down
 - Supination: with arm extended, twist the hand up
- Assess muscle strength: repeat flexion and extension with pressure applied near the elbow on each side
- Hands and wrists
 - Inspect for contour, position, shape, number, and completeness of digits, and finger deviation
 - Palpate joints for texture, swelling, tenderness, boggi-ness, nodules, and bony overgrowths
 - Assess median nerve
 - Tinel sign: tap below the palm, over the middle of the wrist. If there is tingling or pain, there is median nerve irritation.
 - Phalen test: flex hands against each other for approximately a minute. If any tingling or pain develops in the wrist and fingers, there is median nerve irritation.
 - Assess ROM
 - Flexion: move hands down from the wrist
 - Extension: move hands up to “stop traffic”
 - Opposition: touch the thumb to each finger on each hand
 - Abduction: fan the fingers out
 - Adduction: bring the fingers together
 - Rotation: move the wrists in a circular pattern
 - Assess muscle strength
 - Grip: squeeze examiner’s hands
 - Repeat flexion, extension, abduction, and adduc-tion with resistance near the wrist on each side
- Hips
 - Inspect for symmetry, size, and gluteal fold symmetry
 - Palpate for stability and tenderness
 - Assess ROM
 - Flexion: move leg forward at the hip
 - Extension: move leg back at the hip
 - Abduction: move leg laterally
 - Adduction: move leg across the body
 - Internal rotation: with the leg flexed at the hip and knee, move knee medially while moving the lower leg laterally
 - External rotation: with the leg flexed at the hip and knee, move knee laterally while moving the lower leg laterally

- Assess muscle strength: repeat flexion, extension, abduction, and adduction with pressure applied above the knee
- Legs and knees
 - Inspect length, alignment, concavities, and contour
 - Palpate for swelling, tenderness, bogginess, and crepitus
 - Assess ROM
 - Flexion: bend the knee
 - Extension: straighten the leg
 - Assess muscle strength: repeat flexion and extension with pressure applied just below the knee
- Feet and ankles
 - Inspect contour and position
 - Inspect size and number of toes
 - Inspect alignment
 - Inspect ability to weight bear
 - Inspect arch of the foot
 - Palpate for heat, swelling, and tenderness
 - Assess ROM
 - Dorsiflexion: move foot and toes toward the head
 - Plantar flexion: move foot and toes away from the head (put your foot on the gas pedal)
 - Inversion: move foot medially
 - Eversion: move foot laterally
 - Assess muscle strength: repeat dorsiflexion and plantar flexion with pressure just below the ankle
- Nervous system
 - Perform a mental status exam (See separate section below.)
 - Test cranial nerve (CN) function, if not completed during the exam
 - Olfactory CN I: sensory nerve for smell. Test for odor identification (see nose)
 - Optic CN II: sensory and visual acuity. Test for visual acuity, visual fields, perform ophthalmologic exam (see eyes)
 - Oculomotor CN III, Trochlear CN IV, and Abducens CN VI: motor nerves for eye movement, pupil size, and eyelid opening. Assess for eyelid drooping, pupil size and equality, consensual response, accommodation, and extraocular eye movements (see eyes).
 - Trigeminal CN V: mixed motor and sensory for muscle tone and sensation. Inspect face for atrophy/tremors, palpate jaw for tone while client clenches teeth. Push down on chin and try to separate jaws. Test for pain by randomly touching the forehead, cheek, and chin with either a sharp or dull object or repeating on the other side. Test for sensation by lightly touching forehead, cheek, and chin with a cotton ball. Test corneal reflex by lightly touching cornea with cotton wisp while client looks straight ahead.
 - Facial CN VII: mixed motor and sensory for facial expressions and taste. Ask client to smile, frown, raise eyebrows, show upper and lower teeth, keep eyes closed against resistance, and puff out cheeks. Press puffed cheeks in and see if air escapes equally from both sides. Test tongue for salty and sweet sensations.
 - Acoustic CN VIII: sensory nerve for hearing and balance. Test hearing with whisper test, Weber and Rinne (see ears).
 - Glossopharyngeal CN IX: mixed sensory and motor nerve for taste and swallowing. Test tongue for sour and bitter sensations. Test gag reflex (see throat).
 - Vagus CN X: mixed sensory and motor nerve for swallowing and speech. Inspect palate and uvula for symmetry, inspect for swallowing difficulty, and evaluate guttural speech sounds (sounds made in the back of the throat such as g, k).
 - Spinal accessory CN XI: motor nerve for muscle strength of the trapezius and sternocleidomastoid. (see neck).
 - Hypoglossal CN XII: motor nerve for tongue strength. Inspect tongue for symmetry, tremors and atrophy, test tongue movement and strength. Evaluate lingual speech sounds (sounds made in the front of the mouth such as l, t, d, n)
 - Coordination and fine motor skills
 - Test rapid alternating movements
 - Touch the thumb to each finger in rapid succession
 - Touch hands to thighs and flip back and forth rapidly
 - Evaluate: rhythm, flow, speed, and accuracy
 - Test balance
 - Observe gait.
 - Perform Romberg test: ask client to stand feet together and arms by the side of the body with eyes closed for 30–60 seconds. A problem with balance causes the person to step out or fall.
 - Sensory function: ask the client to close his/her eyes and then test the following:
 - superficial touch: lightly touch several areas on upper and lower extremities with a cotton ball. The client states “yes” when touched.
 - superficial pain: using a broken tongue blade with the smooth side being “dull” and the broken side “sharp,” randomly touch upper and lower extremities. The client states whether the sensation was sharp or dull.
 - vibration: place a vibrating tuning fork on a distal interphalangeal joint and then a distal metatarsal joint. Each time, ask the client to state whether

he/she feels anything and what it is. Repeat on the other side.

- joint position: as the examiner moves the client's finger up and down in a random pattern, the client identifies whether the finger is up or down. Repeat with a toe, then on the other side.
- stereognosis: place a familiar object in the client's palm (coin, paperclip, eraser, etc.). The client states what the object is. Repeat with a different object on the other side
- two point discrimination: using toothpicks, touch the client simultaneously and determine at what minimal distance on that body part does the client distinguish two objects. The most sensitive area is the tongue and the least sensitive are the upper arms and thighs.
- extinction phenomenon: simultaneously touch bilateral areas on the client's body, such as the upper arms. The client states if he/she was touched in one place or two.
- point location: lightly touch several areas on upper and lower extremities with a cotton ball. Each time, the client identifies where he/she was touched.

—Test reflexes

- Superficial
 - Plantar reflex: begin stroking the foot along the lateral edge then across the base of the metatarsals. In individuals over 2-years old, the toes should curl. A normal reaction in children less than 2-years old, the 1st digit dorsiflexes and the toes fan out.
- Deep tendon reflexes: tap a reflex hammer
 - Biceps: above the elbow joint anteriorly and observe for elbow flexion
 - Triceps: above the elbow joint posteriorly and observe for elbow extension
 - Brachioradial: above the wrist on the radial side and observe for forearm pronation/elbow flexion
 - Patellar: just below the patella and observe for lower leg extension
 - Achilles: above the heel posteriorly and observe for plantar flexion.

Complete History and Physical Examination

- Complete history and physical examination is performed when a new client is examined.
- It provides a database for future comparison.
- It documents changes over time with subsequent visits.

Focused History and Physical Examination

- Focused history and physical examination is performed when the client's visit is for a particular problem.
- It may occur before the complete history and physical is completed.

- It provides evidence to determine effectiveness of interventions.

Nursing care:

- Address the concerns of the client first.
- Obtain the complete history and physical examination information after the health care issue is addressed. The client may need to be seen at another time to collect this information.
- Compare condition to the client's documented baseline health history and physical examination information. Alert colleagues to deviations from baseline.

Assessment Alert

Allow the client to voice his/her concerns or questions at the beginning of the visit. The client's fears or misconceptions may be alleviated and result in a more efficient and effective examination.

Client teaching for self-care

- Explain procedures and tests to the client.
- Give clear guidance and directions.
- Describe normal findings to alleviate client's anxieties.
- Reschedule for a complete history and physical examination if the client has only time enough for a focused visit.

Clinical Alert

Clear and concise documentation of findings is necessary to provide a record of the client's baseline condition and function. Subsequent visits, when compared to the complete history and physical examination, may indicate steady decline or improvement.

MENTAL STATUS

- Mental status is defined as the expression of the person's cognition, mood, emotions, and personality.
- Seven parameters to assess are level of consciousness, appearance and behavior, speech and language, mood and affect, perception and thought content, insight and judgment, and cognition.
- Assessment continues throughout the entire history and physical examination.

Etiology: Many conditions such as infection, tumors, dementias, toxicities, drug or alcohol intoxication or withdrawal, metabolic imbalances, cerebrovascular accidents, myocardial infarctions, dehydration, and malnutrition may result in changes in mental status.

Precipitating factors: If mental status deviates from baseline, assess for acute illnesses or exacerbations of chronic conditions.

Assessment of mental status:

- Level of consciousness: graded from hypervigilant to alert to comatose.
- Appearance and behavior: note hygiene, grooming, dress, posture, and facial expressions.
- Speech and language: observe pronunciation, tone, volume, clarity, smoothness and rate of speech, comprehension, and the ability to follow verbal directions.
- Mood and affect: note body language and emotional responses to simple and more complex statements or questions.
- Perception and thought content: evaluate the logic and congruence of statements and their basis in reality.
- Insight and judgment: note understanding of situations, events, and the ability to draw conclusions.
- Cognition: evaluate short-term and long-term memory, praxis, visual-spatial skills, calculation, and abstraction.

Assessment Alert

Delirium, clouded sensorium, in a client signifies a medical emergency. Immediately report delirium to the health care team responsible for the client.

Examples of assessment tools:

- Mini Mental State Examination (MMSE): brief, assesses multiple cognitive functions (orientation, memory, praxis, language, attention, calculation), widely used
- Confusion Assessment Method (CAM): tests for delirium
- Hopkins Competency Assessment Test: assesses ability to make decisions about health care
- Short Portable Mental Status Questionnaire (SPMSQ): assesses brain deficits

Examples of assessment questions:

Ask the client

- His/her name, where he/she is, and what time it is
- His/her date of birth, names and ages of children and grandchildren, and recent events.
- To add, subtract, divide, or multiply numbers. Begin with simple problems and advance to more complex with more steps.

- How two objects are similar or different (i.e., an apple and an orange are both fruit).
- To explain a proverb such as “he who hesitates is lost.”
- What he/she would do if he/she saw flames coming from the neighbor’s house?
- To draw a clock face with all the numbers and show 3 o’clock.
- To demonstrate how one brushes teeth, combs hair, or shaves.

Rx: The underlying cause for mental status change should be determined and treated. If the cause is not reversible, all efforts should be made to maintain function and assure safety.

Nursing care:

- Assess mental status whenever there is a change in the client’s condition.
- Obtain baseline mental status when the client’s condition is stable.
- Increase frequency of client evaluation when mental status is impaired.

Assessment Alert

Beware of the client who has completed the MMSE enough times to have learned “the answers.” Vary assessment questions and techniques in order to accurately assess mental status.

Client teaching for self-care

- Much teaching may be geared toward the family if the client is significantly impaired.
- The client will be assessed more frequently for maintenance of functions and safety until stable.
- A change in mental status indicates that further assessment and testing is required to determine a cause.
- If the underlying cause is reversible, all efforts will be focused on reversing the problem. If it is not reversible, all efforts will be focused on maintenance of function and client safety.

Clinical Alert

Age, culture, education, and language fluency will influence mental status testing. All questions should be individualized for the age, culture, educational level, and language of the client.

WORKSHEET

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. To assess the tympanic membrane in a 1-year-old child, you need to pull the pinna back and _____.
2. The last area to assess in a toddler is the _____.
3. During assessment of the eyes in a child less than 6-years old, you need to be able to see the _____.
4. Preschoolers may already feel comfortable sitting on the _____ rather than their parent's/guardian's lap during the physical examination.
5. The comfort and _____ of all clients should be ensured during the physical examination.
6. For an adolescent, the last area to be assessed is the _____ system.
7. Elderly clients may not be able to change _____ as easily as younger clients during the physical examination.
8. The skin produces vitamin _____.
9. The client's _____ of the problem is an important part of the health history.
10. The parasympathetic and sympathetic nerve pathways are part of the _____ nervous system.
11. The expression of a person's cognition, mood, emotions, and personality is called _____.
12. If the underlying cause of a mental status change is not reversible, the goal of care is to maintain _____.
13. The most sensitive part of the hand which is used for palpation is/are the _____.
14. The physical examination contains only _____ information.
15. The head is assessed for _____ and shape.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------|-------|
| 1. You should speak in a louder voice to all elderly clients. | _____ | _____ |
| | T | F |
| 2. When discussing an illness affecting one system, you would reinforce to the client that all body systems are interrelated. | _____ | _____ |
| | T | F |

(continued)

| | | |
|--|------------------|------------------|
| 3. Elderly clients are never victims of abuse. | <u> </u> T | <u> </u> F |
| 4. The Mini-Mental Status Examination is used to screen clients for cognitive dysfunction. | <u> </u> T | <u> </u> F |
| 5. A reflex arc occurs when a sensory impulse travels to the spinal cord and a motor impulse is sent back out to the muscle. | <u> </u> T | <u> </u> F |
| 6. The nurse may never divulge information gained during a client interview. | <u> </u> T | <u> </u> F |
| 7. During the first year of life, the nervous system develops with increasing myelination. | <u> </u> T | <u> </u> F |
| 8. Delirium is a medical emergency. | <u> </u> T | <u> </u> F |
| 9. Baseline mental status is determined when the client is acutely ill. | <u> </u> T | <u> </u> F |
| 10. At the end of the interview, a nurse should summarize what she heard from the client. | <u> </u> T | <u> </u> F |
| 11. The ventral surface of the hand is most sensitive to temperature. | <u> </u> T | <u> </u> F |
| 12. It is normal to hear tympany to percussion over the abdomen. | <u> </u> T | <u> </u> F |
| 13. Subjective information is anything that the examiner observes. | <u> </u> T | <u> </u> F |
| 14. The health history contains objective information. | <u> </u> T | <u> </u> F |
| 15. The review of systems is necessary to prevent omission of important information. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Match the following:

Organ

Function

- | | |
|--------------------------|---------------------------------------|
| 1. Ear _____ | a. Receives visual data |
| 2. Eye _____ | b. Circulates blood cells to body |
| 3. Gall bladder _____ | c. Maintains balance |
| 4. Heart _____ | d. Oxygen and carbon dioxide exchange |
| 5. Large intestine _____ | e. Wound repair |
| 6. Liver _____ | f. Produces bile |
| 7. Lungs _____ | g. Stores bile |
| 8. Mouth _____ | h. Absorbs water |
| 9. Pancreas _____ | i. Produces insulin |
| 10. Skin _____ | j. Begins digestion |

MATCHING QUESTIONS

Match the following:

- | | |
|-------------------------|--|
| 1. Abdomen _____ | a. Trachea midline, thyroid nonpalpable |
| 2. Extremities _____ | b. Red mucosa, septum midline |
| 3. Heart _____ | c. Intact vibratory sense, deep tendon reflexes 2+ |
| 4. Lungs _____ | d. No injection, uvula rises midline |
| 5. Lymph nodes _____ | e. No vascularities, warm, turgor intact |
| 6. Neck _____ | f. Full range of motion |
| 7. Nervous system _____ | g. Palpable in the occipital area, less than 1 cm, tender |
| 8. Nose _____ | h. Alternating tympany and dullness, liver 6 cm right midclavicular line |
| 9. Skin _____ | i. S ₁ S ₂ , no murmurs |
| 10. Throat _____ | j. Clear to auscultation |

APPLICATION QUESTIONS

- | | |
|--|--|
| 1. When assessing the abdomen, which sequence does the nurse follow? a. Palpation, percussion, auscultation, and inspection b. Inspection, palpation, percussion, and auscultation c. Percussion, inspection, auscultation, and palpation d. Inspection, auscultation, percussion, and palpation | 3. When using an ophthalmoscope to assess a 3-year-old girl's eyes, for what does the nurse look? a. Optic disk b. Macula c. Red reflex d. Fovea centralis |
| 2. Which action is correct for the nurse to take when examining the ear of an 18-month-old boy? a. Pulling the ear back and down b. Pulling the ear back and up c. Pulling the ear forward d. Looking into the ear without pulling it in any direction | 4. At which age may a head to toe assessment first be done? a. Toddlers b. School-aged children c. Adolescents d. Adults |
| | 5. When assessing an adolescent, which structures would the nurse examine last? a. Head, eyes, ears, nose, and throat b. Neurological |

(continued)

- c. Musculoskeletal
 - d. Genitourinary
6. Adolescents should always be interviewed
- a. With and without their parents/guardians
 - b. Only with their parents/guardians
 - c. Only without their parents/guardians
 - d. Once a year
7. Which type of abuse is the nurse most likely to discover when assessing the elderly?
- a. Physical abuse
 - b. Emotional abuse
 - c. Neglect
 - d. Social
8. A child's interactions with his/her parent/guardian are important to observe because you learn about the child's:
- a. Relationship with the parent/guardian
 - b. Level of functioning
 - c. Neuromuscular functioning
 - d. All of the above
9. During a skin assessment, a client asks a question about what the skin does. The nurse's response would be based on the knowledge that the functions of the skin include: (Mark all that apply.)
- a. ___ Temperature regulation
 - b. ___ Sensory perception
 - c. ___ Identification of the individual
 - d. ___ Protection
10. In order to localize a symptom, which direction should the nurse give a client?
- a. Point to where the symptom occurs.
 - b. Come back when you are experiencing the symptom.
 - c. Bring someone in with you who has witnessed you having the symptom.
 - d. Tell me which body part is affected by the symptom.
11. When a client complains of right knee pain, which areas should the nurse examine?
- a. Only the right knee
 - b. The right ankle, the right knee, and the right hip
 - c. The left lower abdominal quadrant and the left knee
 - d. The right leg and left arm
12. Which is the best approach to gathering information about diet as part of a client assessment?
- a. You don't eat much fatty food, do you?
 - b. Tell me about your diet.
 - c. Do you like potato chips?
 - d. Do you eat three meals each day?
13. When percussing over organs, which percussion note would the nurse interpret as normal?
- a. Dull
 - b. Flat
 - c. Hyperresonant
 - d. Resonant
14. Which test is an indicator of coordination?
- a. Rinne test
 - b. Weber test
 - c. Corneal reflex response
 - d. Rapid alternating movement test
15. Which are components of a complete health history? Mark all that apply.
- a. ___ Chief complaint
 - b. ___ History of the present illness
 - c. ___ Past medical/surgical history
 - d. ___ Family, personal, and social history
 - e. ___ Review of systems
 - f. ___ Physical exam
16. When shining a light in a client's eye, which reaction would the nurse interpret as normal? The pupils:
- a. Contract
 - b. Dilate
 - c. Move to the left
 - d. Oscillate laterally
17. Which test is the nurse performing when a vibrating tuning fork is placed on top of a client's head and the client is asked if the sound is heard equally in both ears?
- a. Rinne test for bone and air conduction
 - b. Romberg for balance
 - c. Test for extinction
 - d. Weber test for sound lateralization
18. When testing a client's ability to identify odors, the nurse is assessing the function of which cranial nerve?
- a. Facial
 - b. Trigeminal
 - c. Olfactory
 - d. Spinal accessory
19. Which notation correctly indicates normal muscle strength?
- a. 0/5
 - b. 5/5
 - c. 5/10
 - d. 10/10

20. During a presentation at a health fair, a client asks about the cause of presbyopia. On which information should the nurse's response be based? Presbyopia results when the
- lens becomes less flexible.
 - iris does not open fully.
 - retina is covered by a cataract.
 - optic blood vessels are engorged.
21. A new mother asks how far her baby is able to see. Which is the correct response for the nurse to make?
- Across a 10 ft × 10 ft room
 - Only distant objects
 - Only within 2 in. of the eyes
 - Objects to 1 ft away
22. Where would the nurse auscultate to best hear S1, the first heart sound?
- Apex of the heart
 - Base of the heart
 - Aortic area
 - Third left intercostal space
23. A client with right heart failure asks what the right side of the heart does. The nurse's response is based on the fact that the right ventricle pumps deoxygenated blood through the
- pulmonary veins to the aorta
 - aorta to the left atrium
 - pulmonary arteries to the left ventricle
 - pulmonary arteries to the lungs
24. When assessing the abdomen of a client who is complaining of diarrhea, which finding would the nurse expect?
- Absent bowel sounds
 - Hypoactive bowel sounds
 - Hyperactive bowel sounds
 - Normal bowel sounds
25. While the nurse is trying to assess an infant's lungs, the infant is crying. Which conclusions should the nurse draw? Check all that apply.
- Airway is patent
 - The infant may be distressed
 - The infant is in need of emergency treatment
 - Vocal cords are intact

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

- To assess the tympanic membrane in a 1-year-old child, you need to pull the pinna back and ___ down ____.
- The last area to assess in a toddler is the ____ ears _____.
- During assessment of the eyes in a child less than 6-years-old, you need to be able to see the ___ red reflex ____.
- Preschoolers may already feel comfortable sitting on the ____ exam table _____ rather than their parent's/guardian's lap during the physical examination.
- The comfort and ____ privacy _____ of all clients should be ensured during the physical examination.
- For an adolescent, the last area to be assessed is the ____ genitourinary _____ system.
- Elderly clients may not be able to change ___ positions _____ as easily as younger clients during the physical examination.

(continued)

8. The skin produces vitamin ____ D ____.
9. The client's ____ perception ____ of the problem is an important part of the health history.
10. The parasympathetic and sympathetic nerve pathways are part of the ____ autonomic ____ nervous system.
11. The expression of a person's cognition, mood, emotions and personality is called ____ mental status ____.
12. If the underlying cause of a mental status change is not reversible, the goal of care is to maintain ____ function ____.
13. The most sensitive part of the hand which is used for palpation is/are the ____ finger pads ____.
14. The physical examination contains only ____ objective ____ information.
15. The head is assessed for ____ symmetry ____ and shape.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. You should speak in a louder voice to all elderly clients. *False*
With aging the ability to hear high tones decreases (presbycusis). Therefore one should use lower tones when speaking to older clients; speaking more loudly tends to raise the tone of the voice and thus can make hearing more difficult.
2. When discussing an illness affecting one system, you would reinforce to the client that all body systems are interrelated. *True*
3. Elderly clients are never victims of abuse. *False*
Persons of all ages are abused. Neglect is the most common type of abuse among the elderly.
4. The Mini-Mental Status Examination is used to screen clients for cognitive dysfunction. *True*
5. A reflex arc occurs when a sensory impulse travels to the spinal cord and a motor impulse is sent back out to the muscle. *True*
6. The nurse may never divulge information gained during a client interview. *False*
Information can be divulged in accord with HIPAA guideline. Information can be shared with appropriate agencies when necessary to ensure the safety of the client and those around him or her.
7. During the first year of life, the nervous system develops with increasing myelination. *True*
8. Delirium is a medical emergency. *True*
9. Baseline mental status is determined when the client is acutely ill. *False*
Baseline mental status is determined when the client is at his or her usual level of health and function.
10. At the end of the interview, a nurse should summarize what was heard from the client. *True*

11. The ventral surface of the hand is most sensitive to temperature. *False*
The dorsal surface of the hand (back of the hand) is most sensitive to temperature.
12. It is normal to hear tympany to percussion over the abdomen. *True*
13. Subjective information is anything that the examiner observes. *False*
Objective information is anything that the examiner observes.
14. The health history contains objective information. *False*
The health history contains subjective information.
15. The review of systems is necessary to prevent omission of important information. *True*

MATCHING ANSWERS

Match the following:

Organ

Function

- | | |
|----------------------------|---------------------------------------|
| 1. Ear ___c___ | a. Receives visual data |
| 2. Eye ___a___ | b. Circulates blood cells to body |
| 3. Gall Bladder ___g___ | c. Maintains balance |
| 4. Heart ___b___ | d. Oxygen and carbon dioxide exchange |
| 5. Large intestine ___h___ | e. Wound repair |
| 6. Liver ___f___ | f. Produces bile |
| 7. Lungs ___d___ | g. Stores bile |
| 8. Mouth ___j___ | h. Absorbs water |
| 9. Pancreas ___i___ | i. Produces insulin |
| 10. Skin ___e___ | j. Begins digestion |

MATCHING ANSWERS

Match the following:

- | | |
|------------------------|--|
| 1. Abdomen ___h___ | a. Trachea midline, thyroid non-palpable |
| 2. Extremities ___f___ | b. Red mucosa, septum midline |

(continued)

- | | |
|---------------------------|--|
| 3. Heart ___I___ | c. Intact vibratory sense, deep tendon reflexes 2+ |
| 4. Lungs ___j___ | d. No injection, uvula rises midline |
| 5. Lymph nodes ___h___ | e. No vascularities, warm, turgor intact |
| 6. Neck ___a___ | f. Full range of motion |
| 7. Nervous system ___c___ | g. Palpable in the occipital area, less than 1 cm, tender |
| 8. Nose ___b___ | h. Alternating tympany and dullness, liver 6 cm right midclavicular line |
| 9. Skin ___e___ | i. S1S2, no murmurs |
| 10. Throat ___d___ | j. Clear to auscultation |

APPLICATION ANSWERS

- When assessing the abdomen, which sequence does the nurse follow?
 - Palpation, percussion, auscultation, and inspection
 - Inspection, palpation, percussion, and auscultation
 - Percussion, inspection, auscultation, and palpation
 - Inspection, auscultation, percussion, and palpation

Rationale

Correct answer: d.

Palpation is last in order to prevent distortion of bowel sounds.

- Which action is correct for the nurse to take when examining the ear of an 18-month-old boy?
 - Pulling the ear back and down
 - Pulling the ear back and up
 - Pulling the ear forward
 - Looking into the ear without pulling it in any direction

Rationale

Correct answer: a.

An infant's ear canal is positioned lower than older children and adults.

- When using an ophthalmoscope to assess a 3-year-old girl's eyes, for what does the nurse look?
 - Optic disk
 - Macula
 - Red reflex
 - Fovea centralis

Rationale

Correct answer: c.

Often children will not remain stationary long enough to view further structures in the eye. Being able to view the red reflex rules out a congenital cataract.

- At which age may a head to toe assessment first be done?
 - Toddlers
 - School-aged children
 - Adolescents
 - Adults

Rationale

Correct answer: b.

Some preschool-aged children may already be able to be examined head to toe as well.

- When assessing an adolescent, which structures would the nurse examine last?
 - Head, eyes, ears, nose, and throat
 - Neurological
 - Musculoskeletal
 - Genitourinary

Rationale

Correct answer: d.

Developing adolescents find the genitourinary exam the most difficult.

- Adolescents should always be interviewed
 - with and without their parents/guardians.
 - only with their parents/guardians.

- c. only without their parents/guardians.
- d. once a year.

Rationale

Correct answer: a.

Adolescents may not want to reveal risky behaviors in front of their parents/guardians.

7. Which type of abuse is the nurse most likely to discover when assessing the elderly?
- a. Physical abuse
 - b. Emotional abuse
 - c. Neglect
 - d. Social

Rationale

Correct answer: c.

Neglect is the most common type of abuse against the elderly. Often, the elderly person does not want those close to them to help with physical functions or their caregivers may not be willing to perform incontinence and personal care.

8. A child's interactions with his/her parent/guardian are important to observe because you learn about the child's
- a. relationship with the parent/guardian.
 - b. level of functioning.
 - c. neuromuscular functioning.
 - d. all of the above.

Rationale

Correct answer: d.

You learn about the child's relationship with the caregiver, what the child can or is allowed to do for him/herself and how the child manipulates the environment both physically and emotionally.

9. During a skin assessment, a client asks a question about what the skin does. The nurse's response would be based on the knowledge that the functions of the skin include (Mark all that apply.)
- a. ___temperature regulation
 - b. ___sensory perception
 - c. ___identification of the individual
 - d. ___protection

Rationale

Correct answers: a, b, c, and d.

The skin regulates temperature through changes in its blood flow and through sweating. The skin provides sensory information through its nerve endings. Fingerprints allow for identification of individuals. The skin and mucous membranes are the first line of defense against injury and invasion of microorganisms.

10. In order to localize a symptom, which direction should the nurse give a client?
- a. Point to where the symptom occurs
 - b. Come back when you are experiencing the symptom

- c. Bring someone in with you who has witnessed you having the symptom
- d. Tell me which body part is affected by the symptom.

Rationale

Correct answer: a.

This gives the examiner an understanding of where the problem may be without the possibility of confusion due to terminology used by the client for various body parts. There are times when a client may need to return during the time a symptom is being experienced but this is not primarily to localize the symptom. There are also times such as in the case of loss of consciousness or a seizure when a witness can provide valuable information but again, this is not primarily directed at localizing the symptom.

11. When a client complains of right knee pain, which areas should the nurse examine?
- a. Only the right knee
 - b. The right ankle, the right knee and the right hip
 - c. The left lower abdominal quadrant and the left knee
 - d. The right leg and left arm

Rationale

Correct answer: b.

Pain in the right knee may be referred from the right hip or right ankle.

12. Which is the best approach to gathering information about diet as part of a client assessment?
- a. You don't eat much fatty food, do you?
 - b. Tell me about your diet.
 - c. Do you like potato chips?
 - d. Do you eat three meals each day?

Rationale

Correct answer: b.

This is an open-ended question which allows the client to describe the answer and say more than "yes" or "no."

13. When percussing over organs, which percussion note would the nurse interpret as normal?
- a. Dull
 - b. Flat
 - c. Hyperresonant
 - d. Resonant

Rationale

Correct answer: a.

A flat percussion note is heard over bone, hyperresonant over over-inflated lungs and resonant over normal lung tissue.

14. Which test is an indicator of coordination?
- a. Rinne test
 - b. Weber test
 - c. Corneal reflex response
 - d. Rapid alternating movement test

(continued)

Rationale

Correct answer: d.

Weber and Rinne are both hearing tests and corneal reflex response is an eye test.

15. Which are components of a complete health history? Mark all that apply.
- ___ Chief complaint
 - ___ History of the present illness
 - ___ Past medical/surgical history
 - ___ Family, personal and social history
 - ___ Review of systems
 - ___ Physical exam

Rationale

Correct answers: a, b, c, d, e, and f.

The physical examination is not part of the health history.

16. When shining a light in a client's eye, which reaction would the nurse interpret as normal? The pupils:
- Contract
 - Dilate
 - Move to the left
 - Oscillate laterally

Rationale

Correct answer: a.

Light causes the direct and consensual reactions of the pupil the light is shined on and the other pupil. The pupils should not dilate, move, or oscillate when light is shined on one or both.

17. Which test is the nurse performing when a vibrating tuning fork is placed on top of a client's head and the client is asked if sound is heard equally in both ears?
- Rinne test for bone and air conduction
 - Romberg for balance
 - Test for extinction
 - Weber test for sound lateralization

Rationale

Correct answer: d.

For the Rinne test, the vibrating tuning fork is placed on the mastoid. No tuning forks are used in the Romberg test and in the test for extinction.

18. When testing a client's ability to identify odors, the nurse is assessing the function of which cranial nerve?
- Facial
 - Trigeminal
 - Olfactory
 - Spinal accessory

Rationale

Correct answer: c.

The sensory function of the facial nerve relates to taste. The trigeminal nerve mediates light touch sensation. The spinal accessory nerve is a motor nerve tested by asking the client to turn the head against the resistance of the examiner's hand placed against the side of his or her chin and face and to shrug the shoulders against the resistance of the examiner's hands on them.

19. Which notation correctly indicates normal muscle strength?
- 0/5
 - 5/5
 - 5/10
 - 10/10

Rationale

Correct answer: b.

Muscle strength is graded against gravity and resistance on a scale of 0–5 with 5 being normal and 0 being completely paralyzed. Grades of 4, 3, 2, or 1/5 indicate varying degrees of weakness.

20. During a presentation at a health fair, a client asks about the cause of presbyopia. On which information should the nurse's response be based?
- Presbyopia results when the
- lens becomes less flexible.
 - iris does not open fully.
 - retina is covered by a cataract.
 - optic blood vessels are engorged.

Rationale

Correct answer: a.

The other answers are unrelated to the development of presbyopia, which is the decrease in ability to see near objects that occurs with age.

21. A new mother asks how far her baby is able to see. Which is the correct response for the nurse to make?
- Across a 10 ft × 10 ft room
 - Only distant objects
 - Only within 2 in. of the eyes
 - Objects to 1 ft away

Rationale

Correct answer: d.

This is the distance between the mother's face and the infant in her arms.

22. Where would the nurse auscultate to best hear S1, the first heart sound?
- Apex of the heart
 - Base of the heart
 - Aortic area
 - Third left intercostal space

Rationale

Correct answer: a.

The closing of the mitral and tricuspid valves forms the first heart sound. The apex of the heart is actually the bottom of the heart, where the left ventricle is found.

23. A client with right heart failure asks what the right side of the heart does. The nurse's response is based on the fact that the right ventricle pumps deoxygenated blood through the
- pulmonary veins to the aorta.
 - aorta to the left atrium.
 - pulmonary arteries to the left ventricle.
 - pulmonary arteries to the lungs.

Rationale

Correct answer: d.

Blood flows from the right atrium through the tricuspid valve to the right ventricle through the pulmonic valve to the pulmonary arteries to the lungs, then back into the pulmonary veins to the left atrium, through the mitral valve to the left ventricle and through the aortic valve to the aorta and out to the body. The pulmonary arteries are the only arteries in the body that carry deoxygenated blood while the pulmonary veins are the only veins in the body that carry oxygenated blood.

24. When assessing the abdomen of a client who is complaining of diarrhea, which finding would the nurse expect?
- Absent bowel sounds
 - Hypoactive bowel sounds
 - Hyperactive bowel sounds
 - Normal bowel sounds

Rationale

Correct answer: c.

Hypoactive bowel sounds may be a result of ileus or abdominal infection.

25. While the nurse is trying to assess an infant's lungs, the infant is crying. Which conclusions should the nurse draw? Check all that apply.
- Airway is patent
 - The infant may be distressed
 - The infant is in need of emergency treatment
 - Vocal cords are intact

Rationale

Correct answers: a, b, and d.

If the infant can generate the sound of crying, vocal cords are intact and the airway is patent. The infant does not need emergency treatment for simply crying. The examination may be distressing to the infant.

Psychosocial Integrity—Part 1

Sub-category: None

Topics: Mental Health Concepts

Cultural Diversity

Coping Mechanisms

Religious and Spiritual Influences on Health

Situational Role Changes

Stress Management

Support Systems

Family Dynamics

Unexpected Body-Image Changes

Grief and Loss

End of Life

| | | | |
|----------------------|-----|---|-----|
| ▸ Cultural Diversity | 238 | ▸ Religious and Spiritual Influences on Health | 240 |
| ▸ Coping Mechanisms | 244 | ▸ Situational Role Changes | 246 |
| ▸ End-of-Life Care | 250 | ▸ Stress Management | 240 |
| ▸ Family Dynamics | 242 | ▸ Support Systems | 242 |
| ▸ Grief and Loss | 248 | ▸ Unexpected Body-Image Changes | 247 |

Psychosocial integrity is important for the promotion and support of the emotional, mental, and social well-being of

the client, family, and significant others experiencing stressful events and acute or chronic illnesses.

CULTURAL DIVERSITY

- Culture is a shared system of beliefs, values, and behavioral expectations that influence daily living.
- Including the client's culture and ethnicity into the plan of care eliminates ethnocentrism—judging others by one's own standards of acting, believing, and thinking.
- Acculturation—also called cultural assimilation—occurs when a member of a cultural group adapts to the new dominant culture in order to survive.
- Cultural competence is a set of practice standards that ensures that clients of all cultures receive information about treatment in familiar ways, considering education, acculturation, and language.
- To maintain cultural competence, nurses must assess the client's health care practices including health-seeking behaviors, responsibility for health care, folklore practices, barriers to health care, and cultural responses to health and illness.
- Cultural competence standards in clinical practice include the use of interpreters, multilingual and multicultural staff that reflects the community, culturally sound psychological and diagnostic testing, recognition that cultural factors influence treatment compliance, availability of printed client education materials in the preferred language of the client, and documentation of how the client language needs were met.
- In addition to translation services, spiritual support and pastoral counseling should be made available to cross-cultural clients.
- A client's cultural influences on health care are many. The nurse must take these factors into consideration when planning nursing care.
 - Physiologic characteristics: Certain illnesses are associated with race and culture, such as sickle cell anemia in people of African or Mediterranean origin.
 - Psychological characteristics: A client may view some health care practices as irrelevant, whereas the nurse views the same practices as important. For example, the nurse may view a yearly mammogram in a Hispanic client with a past history of breast cancer as important, whereas the client views the procedure as interfering with God's ultimate plan.
 - Pain: Some cultures express pain openly and embrace measures to reduce pain, while other cultures remain stoic. The nurse must respect the client's cultural beliefs regarding pain. For example, Native Americans use relaxation such as meditation to help quell pain prior to using medications.
 - Mental health: Some cultures view mental illness as a stigma. For example, a traditional Chinese client may ignore symptoms of mental illness and thus not seek care due to the stigma associated with mental illness in the traditional Chinese culture.
- Gender: In some cultures the male is the dominant figure, whereas the female is the dominant figure in other cultures. For example, in African-American families, the female typically makes the decisions for all family members.
- Communication: Verbal and nonverbal communication techniques vary among cultures. For example, American culture emphasizes eye contact while speaking, whereas Arabs view this communication technique as impolite and aggressive. All written materials must be provided in the client's spoken language.
- Personal space: Some cultures believe in maintaining physical distance while others prefer to be physically close to other humans. For example, Arabs prefer to sit and stand close to one another when talking, whereas Asians prefer distance between themselves and others.
- Time: Being punctual for appointments is not important to all cultures. For example, some Asian cultures view being late as a sign of respect.
- Food: Certain foods serve as dietary staples based on culture. Rice is a staple of the Chinese, and pasta is a staple of the Italians. The nurse should ask every client about food preferences and dietary practices.
- Family support: Many cultures include family members in the health care decision-making process. For example, Chinese and Arab family members consult with the family's elders regarding health care advice.
- Socioeconomic factors: Poverty impedes access to health care. Populations impacted by poverty include migrant farm workers, families living on welfare, and people living in isolated areas, such as the Appalachian Mountains.
- Many cultures rely on traditional healers to improve health outcomes. Healers may prescribe herbs, massage, heat and cold therapies, and acupuncture to alleviate pain and treat illness. Clients who use traditional healers may view health care providers as incompetent because they ask many questions and implement trial-and-error methods of healing.
- Cultural differences can affect responses to medications. For example, Asians require smaller doses of a drug because their bodies metabolize drugs at a slower rate. African-Americans may require larger doses of blood pressure medication.
 - Traditional herbal treatments may interfere with a prescribed medication's action.
 - Culture beliefs can affect compliance and response to a medication regimen. For example, an Asian client may prefer herbal tea over a sleeping medication to promote relaxation.

- A client's cultural practices can cause sensory deprivation, sensory overload, and sleep deprivation. The nurse asks the client what level of stimulation is acceptable to the client.
- Some cultures believe surgical intervention is the last option for treating illness. Clients of these cultures may be convinced that death will result due to surgery. This anxiety may increase the client's surgical risk.
 - For example, a client from a culture that believes bed rest is the best treatment for illness may refuse to participate in postoperative ambulation and exercises.
- Culture influences a client's reaction to grief and loss. In Western culture, families grieve privately and internalize their feelings of loss.
- During the nursing assessment, the nurse asks clients how they wish to be treated based on their cultural values and beliefs while remembering each client is an individual.
- The nurse's role in caring for culturally diverse clients is to understand the client's needs and to adapt care to meet those needs. The nurse must blend his or her own beliefs with those of the nursing profession and individual clients to deliver safe, considerate, and successful nursing care to all clients.
- Table 10–1 addresses cross-cultural perspectives of health.

Nursing Intervention Alert

When delivering care to cross-cultural clients, the nurse must maintain the client's cultural mental health practices, facilitate effective verbal and nonverbal communication, and promote the client's understanding of treatment and the rationale behind the care received.

Table 10–1 Cross-Cultural Perspectives of Health

| Culture | Family | Health Care Preferences | Health Care Concepts | Mental Illness | Communication Preferences | Health Promotion |
|------------------|--|--|--|--|---|--|
| African American | Matriarchal structure; many single-parent households headed by women | Traditional medicines; healers and voodoo priests; herbs | Health is freedom from pain and stress; a sense of well-being | Due to spiritual distress | Close personal space; present time over future | Protect against excessive cold Consume proper diet Maintain proper behavior Exercise in fresh air |
| Asian American | Hierarchical structure; loyal family members | Traditional medicines and healers; herbs | Balance of <i>yin</i> and <i>yang</i> to promote harmony | Stigma attached to mental illness; metabolic imbalance and organic problem | No physical contact; present time orientation | Maintain harmony with friends and family Consume a diet balanced with <i>yin</i> and <i>yang</i> foods |
| Hispanic | Nuclear structure; large extended family; strong church affiliation | Traditional medicines and healers; herbs; diagnostic techniques include exorcism | Ability to maintain role function; sense of well-being | Due to spells or bad spirits | Value physical presence and touch; present time orientation | Show aversion to health screenings and routine physicals because future is in God's hands |
| Native-American | Nuclear structure; large extended family | Traditional medicines and healers; herbs; diagnostic techniques include stargazing | Holistic approach to health: mind, body, spirit | Due to curse; holistic approach | Space important and has no boundaries; future over present time | Practise religious ceremonies and prayer Perform physical exercise and meditation |
| Arab | Patriarchal structure; men valued over women | Traditional medicines and healers | Turn to elders in the family for medical advice Health is freedom from pain | Due to physical or emotional trauma; attributed to supernatural beings | Formal manners; time orientation varies by religion | Value modern Western medical practices Care for personal hygiene Consume healthy diet |

RELIGIOUS AND SPIRITUAL INFLUENCES ON HEALTH

- Every person has a spiritual dimension, which may be expressed formally or informally.
- Spirituality allows individuals to make sense of the cycle of life and death by offering hope and support.
- Spirituality is a search for the sacred.
- Religion is an expression of spirituality.
- Faith is the ability to draw on spiritual resources without requiring physical proof.
- Hope is responsible for a positive outlook even during the bleakest moments.
- Spiritual health occurs when the spiritual needs for meaning and purpose, love and belonging, and forgiveness are met.
- Spiritual assessment incorporates a holistic view of the client and addresses meaning and purpose in life, ability to recognize inner strengths, and self-concept.
- Many people seek support from their religious faith during times of illness.
- Religious beliefs can conflict with health care practices, as in the case of Muslims who view illness as fate instead of a condition in which action may be taken.
- Some people view illness as a punishment for sin, thus causing spiritual distress.
- In cases of spiritual distress, the nurse may explore with the client spiritual beliefs and practices, factors that challenge spiritual beliefs, and alternatives to reaffirm or modify beliefs.
- Nursing interventions to assist clients and their families meet their spiritual needs include offering support, facilitating the client's practice of religion, praying with a client and family, contacting a spiritual counselor, and resolving conflicts between treatment and spiritual beliefs.

Nursing Intervention Alert

An objective explanation of alternative treatments and the predicted consequences of each may help the client determine acceptable treatment that does not conflict with religious beliefs.

STRESS MANAGEMENT

- Stress is a condition in which the human system responds to changes in its normal balanced state.
- A stressor is anything that is perceived as challenging, demanding, or threatening.
- A state of psychological stress results when resources are not available to reestablish balance.
- A person's age, developmental level, past experiences, support systems, and coping mechanisms influence adaptations to stress.
- Stress can cause illness and illness may precipitate stress.
- Prolonged stress can perpetuate ineffective coping and mental illness.
- Stress that affects the client also influences the family and significant others.
- Two main types of stress exist: developmental and situational.
- Developmental stress occurs as an individual progresses through the normal stages of growth and development.
- Situational stress is unpredictable and can occur at any time.
- The human body responds to stress by releasing epinephrine, norepinephrine, and other hormones that increase the metabolic rate and protect the immune system.
- Physiologic stressors include viruses, bacteria, fungi, drugs, alcohol, poison, heat/cold, radiation, trauma, electric shock, suppressed immune system, genetic disorders, acute and chronic illnesses, and the process of aging.
- Psychosocial stressors include trauma, accidents, lack of knowledge, fear, noise, uncertainty, and rapid changes in the world, which can include both real and perceived threats.
- See Table 10–2 for the physical and psychological responses to stress.
- Stress increases the client's chances of developing disease or illness.
- Clients who are under stress experience more depression, require more anesthesia and analgesia, and have lower immune functioning than those who experience minimal or no stress.

Table 10–2 Physical and Psychological Responses to Stress

| Physical Responses | Psychological Responses |
|--|---|
| Dry mouth Tachycardia Insomnia Increased urinary frequency Muscle tension or pain Headaches Loss of or excessive appetite Gastrointestinal distress | Nightmares Irritability Depression Disturbed behavior Anxiety Tearfulness Inability to concentrate Increased use of nicotine, alcohol, and drugs |
| Fatigue Dizziness Change in menstrual cycle | Impulsive behavior Disturbed behavior Easily startled |

- Clients who are able to cope with stress have better health outcomes. Coping mechanisms that help decrease stress are
 - exercise: Improves oxygenation, decreases heart rate, improves sleep, increases appetite, and produces a general sense of well-being.
 - music therapy: Relieves tension and promotes relaxation.
 - humor: Improves oxygenation, improves circulation, and reduces aggression.
 - pet therapy: Reduces depression.
 - art therapy: Invigorates the senses and reduces depression.
- See Table 10–3 for common stress management techniques.
- Inappropriate coping processes include alcohol and drug use, hostile behavior, denial, avoidance, and distancing.
- People who have hope, a strong sense of self, and effective support systems are better equipped to handle physical and psychosocial stressors.
- Stress is the wear and tear of life on an individual. Prolonged or unrelenting stress leads to anxiety.
- When a client encounters a stressful situation, three stages of reaction to stress occur: the alarm reaction stage, the resistance stage, and the exhaustion stage.
- In the alarm reaction stage, the stress stimulates the adrenal glands to produce adrenalin, which is needed for the “fight or flight” response.
- In the resistance stage, blood is shunted away from the digestive tract to areas needed for defense. Heart rate and respirations increase to circulate highly oxygenated blood to the muscles. If the client adapts to stress, the body relaxes and the systemic responses abate.
- In the exhaustion stage, the client fails to adapt to stress, depleting physical and emotional energy. As a result, the client develops anxiety, which may be classified as mild, moderate, severe, or panic.

Table 10–3 Common Stress-Management Techniques

| Stress-Management Technique | Components |
|-------------------------------|---|
| Relaxation | Rhythmic breathing, reduced muscle tension, altered state of consciousness |
| Meditation | Quiet surroundings, passive attitude, comfortable position, and a word or mental image on which to focus |
| Anticipatory guidance | Teaching to prepare the client for an unfamiliar or painful event; anticipatory socialization to prepare for a new role, such as parenthood |
| Guided imagery | Creation of a mental image, concentration on that image, decreased response to stimuli, such as painful stimuli |
| Biofeedback | Measurement device to measure mental control of the autonomic nervous system to control body responses, such as blood pressure, heart rate, and headaches |
| Progressive muscle relaxation | Tensing and releasing of muscles in sequence |
| Yoga | Combines rhythmic breathing and tensing and releasing of muscles |

- Severe anxiety elicits cognitive, psychomotor, and physiologic responses, which include reduced perceptual fields, difficulty with problem-solving and completing tasks, feelings of dread, crying, headache, nausea and vomiting, tachycardia, chest pain, and ritualistic behaviors.
- Panic results in distorted perceptions, loss of rational thought, decreased ability to verbally communicate, delusions, hallucinations, suicidal thoughts, and dilated pupils. When a client is in a state of panic, the client’s safety is a priority; immediate medical intervention is required.
- Without intervention, continued anxiety may cause both mental as well as physical illnesses.
- Stress precipitates adjustment disorders—feelings of depression or anxiety or combined depression and anxiety. Clients with an anxiety-adjustment disorder experience anxious feelings, nervousness, and worry.
- Anxiety-adjustment disorder can cause or worsen physical illness.
- Antidepressants, therapy, and support systems are beneficial in treating anxiety-adjustment disorder.

Client teaching for self-care

- Teach clients that spiritual components contribute to the holistic view of care
- Teach clients to recognize stressors and skills to manage the stressors
- Demonstrate relaxation techniques and their purpose in reducing stress
- Teach the client, family, and significant others to seek professional help if the client experiences panic

SUPPORT SYSTEMS

- Support systems lead people to believe they are loved, cared for, esteemed and valued, and belong to a network of communication and mutual obligation.
- Support systems provide emotional support that helps an individual identify and verbalize feelings, maintain a positive self-concept, and establish new relationships and social roles.
- Sources of support include families, significant others, friends, neighbors, religion, community organizations and resources, and support groups.
- Social networks assist with management of stress, thus improving health outcomes. Families and significant others provide love, a sense of sharing the burden, and information that helps the nurse in developing the plan of care.
- Friends and neighbors offer guidance, humor, and validation of feelings.
- Religion confirms values, beliefs, and spirituality.
- Community resources offer financial assistance, counseling, transportation, and education.
- Support groups provide an accepting environment, allowing exploration of problem-solving methods and implementation of new coping skills.
- Other support systems include encounter groups, assertiveness-training programs, and consciousness-raising groups.
- People who are loners, or lack support systems, are at high risk for ineffective coping with failure and illness.
- The nurse's role is to encourage client, family, and significant others' involvement in the health care decision-making process while promoting the independence of these individuals.
- The nurse uses therapeutic communication to evaluate client, family, and significant others' feelings about the diagnosis, illness, and treatment plan.

FAMILY DYNAMICS

- Family is defined as two or more people who are emotionally involved with each other and live together.
- Family is concerned with all aspects of a person's life, including meeting basic human needs to promote health.
- Researchers state that the role of the family is to help meet the basic human needs (health and survival) of its members while also meeting the needs of society.
- The nurse must respect all family structures and remember that there is no absolute "right" or "wrong" family structure. See Table 10-4 for the different types of family structures.
- Individuals with chronic mental illness who live at home with family drain financial, emotional, and personal resources, thus impacting the family's well-being.
- Stressors such as divorce, loss of employment, or death impact family functioning.
- The nurse assesses family dynamics by observing the communication and coping mechanisms utilized by the family.
- The nurse provides resources, such as group counseling, to assist in family functioning.

Assessment Alert

Ask all clients about their family structure to determine how the family will cope with the impact of the health condition. This information guides the nurse in creating each client's plan of care.

FAMILY FUNCTIONS

- Family functions are necessary for the growth of the individual and the family and for the maintenance of health.
- Physically, the family provides a safe, comfortable environment necessary for growth, development, and rest.
- The adults of the family use management skills to establish rules, make decisions about resources and finances, and plan for the future.

Table 10–4 Family Structures

| Nuclear Family | Extended Family | Blended Family | Single-Parent Family | Other |
|--|--|---|--|---|
| Also called “traditional family” | Considered nontraditional | Also a “traditional family” | Considered nontraditional | Cohabiting family: Comprised of two unmarried adults living together |
| Comprised of two parents and their children; couples without children; or couples with grown children who no longer live at home | Comprised of aunts, uncles, cousins, and grandparents who live in close proximity to the nuclear family. | Comprised of parents who bring unrelated children from previous relationships together to form a new family | Comprised of one parent and his or her children | Binuclear family: Comprised of divorced parents who share joint custody of children |
| Parents may be heterosexual or homosexual; married or in a committed relationship | Extended family has their own nuclear family; the nuclear families within the extended family offer support to each other and share responsibilities | Parents may be heterosexual or homosexual; married or in a committed relationship | Parent may be separated, divorced, widowed, or never married | Dyadic nuclear family: Couple chooses not to have children |
| Comprised of biologic parents and children, adoptive parents and children, surrogate parents and children, or stepparents and children | Extended family may offer support to the nuclear family: child care, business partnerships, and sharing of household responsibilities | Comprised of parent and step-parent and biological and step-children | Majority are African-American and headed by women | Single adults: May not live with others, but are part of a family of origin |
| All members live in the same house until the children leave home as young adults | Some members of the extended family may live with the nuclear family; most commonly, a grandmother who lives with her children and grandchildren | All members live in the same house until the children leave home as young adults | Challenges include role shifts and financial concerns | Pets as family members: Many members of traditional and nontraditional families view pets as family members |

- The reproductive function of the family is to raise children and set boundaries to distinguish the roles of adults and children within the family.
- Communication enhances the teaching of family beliefs, values, attitudes, and coping mechanisms.
- Providing emotional comfort and support helps family members endure stress and guides problem solving.
- Families teach their young the acceptable behaviors and cultural norms that enable them to interact with society.
- Family members can be in several different developmental stages simultaneously, thus putting them at increased risk for altered health. See Table 10–5 for the risk factors that may alter family health.

FAMILY RISK FACTORS

- Family members can be placed at risk for health problems due to patterns of behavior, the environment in which the family lives, and genetic factors.

Nursing Intervention Alert

Nursing interventions for the family in health crisis include teaching using therapeutic communication skills, knowledge of family dynamics, referral to community financial and health care resources, and involvement of family members in the plan of care and implementation of care.

Table 10–5 Risk Factors for Altered Family Health

| Biological Risks | Developmental Risks | Psychosocial Risks | Environmental Risks | Lifestyle Risks |
|-----------------------------------|--|---|--|---|
| Genetic predisposition to disease | Unmarried adolescent mothers | Inadequate income and resources, especially related to child care | Exposure to environmental toxins and pollutants including water and food pollution | Alterations in nutrition: more or less than body requirements |
| Birth defects | Older adults living alone or on a fixed income | Conflict among family members | Lack of knowledge to provide safe, clean living conditions | Chemical dependency: alcohol, drugs, and nicotine |
| Mental retardation | Families who have new babies | Lack of social support systems | Lack of resources to access healthcare | Inadequate hygiene: dental care |

Client teaching for self-care

- Teach clients and their families how to access community resources to provide social support
- Teach clients and their families effective communication skills to strengthen family support
- Teach families the difference between coping mechanisms and defensive mechanisms to strengthen family communication and support
- Teach families stress management skills, relaxation techniques, and effective problem-solving skills to promote harmony
- Teach families to recognize risk factors and to access community resources in the presence of conflict or risk for altered psychosocial health
- Teach families techniques to implement roles and divide responsibilities among family members

COPING MECHANISMS

- Individuals use many methods to cope with their problems.
- The concept of coping is used interchangeably with the terms adaptation, defense, mastery, and adjustive reactions.
- Coping involves all of the behaviors individuals use, consciously or unconsciously, to deal with stress from threats to psychological integrity.
- When the stress involves the ego, coping reactions include complicated ego-defense mechanisms.
- Defense mechanisms are important for survival and are used in the process of coping (Table 10–6).
- Defense mechanisms are considered pathologic when they are used to deny, falsify, or distort perceptions of reality.
- Attack reactions attempt to overcome the stress-causing obstacle.
- Flight, withdrawal, or fear reactions include physical and psychological maneuvering to get rid of the threat.
- Compromise or substitution reactions occur when attack or flight options are not possible. These reactions involve accepting substitute goals or changing values.
- Tension-reducing reactions include aggression, regression, withdrawal, and repression.
- Individuals cope by crying, exercising, talking over their feelings, becoming angry or defensive, or withdrawing from a situation.
- These coping mechanisms are effective in maintaining emotional stability.

Assessment Alert

The following assessments are important to psychosocial health of the client, family, and significant others: support systems, available resources, psychological response to illness, and emotional reaction to illness.

- Past coping mechanisms may no longer be effective in adjusting to stressors later in life. See Table 10–7 for nursing actions to promote psychosocial health in older adults.

Table 10–6 Common Defense Mechanisms

| Defense Mechanism | Definition | Example |
|----------------------------|--|---|
| Acting out | Use of action to deal with stress | A husband learns his wife is having an affair, and then goes to a bar where he engages in two fistfights. |
| Affiliation | Turning to others for support in times of conflict | A mother moves to the same city as her adult daughter after loss of a job. |
| Altruism | The gratifying self-serving of others to manage stress | Nurses serve others for unselfish reasons and gain gratification through giving. |
| Anticipation | Considering options and solutions in anticipation of future events | An athlete spends the hours before a race mentally rehearsing her race technique. |
| Compensation | Excelling in one area to counterbalance deficiencies in another area | A child with a heart condition that prohibits participation in sports excels in playing the violin. |
| Denial | Refusal to face an unpleasant reality as it exists | A client refuses to accept her diagnosis of multiple sclerosis. |
| Displacement | Placing feelings of hostility onto something or someone less threatening in the environment | After a man loses his job, he comes home and kicks the dog. |
| Fantasy | Substituting frustrated desires or relationships with daydreams and imagery | An unhappily married woman with four children imagines a life as a wildlife photographer. |
| Help-rejecting complaining | Repeated requests for help and advice from others that is then rejected; this behavior disguises covert feelings of hostility for others | A husband constantly complains of back pain to his wife, but refuses to take the wife's advice to receive medical treatment. |
| Humor | Emphasis on the amusing aspects of a situation | A client undergoing chemotherapy smiles and laughs when telling the nurse that she was so tired after the last treatment that she crawled into bed with her raincoat and rain boots still on. |
| Identification | Unconscious mimicking of an admired person | A high school girl dresses and speaks like her peer group's leader. |
| Intellectualization | Overuse of abstract thinking to minimize painful feelings | An alcoholic speaks of the illnesses associated with alcoholism to an Alcoholics Anonymous group, but never discusses his own fears associated with his alcoholism. |
| Introjection | Treating something that is outside the self as if it is inside the self | A child who fears monsters becomes a monster during play. |
| Isolation of affect | Separation of feelings from associated thoughts | A rape victim displays no emotion as she recounts the details of the rape to the police. |
| Omnipotence | Feeling or acting as if one have special powers or superiority over others | A scientist treats his team condescendingly. |
| Passive aggression | Indirect expression of aggression | A physically abused child repeatedly “forgets” his daily chores and begs forgiveness. |
| Projection | Attributing one's own unacceptable characteristics to another person or group | An egocentric teacher complains of her students' narcissism. |
| Rationalization | Using a socially acceptable explanation to justify unpleasant consequences | An obese client tells the nurse that he does not wish to be thin. |
| Reaction formation | Exaggerated adoption of opposite behaviors to those that are unpleasant | A couple that does not want its child before it is born becomes overly protective after the birth. |

(continued on next page)

Table 10–6 (continued from previous page)

| Defense Mechanism | Definition | Example |
|-------------------|---|---|
| Regression | Returning to an earlier level of adaptation | An elderly client dresses like a child and insists on playing dolls. |
| Self-assertion | Direct expression of thoughts and feelings that are not manipulative or intimidating | A client informs the nurse that he appreciates the nurse's care. |
| Self-observation | Reflection of one's behavior, thoughts, and feelings, followed by appropriate behavior. | A client thinks about why she feels depressed, and then shares these feelings in group therapy. |
| Splitting | View of self and others as all good or all bad | A psychiatric client views the nurses in the facility as angels who are kind, while viewing the physicians as devils who wish to change the client's behavior and thinking. |
| Sublimation | Modification of a socially unacceptable impulse into an acceptable behavior | An aggressive young man becomes a star football player. |
| Suppression | Conscious inhibition of a thought or action | A victim of a near-fatal automobile accident does not think of the accident as he drives to work everyday. |
| Undoing | Attempt to dispel unacceptable behavior | An elderly client yells at the nurse, and then tells the nursing supervisor that the nurse is an outstanding employee. |

Table 10–7 Psychosocial Health Promotion in Older Adults

| Nursing Actions |
|---|
| Assess for abnormal responses to the aging process: anger, isolation, denial, and depression. |
| Be aware of major stressors: illness, hospitalization, and changes in living arrangements. |
| Assess support systems including cultural beliefs, spiritual values, and rituals. |
| Encourage use of support systems: family, friends, community resources, and pets to increase stimulation. |
| Set mutual goals; encourage the client to participate in the decision-making process. |
| Encourage life review and reminiscence. |
| Encourage self-care. |
| Consider the client's background, capabilities, interests, values and beliefs, culture, and lifestyle when planning care. |
| Facilitate individual, group, and family therapy when appropriate. Incorporate therapy goals into the plan of care. |

Client teaching for self-care

- Teach older adults to focus on accomplishments instead of decline, to promote self-esteem
- Teach the older client that antidepressants may take 4–6 weeks to be effective in decreasing symptoms of depression
- Teach cross-cultural clients the importance of their heritage in self-care behaviors
- Teach clients how to differentiate coping mechanisms from defense mechanisms
- Teach client that coping mechanisms such as crying, kicking a chair, and yelling are normative behaviors
- Teach client that hitting others, hurting oneself, and destroying property are ineffective coping mechanisms
- Teach client that controlling anger by counting to 10, inhaling deeply through the nose and exhaling through the mouth, and diverting attention to another task, such as exercise, are healthy coping mechanisms

SITUATIONAL ROLE CHANGES

- Individuals play many roles both at home and in society.
- Role performance is a measure of how successfully an individual performs in a designated role.
- Role performance is easily compromised by illness and injury.
- An alteration in an individual's role performance can result in a situational role change.

Table 10–8 Disturbances in Self-Concept

| Self-Concept Disturbance | Causes | Nursing Interventions |
|------------------------------|---|--|
| Disturbed body image | Weight changes: extreme thinness or obesity Changes in body image: amputation, mastectomy, scars, burns, colostomy, disfigurement, loss of vision, alopecia, and paralysis Use of ancillary devices: braces, canes, casts, and wheelchairs Development of secondary sex characteristics: aggressive development, delayed development | Allow client to express feelings about body image. Explore with the client perceptions of altered body image. Support the client through stages of grief, loss, and mourning. Implement play therapy with children to work through feelings of grief. Use open and accepting body language when interacting with clients. Encourage the client to participate in self-care activities. Intervene if the client's significant others negatively influence the client. Notice and voice positive physiologic characteristics. |
| Low self-esteem | Feelings of powerlessness, helplessness, and frustration Feelings of incompetence and inadequacy Feeling unloved or unapproved of by significant others Failure to live according to personal values or moral code Deficient knowledge: poor parenting skills, illiteracy | Allow the client to explore alternatives and make decisions. Listen to the client openly without instilling judgment. Teach the client to replace negative self-talk or thoughts with positive affirmations. Explore with the client alternative ways of viewing the same situation. |
| Ineffective role performance | Role conflict Role fatigue Rejection of role Multiple life stressors Physical and mental health changes Decline in motivation, commitment Decline in independence Loss of key roles: separation, retirement, or death of spouse or child | Allow client to express feelings about ineffective role performance. Facilitate grieving over valued roles that can no longer be performed. Explore new roles with the client. Facilitate options to alleviate stress and foster independence. |
| Disturbed personal identity | Unresolved crisis: divorce, loss of job, and abusive relationship Declining physical, mental, or sensory abilities Rejection by peers or group | Evaluate the client's coping strategy. Treat causes of disturbed personal identity: pain, substance abuse, and abusive living arrangement. |

- Role changes may be due to death of a parent, spouse with chronic illness, or the aging process.
- Individuals whose roles are altered are at risk for disturbances in self-concept.
- Disturbances in self-concept may include the following diagnostic labels: *disturbed body image*, *chronic low self-esteem* or *situational low self-esteem*, *ineffective role performance*, and *disturbed personal identity*. See Table 10–8 for examples of disturbances in self-concept and related nursing interventions.
- The nurse's role is to assess client, family, and significant others' role changes, whether temporary or permanent.
- The nurse provides support to the client and/or family in coping with a new diagnosis, ongoing stressors, or role change.
- The nurse evaluates whether the client, family, and significant others have successfully adapted to situation role changes.

UNEXPECTED BODY-IMAGE CHANGES

- Body image is the subjective view an individual has about his or her physical appearance including body shape, size, weight, and proportions.
- Body-image disturbances are expected with any alteration in bodily appearance, structure, or function.
- See Table 10–8 for the causes and nursing interventions associated with body-image changes.

GRIEF AND LOSS

- Grief is the painful psychologic and physiologic response to any real or perceived loss.
- Grief accompanies any significant loss: death of a loved one and loss of self-esteem, identity, dignity, or self-worth.
- The manifestations of grief are found in Table 10–9.
- Grief has three basic stages: avoidance, confrontation, and reestablishment.
- Reestablishment is the gradual decrease of symptoms and adjustment to a different life.
- Kubler-Ross identified the five stages of grief as
 - denial: shock and disbelief regarding the loss
 - anger: expression of hostility which may be directed toward God, friends, relatives, or health care providers
 - bargaining: making attempts to negotiate to prevent or remove the loss
 - depression: sense of sadness, emptiness over the loss
 - acceptance: coming to terms with the loss
- The types of grief are anticipatory, acute, and complicated (Table 10–10).
- Factors influencing the grieving process include
 - culture and religion: Bereavement rituals have roots in the cultural and spiritual background of the person experiencing the grief and influences
 - the manner of public expression of the grief whether it is loud and expressive or quiet and hidden
 - the acceptable length of bereavement
 - outward display such as wearing black garments
 - funeral and burial rites and rituals
 - significance of the loss or death
 - cause of the loss or death
 - gender: In general, women are more overt with their expressions of grief and are more accepting of support
 - age and development: Ability to perceive permanence of death and the process in dealing with it differ according to age.
 - Infancy to 5 years—death is temporary and reversible
 - 5–9 years—develops sense of finality of death, believes own death can be avoided and may believe loss is related to own thoughts and actions
 - 9–12 years—death is inevitable, begins to understand own mortality
 - 12–18 years—may seem to reach “adult” perception of death but is emotionally unable to accept it
 - 18–45 years—attitude toward loss or death influenced by the religious and cultural beliefs
 - 45–65 years—accepts own mortality, experiences more deaths of close family members and peers
 - 65+ years—death may have multiple meanings ranging from freedom from pain to being with already deceased loved ones

Table 10–9 Manifestations of Grief

| Physical Manifestations | Cognitive Manifestations | Behavioral Manifestations | Affective Manifestations |
|--|--|---|---|
| Weakness, anorexia, shortness of breath, dry mouth, gastrointestinal disturbances | Preoccupation with the deceased: conversations with the deceased | Inability to perform basic activities of daily living | Feelings of sadness, guilt, anger, loneliness, and helplessness |
| Fatigue, exhaustion, insomnia | Difficulty concentrating, focusing | Dragging through activities of daily living | Feelings of shock, disbelief, and denial |
| Decreased immune response | Disorientation to time and place | Old behavior patterns lose meaning | Impulse to use alcohol or drugs |
| Increased vulnerability to physical illness: myocardial infarction, hypertension, rheumatoid arthritis, malnutrition | Hallucinations: hearing voices, seeing the deceased | Despair, hopelessness | Loss of self-esteem; identity and role confusion |
| Increased vulnerability to mental illness: depression, alcohol abuse, drug abuse | Long periods of time spent reminiscing | Restless, disorganized behavior | Feelings of ambivalence about living |

Table 10–10 Types of Grief

| Anticipatory Grief | Acute Grief | Complicated Grief |
|---|---|---|
| Grief associated with impending death or loss | Painful experience associated with loss | Beyond the point of “normal” grief: major depressive disorder; posttraumatic stress disorder (PTSD) |
| Associated with depression or family withdrawal from the client | No clear ending | Associated with unresolved issues in the relationship with the person who died |
| Allows the client and family time to adapt to anticipated loss | May recur with holidays, birthdays, or other milestones | May be felt by those who experience an abortion or miscarriage |

- Assessment of the grief process includes the grief experience of the mourner, factors that promote or inhibit working through the grief process, including cultural and religious norms, the mourner’s ability to implement cognitive, behavioral, and emotional coping strategies.

Assessment Alert

Loss and grief are personal: Each person proceeds through the grieving process differently and varying amounts of time are required.

- The plan of care for the person experiencing acute grief includes mobilizing personal and community resources, providing information about the grief process, and supporting the individual in grief work—means by which a person moves through the state of grieving, also known as bereavement.
- Table 10–11 discusses the nursing interventions associated with bereavement.

Practice Alert

Grief does not progress in an orderly manner through stages, but rather moves fluidly back and forth among the stages.

Think Smart/Test Smart

- Loss occurs when a valued person, object, or situation is changed or removed.
- Grief is the emotional reaction to loss. Bereavement is the state of grieving.

- Mourning is the period of acceptance of loss.
- Anticipatory grieving occurs when a person facing an impending loss begins to deal with the possibility of the loss or death.
- Dysfunctional grieving is related to the extended unsuccessful attempt to work through the process.

Table 10–11 Nursing Interventions for Bereavement

| | |
|---|---|
| Allow adaptive denial | Denial is beneficial for a period of time |
| Remind of importance of meeting own needs and assist when necessary | Offer food, encourage rest, advocate for a sleeping aid |
| Ensure safety and prevent violence | Assess for thoughts of suicide or plans to harm others |
| Explore previous coping strategies | Identify strategies that have been successful in the past and encourage their use |
| Encourage open expression of feelings | Validate positive and negative feelings associated with loss |
| Promote interactions with others | Encourage increased social support including referrals to community bereavement resources |
| Teach information associated with grief | Provide information about the physical, cognitive, behavioral, and affective responses to grief |
| Explore spiritual issues | Facilitate spiritual support by including the spiritual or religious leader of choice in the plan of care |

END-OF-LIFE CARE

- Death is defined as an irreversible cessation of circulatory and respiratory functions or of all functions of the entire brain, including the brain stem.
- Dying and death are unique to each individual.
- Physicians are usually responsible for deciding what, when, and how a client should be told about terminal illness.
- Palliative care is an approach to care for the seriously ill, which involves symptom management and psychosocial and spiritual support for diseases not responsive to treatment.
- Hospice is end-of-life care delivered in the client's home or a medical facility.
- Assisted suicide provides another person the means to end his or her own life.
- Terminal weaning is the gradual withdrawal of mechanical ventilation from a client with a terminal illness or irreversible condition with a poor prognosis.
- Palliative sedation differs from euthanasia in that its purpose is to relieve symptoms, not hasten death.
- The Dying Person's Bill of Rights ensures client safety, dignity, and care during the death process.
- Refer to Table 10–12 for the physiologic and psychosocial symptoms associated with dying.
- See Table 10–13 for the ethical and legal dimensions of end-of-life care.

- An organ donation consent card allows clients to donate functional organs, such as heart, corneas, liver, lungs, and kidneys.
- Assessment focuses on the client's and family's knowledge, perceptions, coping strategies, and resources.
- Table 10–14 discusses nursing interventions appropriate for dying clients and their families.

Table 10–13 Ethical and Legal Dimensions

| | |
|---|---|
| Advance Directives | Living will: provides specific instructions about the kind of health care that should be provided or foregone in particular situations. Durable power of attorney for health care: appoints an agent the client trusts to make decisions in the event of incapacity. |
| Do-Not-Resuscitate (DNR)/No-Code orders | No attempts are to be made to resuscitate a client who stops breathing or whose heart stops beating. |
| Comfort-Measures-Only order | The goal of treatment is comfortable, dignified death without implementation of life-sustaining measures. |
| Do-Not-Hospitalize order | Utilized by clients living in long-term care and assisted living facilities who do not wish to be hospitalized for aggressive treatments. |

Table 10–12 Physiologic and Psychosocial Symptoms of Dying

| Physiologic Symptoms | Psychosocial Symptoms |
|---|-----------------------|
| Inability to swallow | Denial and isolation |
| Decreased gastrointestinal and urinary tract activity | Anger |
| Bowel and bladder incontinence | Bargaining |
| Loss of motion, sensation, reflexes | Depression |
| Elevated temperature coupled with cold, clammy skin | Acceptance |
| Cyanosis | |
| Lowered blood pressure | |
| Irregular respirations; Cheyne–Stokes respirations | |

Table 10–14 Nursing Interventions at End of Life

| | |
|---|--|
| Communicate openly with the client and family regarding the dying process. | Provide necessary information for the client and family to engage in the decision-making process regarding end-of-life care. |
| Be cognizant of death-related beliefs and practices of clients of other cultures. | Facilitate spiritual care at the client's and family's request. |
| Manage client pain and dyspnea with pharmacological and nonpharmacological interventions. | Provide nutrition and hydration as indicated or when appropriate. |
| Provide a safe environment for clients who are weak, confused, or delirious. | Provide pharmacological and nonpharmacological interventions for the management of depression. |
| Identify situational role changes and provide support. | Provide after-death care and bereavement support to the family. |

Practice Alert

It is not unusual for clients to die when the family has stepped away from the bed side for a brief moment.

Client teaching for self-care

Teach

- the client about signs of disturbed self-concept and tools to improve self-concept, such as replacing negative thoughts with positive thoughts
- the client to recognize and verbalize negative thoughts and behaviors associated with body-image disturbances
- clients to decrease environmental stressors, such as turning off the television or radio during periods of sensory overload
- clients to change environments or engage in activity, if appropriate during periods of sensory deprivation
- clients the purpose of grief work and its benefit during bereavement
- the dying client and family members the signs and symptoms of impending death, if appropriate
- client's family that hearing is usually the last sense to diminish during the dying process. Encourage family to talk to the dying client
- the client's family about bereavement resources and support available in the community

WORKSHEET

MATCHING QUESTIONS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all):

- | | |
|-----------------------------|---|
| 1. ____ Stress | a. A technique for measuring mental control of body responses, such as blood pressure and heart rate |
| 2. ____ Introjection | b. Treating something that is outside the self as if it is inside the self |
| 3. ____ Self-assertion | c. Direct expression of thoughts and feelings that are not manipulative or intimidating |
| 4. ____ Displacement | d. Occurs when a member of a cultural group adapts to the new dominant culture in order to survive |
| 5. ____ Ethnocentrism | e. A search for the sacred; allows individuals to make sense of the cycle of life and death |
| 6. ____ Acculturation | f. Placing feelings of hostility onto something or someone less threatening in the environment |
| 7. ____ Cultural competence | g. Two or more people who are emotionally involved with each other; may live together |
| 8. ____ Denial | h. A "traditional family" comprised of parents who bring unrelated children from previous relationships together to form a new family |
| 9. ____ Regression | |
| 10. ____ Rationalization | |
| 11. ____ Repression | |
| 12. ____ Reminiscence | |

(continued)

- | | |
|------------------------------|--|
| 13. _____ Spirituality | i. The subjective view an individual has about his or her body shape, size, proportions, and weight |
| 14. _____ Coping | j. The painful psychological and physiological response to loss |
| 15. _____ Faith | k. Symptom management and psychosocial or spiritual support for diseases not responsive to treatment |
| 16. _____ Biofeedback | l. A condition which can cause changes in the body's normal balanced state resulting in illness |
| 17. _____ Family | m. Judging others by one's own standards of acting, believing, and thinking |
| 18. _____ Nuclear family | n. Specific instructions about the kind of health care that should be provided or withheld in particular situations |
| 19. _____ Blended family | o. The act of returning to a previous level of development |
| 20. _____ Body image | p. The process of keeping unacceptable ideas or impulses out of consciousness |
| 21. _____ Sensory perception | q. Type of group therapy used to treat depression in older adults |
| 22. _____ Self-esteem | r. The perception of one's competency, adequacy, or worth |
| 23. _____ Grief | s. The act of using socially acceptable or logical explanations to justify unpleasant thoughts or actions |
| 24. _____ Palliative care | t. A set of practice standards instituted by county health and mental agencies to ensure that all clients receive information with regard to education, background, and language |
| 25. _____ Advance directive | u. A "traditional family" comprised of two parents and their children |
| | v. The refusal to face an unpleasant reality |
| | w. Using conscious or unconscious behaviors to deal with stress |
| | x. The ability to draw on spiritual resources without requiring physical proof |
| | y. Provides another person with the means to end his or her own life |
| | z. The conscious process of selecting, organizing, and interpreting data from the senses into useful information |

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. Antidepressant drugs must be taken for _____ to _____ weeks before symptoms are relieved.
2. _____ is the unconscious mimicking of an admired person.
3. _____ is the attempt to dispel undesirable behavior.

4. When delivering care to cross-cultural clients, the nurse may require the use of an interpreter to ensure effective _____.
5. _____ is the expression of spirituality.
6. The two main types of stress are _____ and _____.
7. Teaching the client to prepare for an unfamiliar or painful event is called _____.
8. Aunts, uncles, and grandparents who live in close proximity to the nuclear family are called an _____.
9. A family that is comprised of divorced parents who share joint custody of children is called a _____ family.
10. Amputation, mastectomy, scars, burns, or other disfigurements may affect one's _____.
11. One who has feelings of inadequacy, incompetence, powerlessness, and frustration may be suffering from low _____.
12. Grief associated with impending death or loss is called _____.
13. _____ is the irreversible cessation of circulatory, respiratory, and brain functions.
14. A _____ for health care is an agent entrusted by the client to make decisions in the event of incapacity.
15. An order written by a physician which states that no attempts are to be made to resuscitate a client who stops breathing or whose heart stops beating is called a _____ order.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|-------|-------|
| 1. Having conversations with the dead person can be a part of normal grieving. | _____ | _____ |
| | T | F |
| 2. Praying with the client is an acceptable nursing intervention to meet the client's spiritual needs. | _____ | _____ |
| | T | F |
| 3. Suppression is the unconscious inhibition of a thought or action. | _____ | _____ |
| | T | F |
| 4. Withdrawal from the dying client is a normal manifestation of anticipatory grieving. | _____ | _____ |
| | T | F |
| 5. Culture is a shared system of beliefs, values, and behavioral expectations that influence daily living. | _____ | _____ |
| | T | F |
| 6. The purpose of cultural competence is to ensure that all clients receive care. | _____ | _____ |
| | T | F |
| 7. Defense mechanisms are important for survival and are used in coping. | _____ | _____ |
| | T | F |
| 8. Developmental stress is unpredictable and can occur at any time. | _____ | _____ |
| | T | F |
| 9. Grief does not progress in an orderly manner through stages. | _____ | _____ |
| | T | F |
| 10. A couple who chooses not to have children is a binuclear family. | _____ | _____ |
| | T | F |

APPLICATION QUESTIONS

1. Maintaining the psychosocial health of the client is an important aspect of caring for the elderly. Which nursing actions should be taken to promote the psychosocial health of the elderly client? (Select all that apply.)
 - a. Assess for abnormal responses to the aging process such as anger, isolation, or depression
 - b. Encourage the use of support systems such as friends and family
 - c. Encourage self-care
 - d. Facilitate individual, group, or family therapy when appropriate
2. During a seminar on coping skills, the nurse is asked about the beneficial effects of humor. Which is a documented beneficial effect of humor around which the nurse should frame his or her reply?
 - a. Lessened depression
 - b. Increased relaxation
 - c. Reduced aggression
 - d. Improved sleep
3. What is the priority nursing concern when a client is in a state of panic?
 - a. Maintenance of client safety
 - b. Identification of the precipitating factor
 - c. Preventing escalation of symptoms
 - d. Provision of privacy
4. A widow of 10 days says to the nurse from hospice who has called to invite her to a grieving support group meeting “I feel like I am losing my mind. I see my husband in the house, in the yard, sometimes even at the store. I even find myself talking to him about things that happen.” Which is the best response for the nurse to make?
 - a. “If these things are still going on in 3 months then you may need to worry about losing your mind but you don’t need to worry now.”
 - b. “That is a concern. Tell me more about what is going on with you.”
 - c. “I understand you find these events very disturbing but they are normal parts of the grieving process.”
 - d. “You need to relax; things will improve with time.”
5. A client admitted for an exploratory laparotomy states he has never been so anxious—that he feels out of control. Which symptoms or physical findings might accompany this anxiety? (Select all that apply.)
 - a. Headache
 - b. Nausea and vomiting
 - c. Tachycardia
 - d. Chest pain
6. When asked why she does not take the prescribed anti-hypertensive medication, a client states she does not take medication to lower her blood pressure because she cannot swallow pills and they probably would not work anyway because her body was just meant to have a higher blood pressure than other people. This is an example of the use of which defense mechanism?
 - a. Sublimation
 - b. Rationalization
 - c. Reaction formation
 - d. Intellectualization
7. To provide culturally competent care, the nurse must assess the client’s health care practices. Which factors should be included in the nurse’s assessment? (Select all that apply.)
 - a. Health-seeking behaviors
 - b. Responsibility for health care
 - c. Folklore practices
 - d. Barriers to health care
8. When preparing a health-promotion presentation on stress and anxiety, which information could the nurse consider including because it is true? (Select all that apply.)
 - a. Stress causes anxiety
 - b. Prolonged anxiety may cause illness
 - c. Severe anxiety may cause psychosis
 - d. Severe anxiety may cause suicidal thoughts
9. Coping involves all of the conscious and unconscious behaviors used by individuals to deal with stress. Coping mechanisms are effective in maintaining emotional stability. Which coping mechanism is an ineffective mechanism?
 - a. Hitting others
 - b. Crying
 - c. Yelling
 - d. Kicking a chair
10. A nurse is caring for a client who is undergoing a major life crisis. Which self-care concepts should the nurse teach the client to enhance the client’s ability to cope with the stress? (Select all that apply.)
 - a. Teach the client that exercise can be a healthy coping mechanism
 - b. Teach the client that hitting others, hurting oneself, and destroying property can be effective coping mechanisms

- c. Teach the client to control anger by counting to 10 and breathing deeply
 - d. Teach the client to divert his or her attention to another task
11. Holistic nursing care involves addressing clients' physical, mental, emotional, and spiritual needs. Which nursing intervention assists clients and their families in meeting their spiritual needs?
 - a. Ensuring the confidentiality of the client
 - b. Notifying the physician of the family's presence
 - c. Resolving conflicts between treatment and beliefs
 - d. Resolving conflicts between family members
 12. A preoperative nurse is preparing a client for surgery. While preparing the client, the nurse informs the client of what can be expected after surgery and how the client's pain will be controlled. Which stress-management technique is being utilized by the nurse?
 - a. Relaxation
 - b. Guided imagery
 - c. Progressive muscle relaxation
 - d. Anticipatory guidance
 13. A labor and delivery nurse is caring for a client who is in the second stage of labor. The nurse instructs the client to create and concentrate on a mental image to help her to manage the pain of labor. Which stress-management technique is being taught to the client?
 - a. Relaxation
 - b. Guided imagery
 - c. Progressive muscle relaxation
 - d. Anticipatory guidance
 14. A labor and delivery nurse is caring for a client who is in the final stage of labor. The nurse assists the client in focusing on the rhythm of her breathing and reducing muscle tension during her contractions. Which stress-management technique is being utilized by the nurse?
 - a. Relaxation
 - b. Guided imagery
 - c. Progressive muscle relaxation
 - d. Anticipatory guidance
 15. A nurse is planning for the discharge of an elderly client from a hospital. Which statement made by the client would indicate to the nurse that the client lacks a support system at home?
 - a. "My sister and her husband are taking me home today."
 - b. "My church members have been sending cards and letters while I have been in the hospital."
 - c. "I am not sure how I am going to get to the grocery store after I get home."
 - d. "My neighbor is retired. We visit and have our meals together every day."
 16. A family is defined as two or more people who are emotionally involved with each other and live together. A nuclear family is also called a "traditional family." Which families are considered nuclear families? (Select all that apply.)
 - a. Two biological parents and their children
 - b. Two parents and their adopted children
 - c. Two parents with grown children who no longer live at home
 - d. Two homosexual parents in a committed relationship and their adopted children
 17. A psychiatric nurse is caring for a client who is involved in an emotionally abusive relationship. The nurse knows that the client may be at risk for which disturbances in self-concept? (Select all that apply.)
 - a. Disturbed body image
 - b. Low self-esteem
 - c. Ineffective role performance
 - d. Disturbed personal identity
 18. Body image is the subjective view an individual has about his or her physical appearance including body shape, size, weight, and proportions. Which condition would put a client at risk for disturbed body image?
 - a. Urinary tract infection
 - b. Hyperlipidemia
 - c. Rheumatoid arthritis
 - d. High blood pressure
 19. A hospice nurse is caring for the family of a client who has died 30 minutes ago. Which type of grief is the family experiencing in response to their loss?
 - a. Anticipatory grief
 - b. Acute grief
 - c. Complicated grief
 - d. Palliative grief
 20. Loss occurs when a valued person, object, or situation is changed or removed. Grief is the painful psychological and physiological response to loss. Which phrase best describes the concept of mourning?
 - a. The emotional reaction to loss
 - b. The state of grieving
 - c. The period of acceptance of loss
 - d. The period of depression following a loss

(continued)

21. A client has just been admitted to a long-term care facility following the loss of a spouse. A nurse assesses the client and determines that the client is in a state of bereavement. Which nursing interventions for bereavement should be included in the client's plan of care? (Select all that apply.)
- Ensure safety and prevent violence
 - Promote interactions with others
 - Teach the client about the stages of grief
 - Facilitate spiritual support by including the client's spiritual or religious leader
22. Death is defined as the irreversible cessation of circulatory, respiratory, and brain functions. Which are physiologic symptoms of impending death? (Select all that apply.)
- Bowel and bladder incontinence
 - Anger
 - Decreased blood pressure
 - Cheyne–Stokes respirations
23. Death is defined as the irreversible cessation of circulatory, respiratory, and brain functions. Which are psychosocial symptoms of impending death? (Select all that apply.)
- Cyanosis
 - Denial
 - Bargaining
 - Acceptance
24. A living will provides specific instructions about the kind of health care that an individual desires in particular situations. Some individuals desire that no attempt be made to resuscitate them if they stop breathing or if their heart stops beating. Which statement is true regarding a Do-Not-Resuscitate Order (DNR)?
- A DNR states that an individual does not wish to be hospitalized for aggressive treatments
 - A DNR states that the goal of treatment is a comfortable, dignified death without implementation of life-sustaining measures
 - A DNR appoints an agent the client trusts to make decisions in the event of incapacity
 - A DNR must be written by a physician
25. A nurse in an intensive care unit is caring for a client who is dying. Which nursing interventions should be utilized in caring for the dying client and the client's family? (Select all that apply.)
- Encourage the family to talk to the dying client as hearing is usually the last sense to diminish during the dying process
 - Communicate openly with the client and family regarding the dying process
 - Provide a quiet, private environment for the client and family
 - Provide after-death care and bereavement support to the family

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all.)

- | | |
|--------------------------------|--|
| 1. <u> l </u> Stress | a. A technique for measuring mental control of body responses, such as blood pressure and heart rate |
| 2. <u> b </u> Introjection | b. Treating something that is outside the self as if it is inside the self |
| 3. <u> c </u> Self-assertion | c. Direct expression of thoughts and feelings that are not manipulative or intimidating |
| 4. <u> f </u> Displacement | d. Occurs when a member of a cultural group adapts to the new dominant culture in order to survive |
| 5. <u> m </u> Ethnocentrism | e. A search for the sacred; allows individuals to make sense of the cycle of life and death |
| 6. <u> d </u> Acculturation | |

- | | |
|-------------------------------------|--|
| 7. <u> t </u> Cultural competence | f. Placing feelings of hostility onto something or someone less threatening in the environment |
| 8. <u> v </u> Denial | g. Two or more people who are emotionally involved with each other; may live together |
| 9. <u> o </u> Regression | h. A “traditional family” comprised of parents who bring unrelated children from previous relationships together to form a new family |
| 10. <u> s </u> Rationalization | i. The subjective view an individual has about his or her body shape, size, proportions, and weight |
| 11. <u> p </u> Repression | j. The painful psychological and physiological response to loss |
| 12. <u> q </u> Reminiscence | k. Symptom management and psychosocial or spiritual support for diseases not responsive to treatment |
| 13. <u> e </u> Spirituality | l. A condition which can cause changes in the body’s normal balanced state resulting in illness |
| 14. <u> w </u> Coping | m. Judging others by one’s own standards of acting, believing, and thinking |
| 15. <u> x </u> Faith | n. Specific instructions about the kind of health care that should be provided or withheld in particular situations |
| 16. <u> a </u> Biofeedback | o. The act of returning to a previous level of development |
| 17. <u> g </u> Family | p. The process of keeping unacceptable ideas or impulses out of consciousness |
| 18. <u> u </u> Nuclear family | q. Type of group therapy used to treat depression in older adults |
| 19. <u> h </u> Blended family | r. The perception of one’s competency, adequacy, or worth |
| 20. <u> i </u> Body image | s. The act of using socially acceptable or logical explanations to justify unpleasant thoughts or actions |
| 21. <u> z </u> Sensory perception | t. A set of practice standards instituted by county health and mental agencies to ensure that all clients receive information with regard to education, background, and language |
| 22. <u> r </u> Self-esteem | u. A “traditional family” comprised of two parents and their children |
| 23. <u> j </u> Grief | v. The refusal to face an unpleasant reality |
| 24. <u> k </u> Palliative care | w. Using conscious or unconscious behaviors to deal with stress |
| 25. <u> n </u> Advance directive | x. The ability to draw on spiritual resources without requiring physical proof |
| | y. Provides another person with the means to end his or her own life |
| | z. The conscious process of selecting, organizing, and interpreting data from the senses into useful information |

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. Antidepressant drugs must be taken for 4 to 6 weeks before symptoms are relieved.
2. Identification is the unconscious mimicking of an admired person.
3. Undoing is the attempt to dispel undesirable behavior.
4. When delivering care to cross-cultural clients, the nurse may require the use of an interpreter to ensure effective communication.
5. Religion is the expression of spirituality.
6. The two main types of stress are developmental stress and situational stress.
7. Teaching the client to prepare for an unfamiliar or painful event is called anticipatory guidance.
8. Aunts, uncles, and grandparents who live in close proximity to the nuclear family are called an extended family.
9. A family that is comprised of divorced parents who share joint custody of children is called a binuclear family.
10. Amputation, mastectomy, scars, burns, or other disfigurements may affect one's body image.
11. One who has feelings of inadequacy, incompetence, powerlessness, and frustration may be suffering from low self-esteem.
12. Grief associated with impending death or loss is called anticipatory grief.
13. Death is the irreversible cessation of circulatory, respiratory, and brain functions.
14. A durable power of attorney for health care is an agent entrusted by the client to make decisions in the event of incapacity.
15. An order written by a physician which states that no attempts are to be made to resuscitate a client who stops breathing or whose heart stops beating is called a Do-Not-Resuscitate (DNR) order.

TRUE OR FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Having conversations with the dead person can be a part of normal grieving. *True*
2. Praying with the client is an acceptable nursing intervention to meet the client's spiritual needs. *True*
3. Suppression is the unconscious inhibition of a thought or action. *False*
Suppression is the conscious inhibition of a thought or action.
4. Withdrawal from the dying client is a normal manifestation of anticipatory grieving. *True*

5. Culture is a shared system of beliefs, values, and behavioral expectations that influence daily living. *True*
6. The purpose of cultural competence is to ensure that all clients receive care. *False*
The purpose of cultural competence is to ensure that all clients receive information about treatment in familiar ways.
7. Defense mechanisms are important for survival and are used in coping. *True*
8. Developmental stress is unpredictable and can occur at any time. *False*
Developmental stress is somewhat predictable and occurs through the normal stages of growth and development. Situational stress is unpredictable and can occur at any time.
9. Grief does not progress in an orderly manner through stages. *True*
10. A couple who chooses not to have children is a binuclear family. *False*
A couple who chooses not to have children is a dyadic nuclear family.

APPLICATION ANSWERS

1. Maintaining the psychosocial health of the client is an important aspect of caring for the elderly. Which nursing actions should be taken to promote the psychosocial health of the elderly client? (Select all that apply.)
- Assess for abnormal responses to the aging process such as anger, isolation, or depression
 - Encourage the use of support systems such as friends and family
 - Encourage self-care
 - Facilitate individual, group, or family therapy when appropriate

Rationale

Correct answers: a, b, c, and d.

All are appropriate nursing actions for promoting the psychosocial health of the elderly client.

2. During a seminar on coping skills, the nurse is asked about the beneficial effects of humor. Which is a documented beneficial effect of humor around which the nurse should frame his or her reply?
- Lessened depression
 - Increased relaxation
 - Reduced aggression
 - Improved sleep

Rationale

Correct answer: c.

Humor has been shown to reduce aggression. Pet therapy and art therapy reduce depression. Music therapy promotes relaxation. Exercise improves sleep.

3. What is the priority nursing concern when a client is in a state of panic?
- Maintenance of client safety
 - Identification of the precipitating factor
 - Preventing escalation of symptoms
 - Provision of privacy

Rationale

Correct answer: a.

Client safety is the priority. Identification of the precipitating factor may be important in understanding the event and in the prevention of recurrence. Preventing escalation of symptoms and provision of privacy are both important goals but do not take priority over client safety.

4. A widow of 10 days says to the nurse from hospice who has called to invite her to a grieving support group meeting “I feel like I am losing my mind. I see my husband in the house, in the yard, sometimes even at the store. I even find myself talking to him about things that happen.” Which is the best response for the nurse to make?
- “If these things are still going on in 3 months then you may need to worry about losing your mind but you don’t need to worry now.”
 - “That is a concern. Tell me more about what is going on with you.”
 - “I understand you find these events very disturbing but they are normal parts of the grieving process.”
 - “You need to relax; things will improve with time.”

(continued)

Rationale

Correct answer: c.

Conversations with a deceased loved one and “seeing” the person in familiar places are normal manifestations of grief. By saying “I understand you find these events very disturbing”, the nurse is acknowledging and accepting the client’s distress as worthy of concern. Response “a” minimizes the client’s concern and is trite in its manner. Response “b” although therapeutic in wording, is incorrect because the events are normal and not a cause for concern. Response “d” gives advice and utilizes a cliché.

5. A client admitted for an exploratory laparotomy states he has never been so anxious—that he feels out of control. Which symptoms or physical findings might accompany this anxiety? (Select all that apply.)
- ___ Headache
 - ___ Nausea and vomiting
 - ___ Tachycardia
 - ___ Chest pain

Rationale

Correct answers: a, b, c, and d.

Headache, nausea and vomiting, tachycardia, and chest pain can all be manifestations of severe anxiety. Cognitive and psychomotor symptoms of severe anxiety include reduced perceptual fields, difficulty with problem solving and completing tasks, feelings of dread, crying, and ritualistic behaviors. Caution must be taken not to interpret physiological signs and symptoms as indicators of anxiety when, in fact, there is a pathophysiological cause.

6. When asked why she does not take the prescribed antihypertensive medication, a client states she does not take medication to lower her blood pressure because she cannot swallow pills and they probably would not work anyway because her body was just meant to have a higher blood pressure than other people. This is an example of the use of which defense mechanism?
- Sublimation
 - Rationalization
 - Reaction formation
 - Intellectualization

Rationale

Correct answer: b.

Rationalization is the use of a socially acceptable explanation to justify unpleasant consequences. Sublimation is modification of a socially unacceptable impulse into an acceptable behavior. Reaction formation is the exaggerated adoption of opposite behaviors to those that are unpleasant. Intellectualization is the overuse of abstract thinking to minimize painful feelings.

7. To provide culturally competent care, the nurse must assess the client’s health care practices. Which factors should be included in the nurse’s assessment? (Select all that apply.)
- Health-seeking behaviors
 - Responsibility for health care
 - Folklore practices
 - Barriers to health care

Rationale

Correct answers: a, b, c, and d.

To provide culturally competent care, the nurse should assess the client’s health care practices, which include health-seeking behaviors, responsibility for health care, folklore practices, barriers to health care, and cultural responses to health and illness.

8. When preparing a health-promotion presentation on stress and anxiety, which information could the nurse consider including because it is true? (Select all that apply.)
- Stress causes anxiety
 - Prolonged anxiety may cause illness
 - Severe anxiety may cause psychosis
 - Severe anxiety may cause suicidal thoughts

Rationale

Correct answers: a, b, c, and d.

Stress causes anxiety, which, over time, may cause mental and/or physical illness. Severe anxiety can cause anxiety disorders and psychosis. Clients with severe anxiety may become suicidal.

9. Coping involves all of the conscious and unconscious behaviors used by individuals to deal with stress. Coping mechanisms are effective in maintaining emotional stability. Which coping mechanism is an ineffective mechanism?
- Hitting others
 - Crying
 - Yelling
 - Kicking a chair

Rationale

Correct answer: a.

Hitting others, hurting oneself, and destroying property are ineffective coping mechanisms. Crying, yelling, and kicking a chair are normative behaviors.

10. A nurse is caring for a client who is undergoing a major life crisis. Which self-care concepts should the nurse teach the client to enhance the client’s ability to cope with the stress? (Select all that apply.)
- Teach the client that exercise can be a healthy coping mechanism

- b. Teach the client that hitting others, hurting one-self, and destroying property can be effective coping mechanisms
- c. Teach the client to control anger by counting to 10 and breathing deeply
- d. Teach the client to divert his or her attention to another task

Rationale

Correct answers: a, c, and d.

Exercise, anger management, and diversion are healthy coping mechanisms, which may enhance the client's ability to cope with stress.

11. Holistic nursing care involves addressing clients' physical, mental, emotional, and spiritual needs. Which nursing intervention assists clients and their families in meeting their spiritual needs?
- a. Ensuring the confidentiality of the client
 - b. Notifying the physician of the family's presence
 - c. Resolving conflicts between treatment and beliefs
 - d. Resolving conflicts between family members

Rationale

Correct answer: c.

Nursing interventions to assist clients and their families to meet their spiritual needs include offering support, facilitating the client's practice of religion, praying with a client and family, contacting a spiritual counselor, and resolving conflicts between treatment and spiritual beliefs.

12. A preoperative nurse is preparing a client for surgery. While preparing the client, the nurse informs the client of what can be expected after surgery and how the client's pain will be controlled. Which stress-management technique is being utilized by the nurse?
- a. Relaxation
 - b. Guided imagery
 - c. Progressive muscle relaxation
 - d. Anticipatory guidance

Rationale

Correct answer: d.

Anticipatory guidance involves preparing the client for an unfamiliar or painful event, such as surgery. By informing the client of what to expect, the nurse reduces the client's stress regarding the event.

13. A labor and delivery nurse is caring for a client who is in the second stage of labor. The nurse instructs the client to create and concentrate on a mental image to help her to manage the pain of labor. Which stress-management technique is being taught to the client?

- a. Relaxation
- b. Guided imagery
- c. Progressive muscle relaxation
- d. Anticipatory guidance

Rationale

Correct answer: b.

The nurse is teaching the client to use guided imagery to help the client manage the pain of labor.

14. A labor and delivery nurse is caring for a client who is in the final stage of labor. The nurse assists the client in focusing on the rhythm of her breathing and reducing muscle tension during her contractions. Which stress-management technique is being utilized by the nurse?
- a. Relaxation
 - b. Guided imagery
 - c. Progressive muscle relaxation
 - d. Anticipatory guidance

Rationale

Correct answer: a.

The nurse is utilizing relaxation to help the client cope with the pain of labor. Relaxation technique utilizes rhythmic breathing, reduced muscle tension, and altered states of consciousness to help clients cope with stressors.

15. A nurse is planning for the discharge of an elderly client from a hospital. Which statement made by the client would indicate to the nurse that the client lacks a support system at home?
- a. "My sister and her husband are taking me home today."
 - b. "My church members have been sending cards and letters while I have been in the hospital."
 - c. "I am not sure how I am going to get to the grocery store after I get home."
 - d. "My neighbor is retired. We visit and have our meals together every day."

Rationale

Correct answer: c.

When the client expresses concern about getting to the grocery store after returning home from the hospital, the nurse should be aware that the client may not have a support system at home to help.

16. A family is defined as two or more people who are emotionally involved with each other and live together. A nuclear family is also called a "traditional family." Which families are considered nuclear families? (Select all that apply.)
- a. Two biological parents and their children
 - b. Two parents and their adopted children

(continued)

- c. Two parents with grown children who no longer live at home
- d. Two homosexual parents in a committed relationship and their adopted children

Rationale

Correct answers: a, b, c, and d.

All of these families are considered nuclear families.

17. A psychiatric nurse is caring for a client who is involved in an emotionally abusive relationship. The nurse knows that the client may be at risk for which disturbances in self-concept? (Select all that apply.)
- a. Disturbed body image
 - b. Low self-esteem
 - c. Ineffective role performance
 - d. Disturbed personal identity

Rationale

Correct answers: b and d.

Victims of emotional abuse are at risk for developing low self-esteem and disturbed personal identity.

18. Body image is the subjective view an individual has about his or her physical appearance including body shape, size, weight, and proportions. Which condition would put a client at risk for disturbed body image?
- a. Urinary tract infection
 - b. Hyperlipidemia
 - c. Rheumatoid arthritis
 - d. High blood pressure

Rationale

Correct answer: c.

Rheumatoid arthritis is a painful, inflammatory, autoimmune condition that results in the enlargement and/or gross disproportion of the joints. Clients who have rheumatoid arthritis are at risk for disturbances in body image.

19. A hospice nurse is caring for the family of a client who has died 30 minutes ago. Which type of grief is the family experiencing in response to their loss?
- a. Anticipatory grief
 - b. Acute grief
 - c. Complicated grief
 - d. Palliative grief

Rationale

Correct answer: b.

The family is most likely experiencing acute grief; a painful experience associated with loss that has no clear ending.

20. Loss occurs when a valued person, object, or situation is changed or removed. Grief is the painful psychological and physiological response to loss. Which phrase best describes the concept of mourning?

- a. The emotional reaction to loss
- b. The state of grieving
- c. The period of acceptance of loss
- d. The period of depression following a loss

Rationale

Correct answer: c.

Mourning is the period of acceptance of loss.

21. A client has just been admitted to a long-term care facility following the loss of a spouse. A nurse assesses the client and determines that the client is in a state of bereavement. Which nursing interventions for bereavement should be included in the client's plan of care? (Select all that apply.)
- a. Ensure safety and prevent violence
 - b. Promote interactions with others
 - c. Teach the client about the stages of grief
 - d. Facilitate spiritual support by including the client's spiritual or religious leader

Rationale

Correct answers: a, b, c, and d.

All of the nursing interventions should be included in the client's plan of care.

22. Death is defined as the irreversible cessation of circulatory, respiratory and brain functions. Which are physiologic symptoms of impending death? (Select all that apply.)
- a. Bowel and bladder incontinence
 - b. Anger
 - c. Decreased blood pressure
 - d. Cheyne–Stokes respirations

Rationale

Correct answers: a, c, and d.

Bowel and bladder incontinence, decreased blood pressure, and Cheyne–Stokes respirations are all physiologic symptoms of impending death. Anger is a psychosocial sign of impending death.

23. Death is defined as the irreversible cessation of circulatory, respiratory, and brain functions. Which are psychosocial symptoms of impending death? (Select all that apply.)
- a. Cyanosis
 - b. Denial
 - c. Bargaining
 - d. Acceptance

Rationale

Correct answers: b, c, and d.

Denial, bargaining, and acceptance are all psychosocial symptoms of impending death. Cyanosis is a physiologic symptom of dying.

24. A living will provides specific instructions about the kind of health care that an individual desires in particular situations. Some individuals desire that no attempt be made to resuscitate them if they stop breathing or if their heart stops beating. Which statement is true regarding a Do-Not-Resuscitate Order (DNR)?
- A DNR states that an individual does not wish to be hospitalized for aggressive treatments
 - A DNR states that the goal of treatment is a comfortable, dignified death without implementation of life-sustaining measures
 - A DNR appoints an agent the client trusts to make decisions in the event of incapacity
 - A DNR must be written by a physician

Rationale

Correct answer: d.

A Do-not-Resuscitate order must be written by a physician. A Do-Not-Hospitalize order states that an individual does not wish to be hospitalized for aggressive treatments. A Comfort-Measures-Only order states that the goal of treatment is a comfortable, dignified death with-

out implementation of life-sustaining procedures. A durable power of attorney appoints an agent the client trusts to make decisions in the event of incapacity.

25. A nurse in an intensive care unit is caring for a client who is dying. Which nursing interventions should be utilized in caring for the dying client and the client's family? (Select all that apply.)
- Encourage the family to talk to the dying client as hearing is usually the last sense to diminish during the dying process
 - Communicate openly with the client and family regarding the dying process
 - Provide a quiet, private environment for the client and family
 - Provide after-death care and bereavement support to the family

Rationale

Correct answers: a, b, c, and d.

All of the nursing interventions are appropriate when caring for a dying client and his or her family.

This page intentionally left blank

Topics: **Therapeutic Communication**
Therapeutic Environment
Behavioral Interventions
Crisis Intervention

| | | | |
|-----------------------------|-----|----------------------------|-----|
| ▸ Behavioral Interventions | 270 | ▸ Therapeutic Relationship | 269 |
| ▸ Crisis Intervention | 271 | ▸ Therapeutic Environment | 269 |
| ▸ Therapeutic Communication | 265 | | |

The nurse plays an important role in promoting and maintaining the psychosocial integrity of the client, family, and significant others. The nurse's success depends largely on the use of therapeutic communication, establishment of a

therapeutic relationship, promotion of a therapeutic environment, implementation of behavioral interventions, and appropriate management of crises.

THERAPEUTIC COMMUNICATION

- Therapeutic communication is the foundation of an effective nurse–client relationship; it helps reduce stress, encourage insight, and support problem solving.
- Therapeutic communication involves both verbal and nonverbal communication.
- The nurse's use of therapeutic communication with clients and other nurses is essential for effective use of the nursing process. See Table 11–1 for the communication factors that influence the steps of the nursing process.
- The nurse builds a rapport with clients to further the nurse–client relationship. Good rapport facilitates open communication. See Table 11–2 for factors that promote trust in the nurse–client relationship.
- The nurse promotes trust by respecting the client's personal values, beliefs, and culture.
- The nurse maintains the client's culture by providing a language interpreter and including other members of the health care team who share the client's culture to assist in providing care.
- The nurse develops and maintains therapeutic relationships with the client, family, and significant others by allowing ample time for communication. He/she

Table 11–1 Communication Factors of the Nursing Process

| Nursing Process Step | Communication Factors |
|----------------------|--|
| Assessment | <ul style="list-style-type: none"> • Verbal and nonverbal communication is gathered. • Data enhances the client history and physical examination. • Data is passed on to appropriate team members through oral and written communication. |
| Nursing diagnosis | <ul style="list-style-type: none"> • Nurse communicates nursing diagnoses to other nursing professionals through written and spoken words. |
| Planning | <ul style="list-style-type: none"> • Communication among the client, nurse, and other health care team members occurs. • Oral and written communication is used to meet objectives and goals of the plan of care. |
| Implementation | <ul style="list-style-type: none"> • Verbal and nonverbal communication is used to teach, counsel, and support clients and their families. • The client communicates his/her ability or inability to meet targeted objectives. • Implementation of the plan of care is documented in the client's record. |
| Evaluation | <ul style="list-style-type: none"> • Client verbal and nonverbal cues verify whether client goals and objectives are achieved. • Communication guides revision of the plan of care. |

communicates and delivers care in an unhurried and calm fashion.

- The nurse uses active listening, silence, touch, and humor to facilitate communication with the client, family, and significant others.
- Open-ended questions by the nurse encourage free verbalization from the client. This provides the nurse with specific, additional information that forms a basis for the plan of care.
- Therapeutic communication techniques provide support to the client, family, and significant others. See Table 11–3 for therapeutic communication techniques.
- Barriers to therapeutic communication negatively impact the nurse–client relationship. See Table 11–4 for barriers to therapeutic communication.
- Impaired verbal communication (NANDA nursing diagnosis) can affect every aspect of the client's life.
 - Impaired verbal communication is the state in which an individual experiences a decreased or absent ability to use or understand human language.
 - Communication in the older adult may be affected by

- aphasia: the inability to recall words, understand what others are saying, or produce speech,
 - dysarthria: the inability to produce clear speech sounds,
 - voice problems: due to malfunction or removal of the larynx (voice box),
 - hearing impairment: presbycusis (hearing loss due to aging process); may hear speech, but is unable to understand distinct words or sounds,
 - other problems: memory loss, disorientation, loss of thought organization.
- Clients with special needs require specific communication techniques.
 - Visually impaired: Speak in a normal tone of voice; explain the reason for touching the client before doing so; keep the call light within easy reach; clean eyeglasses and confirm contacts are in place.
 - Hearing impaired: Face the client while speaking; demonstrate or pantomime ideas as appropriate; write ideas or use sign language; clean hearing aids and confirm proper placement.
 - Cognitively impaired: Maintain eye contact; keep communication simple and concrete; avoid open-ended questions; be client and allow time for the client's responses.
 - Unconscious client: The client can most likely hear even though there is no apparent response; assume the client can hear you; talk in a normal tone of voice; speak with the client before touching.
 - Client with a physical barrier (laryngectomy or endotracheal tube): Select a simple means of communication, such as eye blinks or hand squeezes; ensure that family and significant others are able to utilize the selected communication technique; allow time for the client's responses; ensure the client has an effective means of signaling for assistance (call bell or alarm).
 - Non-English speaking clients: Use an interpreter; speak in a normal tone of voice; speak in simple sentences; demonstrate or pantomime ideas; use accepting non-verbal communication cues.

Nursing Intervention Alert

Clients suspected of a speech, language, or hearing deficit should be referred to a speech—language pathologist or audiologist.

Client teaching for self-care

The nurse teaches

- the client, family, and significant others the benefit of communicating in a therapeutic manner.

Table 11–2 Trust Builders in the Nurse–Client Relationship

| Trust Builder | Rationale | Nursing Action |
|-------------------------|---|---|
| Specific objectives | Achieve a meaningful encounter with the client | <ul style="list-style-type: none"> • Perform a head-to-toe physical assessment • Discuss the client's feelings about a new diagnosis |
| Comfortable environment | Client and nurse comfort promotes interaction | <ul style="list-style-type: none"> • Provide proper lighting, a moderate temperature, and a relaxed, unhurried atmosphere |
| Privacy | Ensures a sense of security | <ul style="list-style-type: none"> • Draw curtains around the client's bed • Stand close to the head of the bed while speaking to the client in order to prevent conversations from being overheard by others |
| Confidentiality | Promotes a sense of security | <ul style="list-style-type: none"> • Inform the client who on the health care team will have access to the client's medical record. |
| Client-centered focus | Facilitates trust and decreases anxiety | <ul style="list-style-type: none"> • While inserting a Foley catheter, calm the client's anxiety with therapeutic communication instead of telling the client to quit distracting the nurse with conversation. |
| Nursing observations | Validates information | <ul style="list-style-type: none"> • Observe the client's hand shaking nervously as the client denies feelings of anxiety. |
| Conversation pacing | Decreases anxiety; assures complete information is gathered | <ul style="list-style-type: none"> • Allow an elderly client plenty of time to answer questions related to the health history |
| Personal space | Decreases anxiety | <ul style="list-style-type: none"> • Use touch while speaking to a visually impaired client |
| Pleasantness | Places the client at ease | <ul style="list-style-type: none"> • Smile • Look the client in the eye when speaking • Offer warm greetings |
| Respect | Facilitates open communication | <ul style="list-style-type: none"> • Offer open, frank communication without prejudice • Respect the client's culture, values, and beliefs by providing for a language interpreter as appropriate |
| Empathy | Facilitates achievement of goals | <ul style="list-style-type: none"> • Ask a dissatisfied client what the nurse may do to help • Validate the client's feelings of frustration and anger |
| Honesty | Decreases anxiety and facilitates achievement of goals | <ul style="list-style-type: none"> • Offer all available resources to the client • Assist the client in making informed health care decisions |
| Caring | Promotes feelings of acceptance | <ul style="list-style-type: none"> • Touch the client in a gentle manner • Address the client by name |
| Competence | Promotes trust and respect | <ul style="list-style-type: none"> • Communicate in an organized, professional manner |

- the client, family, and significant others to recognize communication patterns and barriers to therapeutic communication.
- the client, family, and significant others techniques to build rapport with the goal of promoting health.
- the non-English speaking client, family, and significant others the importance of using a translator to ensure effective communication with the health care team.
- the family and significant others of elderly adults effective modes of communication.
- the family and significant others of clients with special needs effective modes of communication as well as revision of the modes based on evaluation.

Table 11–3 Therapeutic Communication Techniques

| Technique | Purpose | Example |
|----------------------|--|---|
| Broad openings | Encourages client to select topics for discussion; indicate acceptance by the nurse and value of the client's initiative. | "Is there something bothering you today?" "May I answer any questions or address any concerns you may have?" |
| Clarification | Asks the client to explain what he/she means to enhance the nurse's understanding; helps clarify the client's feelings, ideas, and perceptions; provides explicit correlation between the client's words and actions. | "Help me to understand. What do you mean when you say you've had enough of this?" "Are you saying that you are discouraged by the care you are receiving?" |
| Focusing | Questions or statements that help the client expand an idea; guides goal-directed communication. | "What other feelings are you experiencing besides the ones you just described?" "Let's go back to the part where you mentioned being sad. Can you tell me more about that?" |
| Humor | Comic enjoyment of the imperfect; brings repressed material to consciousness, tempers aggression, and reveals new options to promote insight. | The nurse follows the client's lead regarding humor. The nurse should never make jokes at a client's expense, but may want to validate the client's attempt at humor by smiling or laughing. |
| Informing | Provides information about the client's well-being and self-care during client education and teaching. | "If this is a good time for you, I'd like to go over the proper technique for insulin injections." "You look better today. The antibiotics given to you last night must be taking effect." |
| Listening | Active process of receiving information and examining client reactions to the messages received; nonverbally communicates the nurse's interest in the client. | The nurse remains quiet while the client is speaking. The nurse may occasionally interject phrases such as "Uh-huh," "I'm listening," and "Hmm" to indicate active listening. |
| Reflection | Direct back to the client his/her content, feelings, ideas, or questions; validates the nurse's understanding of what the client is saying; signifies empathy, interest, and respect for the client. | "I understand what you're saying. You're saying that living alone can be lonely at times." "I can understand why you would be upset by your family's reaction." |
| Restating | Repeats back to the client the main thought or idea expressed; demonstrates that the nurse is listening and validates the client's words. | "Let me make sure I have this right. You're saying that you no longer wish to undergo chemotherapy because it makes you so sick." "I heard you say that you are ready to be discharged. Let me convey your wish to the physician." |
| Sharing perceptions | Asks the client to verify the nurse's understanding of what the client is thinking or feeling; clarifies confusing communication; conveys the nurse's understanding to the client. | "It seems that you may be experiencing some feelings of anger. Is this correct?" "I sense that you are happy about your prognosis. Am I right?" |
| Silence | Therapeutic use of nonverbal communication; allows the client time to think, slows the pace of the conversation, and encourages the client to initiate communication while conveying the nurse's acceptance, support, and understanding. | The nurse looks at the client during periods of silence to nonverbally express interest and support. |
| Suggesting | Enhances problem-solving by offering the client alternative ideas; increases the client's options or choices. | "Have you ever considered walking with a cane for support?" "It may be helpful to leave the hallway light on at bedtime. This way, you won't have to stumble around in the dark when you have to use the bathroom in the middle of the night." |
| Theme identification | Identifies issues or themes experienced by the client repeatedly during the course of the client–nurse relationship; promotes the client's exploration and understanding of important problems. | "I've noticed that you become agitated every time your family comes to visit. Would you like to talk about this?" |

Table 11–4 Barriers to Therapeutic Communication

| Communication Barrier | Effect |
|--|---|
| Focusing on the diagnosis instead of the client | Increases client anxiety by not focusing on the whole client |
| Using slang terminology | Referring to the client as “honey” or “sweetie” instead of Mr., Mrs., or Dr. demeans the client |
| Using defensive language | Prohibits open and trusting communication; makes the nurse appear incompetent |
| Using clichés | Conveys lack of interest |
| Using closed questions | Asking questions that only require a yes or no answer prohibits discussion |
| Using questions containing the words why and how | Intimidates the client |
| Using probing questions | Causes client resentment and unwillingness to communicate further |
| Using leading questions | Produces answers that please the nurse while discouraging and intimidating the client |
| Giving advice | Prohibits client decision making and increases client dependence on the nurse |
| Casting judgment | Imposes the nurse’s standards on the client |
| Changing the subject | Causes client frustration |
| Giving false assurance | Conveys lack of interest |
| Gossiping and spreading rumors | Undermines the nurse–client relationship; blocks effective team building |

Other types of nontherapeutic communication involve verbal attack, rushing, minimizing, and taking sides.

THERAPEUTIC RELATIONSHIP

- This relationship is a nurse–client interaction that focuses on the client needs and is goal specific.
- Establishment of a therapeutic relationship is the basis of all nursing care of the clients with mental illness.
- There are three phases of therapeutic relationship:
 - Introduction
 - Establishes each person’s role in the relationship.
 - May include making a contract with the client regarding goals and behavior.
 - Working
 - Plan of care is developed with the client.
 - Termination
 - Implementation of the care plan through the process of therapeutic alliance.
 - Review of the client’s progress and development of plans for the immediate future.

THERAPEUTIC ENVIRONMENT

- The goal of the therapeutic environment, or therapeutic milieu, is to promote health and healing.
- The psychiatric unit serves as a social system in its own right. This social system incorporates.
 - a large work group that accepts the task of healing.
 - the activities of communal living, as clients must interact with each other daily with the task of promoting a community of healing.
- The principles of milieu therapy are that clients are active, not passive, participants in their lives; clients own their

behavior and environment; and clients are independent and self-sufficient.

- A therapeutic environment
 - promotes a fundamental respect of individuals, clients, and staff alike.
 - uses opportunities for communication between the client and staff for maximum therapeutic benefit.
 - encourages clients to act at a level equal to their ability and to enhance self-esteem.
 - promotes socialization.
 - provides opportunities for clients to be a part of the unit's management.
- The nurse's role is to support the five goals of a therapeutic environment as listed above, clarify boundaries for all clients, and assist clients in task completion to improve health.
- The nurse acts as a resource person, counselor, surrogate, and technical expert for the client.
- The nurse facilitates the basic concepts of a relationship: boundary development and maintenance, safety development, and trust development.
- Community meetings in the therapeutic environment serve to orient clients to the environment and define boundaries. In these meetings, the nurse defines the structure of the work the clients are to promote.
- Several factors are necessary for successful community meetings:
 - The leader defines the purpose of the meeting.
 - The leader provides structure and boundaries for the tasks.
 - The leader defines the tasks and explains how the clients can utilize the nurse in this role.
 - The leader focuses on the tasks.
 - The leader models acceptance.
- Safety and trust are important factors in the therapeutic environment.
 - Safety is developed by knowing what one's responsibilities are in a given situation.
 - Trust develops through actions that are consistent with an individual's or group's stated intent.
 - Clients need to know what is expected of them in order to feel safe.
 - Safety is promoted by clarifying client tasks.
 - Trust is the promotion of consistency between words and actions.
 - The nurse acts in a consistent manner to achieve objectives and promote trust.
 - The nurse ensures that his/her every interaction is a therapeutic one in order to promote safety and trust.
- Room assignments are based on the fragility of the client, the length of stay, client communication between roommates, the client's overall behavior, and the client's level of personal distress.
 - For example, an anxious, verbal client would not be assigned to the same room as a nonverbal, catatonic client.
- In group therapy, the client defines himself/herself through human interaction and task accomplishment.
- Family therapy promotes health and functionality of the whole family system.
- Client recovery can be influenced by stressors. See Chapter 10 for information related to stress management.
- Family dynamics may also impact client recovery. See Chapter 10 for additional information on family dynamics.
 - Family rules are used to define behaviors and communication styles of family members. These impact how the family views and relates to institutions outside of the family. Ultimately, these influence the client.
 - Role confusion within a family or society at large impedes a client's recovery. For example, the eldest son assumes the patriarchal role of the family after the father's death.
 - Task confusion may result due to the birth of a child in the family resulting in neglect of other family members.
 - Mixed or double messages, such as when verbal and nonverbal messages conflict, can arrest a client's progression towards mental health.

Think Smart/Test Smart

Be aware that the terms therapeutic environment, therapeutic milieu, and milieu therapy are often used interchangeably.

BEHAVIORAL INTERVENTIONS

- The nurse assesses the client's appearance, mood, and psychomotor behavior. Examples of warning signs include disheveled appearance, inappropriate dress (shorts and t-shirt in winter), angry or withdrawn mood, and lack of physical coordination or difficulty speaking.

Table 11–5 Interventions to Relieve Client Anxiety

Discuss the importance of the client's safety and measures taken to ensure safety.

Explore and teach coping strategies such as visualization, imagery, breathing, and progressive relaxation.

Use distraction to relax and calm the client.

Listen actively to the client and encourage open discussion of feelings.

Use therapeutic communication techniques, and focus on positive remarks.

Use appropriate touch with client permission to demonstrate support.

- Clients who are disoriented are gently reminded of who they are, where they are, and what is expected of them. Conspicuous placement of clocks, watches, and calendars orient the client to time.
- Membership in group therapy promotes expression and exchange of ideas.
- The nurse leader of group therapy identifies behavior patterns of the members, promotes balance of the behavior patterns, and promotes self-esteem and socialization.
- The nurse continually evaluates the client, family, and significant others' ability to adhere to the treatment plan. Revisions to the plan are based on the nurse's evaluation.

- The nurse assesses the mental health client for inappropriate or abnormal behavior. These behaviors may range from irrational anger to excessive happiness.
- The nurse assists the mental health client in achieving and maintaining self-control of behavior. Behavioral management techniques are effective in controlling behavior.
 - A contract may be used to hold a client accountable for his/her actions. The contract serves as a constant reminder of client tasks and goals.
 - Cognitive restructuring gives the client a greater degree of control over negative thinking by correcting these distortions or correcting thinking errors that precipitate the distortions, which result in inappropriate behavior.
 - Reframing is used to reinterpret irrational beliefs in a more realistic light.
 - Keeping a diary of significant events and associated feelings, thoughts, and behavior records the client's reaction to stressors.
 - Implementing relaxation and distraction techniques can decrease anxiety.
 - Trying alternative ways of behaving and reacting builds the client's sense of control and self-esteem.
 - Using positive reinforcement and positive language to praise the client when improvements are made.
 - Setting and enforcing limits and boundaries give clients a sense of security and what is expected of them.
- Anxiety is experienced by clients as they face new challenges or threatening situations.
- Anxiety impedes the client's healing. See Table 11–5 for nursing interventions to relieve client anxiety.

CRISIS INTERVENTION

- A crisis is a situation that cannot be resolved by usual coping mechanisms.
- Psychosocial crises may be precipitated by acute or chronic illnesses, natural disasters, acts of violence, or emotional stress.
- During a crisis, the client, family, and significant others cannot function normally and require interventions to regain equilibrium.
- Symptoms of an impending crisis may include mood changes, impaired cognition, poor judgment and reasoning capabilities, and poor hygiene.
- Crisis intervention improves coping abilities. See Table 11–6 for the problem-solving techniques used during a crisis.
- The reason for the crisis may not always be clear to the client or the nurse. The nurse refers the client, family, and significant others to community resources, such as counseling and psychological evaluation to assist in understanding why the crisis occurred.
- Clients who experience psychosocial crisis are at risk for suicide. See Table 11–7 for the risk factors associated with suicide.
- Several factors protect clients from the risk of suicide such as
 - effective clinical care for mental, physical, and substance abuse disorders;
 - easy access to a variety of clinical interventions and support for help seeking;
 - family and community support;

Table 11–6 Crisis Problem-Solving Techniques

| Technique | Factors |
|--------------------------------|--|
| Identify the problem | Clients may have difficulty identifying the causative factor and may require assistance with this technique. |
| List alternatives | A solution to a problem is easier to ascertain when the many options are considered. |
| Choose from among alternatives | Each option is considered to help reach the best solution to the problem. The chosen alternative is based on the client's values and priorities. |
| Implement a plan | The chosen alternative is put into action. The nurse supports and encourages the client to execute the plan. |
| Evaluate the outcome | The effectiveness of the plan is evaluated to help guide future problem-solving efforts. |

Table 11–7 Risk Factors for Suicide

Age: Younger than 20 years or older than 45 years, especially older than 65 years

Gender: Women make more attempts; men are more successful

Dysfunctional family: Experience with multiple losses while possessing limited coping skills

Family history of suicide

Family history of child maltreatment

History of mental disorders, particularly severe depression

Severe, intractable pain

Chronic, debilitating medical illnesses

Substance abuse

Severe anxiety

Overwhelming problems

Altered body image

Altered self-esteem

Detailed suicide plan

Previous suicide attempt(s)

Impulsive or aggressive tendencies

Barriers to accessing mental health treatment

Feelings of hopelessness and isolation

Loss: relational, social, work, or financial

Unwillingness to seek help due to stigma

Cultural and religious beliefs: belief that suicide is a noble resolution of a personal dilemma

—support from ongoing medical and mental health care relationships;
 —skills in problem solving, conflict resolution, and non-violent handling of disputes; and
 —cultural and religious beliefs that discourage suicide and support self-preservation instincts.

- Suicidal clients often mistakenly believe they are doing their family and significant others a favor by committing suicide. This irrational belief drives suicidal behavior. Family members and significant others often blame themselves for the client's suicidal behavior.
- The symptoms of suicide include
 - depression;
 - expression of feelings of guilt;
 - tension or anxiety;
 - nervousness;
 - impulsiveness;
 - sudden change in behavior, especially calmness after a period of anxiety;
 - giving away belongings;
 - attempts to “get one's affairs in order”;
 - direct or indirect threats to commit suicide;
 - direct attempts to commit suicide.
- Suicide attempts should always be taken seriously; dismissing them as attention-seeking behavior can have devastating consequences.
- Suicide precautions are ordered for clients who have either harmed themselves, verbalized intent to do so, or indicated, in an overt or covert manner, a wish to do so.
- Implementing suicide precautions includes placing the client in a private room close to the nurses' station.
- Remove all medications and other items considered unsafe, including glass or sharp items, nail polish remover or other alcohol-containing solutions, matches

or lighter, and any aerosol spray cans (i.e., hairspray). Similar items belonging to the client's roommate must also be removed, if placing the client in a private room is not an option.

- Once the crisis is managed, the client, family, and significant others should be aided in accessing recovery resources, such as social supports.

Nursing Intervention Alert

In crisis situations, nurses should facilitate referrals to a psychiatrist, psychiatric nurse specialist, hospital emergency department, or crisis center.

WORKSHEET

MATCHING QUESTIONS

Match the following:

Column A—Terms

1. _____ Aphasia
2. _____ Dysarthria
3. _____ Presbycusis
4. _____ Conversation Pacing
5. _____ Clarification
6. _____ Reflection
7. _____ Group Therapy
8. _____ Family Therapy
9. _____ Contract
10. _____ Cognitive Restructuring
11. _____ Reframing
12. _____ Anxiety
13. _____ Clarification
14. _____ Active Listening
15. _____ Body Language
16. _____ Trust

Column B—Descriptions

- a. Asking the client to explain what he/she means to enhance the nurse's understanding of what the client is saying
- b. A process that promotes the health and functionality of the family system
- c. A behavioral management technique used to reinterpret irrational beliefs to more accurately reflect reality
- d. The inability to recall words, understand what others are saying, or produce speech
- e. A written agreement that holds a client accountable for his/her actions
- f. Knowing what one's responsibilities are in a given situation
- g. Manifestation of thoughts and feelings through gestures
- h. Directing the client's feelings and ideas back to the client to validate the nurse's understanding of what the client is saying
- i. Sensitivity to what the client is experiencing
- j. Use of all the senses to pick up verbal and nonverbal messages
- k. Technique for reducing miscommunication and misunderstanding
- l. Promoted by consistency between words and actions
- m. The inability to produce clear speech sounds
- n. A behavior management technique used to give the client greater control over negative thinking by correcting mental distortions

(continued)

- | | |
|--------------------------|---|
| 17. _____ Empathy | o. Allowing the elderly client plenty of time to answer health-related questions |
| 18. _____ Personal Space | p. Hearing loss due to the aging process |
| 19. _____ Crisis | q. A situation that cannot be resolved by usual coping mechanisms |
| 20. _____ Safety | r. A manifestation of stress experienced by clients as they face new challenges or threatening situations |
| | s. A process that promotes expression and the exchange of ideas; where the client defines himself/herself through human interaction and task accomplishment |
| | t. Distance needed between self and other in order to feel comfortable |

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. Clients suspected of having a speech or language deficit should be referred to a _____.
2. By informing the client of who will have access to the client's medical record, the nurse is ensuring _____.
3. The process of receiving information and examining the client's reactions to the messages received is a therapeutic communication technique known as _____.
4. _____ is the therapeutic use of nonverbal communication that allows the client time to think and slows the pace of the conversation.
5. A _____ provides socialization, promotes a fundamental respect for individuals, and provides opportunities for communication between the client and staff.
6. Cognitive restructuring, contracting, and reframing are _____ techniques that are effective in controlling behavior.
7. During a _____, the client, family, and significant others cannot function normally and require interventions to regain equilibrium.
8. The symptoms of _____ include: depression, anxiety, impulsiveness, giving away belongings, and attempts to "get one's affairs in order."
9. Community meetings in the therapeutic environment serve to orient clients to the environment and _____.
10. _____ develops through actions that are consistent with an individual's or group's stated intent.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|------------------|------------------|
| 1. Impaired verbal communication is the state in which an individual experiences a decreased or absent ability to use or understand human language. | <u> </u> T | <u> </u> F |
| 2. Using touch while speaking to a visually-impaired client increases anxiety. | <u> </u> T | <u> </u> F |
| 3. Giving advice, changing the subject, and using clichés are examples of barriers to therapeutic communication. | <u> </u> T | <u> </u> F |
| 4. Family rules are used to define the behaviors and communication styles of family members. | <u> </u> T | <u> </u> F |
| 5. Giving false reassurance conveys a lack of interest. | <u> </u> T | <u> </u> F |
| 6. Asking why or how can be intimidating to the client. | <u> </u> T | <u> </u> F |
| 7. Silence is nontherapeutic. | <u> </u> T | <u> </u> F |
| 8. Using broad openings to conversation encourages client to select topic and indicates acceptance and value of the client's initiative. | <u> </u> T | <u> </u> F |
| 9. Honesty promotes feelings of acceptance. | <u> </u> T | <u> </u> F |
| 10. Maintaining a client's personal space helps decrease anxiety. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Match the following:

Column A—Therapeutic Communication Techniques

Column B

- | | |
|-----------------------------------|---|
| 1. _____ Validating | a. Encourages client to talk |
| 2. _____ Restating | b. Rephrases and reviews key statements |
| 3. _____ Focusing | c. Summarizes message in listener's own words |
| 4. _____ Information Offering | d. Asks for explanation of vague response |
| 5. _____ Sharing Impressions | e. Describes client's feelings as perceived by nurse and asks for corrective feedback |
| 6. _____ Suggestive Collaboration | f. Redirects attention to a specific area |
| 7. _____ Open-ended Questioning | g. Allows client to explore pros and cons of a proposed approach |
| 8. _____ Reflecting | |

(continued)

9. ____ Identifying Themes
10. ____ Clarifying
- h. Explains purpose or components of an activity or procedure
- i. Promotes identification and exploration of important problems
- j. Directing back to the client his/her content, feelings, ideas or questions

APPLICATION QUESTIONS

- A nurse is caring for a Hispanic client who speaks very little English. Which interventions by the nurse assist in meeting the client's therapeutic communication needs? Select all that apply.
 - Providing a language interpreter
 - Including Hispanic members of the health care team
 - Providing client education materials written in Spanish
 - Speaking in a normal tone of voice
- A nurse in a long-term care facility is caring for an elderly client. The elderly client is experiencing bilateral hearing loss due to the aging process. Which is the correct term for the client's hearing loss?
 - Aphasia
 - Dysarthria
 - Presbycusis
 - Myopia
- Clients with special needs require specific communication techniques. Which specific communication techniques should a nurse utilize when caring for a client who is cognitively impaired? Select all that apply.
 - Maintain eye contact
 - Keep communication simple and concrete
 - Use open-ended questions
 - Demonstrate or pantomime ideas
- A nurse is caring for a client who has difficulty speaking. To which health care provider should the client be referred?
 - Audiologist
 - Physical therapist
 - Surgeon
 - Speech-language pathologist
- Trust-building is an important nursing activity when establishing a nurse–client relationship. When a nurse draws the curtains around a client's bed, which trust builders are the nurse utilizing? Select all that apply.
 - Providing a comfortable environment
 - Ensuring client confidentiality
 - Enhancing client privacy
 - Providing a personal space
- A nurse is recording the health history of a newly admitted client. The nurse asks the client to explain what he or she means when the client is providing health information. Which therapeutic communication technique is being utilized by the nurse?
 - Informing
 - Restating
 - Clarification
 - Reflection
- A nurse is recording the health history of a newly admitted client. Which statement made by the nurse indicates that the nurse is using the therapeutic communication technique known as reflection?
 - "I can understand why you are upset that you have been admitted to the hospital."
 - "I'm listening."
 - "You are only allowed to have one visitor at a time while in the hospital."
 - "Have you ever considered a weight-loss program to help get your diabetes under control?"
- Which actions by the nurse are barriers to therapeutic nurse–client communication? Select all that apply.
 - Focusing on the diagnosis instead of the client
 - Using slang terminology
 - Using open-ended questions
 - Giving advice

9. The goal of the therapeutic environment is to promote health and healing. Which statements are true regarding clients in a therapeutic environment? Select all that apply.
 - a. Clients are active participants in their own lives
 - b. Clients take ownership of their behavior and environment
 - c. Clients are independent and self-sufficient
 - d. Clients are responsible for safety and trust development
10. Room assignments on a psychiatric unit are based on which factors?
 - a. The client's gender
 - b. The client's fragility
 - c. The client's race
 - d. The client's length of stay
11. The nurse assists the mental health client in achieving and maintaining self-control of behavior. A commonly-used behavioral management technique is the use of contracts made with the client. Which statements are accurate regarding client contracts? Select all that apply.
 - a. A contract gives a client greater control over negative thinking
 - b. A contract may be used to hold a client accountable for his/her actions
 - c. A contract serves as a constant reminder of client tasks and goals
 - d. A contract promotes self-expression and the exchange of ideas
12. Clients who experience psychosocial crisis are at risk for suicide. Which are additional risk factors for suicide? Select all that apply.
 - a. Younger than 20 years of age
 - b. Older than 45 years of age
 - c. Severe, intractable pain
 - d. Substance abuse
13. During a crisis, the client and family cannot function normally and require interventions to regain equilibrium. In crisis situations, the nurse should facilitate referrals to which health care professionals? Select all that apply.
 - a. A psychiatrist
 - b. A psychiatric nurse specialist
 - c. A hospital emergency department
 - d. A crisis center
14. When caring for a client following a mastectomy, the nurse is positioning the affected arm. Which question is the most appropriate to ask?
 - a. Does it hurt?
 - b. Doesn't that feel good?
 - c. That doesn't feel bad, does it?
 - d. How does that feel?
15. During a dressing change, the client states, "My wife was really upset last night when she came to visit." The nurse says, "Your wound really looks good this morning." Of which block to therapeutic communication is this an example?
 - a. Minimizing
 - b. Rushing
 - c. Giving false reassurance
 - d. Changing the subject
15. A 90-year-old long-term care resident tells the nurse she has gotten three or four mosquito bites and they are swollen and very itchy. The nurse replies, "That's nothing; they'll be gone in a few days." What type of communication technique did the nurse use?
 - a. Nontherapeutic minimizing
 - b. Nontherapeutic use of cliché
 - c. Therapeutic informing
 - d. Therapeutic clarification
16. Which is an example of validation of a client's communication?
 - a. "Would you tell me more about your feeling of light headedness?"
 - b. "You said that the pain goes from your shoulder down your right arm?"
 - c. "How would you describe your appetite?"
 - d. "Putting it all together, you are feeling better today."
17. Which nursing approach would likely be most effective in decreasing anxiety in an elderly, visually impaired client during a health history?
 - a. Pace the questions to allow plenty of time for answers
 - b. Allow for increased personal space
 - c. Reassure the client about the confidentiality of the information
 - d. Ensure a private, comfortable environment
18. What does touching the client gently when performing a procedure or treatment communicate?
 - a. Competence
 - b. Client-centered focus
 - c. Caring
 - d. Pleasantness

(continued)

19. As a therapeutic technique, what purpose does humor serve?
- Helps put the nurse at ease with the client
 - Lightens up a client who is too serious
 - Tempers aggression
 - Creates a sense of vitality
20. Which type of room accommodation would the nurse recommend for a suicidal client?
- Multibed room with active, alert clients
 - Double room with a quiet, inactive client
 - Private room near the nurse's station
 - Private room at a quiet place on the unit
21. When caring for a client on suicide precautions, which items should the nurse remove from the room? Mark all that apply.
- Hand mirror
 - Nail file
 - Aerosol deodorant
 - Alcohol based mouth wash
 - Nail polish remover
 - Matches
22. Clients with histories of which of the following factors are at increased risk for committing suicide? Mark all that apply.
- Substance abuse
 - Impulsiveness
 - Intractable, severe pain
 - Family history of child abuse
 - Altered body image
23. A client says to the nurse who is changing his ileostomy bag, "I think I should just die. I am a burden to everyone." Which is a therapeutic response?
- "There is no reason to feel that way, you are a good client."
 - "I find it difficult to believe that you feel that way."
 - "You shouldn't feel that way; your family loves you."
 - "You feel like you are a burden?"
24. While discussing suicide as part of a health day program sponsored by a community group, the nurse is asked about signs that an individual is contemplating suicide. Which information could accurately be included in the nurse's response?
- The only signs of contemplated suicide are suicide notes, threats of suicide, and actual suicide attempts
 - Giving away belongings, getting affairs in order such as paying off debts and preparing tax materials in advance, and sudden calm, directed behavior are often the signs of a decision to commit suicide
 - Increase in use of alcohol, sudden interest in gambling or other "adult entertainment," or activities uncharacteristic of the person typically occur before a suicide
 - There are no identifiable indications of potential suicide; persons can exhibit usual behavior and without warning kill themselves

ANSWERS & RATIONALES

MATCHING ANSWERS

Column A—Terms

- d Aphasia
- m Dysarthria
- p Presbycusis
- o Conversation Pacing
- a Clarification

Column B—Descriptions

- Asking the client to explain what he/she means to enhance the nurse's understanding of what the client is saying
- A process that promotes the health and functionality of the family system
- A behavioral management technique used to reinterpret irrational beliefs to more accurately reflect reality
- The inability to recall words, understand what others are saying, or produce speech

- | | |
|--------------------------------------|---|
| 6. <u>h</u> Reflection | e. A written agreement that holds a client accountable for his/her actions |
| 7. <u>s</u> Group Therapy | f. Knowing what one's responsibilities are in a given situation |
| 8. <u>b</u> Family Therapy | g. Manifestation of thoughts and feelings through gestures |
| 9. <u>e</u> Contract | h. Directing the client's feelings and ideas back to the client to validate the nurse's understanding of what the client is saying |
| 10. <u>n</u> Cognitive Restructuring | i. Sensitivity to what the client is experiencing |
| 11. <u>c</u> Reframing | j. Use of all the senses to pick up verbal and nonverbal messages |
| 12. <u>r</u> Anxiety | k. Technique for reducing miscommunication and misunderstanding |
| 13. <u>k</u> Clarification | l. Promoted by consistency between words and actions |
| 14. <u>j</u> Active Listening | m. The inability to produce clear speech sounds |
| 15. <u>g</u> Body Language | n. A behavior management technique used to give the client greater control over negative thinking by correcting mental distortions |
| 16. <u>l</u> Trust | o. Allowing the elderly client plenty of time to answer health-related questions |
| 17. <u>i</u> Empathy | p. Hearing loss due to the aging process |
| 18. <u>t</u> Personal Space | q. A situation that cannot be resolved by usual coping mechanisms |
| 19. <u>q</u> Crisis | r. A manifestation of stress experienced by clients as they face new challenges or threatening situations |
| 20. <u>f</u> Safety | s. A process that promotes expression and the exchange of ideas; where the client defines himself/herself through human interaction and task accomplishment |
| | t. Distance needed between self and other in order to feel comfortable |

ANSWERS FOR FILL IN THE BLANKS

1. Clients suspected of having a speech or language deficit should be referred to a speech—language pathologist.
2. By informing the client of who will have access to the client's medical record, the nurse is ensuring confidentiality.
3. The process of receiving information and examining the client's reactions to the messages received is a therapeutic communication technique known as active listening.
4. Silence is the therapeutic use of nonverbal communication that allows the client time to think and slows the pace of the conversation.
5. A therapeutic environment provides socialization, promotes a fundamental respect for individuals, and provides opportunities for communication between the client and staff.

(continued)

6. Cognitive restructuring, contracting, and reframing are behavioral management techniques that are effective in controlling behavior.
7. During a crisis, the client, family, and significant others cannot function normally and require interventions to regain equilibrium.
8. The symptoms of suicide include: depression, anxiety, impulsiveness, giving away belongings, and attempts to “get one’s affairs in order.”
9. Community meetings in the therapeutic environment serve to orient clients to the environment and define boundaries.
10. Trust develops through actions that are consistent with an individual’s or group’s stated intent.

TRUE OR FALSE ANSWERS

1. Impaired verbal communication is the state in which an individual experiences a decreased or absent ability to use or understand human language. *True*
2. Using touch while speaking to a visually-impaired client increases anxiety *False*
Using touch while speaking to a visually-impaired client decreases anxiety.
3. Giving advice, changing the subject, and using clichés are examples of barriers to therapeutic communication. *True*
4. Family rules are used to define the behaviors and communication styles of family members. *True*
5. Giving false reassurance conveys a lack of interest. *True*
6. Asking why or how can be intimidating to the client. *True*
7. Silence is nontherapeutic. *False*
Silence can be used therapeutically to allow client time to think and can encourage the client to initiate communication while conveying acceptance, support and understanding.
8. Using broad openings to conversation encourages client to select topic and indicates acceptance and value of the client’s initiative. *True*
9. Honesty promotes feelings of acceptance. *False*
Honesty decreases anxiety and facilitates goal achievement; caring promotes feelings of acceptance.
10. Maintaining a client’s personal space decreases anxiety. *True*

MATCHING ANSWERS

Column A—Therapeutic Communication Techniques

Column B

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. <u> b </u> Validating 2. <u> c </u> Restating | <ol style="list-style-type: none"> a. Encourages client to talk b. Rephrases and reviews key statements |
|---|---|

- | | |
|--------------------------------------|---|
| 3. <u>f</u> Focusing | c. Summarizes message in listener's own words |
| 4. <u>h</u> Information Offering | d. Asks for explanation of vague response |
| 5. <u>e</u> Sharing Impressions | e. Describes client's feelings as perceived by nurse and asks for corrective feedback |
| 6. <u>g</u> Suggestive Collaboration | f. Redirects attention to a specific area |
| 7. <u>a</u> Open-ended Questioning | g. Allows client to explore pros and cons of a proposed approach |
| 8. <u>j</u> Reflecting | h. Explains purpose or components of an activity or procedure |
| 9. <u>i</u> Identifying Themes | i. Promotes identification and exploration of important problems |
| 10. <u>d</u> Clarifying | j. Directing back to the client his/her content, feelings, ideas or questions |

APPLICATION ANSWERS

1. A nurse is caring for a Hispanic client who speaks very little English. Which interventions by the nurse assist in meeting the client's therapeutic communication needs? Select all that apply.
- Providing a language interpreter
 - Including Hispanic members of the health care team
 - Providing client education materials written in Spanish
 - Speaking in a normal tone of voice

Rationale

Correct answers: a, b, c, and d.

The nurse assists in meeting the Hispanic client's therapeutic communication needs by providing a language interpreter, including Hispanic members of the health care team, providing client education materials written in Spanish, and by speaking in a normal tone of voice. It is an inappropriate tendency of some health care professionals to speak loudly to clients from other cultures.

2. A nurse in a long-term care facility is caring for an elderly client. The elderly client is experiencing bilateral hearing loss due to the aging process. Which is the correct term for the client's hearing loss?
- Aphasia
 - Dysarthria
 - Presbycusis
 - Myopia

Rationale

Correct answer: c.

Presbycusis is hearing loss due to the aging process.

3. Clients with special needs require specific communication techniques. Which specific communication techniques should a nurse utilize when caring for a client who is cognitively impaired? Select all that apply.
- Maintain eye contact
 - Keep communication simple and concrete
 - Use open-ended questions
 - Demonstrate or pantomime ideas

Rationale

Correct answers: a and b.

The nurse should maintain eye contact, keep communication simple and concrete, avoid open-ended questions, and be client when communicating with a client who is cognitively impaired. Demonstration or pantomiming ideas are not effective techniques for communicating with those who are cognitively impaired.

4. A nurse is caring for a client who has difficulty speaking. To which health care provider should the client be referred?
- Audiologist
 - Physical therapist

(continued)

- c. Surgeon
- d. Speech–language pathologist

Rationale

Correct answer: d.

The client who is having difficulty speaking should be referred to a speech–language pathologist.

5. Trust-building is an important nursing activity when establishing a nurse–client relationship. When a nurse draws the curtains around a client’s bed, which trust builders are the nurse utilizing? Select all that apply.
- a. Providing a comfortable environment
 - b. Ensuring client confidentiality
 - c. Enhancing client privacy
 - d. Providing a personal space

Rationale

Correct answers: a, b, c, and d.

By performing the simple act of drawing the curtains around a client’s bed, the nurse is providing a more comfortable environment, ensuring client confidentiality, enhancing client privacy, and providing a personal space; all of which aid the client in establishing a sense of trust with the nurse.

6. A nurse is recording the health history of a newly admitted client. The nurse asks the client to explain what he or she means when the client is providing health information. Which therapeutic communication technique is being utilized by the nurse?
- a. Informing
 - b. Restating
 - c. Clarification
 - d. Reflection

Rationale

Correct answer: c.

Clarification is the therapeutic communication technique being utilized to ensure that the nurse has a clear understanding of what the client is saying.

7. A nurse is recording the health history of a newly admitted client. Which statement made by the nurse indicates that the nurse is using the therapeutic communication technique known as reflection?
- a. “I can understand why you are upset that you have been admitted to the hospital.”
 - b. “I’m listening.”
 - c. “You are only allowed to have one visitor at a time while in the hospital.”
 - d. “Have you ever considered a weight-loss program to help get your diabetes under control?”

Rationale

Correct answer: a.

The nurse is using reflection to direct the feelings that have been expressed back to the client; signifies empathy, interest, and respect for the client.

8. Which actions by the nurse are barriers to therapeutic nurse–client communication? Select all that apply.
- a. Focusing on the diagnosis instead of the client
 - b. Using slang terminology
 - c. Using open-ended questions
 - d. Giving advice

Rationale

Correct answers: a, b, and d.

Barriers to therapeutic communication include: focusing on the diagnosis instead of the client; using slang terminology; and giving advice. Using open-ended questions is a therapeutic communication technique.

9. The goal of the therapeutic environment is to promote health and healing. Which statements are true regarding clients in a therapeutic environment? Select all that apply.
- a. Clients are active participants in their own lives
 - b. Clients take ownership of their behavior and environment
 - c. Clients are independent and self-sufficient
 - d. Clients are responsible for safety and trust development

Rationale

Correct answers: a, b, and c.

Clients in a therapeutic environment are active participants in their lives, take ownership of their behavior and environment, and function independently and self-sufficiently. The nurse is responsible for facilitating safety development and trust development within the therapeutic environment.

10. Room assignments on a psychiatric unit are based on which factors?
- a. The client’s gender
 - b. The client’s fragility
 - c. The client’s race
 - d. The client’s length of stay

Rationale

Correct answers: a, b, and d.

Room assignments on a psychiatric unit are based upon numerous factors which include: gender, fragility, length of stay, age, overall behavior, and level of personal distress.

11. The nurse assists the mental health client in achieving and maintaining self-control of behavior. A commonly-used behavioral management technique is the use of contracts made with the client. Which statements are accurate regarding client contracts? Select all that apply.
- A contract gives a client greater control over negative thinking
 - A contract may be used to hold a client accountable for his/her actions
 - A contract serves as a constant reminder of client tasks and goals
 - A contract promotes self-expression and the exchange of ideas

Rationale

Correct answers: b and c.

A contract may be used to hold a client accountable for his/her own actions and serves as a constant reminder of client tasks and goals. Cognitive restructuring gives a client greater control over negative thinking by correcting the distortions. Group therapy promotes self-expression and the exchange of ideas.

12. Clients who experience psychosocial crisis are at risk for suicide. Which are additional risk factors for suicide? Select all that apply.
- Younger than 20 years of age
 - Older than 45 years of age
 - Severe, intractable pain
 - Substance abuse

Rationale

Correct answers: a, b, c, and d.

Risk factors for suicide include: age younger than 20 years, age older than 45 years (especially over 65 years), severe intractable pain, and substance abuse.

13. During a crisis, the client and family cannot function normally and require interventions to regain equilibrium. In crisis situations, the nurse should facilitate referrals to which health care professionals? Select all that apply.
- A psychiatrist
 - A psychiatric nurse specialist
 - A hospital emergency department
 - A crisis center

Rationale

Correct answers: a, b, c, and d.

In crisis situations, it is appropriate for the nurse to facilitate referrals to psychiatrists, psychiatric nurse specialists, hospital emergency departments, and crisis centers.

14. When caring for a client following a mastectomy, the nurse is positioning the affected arm. Which question is the most appropriate to ask?
- Does it hurt?
 - Doesn't that feel good?
 - That doesn't feel bad, does it?
 - How does that feel?

Rationale

Correct answer: d.

"How does that feel?" is an open-ended question which encourages the client to respond as he/she desires. "Does it hurt?" requires only a yes or no response and hence has a limiting effect. "Doesn't that feel good?" and "That doesn't feel bad, does it?" are leading questions which predispose the client to the answer the nurse wants.

15. During a dressing change, the client states, "My wife was really upset last night when she came to visit." The nurse says, "Your wound really looks good this morning." Of which block to therapeutic communication is this an example?
- Minimizing
 - Rushing
 - Giving false reassurance
 - Changing the subject

Rationale

Correct answer: d.

The nurse changed the subject rather than following up the client's statement with a therapeutic technique to encourage further identification and discussion of the problem.

16. A 90-year-old long-term care resident tells the nurse she has gotten three or four mosquito bites and they are swollen and very itchy. The nurse replies, "That's nothing; they'll be gone in a few days." What type of communication technique did the nurse use?
- Nontherapeutic minimizing
 - Nontherapeutic use of cliché
 - Therapeutic informing
 - Therapeutic clarification

Rationale

Correct answer: a.

Saying that is nothing communicates unimportant and not deserving of attention. No cliché was used. No real information was provided about the client's health status or self-care. Clarification refers to asking a client to explain an unclear communication and is not relevant.

(continued)

17. Which is an example of validation of a client's communication?
- "Would you tell me more about your feeling of light headedness?"
 - "You said that the pain goes from your shoulder down your right arm?"
 - "How would you describe your appetite?"
 - "Putting it all together, you are feeling better today."

Rationale

Correct answer: b.

Validating is rephrasing and reviewing key statements made by the client and allowing the client to confirm that the nurse accurately understood what was said. A is a question that focuses the client on a particular area. C is an open-ended question which encourages the client to share information. D is an example of summarizing.

18. Which nursing approach would likely be most effective in decreasing anxiety in an elderly, visually impaired client during a health history?
- Pace the questions to allow plenty of time for answers
 - Allow for increased personal space
 - Reassure the client about the confidentiality of the information
 - Ensure a private, comfortable environment

Rationale

Correct answer: a.

Pacing conversation to allow plenty of time for the elderly client to answer questions without feeling rushed decreases anxiety. Allowing for the personal space desired by the client decreases anxiety but increasing or decreasing the preferred space can increase anxiety and sense of discomfort. Reassuring the client about confidentiality and providing privacy promotes a sense of security.

19. What does touching the client gently when performing a procedure or treatment communicate?
- Competence
 - Client-centered focus
 - Caring
 - Pleasantness

Rationale

Correct answer: c.

Caring is communicated by gentle touch and addressing the client by name. Competence is communicated by an organized, professional manner. Client centered focus is evident when the nurse attends to the client's verbal and nonverbal behavior and responds to it rather than talking about personal concerns or conversing with another health care worker about other than the client. Pleasantness is communicated through smiling and warm greetings.

20. As a therapeutic technique, what purpose does humor serve?
- Helps put the nurse at ease with the client
 - Lightens up a client who is too serious
 - Tempers aggression
 - Creates a sense of vitality

Rationale

Correct answer: c.

Humor can be used as a therapeutic technique to temper aggression, reveal new options and insights, and bring repressed material to consciousness.

21. Which type of room accommodation would the nurse recommend for a suicidal client?
- Multibed room with active, alert clients
 - Double room with a quiet, inactive client
 - Private room near the nurse's station
 - Private room at a quiet place on the unit

Rationale

Correct answer: c.

A private room provides a controlled environment and being near the nurse's station allows for easy observation. A private room is a component of suicide precautions.

22. When caring for a client on suicide precautions, which items should the nurse remove from the room? Mark all that apply.
- Hand mirror
 - Nail file
 - Aerosol deodorant
 - Alcohol based mouth wash
 - Nail polish remover
 - Matches

Rationale

Correct answer: all of the above.

Anything, glass, sharp objects, flammable liquids, or items in any way able to inflict injury must be removed from the room. This includes alcohol-based solutions and aerosol cans. If the client is not in a private room, these types of items belonging to the other person in the room must also be removed.

23. Clients with histories of which of the following factors are at increased risk for committing suicide? Mark all that apply.
- Substance abuse
 - Impulsiveness
 - Intractable, severe pain
 - Family history of child abuse
 - Altered body image

Rationale

Correct answer: all of the above.

Substance abuse, impulsiveness, intractable, severe pain, family history of child abuse and altered body image are all risk factors for suicide.

24. A client says to the nurse who is changing his ileostomy bag, “I think I should just die. I am a burden to everyone.” Which is a therapeutic response?
- “There is no reason to feel that way, you are a good client.”
 - “I find it difficult to believe that you feel that way.”
 - “You shouldn’t feel that way; your family loves you.”
 - “You feel like you are a burden?”

Rationale

Correct answer: d.

This is a form of reflecting back the client’s feelings. It allows for validation and shows interest and respect. It also invites additional communication on the part of the client. Responses a, b, and c are all nontherapeutic responses that are judgmental and trivialize the client’s feeling. The “good client” is a cliché.

25. While discussing suicide as part of a health day program sponsored by a community group, the nurse is asked about signs that an individual is contemplating

suicide. Which information could accurately be included in the nurse’s response?

- The only signs of contemplated suicide are suicide notes, threats of suicide, and actual suicide attempts
- Giving away belongings, getting affairs in order such as paying off debts and preparing tax materials in advance, and sudden calm, directed behavior are often the signs of a decision to commit suicide
- Increase in use of alcohol, sudden interest in gambling or other “adult entertainment,” or activities uncharacteristic of the person typically occur before a suicide
- There are no identifiable indications of potential suicide; persons can exhibit usual behavior and without warning kill themselves

Rationale

Correct answer: b.

Giving away belongings, getting affairs in order such as paying off debts and preparing tax materials in advance, and sudden calm, directed behavior are often the signs of a decision to commit suicide. Other signs are depression, expression of guilt feelings, tension, anxiety, nervousness, impulsiveness, and actual suicide attempts.

Test Plan Category:

Psychosocial Integrity—Part 3

Sub-category: None

Topics: Abuse/Neglect
Chemical Dependency
Sensory/Perceptual Alterations
Psychopathology

| | | | |
|-----------------------------------|-----|--------------------------------------|-----|
| ▸ Abuse and Violence | 305 | ▸ Psychopathology | 288 |
| ▸ Chemical and Other Dependencies | 302 | ▸ Sensory and Perceptual Alterations | 288 |
| ▸ Mental-Health Concepts | 287 | | |

MENTAL-HEALTH CONCEPTS

- Mental health is typically immeasurable by scientific standards.
- Influencing factors for mental health or disorder include inherited factors, biochemical influences, hormonal influences, family, culture, values and beliefs, cognitive abilities, spirituality, and worldview and perceptions.
- Protective defenses are the ways in which clients manage the negative aspects of life.
- A few defense mechanisms are repression, denial, rationalization, affiliation, and passive aggression.
- The nurse assesses factors that influence the client's perceptual, mental, emotional, and behavioral responses to internal and external stressors and crises.
- The nurse offers care to the mental-health client that is client-focused, goal-directed, and objective.
- The key to prevention and management of mental illness is stress reduction and adherence to an established treatment plan.
- Stress reduction and management decrease the occurrence of relapse in illness.

LEGAL OR ETHICAL PRINCIPLES IN MENTAL-HEALTH CARE

- Rights of the mentally ill client
 - Right to treatment
 - Right to refuse treatment
 - Right to informed consent
 - Right to privacy
 - Right to confidentiality
- Involuntary admission
 - Wishes of client regarding hospitalization must be respected unless client is a threat to self or others
 - Each state has laws that govern civil commitment process

- A person can usually be detained in a mental-health facility for 48–72 hours until a hearing can be conducted to determine if he or she should be committed
- Least restrictive environment
 - Restraints and seclusion may only be used to prevent client self-harm or harm to others
 - They are used only when all other physical and psychological means have failed
 - They are never used as a punishment
 - Criteria for the use of physical restraints include
 - examination by physician to determine need
 - physician’s written order
 - application of restraints is for a specified duration only

SENSORY AND PERCEPTUAL ALTERATIONS

- Sensory perception is the conscious process of selecting, organizing, and interpreting data from the senses into useful information.
- Severe sensory alteration may be due to sensory overload, sensory deprivation, sleep deprivation, and cultural care deprivation. See Table 12–1 for the factors associated with sensory deprivation.
- Sensory overload, sleep deprivation, and cultural care deprivation may cause confusion and anxiety.
- Perception is influenced by sights, sounds, tastes, smells, body position, coordination, and equilibrium as well as past experiences, knowledge, and attitudes.
- Gross perceptual alterations result in hallucinations. A hallucination is a subjective disorder of perception in which an impression from one of the five senses is present in the absence of external stimuli.
- Delirium—a state of mental confusion and excitement characterized by disorientation for time and place—usually accompanies hallucinations.
- Clients experiencing sensory and perceptual alterations have difficulty establishing independent living arrangements.
- Limited communication and coping skills are common among individuals experiencing sensory and perceptual alterations. Stressors can greatly impact these individuals’ ability to cope.

PSYCHOPATHOLOGY

- The nurse assesses the mental-health client for level of awareness, level of consciousness, behavior, appearance, memory, abstract reasoning, and language.
- Abnormal assessment findings include poor hygiene, inappropriate dress, disorientation, absent memory recall, and incoherent or illogical thought processes, which may be evidence of psychopathology.
- Several factors are associated with mental illness. See Table 12–2 for the factors associated with mental illness.
- Many clients, their families, and significant others may have difficulty accepting the diagnosis of an acute or chronic mental illness.
 - Reactions may include disbelief, anxiety, confusion, and denial.
 - The nurse responds by offering support and information, dispelling myths and blame, and facilitating community resources and social supports.
- When caring for clients with mental illness, the nurse incorporates the client’s beliefs, culture, spirituality, and religion into the plan of care.
- The nurse continually evaluates the ability of the client, family, and significant others to adhere to the treatment plan. Revisions to the plan are based on the nurse’s evaluation.

Table 12–1 Factors Associated with Sensory Deprivation

| | |
|------------|---|
| Perceptual | Hallucinations, delirium |
| Cognitive | Thought disorganization, decreased attention/concentration, slowness of thought, difficulty with problem solving and task performance |
| Emotional | Rapid mood changes, anxiety, panic, depression, nervousness, and jitteriness |

ANXIETY DISORDERS

- Anxiety is a universal feeling; everyone experiences it at some time to some degree.
- Anxiety disorders are the most commonly seen psychiatric disorder.

Table 12–2 Factors Associated with Mental Illness

| |
|---|
| Desire to hurt self or others |
| Disorganized or disturbed thoughts |
| Extreme feelings of helplessness or hopelessness |
| Extreme negative thoughts |
| History of traumatic experience |
| Inability to accept reality or satisfy basic needs |
| Inability to derive pleasure from living |
| Ineffective coping mechanisms or stress management |
| Illness resulting from severe, unrelenting stress |
| Lack of support system |
| Personality traits associated with dysfunctional behavior |

- These are classified as mild, moderate, or severe depending on the signs and symptoms.
- They can occur at any age and are more prevalent in women than men.

Etiology:

- Exact cause is unknown, often a combination of factors are involved.
- Several theories exist for the etiology of anxiety disorders.
- *Biological factors*
 - Genetic predisposition is partially related to some anxiety disorders.
 - Anxiety can result from improper functioning of the body systems responsible for the normal stress response.
 - Some neurotransmitters have been associated with anxiety.
 - Changes in the brain may be the origin of some anxiety disorders.
- *Psychological factors*
 - The number and severity of stressors may overwhelm unconscious defense mechanisms and become dysfunctional.
 - There is a correlation between parents' fears and those of children lending to the theory that fearful reactions are learned.

S&S:

- Varies according to the specific disorder

Dx:

- There are no diagnostic tests that definitively confirm anxiety disorders. Diagnosis is based upon manifestations of

the disease with data obtained from a mental-status examination, psychiatric history, and careful clinical observation

- A thorough physical and psychiatric evaluation is needed to rule out other possible causes of the symptoms such as a brain tumor or thyroid disorder

GENERALIZED ANXIETY DISORDER

- Generalized anxiety disorder refers to anxiety that is persistent, overwhelming, uncontrollable, and out of proportion to the stimulus.
- It tends to be a chronic condition.
- It can vary from mild to severe.

Etiology:

- Exact cause is unknown.
- It is believed to have a genetic predisposition.

S&S: The client shows

- excessive physiological arousal including
 - restlessness and inability to relax
 - episodes of trembling and shaking
 - shortness of breath
 - tachycardia or palpitations
 - sleep disturbances
 - GI disturbances
 - muscle tension
 - headache
 - cold, clammy hands
 - dry mouth
- distorted thought processes and coping
 - inability to concentrate
 - excessive worry
 - unrealistic assessment of problems
 - procrastination
 - poor problem solving

Rx:

- Often a combination of
 - psychotherapy
 - behavioral therapy
 - relaxation therapy
 - supportive counseling
 - pharmacological therapy
 - Antianxiety agents
 - usually given for several weeks
 - should not take more than 6 weeks in order to reduce potential for abuse
 - Selective serotonin reuptake inhibitors (SSRIs)

- Tricyclic antidepressants
- Buspirone (Buspar)—drug of choice for clients with a history of substance abuse
 - differs from other antianxiety drugs in that it requires several weeks for the onset of therapeutic effect

Nursing Process Elements

- Attend to physical needs such as nutrition and rest
- Stay with the client while acutely anxious
- Encourage client to discuss feelings and thoughts that stimulate anxious reactions

Client teaching for self-care

- Provide nutritional teaching such as avoiding caffeine and alcohol
- Teach appropriate ways of managing anxiety
- Teach about medication administration and monitoring

PANIC DISORDER

- Panic disorder is the most severe form of anxiety.
- It is characterized by recurrent panic attacks with feelings of impending doom.

Etiology:

- Exact cause is unknown.
- It seems to have a family predisposition.

S&S: The client

- may have symptoms of an MI including chest pain, diaphoresis, and shortness of breath
- is unable to focus thoughts or to concentrate
- has a rapid speech
- has an exaggerated startle reaction
- is unable to remain still—fidgets and paces

Rx:

- A combination of therapies and client teaching
- Cognitive therapy
 - teaches the client to replace negative thoughts with realistic, positive thoughts
 - identifies triggers for the panic attacks
 - helps the client to understand that the panic attack is separate and independent of the trigger
- Behavioral therapy involving desensitization
- Relaxation techniques
- Pharmacologic therapy may include a combination of
 - antianxiety drugs especially benzodiazepines
 - antidepressants
 - beta blockers to control cardiac symptoms

Nursing Process Elements

- Stay with client while anxiety is acute
- Avoid using touch to calm client
- Provide a safe, calm, and nonstimulating environment
- Maintain a calm approach with attention to both verbal and nonverbal behavior
- Encourage client to express feelings
- Allow to move and pace as needed
- Administer and monitor effects of medication

Client teaching for self-care

Teach client about

- recognition of triggers
- alternative coping mechanisms
- medication administration and monitoring

OBSESSIVE-COMPULSIVE DISORDER

- Obsessions are persistent intrusive thoughts and ideas.
- Compulsion is the repeated performance of rituals or behaviors designed to prevent some event, divert unwanted thoughts, and decrease anxiety.

Etiology:

- Unknown.

S&S: The client

- has repetitive thoughts that increase stress
- has compulsive behaviors such as hand washing, counting, turning door lock a set number of times each time, etc.

The degree to which these thoughts and behaviors interfere with a person's ability to function determines if and when intervention is needed.

Rx:

- Primarily behavioral therapy
 - exposes client to the situation or object that triggers the obsessive thoughts and then encourages them to refrain from the compulsive behavior used to decrease anxiety
 - is very effective in most cases
- Relaxation techniques
- Social support such as support groups

Nursing Process Elements

- Identify situations that provoke the behaviors
- Allow the client to carry out the behavior until anxiety is decreased (unless behavior puts safety at risk)
- Set reasonable demands and limits on the client's behaviors and make their purpose clear
- Encourage the client to verbalize feelings and concerns

- Make a written contract to assist the client to gradually decrease the frequency of compulsive behaviors

PHOBIC DISORDERS

- A phobia is an irrational fear that persists although the person may recognize it as unreasonable.
- It can lead to panic level anxiety.
- There are many types of phobias including agoraphobia (fear of open spaces), social phobia (fear of situations in which one may be embarrassed), and xenophobia (fear of strangers).

Etiology:

- Unknown.

S&S: The client shows

- fear and avoidance of the object or situation which causes anxiety
- physical reactions such as trembling, GI distress, tachycardia including those associated with panic attacks

Rx:

- Desensitization therapy to gradually expose client to the feared object or situation while coaching on relaxation techniques
- Guided imagery is used to allow client to rehearse ways to relax while confronting the feared object or situation
- Modeling behavior has the client observe someone demonstrate appropriate behavior when confronting the feared object or situation
- Negative-thought stopping teaches the client to recognize negative thoughts, then use a distracting stimulus (such as snapping a rubber band worn on the wrist) and substitute an appropriate thought
- Pharmacologic therapy may be used with other therapies including
 - antianxiety drugs
 - antidepressants
 - beta blockers to reduce cardiac symptoms

Nursing Process Elements

- Do not trivialize client's fears
- Teach and assist with relaxation, guided imagery, and thought-stopping techniques
- Explore with client other ways to relieve stress
- Teach appropriate medication use

MOOD DISORDERS

- Mood disorder refers to the existence of persistent feelings that cause a wide span of both emotional and behavioral problems that hinder the client's psychosocial functioning.

- Depending on the type of disorder, the client experiences either intense high (manic) or low (depressed) mood states.
- Major depressive disorder and bipolar disorder are the primary mood disorders. Related disorders include diagnoses such as dysthymic disorder, cyclothymic disorder, postpartum depression, seasonal affective disorder (SAD), and schizoaffective disorder.

Etiology: There are basically three categories of theories:

- Genetic—Mood disorders occur more frequently in first-degree relatives than in the general population.
- Biological —Deficiencies or abnormalities in hormones or in the brain's neurotransmitters correlate with different mood disorders.
- Psychological—This category includes many theories that in essence fault the client or the family with the mood disorder. There is little use for these theories today.

S&S:

- Major depressive disorder: Two or more weeks of sad mood, lack of interest in life activities and at least four other symptoms such as
 - anhedonia or lack of enjoyment
 - feelings of guilt, helplessness, or hopelessness
 - decreased ability to concentrate and make decisions
 - sleep disturbances
 - appetite loss or overeating with related weight changes
 - lethargy
 - low self-esteem
 - thoughts of death and suicide
- Bipolar disorder: The client experiences extreme highs (mania) alternating with extreme lows (depression) with periods of normal mood interspersed between the highs and lows. Severe episodes of mania or depression can sometimes involve psychotic symptoms (hallucinations and delusions). Characteristics of mania include
 - elation and euphoria
 - agitation and irritability
 - hyperactivity and sleeplessness
 - poor judgment and high-risk behaviors
 - exaggerated sexuality
 - rapid thought and pressured speech

Dx:

- There are no diagnostic tests that definitively confirm mood disorders. Diagnosis is based upon manifestations of the disease with data obtained from a mental-status examination, psychiatric history, and careful clinical observation
- A thorough physical and psychiatric evaluation is needed to rule out other possible causes of the symptoms such as a brain tumor or thyroid disorder

Rx: The primary treatment of mood disorders is drug therapy to control the main symptoms. For persistent depression resistant to medication therapy, electroconvulsive therapy (ECT) may be helpful. In addition, other treatments such as psychotherapy, vocational counseling, and structured milieu therapy are needed to assist the client with social adjustment

- Drug therapy for major depression generally works by modifying the activity of relevant neurotransmitters. Selection of the appropriate antidepressant is often based on factors such as previous effectiveness of medication on client or family members and possible adverse effects. Many antidepressants have other uses including treatment of anxiety disorders, ADHD, and chronic pain.

—SSRIs are often the first-line treatment for clients with depression

- Examples are citalopram (Celexa), escitalopram (Lexapro), fluoxetine (Prozac), paroxetine (Paxil), and sertraline (Zoloft)
- Effects can usually be seen after 1–3 weeks
- Cause fewer side effects than other antidepressant medications
- Common side effects include nausea, insomnia, nervousness, dry mouth, and sexual dysfunction

—Atypical antidepressants are usually used when the client has an inadequate response to or intolerable side effects from SSRIs

- Example of these antidepressants are venlafaxine (Effexor), bupropion (Wellbutrin), and nefazodone (Serzone)
- Side effects vary with each individual medication but commonly include headache, dizziness, drowsiness, nausea, and vomiting

—Tricyclic antidepressants (TCA) are one of the oldest classes of antidepressants.

- Examples are amitriptyline (Elavil) and imipramine (Tofranil)
- Effectiveness does not begin for 4–6 weeks and full therapeutic effects may not be reached for 6–8 weeks
- Common side effects include dizziness, drowsiness, dry mouth, orthostatic hypotension, blurred vision, urinary retention, constipation, nausea, and headache
- TCAs are the least expensive of the antidepressants

—Monoamine oxidase inhibitors (MAOI) are used infrequently because interaction with many common foods and medication causes hypertensive crisis

- Examples are phenelzine (Nardil) and tranylcypromine (Parnate)
- Maximum effectiveness takes 6 weeks
- Side effects include dry mouth, blurred vision, constipation, urinary retention, sedation, weight gain, orthostatic hypotension, and nausea

- Electroconvulsive therapy

Nursing Process Elements

- Hypoactive clients
 - Eliminate need for decision making when possible; when a decision is needed, do not rush the client
 - Accept slowness; do not chastise
 - Encourage easily accomplished activities that do not require prolonged time or concentration
 - Monitor for constipation
- Hyperactive clients
 - Speak softly and slowly
 - Limit environmental stimuli
 - Be kind, firm, and matter of fact; do not argue, get angry, or engage in entertaining behaviors
 - Avoid long discussions and explanations
 - Engage in noncompetitive activities that utilize energy
 - Do not be demanding; it can result in a power play

PERSONALITY DISORDERS

- These are a group of disorders characterized by a pattern of behavior and thinking that noticeably differs from the cultural norm.
- These disorders result in problems with living rather than in clinical symptoms.
- Clients frequently see their behavior or thinking as the norm and do not see it as a painful or uncomfortable experience.

Etiology:

- Unknown although many believe it to be a combination of many factors including biological, social, developmental, and psychological.

S&S:

- Varies according to specific disorder

Dx:

- There are no diagnostic tests that definitively confirm personality disorders. Diagnosis is based upon manifestations of the disease with data obtained from a mental-status examination, psychiatric history, and careful clinical observation.
- A thorough physical and psychiatric evaluation is needed to rule out other possible causes of the symptoms such as a brain tumor or thyroid disorder.

ANTISOCIAL PERSONALITY DISORDER

- The antisocial personality disorder is characterized by selfishness, poor sexual adjustment, failure to accept social

norms, inability to maintain lasting relationships, irritability, and aggressiveness.

- Such a disorder predisposes the person to criminal behavior.

S&S: The client

- shows disregard for others feelings, rights, and society's values.
- has an impulsive and reckless behavior with a disregard for own and others' safety.
- shows a dishonest and deceitful behavior.
- is irritable and aggressive, may display passive-aggressive behavior.
- shows inability to maintain responsible functioning at work, school, or in family role.
- has a lack of shame, guilt, or empathy.
- displays manipulative behavior, seeking power and control.
- can be very charming on a superficial level.

Rx:

- Psychotherapy is treatment of choice
 - Goal is to help the client see connections between feelings and behaviors
- Supporting therapies include
 - group therapy
 - family therapy
 - support groups
 - pharmacologic therapy used to treat some of the symptoms the client may experience such as mood swings

Nursing Process Elements

- Set limits on client's behavior, may use a behavioral contract
- Hold client accountable for own behavior
- Reinforce positive behavior
- Avoid arguing with the client
- Anticipate and recognize manipulative behaviors
- Teach client social skills and what are socially accepted behaviors

BORDERLINE PERSONALITY DISORDER

Etiology:

- Unknown although 50% of those with this disorder have been victims of sexual abuse.

S&S: The client

- has instability in interpersonal relationships which are often intense and stormy, fears abandonment which is manifested in both clinging and distancing behaviors

- experiences extreme feelings of anger, depression and anxiety
- displays mood swings that are rapid and dramatic
- has self-image disturbance with feelings of unworthiness
- has lack of insight
- shows behavior that is often impulsive and unpredictable
- usually does not consider the consequences of own actions
- displays recurrent self-mutilating behavior or suicidal threats

Rx:

- Outpatient psychotherapy is treatment of choice supported by other treatments such as support groups

Nursing Process Elements

- Promote safety with a no-harm contract
- Help client to cope and control emotions with techniques such as journaling and identifying feelings
- Use and teach cognitive restructuring techniques
 - thought stopping
 - decatastrophizing
- Teach social and communication skills
- Set behavioral limits and personal boundaries
- Confront inappropriate behaviors
- Teach time structuring by making lists and written schedule of activities

Think Smart/Test Smart

Be aware that borderline personality disorder is sometimes referred to as emotional regulation disorder.

HISTRIONIC PERSONALITY DISORDER

S&S: The client

- is overly dramatic and displays intensely expressive behavior
- enjoys being the center of attention
- has a behavior that is lively, impulsive, and dramatic
- is overly concerned with appearance
- shows an overly flirtatious and seductive behavior
- is vain with much concern about appearance with possible exhibitionism
- has an intense affect
- does not tolerate being alone
- is egocentric, self-indulgent, and lacking in consideration of others

Rx:

- Individual psychotherapy with focus on solving client's problems rather than making permanent personality changes
- Pharmacologic therapy may be used to relieve some symptoms such as depression or anxiety

NARCISSISTIC PERSONALITY DISORDER

S&S: The client

- has an increased sense of self-importance
- has a constant need for attention and admiration
- lacks empathy and may use people to achieve own goals
- is self-absorbed and self-centered
- expects to be seen as superior
- is driven and goal oriented
- exaggerates talents, achievements, and self-importance
- expects special and favorable treatment

Rx:

- Most clients seek treatment when in a crisis and then terminate it when symptoms ease
- If willing to continue treatment, long-term psychotherapy is treatment of choice
- Group therapy is not effective because client often dominates group with need for attention and sense of superiority

Nursing Process Elements

- Always approach client in a matter-of-fact manner
- Avoid reinforcing inappropriate behavior and superior view of self
- Avoid defensiveness and arguing
- Focus on positive traits
- Teach appropriate social skills

PARANOID PERSONALITY DISORDER

S&S: The client

- is suspicious and distrusting of others' motives
- is unable to confide in others
- is unable to relax
- shows social detachment and aloofness
- displays hypersensitivity

Rx:

- Individual psychotherapy.
- Pharmacologic therapy on a limited basis to treat severe symptoms of anxiety, agitation, or depression.

Nursing Process Elements

- Establish an honest therapeutic relationship using a professional approach rather than a casual approach
- Listen to client's expression of feelings without becoming defensive or arguing
- Do not challenge the paranoid beliefs
- Identify behaviors that negatively impact relationships and how such behaviors affect others

SCHIZOID PERSONALITY DISORDER

S&S: The client

- shows social detachment and lack of close relationships
- shows emotional detachment
- has a lack of strong emotions with little outward sign of change in mood
- is unconcerned with others' feelings
- is indifferent to praise or criticism
- does not have close friends and is not at ease with people
- seldom feels pleasure

Rx:

- Short-term psychotherapy when individual seeks therapy —Usually will not seek therapy unless under extreme stress
- Group therapy
- Cognitive therapy
- Support groups
- Pharmacologic therapy as needed for overlapping disorders such as depression

DISSOCIATIVE DISORDERS

- Dissociative disorder refers to a disruption in functions of memory, consciousness, or identity.
- It is associated with exposure to an overwhelming traumatic event.
- In general, it is still a poorly understood phenomenon.
- It is classified as four types:
 - dissociative identity disorder
 - dissociative fugue
 - dissociative amnesia
 - depersonalization disorder

Etiology:

- Basically unknown but believed to be a defense mechanism used to cope with severe trauma.

S&S:

- Dissociative identity disorder
 - Presence of two or more distinct and unique personalities existing within the same person

- These personalities may not be aware of each other
- Each personality recurrently takes control of person's consciousness and behavior
- Dissociative fugue
 - Episodes of suddenly traveling away from home or work without any explanation and being unable to remember past or identity
 - May assume a new identity
- Dissociative amnesia
 - Inability to recall important personal information usually related to a traumatic or stressful event
 - Often does not recognize the inability to recall information
- Depersonalization disorder
 - Persistent or recurrent feeling of being detached from his or her mental processes or body
 - Feels as if watching self from a distance or living in a dream

Dx:

- There are no diagnostic tests that definitively confirm dissociative disorders. Diagnosis is based upon manifestations of the disease with data obtained from a mental-status examination, psychiatric history, and careful clinical observation

Rx:

- Individual psychotherapy
- Group therapy
- Cognitive behavioral therapy
- Pharmacologic therapy as needed for related symptoms such as depression or anxiety

**Nursing Process Elements**

- Establish trusting therapeutic relationship with client
- Encourage client to recognize use of defense mechanisms when faced with stressful situations
- Help client to develop effective coping skills
- Monitor for signs of possible self-harm or aggression toward others

SCHIZOPHRENIA

- Schizophrenia is a cluster of psychotic brain disorders that causes distorted and bizarre thoughts, perceptions, movements, emotions, and behavior.
- It is usually diagnosed in late adolescence or early adulthood.
- Subtypes of schizophrenia have similar features, but differ in their clinical presentations.
- Subtypes include paranoid, disorganized, undifferentiated, catatonic, and residual schizophrenia.

- It is often misunderstood by the public who may fear dangerous and uncontrollable behavior.

Etiology: Cause is uncertain, but several factors have been identified as having a high correlation with the development of schizophrenia. These include

- brain structure including imbalance in chemical neurotransmitters.
- genetic factors: studies show there is increased risk for the development of schizophrenia with a positive family history.
- psychological factors especially stress, with the presence of a genetic predisposition.
- environmental factors such as exposure to viruses in infancy or oxygen deprivation at birth.

S&S: Classified as positive, negative, and disorganized symptoms.

- Positive symptoms are those that are present but should be absent such as hallucinations. They indicate the person has lost touch with reality.
- Negative symptoms are those that reflect absence of normal characteristics such as apathy.
- Disorganized symptoms reflect abnormal thinking, inability to communicate, and strange behavior such as walking in circles or incoherent ramblings.

In general, the manifestations of schizophrenia are

- positive symptoms
 - hallucinations
 - false sensory perceptions that may involve any of the five senses
 - often manifests as voices the client hears
 - delusional ideation—a false belief with no basis in reality. Common types of delusions include
 - persecutory/paranoid—belief that “others” are following, tormenting, or planning to harm the client
 - grandiose—belief of being more important or of having powers others do not have
- negative symptoms
 - flat or blunted affect
 - poverty of speech
 - lack of self-care
 - social withdrawal
 - anhedonia: inability to experience pleasure or joy in life
- disorganized symptoms
 - abnormal speech patterns such as
 - word salad—jumbled words or phrases that are disconnected and make no sense to the listener (“See her dress, car, clouds, wall.”)
 - clang associations—words that rhyme or sound alike (“Look at the cow, wow, how, pow.”)

- echolalia—imitation or repetition of what someone else says
- neologisms—inventing new words which are only meaningful to that person
- latency of response—longer than usual hesitation when responding to questions
- loose association and flight of ideas—rapid succession of incomplete ideas that are not connected
 - Bizarre behaviors, examples include inappropriate laughing, walking in circles, and repeated gestures

Dx:

- There are no diagnostic tests that definitively confirm schizophrenia. Diagnosis is based upon manifestations of the disease with data obtained from a mental-status examination, psychiatric history, and careful clinical observation.
- A thorough physical and psychiatric evaluation is needed to rule out other possible causes of the symptoms such as a brain tumor or thyroid disorder.

Rx: The primary treatment of schizophrenia is drug therapy to control the main symptoms. In addition, other treatments such as psychotherapy, vocational counseling, and structured milieu therapy are needed to assist the client with social adjustment.

- Drug Therapy—Use of antipsychotic drugs is a critical component in symptom reduction. Two categories of antipsychotics are available: conventional and atypical. In addition, anti-Parkinsonism medications are often used to prevent or manage extrapyramidal effects (EPS).
- Conventional or typical antipsychotic medications, for example, haloperidol (Haldol) and chlorpromazine (Thorazine)
 - effectively treat the positive symptoms but have no therapeutic effect on the negative symptoms.
 - are used less frequently mostly because they are only partially effective.

**Clinical Alert**

Typical antipsychotic medications haloperidol (Haldol) and fluphenazine (Prolixin) may be suggested for noncompliant clients because they are available in long-acting injection form.

- Atypical antipsychotic medications, for example, risperidone (Risperdal) and olanzapine (Zyprexa)
 - aid in relief of both positive and negative symptoms
 - are less likely to cause the side effects of EPS or tardive dyskinesia (TD)

**Clinical Alert**

Clozapine (Clozaril) is an atypical antipsychotic medication that may cause agranulocytosis—a potentially fatal blood disorder marked by a very low WBC count. WBC counts must be performed every 2 weeks.

- Side effects of antipsychotic medications:
 - Sedation
 - Photosensitivity
 - Anticholinergic effects including orthostatic hypotension, tachycardia, dry mouth, constipation, blurred vision, and urinary retention (These side effects may lessen over time.)
 - EPS

**Clinical Alert**

All EPS effects are reversible and can be treated with anticholinergic medications.

- Pseudoparkinsonism—includes shuffling gait, mask-like face, muscle stiffness, drooling, and difficulty in initiating movement
- Akathisia—characterized by restless movement, pacing, unable to remain still, report of inner restlessness
- Dystonia—characterized by spasms in particular muscle groups such as the neck muscles. May be accompanied by protrusion of the tongue and dysphagia. Laryngeal and pharyngeal spasms can compromise the client's airway causing a medical emergency
 - TD is a late-appearing side effect and includes manifestations such as involuntary and abnormal movements of the mouth, tongue, face, and jaw. It may progress to include the limbs

**Clinical Alert**

TD is an irreversible condition. Put these medications on hold and report findings to health care provider immediately.

Assessment Alert

Administer the Abnormal and Involuntary Movement Scale (AIMS) to assess clients on antipsychotic medications.

- Neuroleptic malignant syndrome (NMS) is a potentially lethal side effect that requires emergency treatment. Manifestation include
 - hyperthermia
 - muscle rigidity
 - tremors
 - altered consciousness
 - tachycardia
 - hypertension
 - incontinence
- Anti-Parkinsonism (anticholinergic) medications are often used to prevent or manage EPS of antipsychotic medications. Examples include benztropine (Cogentin) and trihexyphenidyl (Artane).

Nursing Process Elements

- Assess for the manifestations of schizophrenia. Also assess for suicidal ideation and family/community support
- Promote safety. This includes observing for signs of increasing agitation.
 - Allow personal space
 - Monitor nutritional intake
 - Assist with ADLs as needed
 - Offer a quiet environment
 - Medicate as required
 - Avoid confrontations that may incite physical acting-out behavior that might necessitate restraint or seclusion

Nursing Intervention Alert

Use touch with caution. People with schizophrenia require a large personal space and often do not trust others. Touching could lead to an aggressive reaction.

- Establish a therapeutic relationship
 - Give clear explanations of rules and processes to follow
 - Use therapeutic communication

- Interventions for delusional thoughts
 - Initially, do not argue or try to convince the client that delusions are not real
 - Interact with the client in the here and now and on the basis of real things
 - Never convey that you believe the delusions
 - Later in the relationship and if the delusions are not fixed, nurse may interject doubt by presenting a factual account of the situation as he or she sees it
- Interventions for hallucinations
 - Provide protective supervision and appropriate space
 - Attempt to decrease the associated stimuli if possible
 - Avoid interacting as if the voices were real and let the client know you do not share the same reality. Say something like: “I know the voices are real to you, but I don’t hear them.”
 - Reassure client that you will not let anyone or anything hurt him or her while in the hospital
 - If client is frightened, do not ask for details of what is frightening; acknowledge you know he or she feels frightened; state that you cannot see or hear the frightening things; reaffirm belief that the client is safe
 - Attempt to determine if the voices are telling the client to do something harmful to self or others
 - If possible, engage in short periods of reality based conversation using simple concrete terms and as few words as possible because attention span is limited
 - Keep to simple, basic topics of conversation such as “What activities are planned for today?”
 - Do not share personal information or use terms such as “we”, “us”, or “let’s.” Must maintain separate identity from the client and not provide content for new imaginary figures or situations
 - Do not make promises that you may not be able to keep
 - Validate reality by orienting to time, place, and person, and who the staff are
 - Provide a structured, protective, and nonthreatening, environment with routine activities
 - Be alert for increasing anxiety and agitation then intervene as needed

Clinical Alert

Remember, hallucinations are very real to the client and often cause them to be frightened and respond erratically.

- Promote socialization
 - If the client displays inappropriate behavior in public, attempt to redirect behavior or provide for privacy

- Remind and assist the client to attend to personal hygiene and appearance
- Identify family and community support
- Interventions for paranoia
 - Tell client what you are doing before you do it
 - Follow through on your word to promote trust
 - Do not argue or disagree; be matter of fact and accept what client says
 - Be aware of interpersonal discomfort and do not force closeness or social interaction
 - Limit number of staff members initially involved with client
 - Avoid competitive activities but encourage meaningful activities that can be easily done

Client teaching for self-care

Teach the client about

- how to manage illness and symptoms
- medication regimen
- importance of maintaining prescribed medication regimen and regular follow-up with health care providers
- management of side-effects of medications
- never discontinuing medications abruptly
- avoiding alcohol and other drugs that are not prescribed
- need for self-care and proper nutrition
- social skills
- identifying stressful situations and ways to avoid or cope with them
- signs of relapse and what to do if they occur

Provide the client with names and contact information of community and supportive organizations and groups

Include teaching of all the above to the client's family and other support individuals

SOMATIFORM DISORDERS

- In somatoform disorders, anxiety is redirected into a somatic concern.
- The individual has excessive worry or complaints about physical illness without supporting physical findings.
- Physical signs and symptoms increase with psychosocial stress.
- Primary disorders include
 - somatization disorder
 - conversion disorder
 - hypochondriasis

Etiology:

- Exact cause is unknown.

- Thoughts about cause include theories related to
 - response to repression of emotions.
 - learned response: imitate behavior of a parent especially if secondary gains are reaped in response to the physical symptom.
 - Primary gain—direct external benefits that being sick provides such as relief of anxiety, conflict, or distress.
 - Secondary gain—internal or personal benefits received from others because one is sick such as attention from family and “special” treatment.

S&S:

- Somatization disorder
 - Multiple, usually vague physical complaints that suggest a physical disorder but have no physical basis
 - Most often complaints of GI, neurologic, cardiopulmonary, or reproductive problem
 - Often complaints involve multiple symptoms in more than one body system
 - History usually involves multiple examinations and work-ups by multiple physicians
- Conversion disorder
 - Physical symptoms such as blindness, paralysis, or inability to talk without a demonstrable physiologic basis
 - Tendency to not show concern about the symptom or limitation is a hallmark of the disorder. This is also called *la belle indifference* (French for “beautiful indifference”)
 - Onset may occur at any age, but often begins in adolescence
- Hypochondriasis
 - Persistent belief that one has or is highly predisposed to get a serious disease
 - Usual focus is on one body system
 - Complaints do not fit a recognizable pattern of organic disease
 - Examination and reassurance by health provider does not relieve concerns

Dx:

- There are no diagnostic tests that definitively confirm a somatoform disorder. Diagnosis is based upon manifestations of the disease with the data obtained from a mental-status examination, psychiatric history, and careful clinical observation
- A thorough physical and psychiatric evaluation is needed to rule out other possible causes of the symptoms

Rx:

- Individual, group and family psychotherapy
- Relaxation techniques
- Pharmacological treatment as needed for related symptoms such as depression or anxiety

Nursing Process Elements

- Establish a supportive, therapeutic relationship
- Provide for physical needs when client is unable to do so, for example, if experiencing paralysis due to conversion disorder
- Encourage client to express feelings rather than repress or suppress them
- Assist client in finding ways to increase coping skills
- Common mental-health illnesses in older populations include depression, delirium, and dementia. Table 12–3 discusses nursing strategies to manage mental-health illnesses in the older adult.
- Mental illness can be difficult for the elderly client to manage. Refer to Table 12–4 for nursing interventions to decrease stress and anxiety in the elderly client who is experiencing mental illness.

MENTAL-HEALTH ILLNESS IN OLDER ADULTS

Table 12–3 Nursing Management of Mental-Health Illness in Older Adults

| Illness | Factors | Symptoms | Treatment | Nursing Management |
|------------|---|--|---|---|
| Depression | Most common mood disorder of old age; responsive to treatment; may be an early sign of chronic illness or the result of physical illness; often goes undiagnosed and untreated; alcohol abuse related to depression is significant in the elderly. | Feelings of sadness, fatigue, diminished memory and concentration; feelings of guilt or worthlessness; sleep and appetite disturbances; restlessness; and suicidal ideation | Selective-serotonin reuptake inhibitors: Paroxetine (Paxil) Tricyclic antidepressants: Nortriptyline (Aventyl), desipramine (Norpramin), doxepin (Sinequan) Arrange individual, group, or family therapy to explore feelings and utilize nonpharmacological treatment options when indicated. | Offer explanation of the illness and support for seeking treatment. Encourage expression of feelings and questions regarding treatment. Allow the client time to process any new information to decrease confusion. Encourage treatment for alcohol abuse and facilitate community resources. |
| Delirium | Begins with confusion and progresses to disorientation; is considered a medical emergency; secondary to physical illness, medications, alcohol toxicity, dehydration, fecal impaction, malnutrition, infection, head trauma, and sensory overload or deprivation; if left untreated, permanent brain damage can occur | Disorganized thinking, short attention span, hallucinations, delusions, fear, anxiety, and paranoia | Management varies depending on reason for the symptoms. Discontinue nonessential medications. | Provide a calm and quiet environment. Increase orientation by encouraging friends and family members to speak to and touch the client. Perform ongoing mental-status assessments to help evaluate treatment. |
| Dementia | Mostly affects elderly living in institutional settings; secondary to alcohol abuse, polypharmacy, and psychiatric disorders. Types of dementia include Alzheimer's disease, Parkinson's disease, AIDS-related dementia, Pick's disease. | Subtle in onset; forgetfulness, memory loss, depression, word-finding difficulty, absence of abstract thinking, impulsive behavior, difficulty maintaining activities of daily living, hostility, paranoia, suspicion, combativeness, agitation, night wandering | Medications: tacrine hydrochloride (Cognex), donepezil (Aricept), rivastigmine (Exelon) | Make certain eye glasses, hearing aids, etc., are in use to optimize ability to perceive environment. Determine how the client likes to be addressed and use consistently. Make face-to-face contact with the client. Keep the client in familiar environment. Assist with activities of daily living but do not let the client stop doing those things that he or she can. |

(continued on next page)

Table 12–3 (continued from previous page)

| Illness | Factors | Symptoms | Treatment | Nursing Management |
|---------|---------|----------|-----------|---|
| | | | | Remind client of what he or she can do, no matter how little. Explain physical procedures before carrying them out. Limit environmental stimuli to promote relaxation. Do not distress the client by asking a lot of questions or saying “Remember...” Prominently display clocks and calendars to orient to time. Provide a simple chart of daily activities. Encourage physical activity and communication. Use short, simple, and direct statements and talk about real, concrete, observable things. Promote independence in self-care activities. Reduce anxiety and agitation (see Table 12–4). To reduce confusion occurring at night (sun downing), leave a night light and radio on or have someone stay nearby. |

Table 12–4 Nursing Interventions to Decrease Anxiety in Mentally Ill Older Adults

| |
|---|
| Provide an uncluttered, familiar, and noise-free environment |
| Remain calm and unhurried when delivering care to the client |
| For clients who become agitated, provide music, distraction, and stroking. Structure activities to provide distraction |
| Use clear, easy-to-understand language when communicating with the client |
| Promote independence in self-care activities. Organize daily activities into short, manageable tasks to give the client a sense of accomplishment |
| Balance activity and rest periods |
| Teach the client to listen to soft music or drink warm milk to induce sleep |

Nursing Intervention Alert

Anticholinergic, cardiac, and orthostatic side effects, as well as interactions with other medications require that antidepressants are prescribed and administered with care.

A summary of some common mental illnesses including their symptoms, treatments, and appropriate nursing interventions are given in Table 12–5.

Client teaching for self-care

Summarizing the important points of client teaching, the nurse must teach

Table 12–5 Summary Comparison of Common Mental Illnesses

| Mental Illness | Symptoms | Treatment | Nursing Intervention |
|---------------------------------|---|--|---|
| Alzheimer's disease | <ul style="list-style-type: none"> • Forgetfulness or memory loss • Depression • Disorientation • Speech difficulties • Impulsive behavior • Difficulty performing activities of daily living • Personality changes • Agitation • Increase in physical activity • Sundowning | <ul style="list-style-type: none"> • Medications: cholinesterase inhibitors | <ul style="list-style-type: none"> • Maintain client safety • Reduce anxiety and agitation • Improve communication • Promote independence • Assist in socialization • Increase self-esteem • Manage sleep disturbance • Educate family and significant others |
| Borderline personality disorder | <ul style="list-style-type: none"> • Self-image rapidly changes • View self as evil or bad • Frequent changes in jobs, friendships, goals, values, and gender identity • Engage in impulsive, risky behavior • Inappropriate anger • Fear of being alone • Strong emotions that wax and wane frequently • Difficulty controlling emotions or impulses | <ul style="list-style-type: none"> • Psychotherapy • Medications: antidepressants, antipsychotics, and anxiolytics | <ul style="list-style-type: none"> • Encourage adherence to the treatment plan • Encourage regular attendance at therapy sessions • Explore client feelings of self-blame • Assist client in recognizing symptoms of compulsive behavior, such as substance abuse and facilitate community resources and support systems. |
| Bipolar disorder | <ul style="list-style-type: none"> • Manic episode: elevated mood (feeling extremely happy), irritability, anxiousness, rapid speech, decreased need for sleep, impulsive behavior, delusions, hallucinations, paranoia • Depressive episode: overwhelming feelings of emptiness or sadness, lack of energy, loss of interest in activities, impaired concentration, sleep disturbances, appetite disturbances, suicidal ideation | <ul style="list-style-type: none"> • Psychotherapy • Medications: antidepressants, anxiolytics, antimanic, anticonvulsants | <ul style="list-style-type: none"> • Maintain client safety • Assist client in recognizing symptoms of manic and depressive episodes • Explore client feelings of depression • Assist client in establishing behavioral boundaries • Facilitate community resources and support systems |
| Depression | <ul style="list-style-type: none"> • Feelings of sadness • Fatigue • Diminished memory and concentration • Feelings of guilt or worthlessness • Sleep disturbances • Appetite disturbances • Restlessness • Impaired attention span • Suicidal ideation | <ul style="list-style-type: none"> • Antidepressants • Psychotherapy • Electroconvulsive therapy | <ul style="list-style-type: none"> • Maintain client safety • Encourage client participation in decisions related to care • Encourage self-care • Consider the client's background, capabilities, interests, values and beliefs, culture, and lifestyle when planning care • Facilitate individual, group, and family therapy when appropriate. Incorporate therapy goals into the plan of care • Provide education to the client, family, and significant others |
| Schizophrenia | <ul style="list-style-type: none"> • Delusions • Hallucinations • Incoherent speech • Lack of emotions or inappropriate display of emotions • Paranoia • Social isolation • Poor hygiene • Lack of coordination | <ul style="list-style-type: none"> • Psychotherapy • Medications: antipsychotics | <ul style="list-style-type: none"> • Maintain client safety • Orient the client to surroundings and time • Encourage self-care • Assist in boundary compliance • Assist with communication • Encourage regular attendance at therapy sessions • Facilitate community resources and support systems |

- the client, family, and significant others about the importance of functioning within the therapeutic environment and complying with boundaries
- the client about the importance of attending community meetings and therapy sessions
- the family to identify stressors and their impact on the client's recovery
- the client, family, and significant others about strategies to manage anxiety
- the family and significant others to gently orient the client to the surrounding environment and the present time
- the client about healthy ways to ease painful emotions, rather than to inflict self-injury
- the client, family, and significant others to recognize situations that trigger angry outbursts or impulsive behavior

Nursing Intervention Alert

Smokers may need higher doses of antipsychotic medication because nicotine interferes with these medications.

CHEMICAL AND OTHER DEPENDENCIES

- Substance abuse results when the client is not able to cope with the burdens of life.
- Chemical dependency is significantly related to risk-taking behavior.
- Many clients deny or understate the degree to which they use alcohol and drugs. Refer Table 12–6 for commonly abused substances.
- The nurse may ask questions such as “What kind of alcohol do you enjoy drinking at a party?” to gather specifics about a client's behaviors.
- The nurse documents the specific type of substance ingested, inhaled, or injected (beer, crack cocaine, heroin, nicotine, caffeine, etc.) and the amount per day or week (12-12 oz beers a week for 3 years, 2 packs of cigarettes per day for 20 years).
- Alcohol abuse screening questionnaires such as CAGE, AUDIT, TWEAK, or SMAST can be used to elicit information about alcohol use.
- The nurse uses a nonjudgmental approach when questioning clients.
- The nurse understands that many clients who abuse substances take a variety of drugs simultaneously (alcohol, barbiturates, opioids, and tranquilizers).
- The nurse approaches substance abusers in a calm, consistent, and accepting manner because substance abuse impairs thought processes.
- The nurse assists the client, family, and significant others in identifying behaviors associated with chemical dependency and abuse.
- Clients who are aggressive or belligerent may require sedation.
- The nurse monitors appropriate clients for delirium tremens—the most severe form of alcohol withdrawal. Symptoms include anxiety, uncontrollable fear, tremor, irritability, agitation, hallucinations, and insomnia. This condition is life-threatening and requires immediate intervention.
- In the presence of delirium tremens or drug toxicity, the nurse maintains client safety, administers medications used in treatment, and promotes a quiet environment for recovery. The client's private room remains lighted to minimize the potential for hallucinations.
- The client is observed for suicidal behavior and is later referred to a rehabilitation center for treatment and counseling.
- The nurse helps the family members confront the situation, decrease their enabling behaviors, and motivate the client to obtain treatment.
- Some family members of substance abusers exhibit codependent behavior like exercising control over others, remaining involved and suffering with a client who has a drug problem, and struggling with the need to be needed. The nurse guides the family in breaking this unhealthy pattern.
- Social support services for the client, family, and significant others include Alcoholics Anonymous, Narcotics Anonymous, Al-Anon, Alateen, and church groups.
- The nurse works with the client, family, and significant others to prevent and prepare for relapse. Relapse is viewed and treated in the same way as chronic illness.
- Nonsubstance-related dependencies include gambling, sexual addiction, and pornography.

Table 12–6 Commonly Abused Substances

| Substance | Effect of Substance | Effect of Withdrawal | Treatment | Nursing Interventions |
|--|--|--|---|--|
| Alcohol | Drunkenness, drowsiness, behavioral changes, poor judgment, coordination difficulty, slurred speech, aggression, inappropriate sexual behavior, nystagmus, memory problems, poor attention span, stupor, coma | Agitation, altered consciousness, aggressiveness, fear, anxiety, confusion, disorientation, delusions, hallucinations, insomnia, blackouts, acute psychosis, profuse sweating, tachycardia, hypertension, tachypnea, grand mal seizures, anorexia, nausea, abdominal cramps, vomiting, tremors | <ul style="list-style-type: none"> • Detoxification • Medication: benzodiazepines, anti-seizure medications • Psychotherapy • Behavior therapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Maintain client safety • Monitor vital signs and neurologic status; notify physician of abnormal readings • Provide a quiet environment with a light on • Orient client to place, person, and time • Record I&O • Allow client to express fears and anxiety • Implement seizure precautions • Allow ambulation ad lib • Provide small, frequent, high-carbohydrate feedings • Provide support to the client, family, and significant others |
| Barbiturates Amobarbital (Amytal), pentobarbital (Nembutal), secobarbital (Seconal) | Sluggish coordination, emotional lability, aggressiveness, faulty judgment, nystagmus, diplopia, strabismus, decreased reflexes, ataxic gait, stupor, bradycardia, respiratory depression, decreased tendon reflexes | Anxiety, irritability, tachycardia, tachypnea, muscle pain, nausea, tremors, hallucinations, confusion, seizures, insomnia, vivid dreaming, coma, death | <ul style="list-style-type: none"> • Detoxification • Medications: slowly taper the abused barbiturate; sodium bicarbonate promotes excretion of barbiturates; use activated charcoal for overdose • Psychotherapy • Behavior therapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Maintain client safety • Maintain airway • Monitor for alcohol abuse • Monitor vital signs and neurologic status; notify physician of abnormal readings • Provide a quiet environment with a light switched on • Orient client to place, person, and time • Control combative behavior • Allow client to express fears and anxiety • Implement seizure precautions |
| Benzodiazepines: Diazepam (Valium) Lorazepam (Ativan) | Sleepiness and deep sleep, slurred speech, poor coordination and falling, poor thought processes, weak comprehension, memory difficulty, poor judgment, mood swings, nystagmus, constricted pupils, tachypnea | Anxiety, panic attacks, rage, insomnia, nightmares, depression, dizziness, shaking, nausea, constipation, diarrhea, headache, muscle pain, sweating, tachycardia, paresthesia, seizures, death if combined with alcohol | <ul style="list-style-type: none"> • Detoxification • Medications: antagonist flumazenil (Romazicon); slowly taper the abused benzodiazepine • Psychotherapy • Behavior therapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Maintain client safety • Monitor for alcohol abuse • Monitor vital signs and neurologic status; notify physician of abnormal readings • Monitor for dysrhythmias • Provide a quiet environment • Allow client to express fears and anxiety • Implement seizure precautions |

(continued on next page)

Table 12–6 (continued from previous page)

| Substance | Effect of Substance | Effect of Withdrawal | Treatment | Nursing Interventions |
|--|--|---|---|---|
| Cocaine Cocaine hydrochloride (sniffed), free-base cocaine (smoked), crack cocaine (small rocks that are smoked); cocaine may be injected intravenously | Euphoria, feelings of confidence, risk taking behavior, anorexia, inappropriate sexual behavior, tachycardia, tachypnea, hypertension, dilated pupils, nervousness, agitation, fever, inability to concentrate | Psychosis, hallucinations, delusions, depression, paranoia, ideas of persecution, hypervigilance, aggression, tremors, insomnia, fatigue, muscle pain, suicidal ideation, nausea, vomiting, general malaise | <ul style="list-style-type: none"> • Detoxification • Medications: antidepressants, antipsychotics • Charcoal to treat ingested cocaine • Psychotherapy • Behavior therapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Ensure airway and ventilation • Maintain client safety • Monitor the client for alcohol and benzodiazepine use • Control seizures • Monitor cardiovascular status • Treat hyperthermia • Provide a quiet environment • Allow client to express fears and anxiety |
| Methamphetamines amphetamine (Benzedrine), dextroamphetamine (Dexedrine), MDMA (Ecstasy), methylphenidate (Ritalin) | Increased attention, decreased fatigue, increased activity, decreased appetite, euphoria, hyperthermia, tachycardia | Restlessness, insomnia, irritability, confusion, panic, paranoia, homicidal behavior, depression with suicidal ideation, hallucinations, nausea, vomiting, chills | <ul style="list-style-type: none"> • Detoxification • Medications: small doses of diazepam IV or haloperidol to combat CNS hyperactivity; treat seizures with benzodiazepines • Activated charcoal for overdose • Psychotherapy • Behavior therapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Maintain client safety • Monitor for suicide attempts • Maintain airway • Maintain a calm, cool, quiet environment • Monitor vital signs and neurologic status; notify physician of abnormal readings • Allow client to express fears and anxiety |
| Nicotine Tobacco smoking, chewing, dipping | Mild euphoria, anorexia, feelings of relaxation, tachycardia, hypertension | Irritability, restlessness, difficulty in concentrating, insomnia, depression, increased appetite, weight gain | <ul style="list-style-type: none"> • Detoxification • Medications: nicotine gum, nicotine nasal sprays, nicotine patches • Psychotherapy • Behavior therapy • Support groups | <ul style="list-style-type: none"> • Maintain client safety • Monitor vital signs and neurologic status; notify physician of abnormal readings • Allow client to express fears and anxiety • Offer support to client, family, and significant others |
| Opioids Heroin, codeine, hydromorphone (Dilaudid), meperidine (Demerol), methadone, propoxyphene (Darvon), oxycodone (OxyContin), fentanyl (Sublimaze) | Temporary sense of well-being, poor coordination, drowsiness, light-headedness, impaired thought processes, confusion, memory difficulty | Gastrointestinal distress, anxiety, nausea, insomnia, muscle pain, fevers and chills, sweating, runny nose and eyes, tachypnea, coma, pinpoint pupils | <ul style="list-style-type: none"> • Detoxification • Medications: opiate antagonist naloxone (Narcan) IV in emergency situations; in morphine and heroin addicts, give methadone daily to stabilize the client; in other opioid addicts, slowly taper the abused opioid • Psychotherapy • Twelve-step support groups • Halfway houses • Day or night hospitalization | <ul style="list-style-type: none"> • Maintain client safety • Do not leave client unattended due to risk of lapsing into coma quickly • Maintain airway • Monitor for pulmonary edema • Monitor vital signs and neurologic status; notify physician of abnormal readings • Provide a quiet environment • Allow client to express fears and anxiety |

- These addictions can cause stress, alcohol abuse, loss of income and assets, treatment nonadherence, malnutrition, safety risks related to associated alcohol usage and financial losses, and increased psychiatric problems such as depression.
- Pharmacological treatment strategies include mood stabilizers, serotonin reuptake inhibitors (SRIs), selective-serotonin reuptake inhibitors (SSRIs), and antipsychotics. Nonpharmacological treatment includes behavioral therapy to control obsessive compulsions.
- The nurse's role in management of the client who experiences dependency is to provide information and support to the client, family, and significant others, evaluate treatment measures and revise the plan of care as needed, and facilitate community resources and social support systems.

Clinical Alert

Alcohol withdrawal delirium is a life-threatening event that requires immediate intervention.

Client teaching for self-care

The nurse must teach

- the client, family, and significant others about the symptoms of chemical abuse and other dependencies
- family members and significant others about strategies to decrease codependent behavior
- the client, family, and significant others about how to access community resources and social supports
- the client, family, and significant others about the risk factors and signs of suicidal behavior, and to access help immediately if suicide is suspected

ABUSE AND VIOLENCE

ABUSE/NEGLECT

- Abuse and neglect can occur as physical, sexual, and psychological. Abuse and neglect occur at all ages and affect both genders from all socioeconomic, ethnic, and cultural groups.
- Few clients openly admit to abuse and neglect, especially elderly clients. The nurse should ask direct questions during the client's assessment. These questions should be asked in private, away from others. Refer to Table 12-7 for a list of questions to ask when assessing a client for abuse or neglect.
- All disabled and elderly clients should be assessed for possible abuse and neglect. Refer to Table 12-8 for the types of abuse and neglect directed at disabled and elderly clients.
- In caring for an elderly or disabled client who has experienced abuse or neglect, the nurse must enlist the interdisciplinary team to help the caregiver develop self-awareness, increased insight, and an understanding of the aging process and limitations of the disabled. The nurse also provides information to the client and caregiver regarding community resources and social supports.
- Domestic violence includes child abuse, elder abuse, and abuse of women and men.

Table 12-7 Abuse and Neglect Assessment Questions

Sometimes women (or men or children) are forced into sexual activity. Has this ever happened to you? Has anyone ever suggested they wish to engage you in sexual activity even when you've resisted?

If the client is pregnant—Since you have been pregnant, have you been hit, slapped, kicked, or physically hurt in any other manner by someone?

Has anyone failed to help you when you needed help?

I noticed that you have a number of bruises. Can you tell me how they happened? Has anyone hurt you?

You seem anxious. Has anyone ever hurt you or threatened to do so? Are you ever afraid of anyone close to you, such as your partner, caretaker, or any other family member?

Sometimes clients tell me that they have been hurt by someone at home or work. Is this happening to you?

Has anyone ever prevented you from seeing your friends or family members?

Have you ever been pressured to sign papers you did not understand or did not wish to sign?

- Violence is rarely a one-time occurrence in a relationship; it usually continues and escalates in severity.
- Female survivors of sexual abuse have more health problems and undergo more surgeries than nonvictims.
- Victims of childhood sexual abuse experience more chronic depression, posttraumatic stress disorder, morbid obesity, marital instability, gastrointestinal problems, headaches, and greater reliance on health care services than nonvictims.
- Risk factors for abuse include high levels of stress or alcoholism in caregivers, evidence of violence, high emotions, and financial, emotional, or physical dependency.
- Client symptoms of abuse may include suicide attempts, drug and alcohol abuse, frequent emergency department visits, multiple injuries in various stages of healing, unexplained injuries, vague pelvic pain, insomnia, and depression.
- Client symptoms of neglect may include poor hygiene, unkempt appearance, hunger, dehydration, pain, inadequate clothing or shoes, unfilled medication prescriptions, missed appointments with healthcare providers, and lack of ancillary devices when warranted (cane, walker, eyeglasses, or hearing aid).
- When evidence indicates possible abuse or neglect, the nurse documents the events and provides drawings or photos of injuries. The nurse examines the entire surface of the client's body, assesses the client's interactions with significant others, and performs a mental-status examination.
- Sometimes, no obvious signs or symptoms of abuse or neglect are present.
- The nurse's primary concern is the safety of the client. The client is separated from the abuser, and the interdisciplinary team and community agencies work collaboratively to support the client.
- Alternative living arrangements may be necessary if the abuser or neglecter experiences mental illness.
- Caregivers who inflict abuse or neglect are relieved of their immediate duties by respite services. Support groups are helpful to these caregivers.
- The nurse evaluates the response of the client, family, and significant others to these interventions and updates the plan of care as necessary.

Table 12–8 Forms of Elder- and Disabled-Client Abuse

| |
|------------------------|
| Physical violence |
| Personal neglect |
| Financial exploitation |
| Violation of rights |
| Denial of health care |
| Self-inflicted abuse |

Assessment Alert

During the health history, the nurse explores the client's past coping patterns, perceptions of current stresses, and the client's expectations of family, friends, and caregivers in providing financial, emotional, and physical support.

Practice Alert

The role of the nurse is not to prove the neglect or abuse, but to report it to an official agency.

Spouse or Partner Abuse

- Spouse or partner abuse may be emotional, physical, economic, sexual, or a combination which is very common.
- The most frequent abuse is that of a male on a female.
- Victims are more likely to abuse alcohol or drugs and to commit suicide.
- Attacks escalate in severity and frequency over time.
- Such abuse usually follows a cycle or pattern:
 - escalating tension
 - abuse
 - remorse, also called honeymoon period, in which the abuser
 - apologizes, promises it will never happen again
 - professes love for partner
 - often engages in romantic behaviors
 - tension-building phase begins again
- The most dangerous period is when the victim leaves the abuser.

Nursing Process Elements

- Identify possible victims—SAFE questions
 - Stress/safety: Do you feel safe?
 - Afraid/abused: Are you ever afraid in your relationship?
 - Friends/family: Are they aware you have been hurt?
 - Emergency plan: Do you have a safe place to go and the resources you may need?
- Refer to appropriate resources
 - Police or legal aid
 - Local shelters
 - Support groups

Elder Abuse

- Elder abuse includes both abuse and neglect such as physical harm, sexual or verbal intimidation, emotional or physical neglect, and/or economic exploitation.

- The risk factors include declining strength and mobility, functional decline and dependence on others, being cared for by a family caregiver, and cognitive decline.
- Elders are often reluctant to reveal abuse out of fear of abandonment or retaliation.
- Perpetrators are usually family members.

S&S:

- Unexplained bruising, burns, or injuries
- Dehydration and malnutrition
- Oversedation
- Bruises, wounds, and pressure ulcers
- Unmet physical and medical needs
- Fearfulness
- Conflicting stories from client and caregiver
- Reports of restraints or being locked in a room

**Nursing Intervention Alert**

- Nursing intervention includes
 - assessing for signs of abuse or neglect
 - treating existing injuries
 - reporting abuse to appropriate authorities, for example, hotline or Adult Protective Services
- Refer to community agencies offering services to older adults and their families
 - Respite for caregivers
 - Support groups for caregivers

**Assessment Alert**

Demands of caring for a family member can exceed the caregiver's capacity for adjustment and result in anxiety, depression, and physical illness. Therefore, assessment for caregiver distress, provision of support and validation, teaching about the role of Support groups and Respite Care, and referral to appropriate community agencies for help are critical parts of the nursing role.

Sexual Abuse

- Sexual abuse ranges from sexual harassment to molestation and rape.
- Immediate consequences of rape include
 - physical injury
 - pregnancy and sexually transmitted diseases

- rape-trauma syndrome
 - high level of anxiety
 - difficulty making decisions
 - flashbacks, violent dreams, and preoccupation with future danger
 - problems with intimate relationships
- In the long-term, the victim may experience posttraumatic stress disorder (PTSD), in which she
 - uses denial, repression, and suppression to cope with anxious feelings
 - shows symptoms including flashbacks, intrusive memories of the event, hopelessness, depression, nightmares, and outbursts of anger and rage

**Nursing Process Elements**

- Assess for sexualized behaviors in children
 - “seductive” behavior used to gain affection
 - unusual curiosity regarding genitalia
 - decreased personal boundaries
 - extreme reaction to bathing
 - extraordinary fear of the opposite sex
 - unwillingness to participate in age-appropriate physical or social activity
- In the emergency department, gather evidence with permission of the victim following policies of facility and law enforcement
- Give as much control as possible to the victim during the assessment and evidence-gathering process
- Treat physical injuries
- Advise about potential for pregnancy and STDs
- Listen to the client discuss feelings about the assault
- Provide information about community services

Child Abuse**Signs of physical abuse**

- Unexplained bruises or welts
 - Involve several different areas such as face, lips, and mouth or torso, back, buttocks, and thighs and show various stages of healing
 - Clustered in regular patterns often reflecting the shape of what was used to inflict injury, for example, belt, buckle, etc.
 - Often regularly appear after weekends, absences, or vacations
- Unexplained burns
 - Cigarette or cigar end shaped burns often on soles, palms, back, or buttocks
 - Immersion burns on hands and feet, appear like gloves or socks, round or donut shaped on buttocks
 - Shaped like an iron
 - Rope burns on arms, legs, neck, or torso

- Unexplained fractures particularly multiple and/or in various stages of healing
- Unexplained lacerations or abrasions especially to mouth, eyes, and external genitalia
- Reports of being injured by parents
- Expresses fear of going home
- Appears frightened of parents
- Exhibits either extreme aggressiveness or withdrawal
- Becomes apprehensive when other children cry
- Acts wary of contact with adults

Signs of physical neglect

- Always hungry
- Inappropriate dress
- Poor hygiene
- Consistent lack of supervision often for long periods of time and even when engaged in dangerous activities
- Uncared for medical or physical problems
- Abandonment
- Begging or stealing food
- Early arrival and late departure from school
- Fatigue
- Listlessness
- Alcohol or drug abuse
- Delinquency
- Reports lack of a caretaker

Risk factors for becoming an abusive parent

- Abused as a child
- Under significant stress
- Deficient in social and financial resources
- Uses inappropriate coping skills
- Lack of impulse control
- Anger and hostility
- Ambivalent toward parenthood

- Marital problems
- Mental illness
- Substance abuser
- Lack of knowledge regarding child development

Nursing Process Elements

- the client, family, and significant others about the signs of an impending crisis and effective problem-solving techniques to manage a crisis
- the client, family, and significant others about the signs of abuse and neglect, and to access help immediately if abuse or neglect are suspected
- caregivers about coping strategies to prevent abuse and neglect

Shaken Baby Syndrome

Shaken baby syndrome (SBS) is a form of physical abuse caused by rigorous shaking.

Risk factors

- Gender
- Financial stress
- Mental-health problems

S&S:

- Bulging fontanel
- Poor feeding
- Lethargy
- Seizures
- Retinal detachment
- Apnea

Nursing Process Elements

- Assure parents that age-appropriate play with infants will not cause injuries seen in SBS.

WORKSHEET

MATCHING QUESTIONS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all):

- | | |
|----------------------------|-------------------------------------|
| 1. ___ Psychopathology | a. Form of physical abuse |
| 2. ___ Alzheimer's disease | b. Screening tool for alcohol abuse |

- | | |
|---|---|
| 3. ___ Borderline personality disorder | c. False belief with no basis in reality |
| 4. ___ CAGE | d. Subjective disorder of perception |
| 5. ___ Bipolar disorder | e. Social support service for teenagers |
| 6. ___ Depression | f. An effective treatment for some depressions, catatonia, mania, and schizophrenia |
| 7. ___ Schizophrenia | g. A mental illness characterized by manic episodes, irritability, and anxiety |
| 8. ___ Suicide precautions | h. State of mental excitement accompanied by disorientation to time and place |
| 9. ___ Abuse | i. A common mental illness characterized by prolonged feeling of sadness, fatigue, diminished concentration, and feelings of guilt or worthlessness |
| 10. ___ Neglect | j. A mental illness characterized by memory loss, disorientation, speech difficulties, or impulsive behaviors; treated with cholinesterase inhibitors |
| 11. ___ Ecstasy | k. The most severe form of alcohol withdrawal; it is life-threatening and requires immediate intervention |
| 12. ___ Delirium tremens | l. A serious mental illness characterized by delusions, hallucinations, and paranoia |
| 13. ___ Shaken Baby Syndrome | m. A mood disorder related to time of year |
| 14. ___ TWEAK | n. A behavior-management technique used to give the client greater control over negative thinking by correcting mental distortions |
| 15. ___ Alateen | o. A commonly abused substance that produces increased attention, increased activity, decreased fatigue, decreased appetite, euphoria, and hyperthermia |
| 16. ___ Hallucinations | p. A mental illness characterized by rapid changes in self-image, inappropriate anger, and difficulty controlling emotions or impulses; treated with antidepressants, antipsychotics, and anxiolytics |
| 17. ___ Seasonal affective disorder | q. The act of withholding care from another individual; symptoms may include: poor hygiene, hunger, dehydration, or pain |
| 18. ___ Delirium | r. Measures that are ordered for clients who have either harmed themselves, have verbalized the intent to do so, or have overtly indicated a wish to do so |
| 19. ___ Delusion | s. Allowing the elderly client plenty of time to answer health-related questions |
| 20. ___ Electroconvulsive therapy (ECT) | t. Hearing loss due to the aging process |

(continued)

- u. Screening tool for psychological abuse
- v. Disorders of the psyche which may be characterized by disorientation, incoherent or illogical thought, or inappropriate dress
- w. A manifestation of stress experienced by clients as they face new challenges or threatening situations
- x. The most commonly abused substance in the United States
- y. A process that promotes expression and the exchange of ideas where the client defines himself or herself through human interaction and task accomplishment
- z. The act of harming another individual in a physical, sexual, and/or psychological way

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. _____ is a common mental illness affecting the elderly that is characterized by forgetfulness, memory loss, depression, disorientation, and impulsive behavior.
2. Bipolar disorder is characterized by an extreme elevation in mood called a _____.
3. _____ is sometimes referred to as an emotional regulation disorder.
4. Smokers may need higher doses of antipsychotic medications because _____ interferes with these medications.
5. _____ includes child abuse, elder abuse, and abuse of women and men.
6. Symptoms of _____ abuse include drowsiness, behavioral changes, slurred speech, and nystagmus.
7. _____ is given for an overdose of methamphetamines.
8. Desensitization therapy may be used in the treatment of _____ disorders.
9. Psychotherapy with the goal of helping the client see the relationship between feelings and behaviors is the treatment of choice for _____.
10. Extrapyramidal effects of antipsychotic drugs can be treated with _____ medications.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Because they are available in long-acting injectable form, the antipsychotic drugs haloperidol (Haldol) and fluphenazine (Prolixin) may be used for noncompliant clients. _____ T _____ F
2. Persons with schizophrenia prefer a smaller personal space than usual. _____ T _____ F

| | | |
|--|------------------|------------------|
| 3. Mood disorders are diagnosed based on clinical presentation because there are no definitive diagnostic tests. | <u> </u> T | <u> </u> F |
| 4. Smokers may need lower doses of antipsychotic medications because of the interaction with nicotine. | <u> </u> T | <u> </u> F |
| 5. Family reaction to a diagnosis of mental illness may include disbelief, anxiety, confusion, and denial. | <u> </u> T | <u> </u> F |
| 6. Poor hygiene, inappropriate dress, disorientation, and absent memory recall may be evidence of psychopathology. | <u> </u> T | <u> </u> F |
| 7. Strong emotions that wax and wane frequently and difficulty controlling these emotions are symptoms of Alzheimer's disease. | <u> </u> T | <u> </u> F |
| 8. Schizophrenia is characterized by delusions, hallucinations, social isolation, and paranoia. | <u> </u> T | <u> </u> F |
| 9. Abuse and neglect occur at all ages and affect both genders from all socioeconomic, ethnic, and cultural groups. | <u> </u> T | <u> </u> F |
| 10. Common substance-related dependencies include alcohol, gambling, and pornography. | <u> </u> T | <u> </u> F |

MATCHING QUESTIONS

Match the following (note that descriptions may be used once, more than once, or not at all):

- | | |
|--|--|
| 1. ___ Diazepam (Valium) | a. Benzodiazepine antianxiety agent |
| 2. ___ Escitalopram (Lexapro) | b. Monoamine oxidase inhibitor (MAOI) antidepressant |
| 3. ___ Phenelzine (Nardil) | c. Benzodiazepine antagonist |
| 4. ___ Sertraline (Zoloft) | d. Psychedelic |
| 5. ___ Methylphenidate (Ritalin) | e. Selective serotonin reuptake inhibitor antidepressant |
| 6. ___ Buspirone (Buspar) | f. Methamphetamine |
| 7. ___ Tranylcypromine (Parnate) | g. Opiate antagonist |
| 8. ___ Lorazepam (Ativan) | h. Antipsychotic |
| 9. ___ Flumazenil (Romazicon) | i. Serotonin modulator antidepressant |
| 10. ___ Naloxone (Narcan) | j. Tricyclic antidepressant |
| 11. ___ Chlorpromazine HCl (Thorazine) | k. Alcohol deterrent |
| 12. ___ Bupropion (Wellbutrin) | l. Antimania (mood stabilizing) agent |
| 13. ___ Loxapine (Loxitane) | m. Anti-Parkinsonism agent |

(continued)

- | | |
|--------------------------------------|----------------------------|
| 14. ___ Amitriptyline HCl (Elavil) | n. Anticonvulsant |
| 15. ___ Disulfiram (Antabuse) | o. Other antianxiety agent |
| 16. ___ Trazodone (Desyrel) | p. Other antidepressant |
| 17. ___ Lithium carbonate (Eskalith) | |
| 18. ___ Benzotropine (Cogentin) | |
| 19. ___ Nortriptyline HCl (Aventyl) | |
| 20. ___ Paroxetine (Paxil) | |
| 21. ___ Haloperidol (Haldol) | |
| 22. ___ Carbamazepine (Tegretol) | |
| 23. ___ Venlafaxine (Effexor) | |
| 24. ___ Fluphenazine (Prolixin) | |
| 25. ___ Valproic acid (Depokene) | |
| 26. ___ Fluoxetine (Prozac) | |
| 27. ___ Chlordiazepoxide (Librium) | |
| 28. ___ Risperidone (Risperdal) | |
| 29. ___ Alprazolam (Xanax) | |
| 30. ___ Clonazepam (Klonopin) | |
| 31. ___ Doxepin (Sinequan) | |
| 32. ___ Imipramine HCl (Tofranil) | |
| 33. ___ Clozapine (Clozaril) | |
| 34. ___ Olanzapine (Zyprexa) | |
| 35. ___ Citalopram (Celexa) | |

APPLICATION QUESTIONS

- | | |
|---|---------------------------|
| 1. Domestic violence is rarely a one-time occurrence in a relationship; it usually continues and escalates in severity. Which factors increase the risk of an individual becoming violent? (Select all that apply.) | a. Alcoholism |
| | b. High stress levels |
| | c. Financial independency |
| | d. Physical dependency |

2. Which symptoms are indicative of neglect? (Select all that apply.)
 - a. Emergency department visits
 - b. Missed appointments with health care providers
 - c. Dehydration
 - d. Unexplained injuries
3. A nurse in an Emergency Department (ED) is caring for a client who has been drinking alcohol everyday for the past 10 days. The client is drowsy, has slurred speech, and lacks coordination. As the client experiences alcohol withdrawal, which potential side effect concerns the nurse most?
 - a. Anxiety
 - b. Hypoglycemia
 - c. Esophagitis
 - d. Delirium tremens
4. Which nursing interventions are appropriate for a client experiencing alcohol withdrawal? (Select all that apply.)
 - a. Provide a private, lighted environment for recovery
 - b. Implement seizure precautions
 - c. Orient the client to person, place, and time
 - d. Provide small, frequent, high-carbohydrate feedings
5. A nurse in the Emergency Department is caring for a client who has been smoking crack cocaine. The client's pupils are dilated and the client is euphoric, tachycardic, and agitated. As the client experiences withdrawal from crack cocaine, which side effects should the nurse anticipate? (Select all that apply.)
 - a. Psychosis
 - b. Hallucinations
 - c. Illusions
 - d. Nausea and vomiting
6. Opioids are often prescribed by physicians for pain control and are commonly abused substances. Which medications are opioids? (Select all that apply.)
 - a. Hydromorphone (Dilaudid)
 - b. Meperidine (Demerol)
 - c. MDMA (Ecstasy)
 - d. Lorazepam (Ativan)
7. A nurse is discharging a client from a psychiatric unit who has been under suicide precautions. The nurse is providing discharge teaching to the client and the family. Which content would be appropriate for the nurse to teach? (Select all that apply.)
 - a. Signs of an impending crisis
 - b. Signs of suicidal behavior
 - c. Signs of chemical abuse and dependency
 - d. Signs of emotional abuse
8. Electroconvulsive therapy (ECT) is used as an effective treatment for which mental disorders? (Select all that apply.)
 - a. Depression
 - b. Severe catatonia
 - c. Mania
 - d. Schizophrenia
9. A nurse on a psychiatric unit is performing an initial assessment on the mental health of a client. Which assessment finding could be indicative of psychopathology? (Select all that apply.)
 - a. Calm affect
 - b. Disorientation
 - c. Inappropriate dress
 - d. Poor hygiene
10. A nurse in a long-term care facility is admitting an elderly client. The family informs the nurse that the client became forgetful a couple of years ago but now cannot remember family members' names and has become disoriented, impulsive, and easily agitated. Which common mental illness is most likely affecting the elderly client?
 - a. Borderline personality disorder
 - b. Bipolar disorder
 - c. Schizophrenia
 - d. Alzheimer's disease
11. A nurse in a psychiatric unit is caring for a client who engages in impulsive, risky behavior, has strong emotions that frequently wax and wane, and has difficulty controlling emotions and impulses. Which common mental illness is most likely affecting the client?
 - a. Borderline personality disorder
 - b. Bipolar disorder
 - c. Schizophrenia
 - d. Alzheimer's disease
12. A nurse in a psychiatric unit is caring for a client who is delusional, paranoid, and has been diagnosed with schizophrenia. Which type of medication is commonly used to treat schizophrenia?
 - a. H2 inhibitors
 - b. Cholinesterase inhibitors
 - c. Antipsychotics
 - d. Antiemetics

(continued)

13. A nurse is caring for an elderly client in a long-term care facility. The nurse knows that the client is most likely to experience which mental-health illness?
 - a. Dementia
 - b. Delirium
 - c. Depression
 - d. Dysgraphia
14. Antidepressant medications must be prescribed and administered with care, particularly when being given to elderly clients. Which adverse effects should the nurse anticipate when administering antidepressants to elderly clients? (Select all that apply.)
 - a. Anticholinergic effects
 - b. Cardiac effects
 - c. Agitation
 - d. Hostility
15. A nurse is caring for an elderly client who is experiencing dementia. Which assessment findings would the nurse expect? (Select all that apply.)
 - a. Forgetfulness
 - b. Memory loss
 - c. Hostility
 - d. Hallucinations
16. When speaking to a community group on the topic of dementia, which medications would be identified as currently being used in its treatment? (Select all that apply.)
 - a. Nortriptyline (Aventyl)
 - b. Donepezil (Aricept)
 - c. Doxepin (Sinequan)
 - d. Rivastigmine (Exelon)
17. Which statement made by a participant in a seminar on delirium indicates that additional clarification is needed?
 - a. "If untreated, permanent brain damage can occur."
 - b. "It is considered a medical emergency."
 - c. "It mostly affects elderly living in institutional settings."
 - d. "It may result in hallucinations."
18. For which client would the nurse expect the plan of care to include assessment using the Abnormal and Involuntary Movement Scale (AIMS)?
 - a. Client with panic disorder
 - b. Client with schizophrenia taking chlorpromazine (thorazine)
 - c. Client with a mood disorder taking amitriptyline (Elavil)
 - d. Client taking bupropion (Wellbutrin)
 - e. Client taking paroxetine (Paxil)
19. Which assessment finding should the nurse interpret as indicative of agranulocytosis in a client taking clozapine (Clozaril)?
 - a. Photosensitivity
 - b. Tachycardia
 - c. Low WBC
 - d. Orthostatic hypotension
20. Which signs and symptoms are expected effects associated with withdrawal from oxycodone (OxyContin)? (Select all that apply.)
 - a. Fevers and chills
 - b. Runny nose and eyes
 - c. Dilated pupils
 - d. Paranoia
 - e. Muscle pain
 - f. Nausea
 - g. Insomnia
 - h. Tachypnea
 - i. Hallucinations
21. When assessing a client for cocaine use, for which signs would the nurse observe? (Select all that apply.)
 - a. Hypotension
 - b. Tachycardia
 - c. Tachypnea
 - d. Dilated pupils
 - e. Agitation
 - f. Lack of concentration
 - g. Slurred speech
 - h. Poor coordination
 - i. Hypervigilance
 - j. Tremors
22. When caring for a client being withdrawn from barbiturate use, which nursing intervention is appropriate?
 - a. Institute seizure precautions
 - b. Keep the room dark and quiet
 - c. Monitor for dysrhythmias
 - d. Observe for suicide attempts
23. When discussing obsessive-compulsive disorder with the parents of a newly diagnosed child, the nurse bases the discussion of the compulsive behavior on the knowledge that the behavior serves to
 - a. control unacceptable impulses
 - b. dissipate excess energy

- c. manipulate the environment
 - d. decrease anxiety
24. When reinforcing “negative thought stopping,” which direction might the nurse give?
- a. When a negative thought occurs, immediately verbalize out loud an opposing positive thought.
 - b. At least once per hour while awake, focus for 60 seconds on a positive thought.
 - c. When a negative thought occurs, perform a distracting activity, and then think a positive thought.
 - d. When you recognize a negative thought, repeat your positive mantra to yourself until the thought disappears.
25. When giving dietary instructions to a client for whom an MAO inhibitor has been prescribed, which foods would the nurse tell the client to avoid?
- a. Yellow vegetables, cereals and, chicken eggs
 - b. Cheese, avocados, bananas, beer, and wine
 - c. Beef, broccoli, cauliflower, and rice
 - d. Mushrooms, salmon, celery, and grapefruit

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all):

- | | |
|---|---|
| 1. <u> v </u> Psychopathology | a. Form of physical abuse |
| 2. <u> j </u> Alzheimer’s disease | b. Screening tool for alcohol abuse |
| 3. <u> p </u> Borderline personality disorder | c. False belief with no basis in reality |
| 4. <u> b </u> CAGE | d. Subjective disorder of perception |
| 5. <u> g </u> Bipolar disorder | e. Social support service for teenagers |
| 6. <u> i </u> Depression | f. An effective treatment for some depressions, catatonia, mania, and schizophrenia |
| 7. <u> l </u> Schizophrenia | g. A mental illness characterized by manic episodes, irritability, and anxiety |
| 8. <u> r </u> Suicide precautions | h. State of mental excitement accompanied by disorientation to time and place |
| 9. <u> z </u> Abuse | i. A common mental illness characterized by prolonged feeling of sadness, fatigue, diminished concentration, and feelings of guilt or worthlessness |
| 10. <u> q </u> Neglect | j. A mental illness characterized by memory loss, disorientation, speech difficulties, or impulsive behaviors; treated with cholinesterase inhibitors |
| 11. <u> o </u> Ecstasy | k. The most severe form of alcohol withdrawal; is life-threatening and requires immediate intervention |
| 12. <u> k </u> Delirium tremens | |
| 13. <u> a </u> Shaken Baby Syndrome | |

(continued)

- | | |
|--|---|
| 14. <u> b </u> TWEAK | l. A serious mental illness characterized by delusions, hallucinations, and paranoia |
| 15. <u> e </u> Alateen | m. A mood disorder related to time of year |
| 16. <u> d </u> Hallucinations | n. A behavior-management technique used to give the client greater control over negative thinking by correcting mental distortions |
| 17. <u> m </u> Seasonal affective disorder | o. A commonly abused substance that produces increased attention, increased activity, decreased fatigue, decreased appetite, euphoria, and hyperthermia |
| 18. <u> h </u> Delirium | p. A mental illness characterized by rapid changes in self-image, inappropriate anger, and difficulty controlling emotions or impulses; treated with antidepressants, antipsychotics, and anxiolytics |
| 19. <u> c </u> Delusion | q. The act of withholding care from another individual; symptoms may include: poor hygiene, hunger, dehydration, or pain |
| 20. <u> f </u> Electroconvulsive therapy (ECT) | r. Measures that are ordered for clients who have either harmed themselves, have verbalized the intent to do so, or have overtly indicated a wish to do so |
| | s. Allowing the elderly client plenty of time to answer health-related questions |
| | t. Hearing loss due to the aging process |
| | u. Screening tool for psychological abuse |
| | v. Disorders of the psyche which may be characterized by disorientation, incoherent or illogical thought, or inappropriate dress |
| | w. A manifestation of stress experienced by clients as they face new challenges or threatening situations |
| | x. The most commonly abused substance in the United States |
| | y. A process that promotes expression and the exchange of ideas where the client defines himself or herself through human interaction and task accomplishment |
| | z. The act of harming another individual in a physical, sexual, and/or psychological way |

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. Alzheimer's disease is a common mental illness affecting the elderly that is characterized by forgetfulness, memory loss, depression, disorientation, and impulsive behavior.
2. Bipolar disorder is characterized by an extreme elevation in mood called a manic episode.
3. Borderline personality disorder is sometimes referred to as an emotional regulation disorder.
4. Smokers may need higher doses of antipsychotic medications because nicotine interferes with these medications.
5. Domestic violence includes child abuse, elder abuse, and abuse of women and men.
6. Symptoms of alcohol abuse include drowsiness, behavioral changes, slurred speech, and nystagmus.
7. Activated charcoal is given for an overdose of methamphetamines.
8. Desensitization therapy may be used in the treatment of phobic disorders.
9. Psychotherapy with the goal of helping the client see the relationship between feelings and behaviors is the treatment of choice for antisocial personality disorder.
10. Extrapyramidal effects of antipsychotic drugs can be treated with anticholinergic medications.

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Because they are available in long-acting injectable form, the antipsychotic drugs haloperidol (Haldol) and fluphenazine (Prolixin) may be used for noncompliant clients. *True*
2. Persons with schizophrenia prefer a smaller personal space than usual. *False*
Persons with schizophrenia prefer a larger personal space than usual; in fact, touch may precipitate aggression.
3. Mood disorders are diagnosed based on clinical presentation because there are no definitive diagnostic tests. *True*
4. Smokers may need lower doses of antipsychotic medications because of the interaction with nicotine. *False*
Smokers may need higher doses of antipsychotic medications because of the interaction with nicotine.
5. Family reaction to a diagnosis of mental illness may include disbelief, anxiety, confusion, and denial. *True*
6. Poor hygiene, inappropriate dress, disorientation, and absent memory recall may be evidence of psychopathology. *True*

(continued)

7. Strong emotions that wax and wane frequently and difficulty controlling these emotions are symptoms of Alzheimer's disease. *False*

Strong emotions that wax and wane frequently and difficulty controlling these emotions are symptoms of borderline personality disorder.

8. Schizophrenia is characterized by delusions, hallucinations, social isolation, and paranoia. *True*
9. Abuse and neglect occur at all ages and affect both genders from all socioeconomic, ethnic, and cultural groups. *True*
10. Common substance-related dependencies include alcohol, gambling, and pornography. *False*

Gambling and pornography are non-substance-related dependencies.

MATCHING ANSWERS

Match the following (note that descriptions may be used once, more than once, or not at all):

Column A

1. a Diazepam (Valium)
2. e Escitalopram (Lexapro)
3. b Phenelzine (Nardil)
4. e Sertraline (Zoloft)
5. f Methylphenidate (Ritalin)
6. o Buspirone (BuSpar)
7. b Tranylcypromine (Parnate)
8. a Lorazepam (Ativan)
9. c Flumazenil (Romazicon)
10. g Naloxone (Narcan)
11. h Chlorpromazine HCl (Thorazine)
12. i Bupropion (Wellbutrin)
13. h Loxapine (Loxitane)
14. j Amitriptyline HCl (Elavil)
15. k Disulfiram (Antabuse)
16. i Trazodone (Desyrel)

Column B

- a. Benzodiazepine antianxiety agent
- b. Monoamine oxidase inhibitor (MAOI) antidepressant
- c. Benzodiazepine antagonist
- d. Psychedelic
- e. Selective serotonin reuptake inhibitor antidepressant
- f. Methamphetamine
- g. Opiate antagonist
- h. Antipsychotic
- i. Serotonin modulator antidepressant
- j. Tricyclic antidepressant
- k. Alcohol deterrent
- l. Antimania (mood stabilizing) agent
- m. Anti-Parkinsonism agent
- n. Anticonvulsant
- o. Other antianxiety agent
- p. Other antidepressant

17. l Lithium carbonate (Eskalith)
18. m Benztropine (Cogentin)
19. j Nortriptyline HCl (Aventyl)
20. e Paroxetine (Paxil)
21. h Haloperidol (Haldol)
22. n Carbamazepine (Tegretol)
23. p Venlafaxine (Effexor)
24. h Fluphenazine (Prolixin)
25. n Valproic acid (Depokene)
26. e Fluoxetine (Prozac)
27. a Chlordiazepoxide (Librium)
28. h Risperidone (Risperdal)
29. a Alprazolam (Xanax)
30. a and n Clonazepam (Klonopin)
31. j Doxepin (Sinequan)
32. j Imipramine HCl (Tofranil)
33. h Clozapine (Clozaril)
34. h Olanzapine (Zyprexa)
35. p Citalopram (Celexa)

APPLICATION ANSWERS

1. Domestic violence is rarely a one-time occurrence in a relationship; it usually continues and escalates in severity. Which factors increase the risk of an individual becoming violent? (Select all that apply.)

- a. Alcoholism
- b. High stress levels
- c. Financial independency
- d. Physical dependency

Rationale

Correct answers: a, b, and d.

(continued)

Risk factors for abuse include: alcoholism; high stress levels; physical, emotional, and/or financial dependency; high emotions; and history of violence.

2. Which symptoms are indicative of neglect? (Select all that apply.)
- Emergency department visits
 - Missed appointments with health care providers
 - Dehydration
 - Unexplained injuries

Rationale

Correct answers: b and c.

Symptoms of neglect may include missed appointments with health care providers, dehydration, hunger, poor hygiene, unkempt appearance, pain, unfilled medication prescriptions, and lack of adequate clothing, shoes, or ancillary devices.

3. A nurse in an Emergency Department (ED) is caring for a client who has been drinking alcohol everyday for the past 10 days. The client is drowsy, has slurred speech, and lacks coordination. As the client experiences alcohol withdrawal, which potential side effect concerns the nurse most?
- Anxiety
 - Hypoglycemia
 - Esophagitis
 - Delirium tremens

Rationale

Correct answer: d.

The nurse monitors the client closely and is most concerned about delirium tremens—the most severe manifestation of alcohol withdrawal. Delirium tremens (DT) is characterized by anxiety, uncontrollable fear, tremor, irritability, agitation, hallucinations, and insomnia. This condition is life-threatening and requires immediate intervention.

4. Which nursing interventions are appropriate for a client experiencing alcohol withdrawal? (Select all that apply.)
- Provide a private, lighted environment for recovery
 - Implement seizure precautions
 - Orient the client to person, place, and time
 - Provide small, frequent, high-carbohydrate feedings

Rationale

Correct answers: a, b, c, and d.

When caring for a client who is experiencing alcohol withdrawal, it is appropriate for the nurse to provide a private, lighted environment to reduce the potential for hallucinations, implement seizure precautions, orient the client to person, place, and time, provide small, frequent

high-carbohydrate feedings, monitor vital signs and neurological status, record intake and output, and provide support to the client, family, and significant others.

5. A nurse in the Emergency Department is caring for a client who has been smoking crack cocaine. The client's pupils are dilated and the client is euphoric, tachycardic, and agitated. As the client experiences withdrawal from crack cocaine, which side effects should the nurse anticipate? (Select all that apply.)
- Psychosis
 - Hallucinations
 - Illusions
 - Nausea and vomiting

Rationale

Correct answers: a, b, and d.

A client who is undergoing withdrawal from cocaine may experience side effects which include psychosis, hallucinations, delusions, depression, paranoia, ideas of persecution, hypervigilance, aggression, tremors, insomnia, fatigue, muscle pain, suicidal ideation, nausea, vomiting, hyperthermia and general malaise.

6. Opioids are often prescribed by physicians for pain control and are commonly-abused substances. Which medications are opioids? (Select all that apply.)
- Hydromorphone (Dilaudid)
 - Meperidine (Demerol)
 - MDMA (Ecstasy)
 - Lorazepam (Ativan)

Rationale

Correct answers: a and b.

Hydromorphone (Dilaudid) and meperidine (Demerol) are opioids. MDMA (Ecstasy) is a form of methamphetamine. Lorazepam (Ativan) is a benzodiazepine.

7. A nurse is discharging a client from a psychiatric unit who has been under suicide precautions. The nurse is providing discharge teaching to the client and the family. Which content would be appropriate for the nurse to teach? (Select all that apply.)
- Signs of an impending crisis
 - Signs of suicidal behavior
 - Signs of chemical abuse and dependency
 - Signs of emotional abuse

Rationale

Correct answers: a, b, and c.

It is appropriate for the nurse to teach the client and family about the signs of an impending crisis that could precipitate suicidal thoughts, the signs of suicidal behavior to help the family recognize risk for suicide, and signs of chemical abuse and dependency, which is commonly

associated with suicidal behavior. There is nothing to suggest that the client has been emotionally abused or is an emotional abuser.

8. Electroconvulsive therapy (ECT) is used as an effective treatment for which mental disorders? (Select all that apply.)
- Depression
 - Severe catatonia
 - Mania
 - Schizophrenia

Rationale

Correct answers: a, b, c, and d.

ECT may be used as an effective treatment for depression that does not respond to antidepressant pharmacotherapy, severe catatonia, mania, or schizophrenia.

9. A nurse on a psychiatric unit is performing an initial assessment on the mental health of a client. Which assessment finding could be indicative of psychopathology? (Select all that apply.)
- Calm affect
 - Disorientation
 - Inappropriate dress
 - Poor hygiene

Rationale

Correct answers: b, c, and d.

Abnormal assessment findings that could be indicative of psychopathology include disorientation, inappropriate dress, poor hygiene, absent memory recall, and incoherent or illogical thought processes.

10. A nurse in a long-term care facility is admitting an elderly client. The family informs the nurse that the client became forgetful a couple of years ago but now cannot remember family members' names and has become disoriented, impulsive, and easily agitated. Which common mental illness is most likely affecting the elderly client?
- Borderline personality disorder
 - Bipolar disorder
 - Schizophrenia
 - Alzheimer's disease

Rationale

Correct answer: d.

Alzheimer's disease is a common mental illness among the elderly and is characterized by memory loss, depression, disorientation, speech difficulties, impulsive behavior, personality changes, and agitation.

11. A nurse in a psychiatric unit is caring for a client who engages in impulsive, risky behavior, has strong

emotions that frequently wax and wane, and has difficulty controlling emotions and impulses. Which common mental illness is most likely affecting the client?

- Borderline personality disorder
- Bipolar disorder
- Schizophrenia
- Alzheimer's disease

Rationale

Correct answer: a.

Borderline personality disorder is characterized by rapid changes in self-image, impulsive, risky behavior, inappropriate anger, fear of being alone, strong emotions that wax and wane, and difficulty controlling emotions and impulses.

12. A nurse in a psychiatric unit is caring for a client who is delusional, paranoid, and has been diagnosed with schizophrenia. Which type of medication is commonly used to treat schizophrenia?
- H2 inhibitors
 - Cholinesterase inhibitors
 - Antipsychotics
 - Antiemetics

Rationale

Correct answer: c.

Antipsychotic medications are commonly used, usually in combination with other medications, to treat schizophrenia.

13. A nurse is caring for an elderly client in a long-term care facility. The nurse knows that the client is most likely to experience which mental-health illness?
- Dementia
 - Delirium
 - Depression
 - Dysgraphia

Rationale

Correct answer: c.

Depression is the most common mental illness affecting clients in long-term care facilities.

14. Antidepressant medications must be prescribed and administered with care, particularly when being given to elderly clients. Which adverse effects should the nurse anticipate when administering antidepressants to elderly clients? (Select all that apply.)
- Anticholinergic effects
 - Cardiac effects
 - Agitation
 - Hostility

(continued)

Rationale

Correct answers: a and b.

Antidepressants may cause anticholinergic, cardiac, and orthostatic side effects as well as interactions with other medications. Agitation and hostility are not side effects of antidepressant use.

15. A nurse is caring for an elderly client who is experiencing dementia. Which assessment findings would the nurse expect? (Select all that apply.)
- Forgetfulness
 - Memory loss
 - Hostility
 - Hallucinations

Rationale

Correct answers: a, b, and c.

Forgetfulness, memory loss, and hostility are all signs of dementia in the elderly. Hallucinations are a sign of delirium—a medical emergency.

16. When speaking to a community group on the topic of dementia, which medications would be identified as currently being used in its treatment? (Select all that apply.)
- Nortriptyline (Aventyl)
 - Donepezil (Aricept)
 - Doxepin (Sinequan)
 - Rivastigmine (Exelon)

Rationale

Correct answers: b and d.

Aricept and Exelon are commonly used in the treatment of dementia. Aventyl and Sinequan are tricyclic antidepressants.

17. Which statement made by a participant in a seminar on delirium indicates that additional clarification is needed?
- “If untreated, permanent brain damage can occur.”
 - “It is considered a medical emergency.”
 - “It mostly affects elderly living in institutional settings.”
 - “It may result in hallucinations.”

Rationale

Correct answers: a, b, and d.

Delirium begins with confusion and progresses to disorientation over a brief time span. It is considered a medical emergency and, if untreated, may result in permanent brain damage. Hallucinations are a sign of delirium. Dementia mostly affects elderly living in institutional settings.

18. For which client would the nurse expect the plan of care to include assessment using the Abnormal and Involuntary Movement Scale (AIMS)?

- Client with panic disorder
- Client with schizophrenia taking chlorpromazine (Thorazine)
- Client with a mood disorder taking amitriptyline (Elavil)
- Client taking bupropion (Wellbutrin)
- Client taking paroxetine (Paxil)

Rationale

Correct answer: b.

Clients taking an antipsychotic medication should be assessed using the Abnormal and Involuntary Movement Scale (AIMS) because of the extrapyramidal side effects associated with these drugs. Thorazine is an antipsychotic and therefore the client taking it should be assessed with AIMS.

19. Which assessment finding should the nurse interpret as indicative of agranulocytosis in a client taking clozapine (Clozaril)?
- Photosensitivity
 - Tachycardia
 - Low WBC
 - Orthostatic hypotension

Rationale

Correct answer: c.

Agranulocytosis is another name for neutropenia or a decrease in neutrophils

20. Which signs and symptoms are expected effects associated with withdrawal from oxycodone (OxyContin)? (Select all that apply.)
- Fevers and chills
 - Runny nose and eyes
 - Dilated pupils
 - Paranoia
 - Muscle pain
 - Nausea
 - Insomnia
 - Tachypnea
 - Hallucinations

Rationale

Correct answers: a, b, e, f, g, and h.

Fevers and chills, runny nose and eyes, muscle pain, nausea and other GI distress, insomnia, tachypnea, and coma can all occur with opiate withdrawal. In addition, pupils are pinpoint not dilated. Paranoia and hallucinations occur with withdrawal from methamphetamines.

21. When assessing a client for cocaine use, for which signs would the nurse observe? (Select all that apply.)

- a. Hypotension
- b. Tachycardia
- c. Tachypnea
- d. Dilated pupils
- e. Agitation
- f. Lack of concentration
- g. Slurred speech
- h. Poor coordination
- i. Hypervigilance
- j. Tremors

Rationale

Correct answers: b, c, d, e, and f.

Tachycardia, tachypnea, dilated pupils, agitation, and lack of ability to concentrate are all effects of cocaine use. Hypertension, not hypotension, is also an effect. Slurred speech and poor coordination are signs of benzodiazepine use. Hypervigilance and tremors are signs of cocaine withdrawal.

22. When caring for a client being withdrawn from barbiturate use, which nursing intervention is appropriate?
- a. Institute seizure precautions
 - b. Keep the room dark and quiet
 - c. Monitor for dysrhythmias
 - d. Observe for suicide attempts

Rationale

Correct answer: a.

Seizures can occur with withdrawal from barbiturates and so seizure precautions must be implemented. The environment should be kept quiet but a light should be left on to aid orientation. Monitoring for dysrhythmias is an important nursing intervention for clients undergoing withdrawal from benzodiazepines or cocaine. Monitoring for suicide attempts is essential for clients withdrawing from methamphetamines.

23. When discussing obsessive-compulsive disorder with the parents of a newly diagnosed child, the nurse bases the discussion of the compulsive behavior on the knowledge that the behavior serves to
- a. control unacceptable impulses
 - b. dissipate excess energy

- c. manipulate the environment
- d. decrease anxiety

Rationale

Correct answer: d.

Compulsive behaviors or rituals serve to prevent some event, divert unwanted thoughts, and decrease anxiety. Unless the behavior threatens safety, the client is allowed to carry it out until anxiety is decreased. Intervention is needed for compulsive behavior if it significantly impacts the person's ability to function.

24. When reinforcing "negative thought stopping," which direction might the nurse give?
- a. When a negative thought occurs, immediately verbalize out loud an opposing positive thought.
 - b. At least once per hour while awake, focus for 60 seconds on a positive thought.
 - c. When a negative thought occurs, perform a distracting activity, and then think a positive thought.
 - d. When you recognize a negative thought, repeat your positive mantra to yourself until the thought disappears.

Rationale

Correct answer: c.

Negative thought stopping involves recognition of a negative thought followed by use of a distracting stimulus such as snapping an elastic band on the wrist, and then replacement with a positive thought.

25. When giving dietary instructions to a client for whom an MAO inhibitor has been prescribed, which foods would the nurse tell the client to avoid?
- e. Yellow vegetables, cereals and, chicken eggs
 - f. Cheese, avocados, bananas, beer, and wine
 - g. Beef, broccoli, cauliflower, and rice
 - h. Mushrooms, salmon, celery, and grapefruit

Rationale

Correct answer: b.

Cheese, avocados, bananas, beer, and wine are rich in amines or amino acids, which can cause paradoxical hypertension when combined with an MAO inhibitor. Foods listed in other responses are not high in amines.

| ▶ Elimination | 328 | ▶ Personal Hygiene | 345 |
| ▶ Mobility/Immobility | 333 | ▶ Rest and Sleep | 346 |

COMPLEMENTARY AND ALTERNATIVE THERAPIES

- Complementary and alternative therapies (CATs) include methods of health promotion, health maintenance, disease prevention, and disease treatment that are not part of the standard North American approach to health care.
- These therapies mostly focus on the healing the person not curing the disease; stress the importance of mindfulness and attitude in healing; integrate culture and personal beliefs into the treatment regimen; and promote a general sense of well being and control in the client.

- Often CATs relieve symptoms but do not cure.

ACUPUNCTURE

- Acupuncture is based on belief that when Qi (energy) flow in the body is blocked, pain and dysfunction result in the affected organs.
- This therapy uses hair-sized needles to stimulate selected anatomic areas to restore energy flow to the linked internal organs.

- Research suggests it relieves pain through stimulation of high threshold sensory receptors, which in turn stimulate other CNS structures and result in the release of endorphins and increased cortisol levels.
- It is generally safe although infection and organ perforation can occur.
- It is contraindicated for those with clotting disorders, those who are pregnant, and those unable to cooperate such as children under 7 years of age and clients who are demented or under the influence of alcohol or narcotics.
- It is effectively used in relieving nausea related to anesthesia and chemotherapy, dental pain, headaches, menstrual cramps, osteoarthritis, low back pain, carpal tunnel syndrome, asthma, addiction, and also in stroke rehabilitation.

IMAGERY

- Imagery uses mental processes involving pictures and symbols to promote attitudinal, behavioral, and physiological reactions by opening communication among perception, emotion, and bodily changes.
- It can contribute to insight into concerns, support symptom management, and improve functional status.
- Clinical applications of this therapy include management of perioperative pain and anxiety, N&V related to chemotherapy, cancer pain, wound healing, asthma, stress, burnout, bulimia, and depression. It is also used to enhance immune function, improve client's outlook, and support the dying process.

Practice Alert

Imagery alters brain-wave activity and can induce seizures in susceptible clients. Imagery alters blood glucose levels and so when used with diabetic clients, requires careful blood sugar monitoring—may be contraindicated for an unstable diabetic client. Imagery is contraindicated for use with clients with a history of psychosis.

MEDITATION

- Meditation refers to the deep contemplation associated with decreased heart and respiratory rates and decreased oxygen consumption.
- Twenty minutes of meditation per day decreases stress and renews energy.
- It is contraindicated for those fearing loss of control or with a history of psychosis.

YOGA

- Yoga is a mind–body therapy aimed at self-improvement through focused breathing, stretching, and meditation.
- In yoga, breath is seen as the link connecting mind, body, spirit, and emotion.
- It is effectively used against hypertension, menopausal symptoms, osteoporosis, and depression.

GROUP THERAPY

- Group therapy usually centers on a common theme: breast cancer survival, grieving, Alzheimer's caregiving, living with a laryngectomy, inflammatory bowel disease (IBD), or heart disease.
- This therapy offers mutual support, encouragement, and socialization.

BIOFEEDBACK

- Biofeedback involves the use of noninvasive electronic monitoring equipment to teach clients to regulate internal states such as blood pressure, heart rate, brain-wave patterns, or electrical muscular activity.
- It is effective in relieving hypertension, Raynaud's disease, migraine headache, and low back pain.

RELAXATION THERAPY

- Relaxation therapy is a basic stress-management technique.
- It involves either purposeful relaxation of specific muscles or use of breathing, words, or sounds to induce a general state of mental and muscular relaxation.
- It is easily used at the bedside.
- It is effective in managing chronic pain.

MASSAGE THERAPY

- Massage therapy manipulates skin, muscles, ligaments, tendons, and fascia through touch, stroking, friction, vibration, percussion, kneading, stretching, compression, and joint movement to promote healing/health.
- It reduces muscle tension, improves circulation, reduces blood pressure, decreases pain, improves mobility, relieves anxiety, and induces relaxation and a sense of well-being.
- It is commonly used in rehabilitation, postoperative, maternity, cancer, and hospice-care settings.

TOUCH THERAPIES

- Therapeutic touch involves manipulating the client's energy field without actually touching the body. The goal

is to direct and balance the energy field surrounding the client, which is in interaction with the environment. Its uses include management of pain and anxiety, promotion of wound healing, and relaxation.

- Healing touch mobilizes the client's ability to heal by clearing, energizing, and balancing the client's energy field. It is widely used along with medical treatments.
- Reiki (universal life force energy) therapy involves energy drawn in through the top of the practitioner's head and directed out of the body by way of the practitioner's hands into the client through intentional touch over major body organs to promote healing.

HERBAL THERAPY

- Herbal products are natural but not necessarily safe.
- Herbal preparations vary depending on the part of the plant used, the time of harvest, and the quality of the soil and other growing conditions.
- Herbs frequently take a number of weeks to build up in the body and exert an effect because of their low potency.
- Herbal and dietary supplements are regulated as foods not drugs and hence lack quality standardization.
- Pharmacokinetic effects of herbs are not well understood so great caution is needed while using any herb or nutritional supplement especially during pregnancy or lactation or in combination with other medications (see Table 13–1 for commonly used herbs and related cautions).

Table 13–1 Commonly Used Herbs and Related Cautions

| Herb | Action/Uses | Cautions |
|------------------|---|--|
| Black cohosh | Mild estrogen-like action; used for menstrual irregularities, menopausal symptoms, and stimulation of uterine contractions | Contraindicated in presence of estrogen dependent tumors |
| Butterbur | Migraine, chronic cough, asthma, and bladder spasms | May cause reaction in those allergic to ragweed or daisy |
| Chamomile | Various GI disturbances including constipation, diarrhea, dyspepsia, irritable bowel syndrome and diverticular disease | May cause reaction in those allergic to ragweed, asters, or chrysanthemums |
| <i>Echinacea</i> | Immune system enhancer; used to decrease duration and severity of viral and bacterial URIs; effectiveness decreases with prolonged use | Contraindicated by autoimmune disease or immunosuppressive Rx Not appropriate for prevention of URIs Not to be used for more than 8 wks; recommended use: no more than 10 d |
| Elderberry | Topical use: decreases edema and inflammation Tea: Rx for colds and flu | |
| Feverfew | NSAID and antipyretic action; used for arthritis, fever, inflammation, prevention of migraines (no effect once headache has begun) | Caution with anticoagulants because it inhibits platelet activity Stop 2 wks before surgery |
| Garlic | Lowers cholesterol, increases HDLs and lowers BP (may take months of use); regulates blood glucose; decreases platelet adhesiveness; protects against vascular age changes; antibacterial | Caution with anticoagulants |
| Ginger | Motion sickness; digestive aid | Caution with anticoagulants as it can promote bleeding |
| Gingko | Antioxidant; improves circulation; decreases platelet aggregation; also used for intermittent claudication and dementia | Used with caution after trauma or surgery or in combination with anticoagulants |
| Ginseng | Increases resistance to stress, invigorates | Potentiates anticoagulants |
| Milkvetch | Immune system enhancer | Contraindicated by autoimmune disease |
| St. John's wort | Acts like monoamine oxidase (MAO) inhibitor to treat mild/moderate depression | Many drug interactions; contraindicated if MAO inhibitors are taken; can cause hypertension, headache, insomnia, cardiac dysrhythmias, nervousness, tremor, seizures, cerebrovascular accident (CVA) and myocardial infarction (MI). |
| Senna | Stimulates colon; used for constipation | Can potentiate cardiac glycosides |
| Saw palmetto | Anti-inflammatory/antiedema; used for benign prostatic hyperplasia (BPH) | None |
| Valerian root | Benzodiasapine-like effect on gamma aminobutyric acid receptors; used for restlessness and insomnia | Not recommended for chronic use |

Assessment Alert

Ask all clients about the use of herbal products; consider an interaction with an herbal product whenever an adverse drug reaction occurs. Clients on anticoagulants are at particular risk for adverse reactions from concurrent herbal therapy especially from the use of quai, feverfew, garlic, ginseng, and ginkgo.

ASSISTIVE DEVICES

- Assistive devices are used to enhance a client's functional ability.
- They allow activities to be performed more independently.
- The available devices include those that aid eating, dressing, hygiene, mobility, writing, seeing, and performing household chores.
- No one device is suitable to all—clients need to be guided in trying different devices and models to find the one that works best for them.
- Excellent reviews, prepared by health care professionals, that compare different devices are available on the Internet and can serve as resources for clients. Table 13–2 discusses some assistive devices and their uses.

ELIMINATION

BOWEL ELIMINATION

Feces: Normally feces consists of 75% water and 25% solid; water is absorbed by the colon so the longer the waste products are in the colon the more solid stool will be; conversely the less time in the colon results in a more watery stool.

Age Variations in Stool

- Meconium: Black, tarry, odorless, sticky material found in the intestine of the full term fetus and passed by the newborn within 24 hours of birth.
- Transitional stool: Greenish-yellow, loose, mucus-containing stool passed after meconium for about a week.
- Normal infant stool: Yellow (bright yellow–gold and odorless in breast-fed infants; dark yellow–tan in cow's milk formula-fed infants), moist, and semisolid.
- Normal adult stool: Soft, formed, and brown.

Abnormal Stool

- Clay-colored or white: absence of the bile pigment due to obstruction, barium in the GI tract after a diagnostic test, or use of antacids.
- Black or tarry: bleeding from stomach or small intestine, ingestion of large amounts of red meat, dark green leafy vegetables, or licorice, ingestion of iron supplements or Pepto-Bismol.

- Red: colon or rectal bleeding.
- Gray–green: antibiotics

Defecation

- Defecation refers to the expulsion of feces from the rectum through the anus.
- Frequency of defecation varies from person to person: it ranges from several times per day to two or three times per week; infants often defecate after every feeding; frequency decreases with the introduction of solid food.
- Gastrocolic reflex is the increased peristalsis in the colon resulting in an urge to defecate when food enters the stomach; especially strong in the morning after breakfast.
- If urge to defecate is ignored, the urge usually does not recur for a few hours. If the urge is repeatedly ignored, rectum distends and accommodates so the urge to defecate is no longer felt and constipation can develop.
- Defecation is easiest in sitting position with thighs flexed.
- Ability to control defecation starts at about 18–24 months and daytime control is attained by 30 months.
- Normal defecation requires
 - a diet with adequate amounts of bulk to provide stool volume,
 - 2000–3000 ml fluid daily to prevent excessive drying of intestinal contents as a result of reabsorption of water by colon,

Table 13–2 Examples of Assistive Devices and Their Uses

| Functional Area | Examples of Assistive Devices |
|---------------------|--|
| Eating | Silverware with widened or builtup handles to facilitate grasping Utensils with angled handles that can be used in either left or right hand to compensate for limited motion Utensils with straps that go over wrists to prevent dropping Raised rims for plates to facilitate getting food onto spoon or fork rather than being pushed off edge of plate Suction cups, rubber feet, or rubber mats for under dishes to prevent movement No-spill cups, double-handled cups, cups with spouts to compensate for poor coordination |
| Hygiene | Shower chair for those unable to stand and balance Tub or shower bars to aid getting in or out and maintain balance while bathing Hand-held shower attachment Soap on a rope to prevent dropping and need for bending Long-handled brushes to enable back and lower legs to be reached Battery-powered toothbrushes to decrease need for fine, coordinated movement |
| Toileting | Raised toilet seat to compensate for limited ability to bend at hips Raised toilet seat with arms to compensate for limited ability to bend at hips, difficulty with balance, and difficulty returning to a standing position |
| Dressing | Shoes and clothing with Velcro fasteners to allow one-handed closure and/or to compensate for lack of coordination Shoehorn with a long, tall handle to eliminate the need for bending Button hook for buttoning clothing to compensate for loss of motor function or coordination Dressing stick |
| Moving | Walkers with or without wheels, baskets, and seat mechanisms to provide support Straight canes for support and balance when walking or standing Quadripod canes for use in right or left hand for greater support and balance when walking or standing Curved canes with a lower hand grip for leverage in getting into and out of a sitting position Chairs with built-in hydraulic lifts to decrease need to bend and balance in order to sit and to decrease effort needed to stand Portable hydraulic lifts to aid sitting and rising to a standing position Crutches wheelchairs both motorized and hand driven |
| Seeing | Various nonglare, high-intensity floor and table lamps with goose necks for easy focus on work surface Magnifying devices with and without attached lights Transparent yellow sheets to be placed over print to reduce glare and make letters darker Templates with cutouts to guide writing such as in filling out checks |
| General functioning | Long-handled reachers with or without magnetic tip Telephones with large buttons Door handles that are elongated rather than knobs to allow easy grasping Appliances such as stoves with raised dial markings Cooking utensils with easy-grasp handles |

—activity sufficient to stimulate peristalsis and maintain muscles needed to increase intra-abdominal pressure for defecation, and

—regular time for defecation and obedience to the urge to defecate.

• Factors which affect normal defecation:

—bland, low-residue diet has insufficient bulk to create volume of stool needed to stimulate the defecation reflex,

—irregular eating pattern,

—ingestion of foods that produce constipation (cheese, pasta, eggs, and lean meat), diarrhea (bran, prunes,

chocolate, alcohol, and in some people, spicy foods and foods high in sugar), or flatus (cauliflower, cabbage, Brussels sprouts, beans, onion, bananas, and apples),

—inadequate fluid intake,

—inactivity, for example, lack of exercise, immobilization, and bed rest,

—ignoring the urge to defecate,

—emotions such as anxiety and anger often cause diarrhea while depression is associated with constipation,

—medications

- opioids, iron, some tranquilizers cause constipation

- stool softeners such as Colace (docusate sodium) facilitate defecation
- laxatives stimulate defecation; cathartics have a purgative effect
- types of laxatives are
 - bulk-forming: for example, methylcellulose (Citrucel), requires adequate fluid intake
 - stimulant: for example, bisacodyl (Dulcolax), castor oil; water is lost in stool due to rapid propulsion through intestine; may cause cramping; risk of fluid and electrolyte imbalance with prolonged use
 - lubricant: for example, mineral oil; risk of fat-soluble-vitamin (A, D, E, and K) deficiency with prolonged use
 - saline/osmotic: for example, milk of magnesia (MOM), magnesium citrate; draws water into intestine; risk of fluid and electrolyte imbalance especially in elderly and children with cardiac or renal problems, risk of impaired absorption of some fat-soluble vitamins
- Kaolin–pectin preparations (Kaopectate), diphenoxylate hydrochloride (Lomotil), and loperamide hydrochloride (Imodium) control diarrhea

Clinical Alert

Bismuth preparations used to treat “traveler’s diarrhea” often contain aspirin and should not be given to children or adolescents with flu, chicken pox, or other viral infections because of the risk of Reye syndrome.

—General anesthesia blocks parasympathetic nervous stimulation of the colon causing decreased or absent peristalsis.

—Handling of gut during surgery causes ileus (cessation of peristalsis) for 24–48 hours.

—Spinal cord, head, or other injuries/diseases interfere with sensation, muscle control, or ability to respond to urge to defecate.

—Pain

Problems of Elimination:

- Constipation: Passage of dry, hard stool or no stool (see Chapter 17).
- Fecal impaction: Mass of hard stool in the rectum and above from prolonged stool retention and accumulation.
 - S&S: Seepage of liquid stool and no passage of normal stool, nonproductive urge to defecate, rectal pain, anorexia, abdominal distention, and N&V.
 - Dx: Palpation of hardened mass on digital examination of the rectum.
 - Rx: Oil retention enema with cleansing enema in 2–4 hours followed by daily cleansing enemas, suppositories or stool softeners; if no results, manual extraction of feces.
- Diarrhea: Passage of abnormally liquid feces and/or abnormal frequency of defecation (see Chapter 17).

Assessment Alert

Diagnosis of constipation or diarrhea can only be made when there is deviation from the individual’s normal pattern of elimination. What is constipation or diarrhea for one person may be normal for another

- Flatulence: Excessive flatus (gas) in the intestine.
- Bowel incontinence
 - Loss of ability to voluntarily control passage of stool or flatus through the anal sphincter.
 - Minor incontinence: inability to control passage of gas or minor soiling.
 - Major incontinence: inability to control passage of normal feces.
 - It may be due to impaired functioning of the sphincter or its nerve supply or inability to recognize the need to defecate.

Nursing Process Elements

- Assess stool for color, consistency, shape, amount, odor, and presence of abnormal material
- Determine frequency and pattern of elimination
- Assess toileting self-care ability
- For home care clients, assess access to and safety of toilet facilities, for example, lighting, does walker or wheel chair fit through doorway, need for raised toilet seat, etc.
- Provide privacy
- Schedule other care activities so as not to interfere with time for defecation
- Utilize best possible position and place for facilitation of defecation: toilet, bedside commode, bedpan with bed in high Fowler’s position, bedpan with other position if no better option

- If laxatives are ordered in the form of suppositories, administer 30 minutes before usual defecation time or just after breakfast when the gastrocolic reflex is strongest

Client teaching for self-care

Teach the client about

- the importance of regular timing, diet and fluid needs, and exercise/mobility needs in maintaining normal defecation
- the foods and activities (gum chewing, drinking carbonated liquids, using a straw) that increase flatus; and foods that predispose to constipation or diarrhea
- the importance of avoiding overuse of OTC products for treatment of constipation or diarrhea

Clinical Alert

Laxatives should never be taken if nausea, cramps, colic, vomiting, or undiagnosed abdominal pain is present.

URINARY ELIMINATION

Voiding (Micturition)

- Voiding requires relaxation of abdominal and perineal muscles and the external urethral sphincter.
- The desire to empty bladder occurs in adult when 250–450 ml of urine accumulates in the bladder and in children when the accumulation is 50–200 ml.
- Patterns of urination are highly individualized.

Age Variations in Urine Production and Voiding

- The amount of urine produced varies with fluid intake and fluid loss through other routes as well as with the cardiovascular and renal status.
- Voluntary control is achieved between the age of 2 years and 5 years with daytime control acquired before nighttime control.
- Infants: 250–500 ml urine is produced per day with variation based on fluid intake; pale urine; specific gravity is 1.008 because immature kidneys cannot concentrate urine; voids up to 20 times per day.
- 12–24 months: kidneys mature and concentrate (specific gravity 1.010–1.025); urine is normal amber color.
- School age children: void 6–8 times per day
- Adults: void average of 5 times per day

- Older adults: capacity of bladder and ability to empty completely decreases with age resulting in frequency, nocturia, and increased risk of urinary tract infection (UTI).

Assessment Alert

Normal adult kidneys produce urine at a rate of 60 ml/hr (1500 ml/d). Output less than 30 ml/hr must be reported as it may indicate low blood volume or renal disease.

Factors which affect normal voiding

- Lack of privacy can affect normal voiding.
- Upright sitting position is the most conducive to voiding.
- Sound of running water, or pouring water over the perineum can induce voiding.
- Increased fluid intake normally increases voiding; alcohol and caffeine inhibit antidiuretic hormone (ADH) secretion and result in increased urine production.
- Medications
 - Diuretics move water out of the body by increasing production of urine
 - Urinary retention can result from atropine, papaverine, phenothiazines, MAO inhibitors, Sudafed, hydralazine, methyldopate, levodopa, trihexyphenidyl, benztrapine mesylate, propranolol, and hydrocodone
- Muscle tone of detrusor muscle is necessary for the bladder to fill and empty normally; loss of this muscle tone can result from prolonged use of indwelling catheters, which eliminate bladder filling and intermittent emptying.

Problems of Urinary Elimination

- Polyuria: Production of abnormally large amounts of urine; may result from excessive fluid intake, change in hormone levels postpartum, diabetes mellitus or insipidus, or chronic nephritis.
- Oliguria: Production of less than 500 ml of urine per day or less than 30 ml/hr.

Nursing Intervention Alert

Oliguria can occur from lack of fluid intake or fluid loss by another route (diarrhea, diaphoresis, vomiting, burn injury, or drainage) but most often is a result of poor blood flow to the kidneys or impending renal failure. It should be reported promptly.

- Anuria: No production of urine by kidneys.
- Frequency: Voiding at frequent intervals; normal adult voids every 3.5–4 hours during the day and no more than once at night; occurs with UTIs, stress, pressure from pregnancy or an abdominal mass, increased volume of urine, and decreased bladder capacity.
- Nocturia: Voiding two or more times at night.
- Urgency: Feeling of immediate need to void even with little urine in bladder; occurs with irritation of the bladder and urethra; may be triggered by the sound of running water, an abrupt change in position or the feel of warm water on the skin.
- Dysuria: Painful or difficult voiding; usually accompanied by frequency and urgency creating the classic triad of symptoms of UTI; dysuria at start of voiding suggests urethral inflammation while dysuria during or after voiding suggests bladder inflammation.
- Hesitancy: Difficulty initiating the stream; seen when urethra is partially blocked as with a urethral stricture or benign or malignant prostatic hypertrophy.
- Enuresis: Involuntary micturition in children beyond the time bladder control is normally achieved.
- Nocturnal enuresis: Involuntary release of urine during sleep; in adults it is generally due to a neurological problem.
- Urinary incontinence: Involuntary urination; risk factors include repeated UTIs, urinary tract surgery or trauma, sexual transmitted infections (STIs), multiple vaginal births, musculoskeletal, neurological, or endocrine disorders, cognitive impairment, self-care deficit. The types of urinary incontinence are
 - total incontinence
 - constant, involuntary dribbling of urine
 - cause is neurological or related to trauma or anatomical abnormality
 - reflex incontinence
 - urine is retained in bladder and when pressure builds to a critical point, urine leaks out
 - causes include spinal cord injury and bladder neck obstruction
 - urge incontinence
 - urge to urinate is so strong that uncontrolled bladder emptying occurs
 - causes include spinal cord injury, bladder tumor, and bladder infection
 - stress incontinence
 - loss of small amounts of urine when intra-abdominal pressure is increased by activities such as laughing, coughing, sneezing, and physical straining
 - more common in women
 - causes include loss of tone in the pelvic muscles from obesity or aging, and childbirth injury

—functional incontinence

- inability to get to the bathroom to void as a result of physical or mental disability or environmental obstacles
- Urinary retention: Overdistention of bladder because of inability to expel urine; may have overflow voiding of 20–50 ml at frequent intervals; on palpation bladder is firm and distended and may be to one side of midline.

Nursing Process Elements

- Assess color, odor, and consistency of urine
- Measure urinary output; report output of less than 30 ml/hr in adults
- Assess color, texture, and turgor of skin as well as for edema when assessing urinary elimination status
- Facilitate voiding:
 - Position
 - standing for men, sitting upright for women is best. Sitting is better than lying down for men
 - Provide privacy
 - Have client press over suprapubic area to increase pressure on bladder
 - Run water; pour water over perineum, apply hot water bottle to lower abdomen
 - Administer ordered analgesics if pain is a problem
- Manage incontinence according to individualized need:
 - Teach Kegel exercises to women to strengthen pelvic floor muscles.
 - Institute timed voiding (habit training):
 - have client void at scheduled intervals; further enhance by prompting/encouraging to void as scheduled (prompted voiding)
 - Use a bladder-training program:
 - Set a voiding schedule based on the frequency of incontinence and have client void accordingly, for example, on waking in morning, then every 2 hours, on going to bed at night, and every 4 hours till morning
 - Have the client use slow, deep breathing to overcome the urge to go if sooner than the set schedule
 - Increase time between voiding gradually
 - Encourage fluid intake half an hour before scheduled voiding times
 - Restrict fluid intake in the evening
 - Avoid liquids such as citrus juices, caffeinated, and artificially sweetened drinks that irritate the bladder
- If any incontinence is reported, assess perineum for irritation from exposure to urine and initiate measures to maintain/restore skin integrity

Client teaching for self-care

Instruct client to

- maintain minimum daily fluid intake of 1500 ml
- decrease risk of UTI by
 - drinking 2000–3000 ml fluid per day to flush out the urinary tract
 - voiding every 2–4 hours and immediately after intercourse to wash bacteria away
- avoiding tight-fitting, noncotton clothing that prevents air circulation to the perineal area
- avoiding the use of irritating soaps or other products in the perineal area
- females wiping front to back to prevent spread of intestinal bacteria to urethra and discarding tissue after each wipe
- taking showers rather than baths
- drinking two to three glasses of cranberry juice daily and ensuring adequate vitamin C in daily diet to increase acidity of urine

MOBILITY/IMMOBILITY

MOBILITY

Mobility is the ability to physically move about for work, pleasure, or exercise.

IMMOBILITY

- Immobility refers to the lack of movement or the inability to move without assistance.
- It affects the entire body both physically and psychosocially.
- Forced immobility, even for a short period of time affects multiple body systems. Immobility disrupts client's self-esteem (not being able to care for self); causes many emotional reactions, such as anger, apathy, regression, or frustration due to loss of control; causes change in perception of time or difficulty with problem solving due to a lack of stimuli.

Musculoskeletal System Effects

- Disuse osteoporosis: Loss of calcium (negative calcium balance) occurs when the body does not have the stress of weight bearing and can result in osteoporosis.
- Disuse atrophy: Muscles decrease in size (atrophy) when not used leading to a loss of both strength and muscle mass.
- Contractures: These occur as a result of the extremities not being used, such as with walking or self-grooming. The loss of movement to the muscles of the extremities leads to shortening of the muscle fibers, which is an irreversible condition except for surgical intervention.
- Stiff, painful joints: These result from shortening of tissue and a higher concentration of calcium at joints from being immobile.

Cardiovascular System Effects

- Decrease in cardiac reserve: Imbalance in the autonomic nerve system resulting from immobility leads to sympathetic activity without compensatory parasympathetic stimulation and causes an increase of heart rate with minimal exertion by the client.
- Increased use of the Valsalva maneuver: Clients typically hold their breath and strain against the closed glottis (Valsalva maneuver) when moving themselves in bed; this can cause cardiac arrhythmias in persons with a known cardiac history.
- Orthostatic hypotension: It occurs as a result of the loss of normal vasoconstriction in the lower extremities leading to pooling of blood in the lower extremities with a decrease in core blood pressure. Upon sitting or standing, the microcirculation fails to respond normally causing the client to feel dizzy as a result of a decrease in cerebral perfusion. A sudden increased heart rate is noted due to the body's response of protecting the brain from a sudden decrease in blood flow.
- Venous vasodilatation and stasis: Immobility results in the loss of the contraction and release of skeletal muscles in the lower extremities, which normally prevents pooling of blood in them.
- Dependent edema: Occurs as the serous component of blood is forced into the interstitial tissues.
- Thrombus formation: Shortened thromboplastin time and increased number of procoagulants lead to clot formation, which can result in an emboli, should the clot break loose.

Respiratory System

- Decrease in respiratory movement: Pressure of the body against a solid surface does not allow the lungs to expand fully due to the pressure of internal organs against the diaphragm. Immobility also decreases sighing with respirations secondary

to muscle atrophy and lack of the exercise stimulus. Over time, these changes lead to a decreased vital capacity (maximum amount of air exhaled following a maximum amount of air inhaled) and shallow breathing.

- Pooling of respiratory secretions: Secretions from the lung are usually raised through coughing and changes in position, which are decreased with immobility. As a result, secretions pool in the respiratory tract.
- Hypostatic pneumonia: Pooled secretions impair gas exchange and provide an excellent medium for bacterial growth, which can result in hypostatic pneumonia.
- Atelectasis: It occurs when pooled secretions block a dependent area of the lung and the production of surfactant is decreased.

Metabolic System

- Decreased metabolic rate: Energy requirements of the body decrease with immobility.
- Negative nitrogen balance: Protein stores are depleted due to catabolism of muscle mass releasing more nitrogen than what is ingested.
- Anorexia: Decreased metabolic rate and catabolism lead to anorexia. Prolonged anorexia leads to severe negative nitrogen balance if protein intake is minimal.

Urinary System

- Urinary stasis: In a horizontal position, the client is forced to push against gravity resulting in incomplete emptying of the bladder and renal pelvis.
- Urinary retention: It results due to the loss of detrusor muscle tone with prolonged immobility.
- Urinary infection: It results from stasis of urine in the bladder and renal pelvis from both loss of gravity assistance for emptying and urinary retention; the client is at a higher risk for a urinary infection and the most common infection-causing organism is *Escherichia coli*.
- Urinary calculi: It is caused due to the loss of calcium from bone which results in alkaline urine containing large amounts of calcium, which crystallizes as calcium salts, becoming calculi in the renal pelvis.

Gastrointestinal System

- Constipation: Decreased peristalsis causes hardening of stool; muscle weakness and a horizontal position create difficulty in defecating.

- Increased use of the Valsalva maneuver to defecate causes increased intra-abdominal and intrathoracic pressure that impacts on the function of both the heart and circulatory system.

Integumentary System

- Decreased skin turgor and skin atrophy: Impaired hydration of the dermis occurs due to fluid shifts associated with immobility.
- Skin breakdown: Results from prolonged pressure, particularly over bony prominences, that decreases blood flow and delivery of oxygen and nutrients.

Nursing Process Elements

- Encourage or help to perform ROM
- Monitor for dehydration
- Monitor serum electrolytes (sodium, potassium, chlorine, and calcium)
- Assess for deep vein thrombosis (DVT)
- Apply compressive stockings (TEDS) or device (SCD)
- Encourage deep breathing and use of incentive spirometry
- Administer calcium and phosphorous supplements
- Monitor for infection
- Monitor bowel function
- Administer stool softener
- Encourage foods high in fiber
- Assess vulnerable body surfaces for changes in skin integrity
- Reposition at least every 2 hours
- Provide a pressure relief surface that is appropriate for client

Client teaching for self-care

Teach client to

- reposition self at 15-minute increments when out of bed in chair
- replace fluids and maintain adequate protein and calcium intake in foods
- perform active ROM
- perform respiratory hygiene activities

NONPHARMACOLOGICAL COMFORT CARE/INTERVENTIONS

COMFORT

- Comfort refers to personal experiences of a client with physical, psychospiritual, social and environmental components, where
 - the physical component relates to bodily sensations,
 - the psychospiritual component relates to aspects of self or the meaning of life,
 - the social component relates to interpersonal relationships within and outside of the family, and
 - the environmental component relates to external conditions (e.g., noise, light, and climate) and events that impact the client.
- Absence of distress: This is the most basic degree of comfort.
- Positive feeling of ease: This is a higher degree of comfort.
- The promotion of comfort requires paying attention to all four components.

Nursing Process Elements

- Assess comfort level in all four areas.
- Identify sources of comfort and discomfort for the individual client
- Implement nursing actions designed to relieve discomfort and promote a positive sense of ease in each of the component areas of comfort
- Examples of comfort measures:
 - Physical
 - Apply lotion
 - Rub back
 - Offer fluids
 - Straighten sheets
 - Provide mouth, nail, and hair care
 - Elevate edematous parts
 - Maintain good body alignment to prevent pull on tissues and joints
 - Use pillow under arms of weak, paralyzed clients to prevent pull on shoulder joints
 - Use pillow to support upper leg for clients in side-lying position to prevent pull on hip
 - Apply heat and cold
 - Heat causes vasodilation, increased capillary permeability, increased cellular metabolism, and a

quieting effect; cold causes vasoconstriction, decreased capillary permeability, decreased cellular metabolism, decreased inflammation, and a local anesthetic effect

- Both heat and cold cause a rebound phenomenon: maximum vasodilation or vasoconstriction is followed by the reverse effect; therefore, intermittent application of heat and cold is needed to maintain the desired effect
- Heat is used to support inflammation by increasing blood flow and softening exudates; increase joint range of motion and decrease joint stiffness; and reduce pain
- Cold is used to relieve muscle spasm, decrease inflammation, decrease edema unrelated to inflammation, and decrease pain

Nursing Intervention Alert

Do not use heat when active bleeding is present because vasodilation will increase bleeding; in the first 24 hours after trauma, because vasodilation and increased capillary permeability will increase edema and risk of bleeding; when edema unrelated to inflammation exists; or when skin is irritated and reddened.

Do not use cold on open wounds or when circulation is impaired because it can increase tissue injury; do not use on clients who exhibit an allergic type reaction on exposure to cold. Apply heat and cold with caution when the client has sensory impairment, cognitive impairment, altered circulation, or an open wound.

Assessment Alert

Assess skin area before applying heat or cold; reassess 15 minutes after application; stop application if an untoward response has occurred.

- Psychospiritual
 - Be present
 - Use soothing tones
 - Be nonjudgmental and accepting
 - Allow expression of feelings
 - Exhibit empathy
 - Use touch therapeutically
 - Be efficient and coordinated in providing care
 - Facilitate spiritual practices
- Social
 - Promote communication with family/friends
 - Suggest visiting

- Facilitate satisfying visits with family/friends by having client prepared for visit and avoiding interruptions
- Environmental
 - Provide warm blanket
 - Maintain quiet
 - Open a window
 - Adjust heat or air conditioning
 - Maintain a tidy room

see Chapter 17 for management of pain, which is considered the fifth vital sign.

NUTRITION AND ORAL HYDRATION

ESSENTIAL NUTRIENTS

- Macronutrients: carbohydrates, proteins, lipids
- Micronutrients: vitamins, minerals
- Water

CARBOHYDRATES (CHO)

- Simple CHO (sugars)
 - Monosaccharides or disaccharides
 - Water-soluble
 - Glucose is a monosaccharide, the simplest form of carbohydrate, and the energy source of cellular metabolism
 - Sources: sugar, syrups, molasses, honey, fruit, and milk
 - Energy yield: 4 kcal/g of CHO
- Complex CHO (starches and fiber)
 - Insoluble, nonsweet CHO
 - Polysaccharides
 - Sources: bread, cereals, potato, rice, pasta, crackers, flour products, and legumes
 - Fiber is a nondigestible, complex CHO, which provides roughage
- Functions of CHO
 - Provides energy thereby sparing protein
 - Essential for normal fat metabolism
 - Promotes growth of normal flora in GI tract thereby supporting synthesis/absorption of vitamins K and B12
 - Needed for the synthesis of nonessential amino acids

- Fiber supplies bulk to the diet stimulating peristalsis and maintaining bowel function
- CHO is stored as glycogen or converted to fat:
 - glycogenesis
 - formation of glycogen from glucose
 - glycogen is stored primarily in liver and skeletal muscle
 - glycogen is converted back to glucose as needed for energy

Clinical Alert

Processed CHOs have been extracted from the plants that produce them and concentrated, thereby removing other nutrients such as proteins, vitamins, and minerals leaving a high-calorie, relatively nutrient-poor foodstuff. Therefore, a healthy diet should contain natural as opposed to processed sources of CHO.

PROTEINS

- Proteins are composed of amino acids and contain nitrogen (amino acids are the simplest form of protein).
 - Essential amino acids
 - There are nine different essential amino acids.
 - They cannot be made by body.
 - They must be taken in as part of diet.

- Nonessential amino acids
 - They can be made by the body.
 - Each does not have to be ingested as part of the diet.
- Complete proteins
 - These contain all nine essential amino acids.
 - Most animal proteins are complete: meat, fish, dairy products, and eggs.
 - Soy is the only complete vegetable protein.
- Partially complete proteins: These contain all essential amino acids but less than needed amount of one or more of them, Gelatin is a partially complete protein.
- Incomplete proteins
 - These do not contain one or more essential amino acids.
 - They are usually vegetable proteins.
 - Sources: dried beans and peas, peanut butter, seeds, fruits, vegetables, bread, cereal, rice, and pasta.
 - Client can utilize incomplete protein well by mixing with a small amount of complete protein, for example, cereal and milk, and pasta and cheese.
- Complementary proteins: incomplete proteins that when taken together make a complete protein, for example, corn and beans, peanut butter and wheat bread, and black beans and rice.
- Energy yield: 4 kcal/g.
- Functions of proteins
 - Maintenance of tissue and growth.
 - Regulation of body functions (enzymes are composed of protein).
- Protein metabolism
 - Anabolism: building of proteins from amino acids by cells.
 - Catabolism: breakdown of excess amino acids by liver for energy or conversion to fat.
 - Amino acids are not stored in body.
 - Nitrogen balance: state in which nitrogen intake equals output.
 - Negative nitrogen balance: output greater than intake.
 - Positive nitrogen balance: intake exceeds output.

LIPIDS

- Fats—name for lipids that are solid at room temperature.
- Oils—name for lipids that are liquid at room temperature.
- Fatty acids—building blocks (simplest form) of lipids.
 - Saturated fatty acids: all carbon atoms contain as many hydrogen atoms as possible
 - Unsaturated fatty acids:
 - monounsaturated
 - polyunsaturated

- Glycerides—glycerol molecule with up to three fatty acids attached (triglycerides refers to those that have three fatty acids attached).
 - Saturated triglycerides: glycerol with three saturated fatty acids.
 - Usually are in animal fats.
 - Usually solid at room temperature.
 - Example: butter, salt pork, etc.
 - Unsaturated triglycerides: glycerol with three unsaturated fatty acids.
 - Usually are in vegetable fats.
 - Usually liquid at room temperature.
 - Example: olive oil, corn oil, etc.
 - Energy yield: 9 kcal/g (concentrated energy source).

Function of Lipids

- Cellular transport
- Insulation
- Protection of vital organs
- Source of energy (9 kcal/gram)
- Vitamin absorption
- Transport of fat soluble vitamins

Cholesterol

- Cholesterol is a fat-like material.
- It is produced by the liver.
- It is found in animal products (egg yolk, milk, and organ meats).
- Use: formation of bile acids and steroid hormones; it is a component of cell membranes and other structures.

VITAMINS

- Small quantities of vitamins are required for metabolism.
- Vitamins cannot be made in the body.
- They must be taken in as part of diet.

Water-Soluble Vitamins

- Vitamin C (ascorbic acid) is needed for the formation of collagen in healing wounds and for absorption of iron; found in citrus fruits; deficiency results in impaired healing and scurvy.
- Vitamin B1 (thiamine) is essential for carbohydrate metabolism; found in enriched flour; deficiency causes beriberi.
- Vitamin B2 (riboflavin) is needed for the breakdown of fatty acids and amino acids for energy; found in milk and milk products; deficiency causes inflamed eyes, cracked lips, and a red, swollen tongue.
- Vitamin B5 (niacin) converts glucose to energy; found in enriched bread and wheat, and rice.

- Vitamin B6 (pyridoxine) is needed for the formation of RBCs and amino acids and for the metabolism of glucose; found in meats and whole grains.
- Vitamin B12 (cobalamin) is needed for protein metabolism and RBC formation; found only in meat, fish, cheese, and eggs; deficiency that occurs when the vitamin is not absorbed because of a lack of intrinsic factor in the stomach required for the absorption of vitamin B12 in the terminal ileum is called pernicious anemia.
- Folic acid (folacin) is essential to RBC development; it is found in organ meats and green, leafy vegetables. Its deficiency causes anemia.
- Pantothenic acid is a component of coenzyme A, which is necessary for metabolism of CHO, proteins, and fats and synthesis of cholesterol, steroid hormones, acetylcholine, and heme; found in foods such as liver, kidney, yeast, egg yolk, broccoli, and yogurt.
- Biotin is needed for synthesis of fatty acids, gluconeogenesis, energy production, and protein metabolism; found in brewer's yeast, egg yolk, organ meats, milk, soya, and barley.
- Water-soluble vitamins
 - cannot be stored in the body,
 - need to be ingested daily, and
 - can be lost from foods by boiling, sitting in water.

Fat-Soluble Vitamins

- Vitamin A (retinol) is necessary for good eyesight; found in yellow fruits and vegetables.
- Vitamin D (calciferol) is essential to bone health; it is manufactured in the body by the action of sunlight on substances in the skin and found in fortified milk and fish oils; deficiency causes rickets.
- Vitamin E (tocopherol) protects essential fatty acids and decreases destruction of RBCs; found in wheat germ.
- Vitamin K (menadione) is essential for the formation of prothrombin, and is therefore essential to clotting; manufactured by bacteria in the gut and found in green, leafy vegetables; deficiency results in bleeding problems.
- Fat-soluble vitamins
 - are stored in liver,
 - do not need to be ingested daily, and
 - excessive intake can result in hypervitaminosis for vitamins A and D.

MINERALS

- Major minerals (macrominerals): sodium (Na), chlorine (Cl), potassium (K), calcium (Ca), phosphorus (P), magnesium (Mg), and sulfur (S).
- Trace minerals (microminerals): iron (Fe), zinc (Zn), iodine (I), selenium (Se), copper (Cu), manganese (Mn), fluorine (F), chromium (Cr), and molybdenum (Mo).

DAILY ENERGY REQUIREMENT

Energy is needed

- for essential body functions,
- for additional physical activity, and
- to digest, absorb, transport, metabolize, and store nutrients.

IDEAL BODY WEIGHT

Weight recommended for optimal health is calculated using

- standardized weight tables and
- body mass index (BMI).

FACTORS AFFECTING NUTRITIONAL STATUS

- Age/development: nutritional needs increase during growth periods; decrease with old age and related risk of chronic disease (see Table 13–3 for detail).
- Gender: large muscle mass of men requires more calories and proteins; in women, menstruation requires additional iron, pregnancy and lactation require additional nutrients, calories, and fluids.
- Food preferences: both culturally determined and determined by the individual.
- Religious practices: fasting, avoidance of certain foods.
- Lifestyle factors: schedules, facilities for food preparation, level of exercise, and economic level.
- Physiological/health factors: problems such as difficulty in chewing (edentulous or poorly fitting dentures), swallowing (stroke), digesting (lactose intolerance), or absorbing nutrients (malabsorption syndromes).
- Therapeutic: effects or requirements of medications and treatments.
- Psychologic factors: under- or overeating in response to stress, depression; response to advertising

GUIDELINES FOR HEALTHY EATING

- Guiding principle: Eat a varied diet— heavy on fruits, vegetables, and grains, low in fat and cholesterol, moderate in everything else.
- Food-guide pyramid
 - It is the guide to daily food intake.
 - It identifies five food groups and recommends number of servings per day of each (see Table 13–4).
 - Variations of the standard pyramid are available for specific age groups and specific ethnic groups.

Table 13–3 Lifespan Nutritional Considerations

| | |
|------------------------------|---|
| Birth to 1 Year | <p>Period of greatest nutritional demand per unit body weight because it is period of most rapid growth Breast milk of formula; no cow's milk until 1 year; solid foods begun no earlier than 6 months because of risk of allergic reactions. Vitamin supplements and iron enriched foods are recommended; iron stores from birth deplete by 3–4 months.</p> |
| PEDS Toddler | <p>Can eat most adult foods and adjust to 3 meals per day Needs 1250 ml per 24 hours of fluid approximately Required calories decrease to 900--1800 kcal/d Table foods more nutritious than prepared toddler foods Toddlers may refuse certain foods or follow a certain ritual in eating</p> |
| PEDS Preschooler | <p>Snacks between meals for active children: cheese, fruits, raw vegetables, milk, and yogurt May rush through meals to play so need to monitor that nutritional needs are being met If in daycare or preschool, become informed about diet Needs 1500 ml per 24 hours of fluid approximately</p> |
| PEDS School-age child | <p>Require 2400 kcal/d: 3 meals and 1--2 snacks Protein-rich food for breakfast essential to physical and mental demands of school 1750 ml per 24 hours of fluid To prevent obesity, monitor child's eating habits, provide balanced meals and lunches, healthy snacks, do not use food as reward, and promote regular exercise</p> |
| PEDS Adolescent | <p>Increased need for nutrients especially protein, calories, vitamins (groups B and D) and minerals (calcium and iron) particularly during growth spurt Typically have irregular eating patterns with frequent snacking or dieting Encourage healthy snacks; limit availability of junk food Be alert for developing problems such as anorexia nervosa, bulimia, and obesity</p> |
| Young adult | <p>Focus on dietary teaching to decrease risk of obesity, anemia, osteoporosis, and hypertension Number and size of nutrient servings for a healthy diet Females need 18-mg iron daily Need for calcium and vitamin D for bones</p> |
| Middle age | <p>Focus on adequate protein, calcium to prevent osteoporosis, and limit cholesterol to decrease risk of heart disease. 2000–3000 ml of fluid daily Caloric need decreased because of decreased metabolic rate and decreased activity so calories need to be limited to avoid obesity and decrease risk of diabetes, heart disease, and problems with mobility</p> |
| Older adult | <p>Nutritional needs are basically unchanged May need additional fiber Decreased smell, taste, saliva, and gastric acid, problems with chewing and swallowing may require dietary adjustments Economic, mobility, and psychological issues such as loneliness may result due to inadequate nutrition Encourage inclusion of high-nutrient foods in diet</p> |

VEGETARIAN DIETS

- Vegans—eat only plant foods, no meat, fish, eggs, and dairy products.
- Other variations allow dairy products (lacto-vegetarians); dairy products and eggs (lacto-ovo-vegetarians); eggs but no meat or dairy products (ovo-vegetarians); dairy products, eggs, and fish but not meat (pesco-vegetarians); only certain types of meat (partial vegetarians); and only fresh fruit, juice, nuts, honey, and olive oil (fruitarians—not an adequate diet).

Nursing Intervention Alert

Vitamin B12 and iron are specific concerns for vegetarians. Brewer's yeast, B12-fortified foods, or B12 supplements should be included in diet. Foods rich in iron such as raisins, leafy green vegetables, whole grains, and iron-enriched foods should be ingested daily along with foods high in vitamin C, which promotes absorption of iron.

Table 13–4 Food Groups and Recommended Daily Servings

| Age Group | Bread, Cereal Rice and Pasta | Vegetable Group | Fruit Group | Meat, Poultry, Fish, Beans, | Milk, Yogurt, Eggs, and Nuts | Fats, Oils, and Sweets and Cheese |
|----------------------------|------------------------------|-----------------|-------------|-----------------------------|------------------------------|-----------------------------------|
| Recommended servings | 6–11 | 3–5 | 2–4 | 2–3 | | Use sparingly |
| PEDS Under 9 years | | | | | 2–3 | |
| PEDS Age 9–12 years | | | | | 3 or more | |
| PEDS Teen | | | | | 4 or more | |
| Adult | | | | | 2 or more | |
| OB Pregnant | | | | | 3 or more | |
| OB Lactating | | | | | 4 or more | |

NUTRITIONAL ASSESSMENT

Nutritional Screening

- Nutritional assessment is used to identify clients who are at risk of becoming malnourished. Once identified, more in-depth assessment is obtained.
- Screening tools for particular population groups such as the elderly, those with heart disease, and the pregnant have been developed.

Specific Methods of Obtaining Dietary Data

- 24-hour food recall—Client reports all food and beverage ingested in a typical 24-hour period.
- Food frequency record—Checklist of foods marked by the client as number of times eaten in a day, week, or month or marked as frequently eaten, seldom eaten, or never eaten. May include only foods suspected of being eaten in insufficient or excessive quantities.
- Food diary—Record of measured amounts of all food and fluids eaten in a specified time, usually 3–7 days.
- Diet history—Comprehensive analysis of type and amount of foods eaten and factors influencing their selection; obtained by a nutritionist or dietician.

Information reported on these tools can be analyzed against food pyramid recommendations to judge adequacy.

Physical Examination

- Obtain accurate height and weight measurements.
- Identify amount and direction of weight change: compare current body weight to usual body weight.
- Identify any weight change as intentional or unintentional.
- Observe for signs of malnutrition such as listless, tired appearance; dry, lackluster hair, pale, dry skin and nails; dull eyes with pale or reddened conjunctiva; swollen, smooth beefy-red or magenta tongue and swollen, spongy gums; swollen lips with cracks at the corners, slight musculature; irritability; and decreased reflexes.

Anthropometric Measurements

- Triceps skinfold measurement (TSF)
 - Determines fat stores.
 - Grasp skin on back of upper arm halfway between the elbow and the shoulder; place calipers 1 cm below fingers and record the size of the TSF to the nearest millimeter.
- Mid-arm circumference (MAC)
 - Measures fat, muscle, and skeleton.
 - Instruct client to let arm hang freely and bend elbow 90 degrees.
 - Measure circumference of upper arm at midpoint between elbow and shoulder.
 - Record in centimeters and to the nearest millimeter.

- Mid-arm muscle circumference (MAMC)
 - Using the above two measurements, determine MAMC by checking a table or using a formula.
- Compare to standard measurements.

Assessment Alert

Changes in these measures occur slowly so they are used to monitor clients over months or years, not days or weeks. Measurements are affected by fluid status and normal age changes.

Laboratory Tests

- Serum proteins: used to estimate protein stores
 - Hemoglobin: low levels indicate iron-deficiency anemia; may or may not be dietary in cause.
 - Albumin: low albumin suggests long-term protein depletion as opposed to short-term depletion.
 - Transferrin: protein that transports iron from intestine through serum; decreases in response to protein lack more quickly than albumin.
 - Total iron-binding capacity: amount of iron in blood available to be bound; it provides an indirect measure of transferrin in the blood.
 - Prealbumin: responds most quickly of all the serum proteins to changes in nutrition; not routinely used because of expense.
- Urinary tests
 - Urinary urea nitrogen: compares nitrogen intake, calculated based on grams of protein intake, to nitrogen output calculated by the amount of urea (end product of amino acid metabolism) in the urine over 24 hours to provide a measure of protein catabolism and nitrogen balance.
 - Urinary creatinine: measures amount of creatinine (product of skeletal muscle metabolism; the more skeletal muscle, the more creatinine) excreted by kidney; reflects muscle mass, which decreases with malnutrition.
- Total lymphocyte count
 - Number of lymphocytes decrease as protein depletion occurs.

Assessment Alert

No one laboratory test is diagnostic of malnutrition—all findings can be due to a number of different causes.

TYPES OF DIETS

- Standard diet (house diet)
 - Balanced 2000 kcal diet based on the needs of a sedentary adult.
- Light diet
 - Plainly cooked.
 - No fat.
 - Limited fiber.
 - Used for persons not ready for full normal diet such as postoperative clients or those resuming eating full diet after an illness.
- Modified-consistency diets
 - Clear liquid diet
 - consists of clear liquids including broth and gelatin.
 - provides sugar; rests GI tract, relieves thirst, and prevents dehydration.
 - does not meet the need for protein, fat, vitamin, minerals, or calories.
 - is prescribed for short intervals only (24–36 hours).
 - is used postoperatively; as preparation for tests/surgery on GI tract; for GI infection/disease.
 - Full liquid diet
 - consists of foods liquid at body temperature including ice cream, yogurt, cream of wheat or rice cereal, pudding, and custard.
 - lacks in iron, protein, and calories; high in cholesterol.
 - is balanced with an oral supplement, such as Ensure, if required for more than a short time.
 - Soft diet
 - consists of foods that are easy to chew and swallow.
 - contains little fiber so is low-residue.
 - Pureed diet
 - is an adaptation of soft diet.
 - is prepared by adding liquid to foods and blending to create semi-solid consistency.
- Modified-nutrient diets
 - Low-sodium diet
 - Used in management of cardiovascular and kidney disease; portal hypertension.
 - Examples of food stuffs not allowed: Deli meats, bacon, ham; canned soups, bouillon, vegetables, and meats; table salt and salt based seasonings; olives; salted-snack foods; cheese and regular butter; gravies; frozen fish, pizza, and sausage products.
 - Potassium-rich diet
 - Used to replace potassium lost through the kidneys as a result of potassium-losing diuretics.
 - Foods rich in potassium include baked potato, cantaloupe, bananas, and oranges.

- Low-protein diet
 - Used in management of hepatic encephalopathy and renal failure.
 - Foodstuffs that are limited include meat, poultry, fish, cheese, eggs, and milk.
- High-protein diet
 - Used whenever tissue needs to be built: after extensive burns, surgery, or malnutrition.
 - All complete protein foods limited in low-protein diet are encouraged in a high-protein diet. Incomplete proteins are not useful in high-protein diets.
- Low-purine diet
 - Used in the management of gout and certain types of kidney stones.
 - Foods to be avoided include organ meats, sardines, anchovies, bouillon and other meat soups and gravies, and alcohol.
- Acid-ash diet
 - Used in the prophylaxis and management of UTIs.
 - Foods allowed include meat, fish, poultry, eggs, cereals, and cranberries, prunes, and plums; all other fruits are disallowed.
- Alkaline-ash diet
 - Used to dissolve urinary stones composed of uric acid or cystine
 - Foods allowed include fruits except cranberries, prunes, and plums, milk, vegetables, and carbonated vegetables.
- Modified kilocalorie diets

PARENTERAL AND ENTERAL NUTRITION

Parenteral Nutrition (Total Parenteral Nutrition, Intravenous Hyperalimentation)

- In parenteral nutrition, nutrient solutions are given directly into a high-flow central vein (e.g., through a central venous catheter into the superior vena cava) because they are hypertonic and need to be immediately diluted by the client's blood.
- This type of nutrition is used when GI tract is nonfunctioning.

Nursing Process Elements

- Assess for problems/risk for problems related to nutrition:
 - Signs of under- or overnutrition using anthropometric measures, laboratory data, physical characteristics, and dietary data

- Anorexia
- Dysphagia
- Difficulty in chewing
- Mobility problems that interfere with obtaining or preparing food or feeding self
- Stimulate appetite
 - Do not schedule unpleasant treatments for immediately before or after mealtime
 - Ensure clean, attractive environment free of odors or unpleasant sights
 - Make client comfortable for meals:
 - Encourage going to toilet
 - Instruct to wash hands
 - Provide mouth care
 - Provide a comfortable seat
 - Seat in a good position
 - Avoid constricting clothing or linens
 - Medicate for pain or other symptoms
 - Provide small portions of liked foods served neatly and attractively with clean utensils
 - Provide a stress-free social setting for meals when possible
- Assist with eating as needed:
 - Prepare food for eating: cut meat; butter bread; pour tea
 - Provide adaptive feeding aids to enable maximal independence (see section on “Assistive Devices”)
 - Orient clients with impaired vision to type and location of foods and utensils. Describe location in terms of numbers on a clock face
 - If feeding client:
 - Create an unhurried environment
 - Make the client sit to feed if possible
 - Have client select order of foods fed
 - Provide manageable size bites
 - Allow sufficient time for swallowing
 - Offer fluids after every three or four bites of solid food
- Record intake, output, calorie count PRN, and document client's tolerance of the meal: difficulty in swallowing, nausea, and fatigue

Client teaching for self-care

Teach client about

- components of a healthy diet
- dietary/caloric requirements relative to the client's age, weight, and health status
- need for fluids
- food sources of specific nutrients

- giving special emphasis on complete and incomplete proteins and complementary food equations (for vegetarians)
 - grains + legumes = complete protein
 - legumes + nuts or seeds = complete protein
 - grains, legumes, nuts or seeds + dairy = complete protein
- how to read food labels
- proper food storage and preparation
- resources to aid in obtaining and preparing nutritious foods
- purpose of special diets as well as allowed and prohibited foods
- strategies to promote compliance with therapeutic diet
- alternatives to prohibited foods
- controlling desire to eat by using a “10-minute wait”, drinking water, and taking a walk
- involving family members for support
- utilizing community resources and support groups

Enteral Nutrition

Clinical Alert

PEDS

Orogastric tubes are used for infants because infants are obligatory nose breathers. Orogastric feedings are used for premature infants who have no gag reflexes, and therefore are at risk of aspiration if regular oral feedings are given.

Nursing Intervention Alert

Bolus feedings can only be given into the stomach.

Enteral feedings are directly administered into the stomach or intestine by a nasogastric (through nose to stomach) tube, an orogastric (through mouth to stomach) tube, a nasoenteric (through nose into intestine) tube, a gastrostomy (through abdominal wall into stomach) tube, or a jejunostomy (through the abdominal wall into the jejunum) tube.

- Use nasogastric tubes (NG tubes) when
 - need for feedings is short-term,
 - gag and cough reflexes are intact, and
 - gastric emptying is normal.
- **PEDS** Use orogastric tube
 - for infants because infants cannot breathe through the mouth; they are obligatory nose breathers, and therefore the nostril can not be obstructed.
- Use a nasoenteric tube
 - for clients at risk for aspiration from the stomach such as restless, confused, or agitated clients; clients with an endotracheal tube or who have been recently extubated, and those with impaired cough or gag reflexes or decreased level of consciousness (LOC).
- Use a gastrostomy tube when
 - feedings will be needed for longer than 6–8 weeks.
- Use a jejunostomy tube when
 - feedings will be long term and the risk of aspiration from the stomach is great.
- Types of gastrostomy/jejunostomy
 - Traditional
 - Tube is inserted surgically and sutured in place; in 10–14 days, when healing is complete, the tube can be removed and then reinserted for each feeding; when the tube is not in place a prosthetic cap is worn to cover the ostomy.
 - PEG or PEJ
 - Tube with rubber bumpers and an inflatable balloon to hold it in place is inserted through the abdominal wall with an endoscope; once healing has occurred, tube can be inserted without an endoscope.
- Schedule of feedings
 - Intermittent (300–500 ml several times daily)
 - Continuous (given over 24 hours via infusion pump to maintain a set rate)
 - Bolus feeding (type of intermittent feeding in which a syringe is used to rapidly administer the feeding)
 - Cyclic feedings (continuous feedings given over less than 24 hours, e.g., 12 or 16)
 - Only continuous feedings can be given into the intestine
- Formulas and feeding systems
 - The formulas are selected based on client needs: with a standard formula, there is 1 kcal/ml of solution with nutrients in specified proportions.
 - Feedings come in open and closed systems.
 - Open systems
 - Feedings are canned liquids or powders to be reconstituted.
 - Once opened, canned liquid formulas must be refrigerated and used within 24 hours.

Nursing Intervention Alert

When formula must be reconstituted, sterile water is used to decrease the risk of contamination. The formula must be labeled with time, date, type of formula, and strength. Formula must be refrigerated and disposed of if more than 24-hours old.

—Closed systems consist of prefilled bags that are spiked with enteral tubing; these can be used within 24–36 hours.

—Feedings are given at room temperature unless otherwise prescribed.

Nursing Process Elements

- Assess bowel function by checking for bowel sounds before intermittent feedings and every 4–8 hours for continuous feedings
 - Check order for type of feeding and rate
 - Use enteral controller to regulate the amount of feeding the client is receiving
 - Check expiration date of formula
 - Label all equipment with name, date, rate, formula used, and the date when started
 - Check tube placement by aspirating and checking pH of aspirate. Stomach secretions are usually green, tan, or off-white with a pH of 1–4 while intestinal secretions are yellow or brownish green stained with bile, with a pH up to 6
- If residual feeding of more than 100 ml for NG tube or more than 200 ml for gastrostomy tube is obtained on aspiration, hold feeding for 30 minutes to an hour and recheck. If it is still 100 ml/200 ml, contact physician.
 - Place client in Fowler's position, or if contraindicated, in a right-sided position with head of bed elevated 30–45 degrees to prevent aspiration during feeding
 - Flush tube with 30–50 ml of water before and after each feeding, to ensure patency
 - Monitor for abdominal distention which can indicate intolerance of previous feedings; regurgitation and sense of fullness after feedings which can indicate need to decrease rate or amount of feeding; and for diarrhea or constipation which can develop due to the concentrated ingredients in the formula or the lack of bulk respectively
 - Monitor for dumping syndrome if feedings are via a jejunostomy tube
 - When administering medications, shut off feeding, give each separately and flush with water in between
 - Do not mix medications with feeding formula
 - Irrigate clogged tube with water or Viokase according to agency policy
 - Document
 - date and time
 - amount of residual feeding
 - formula type, strength, and amount as well as any water instilled on the I&O sheet
 - client's tolerance of the procedure
 - any care of the stoma site
 - Change disposable equipment every 24 hours
 - If feeding is via an NG tube, check that the tube is securely taped, and not causing nasal irritation; if feeding is given through a gastrostomy or PEG tube, assess site for infection or skin breakdown
 - Monitor for complications as aspiration, diarrhea, constipation, unplanned extubation, obstruction, or hyperglycemia
 - When client requires long-term feeding at home, teach procedure to client or caregiver, arrange visits by home care RN

Think Smart-Test Smart

Recognize the fact that the appearance of secretions and measurement of pH cannot guarantee correct verification of tube placement. Secretions vary and sometimes secretions that are similar in appearance to GI secretions, can be aspirated from the respiratory tree. The pH can also vary and respiratory secretions can be as low as 6 and gastric secretions can be as high as 6 in clients with disorders of gastric acid secretion or who are taking medications to decrease it. The most reliable method of verifying tube placement is by X-ray visualization.

- Respiratory secretions are typically, though not always, 7 or higher

Before starting an enteral feeding, the client must be in a semi-Fowler's position for at least 30 minutes and the tube aspirated to check for residual feeding. If more than 100 ml of residual feeding is aspirated, the physician is notified. Following an *intermittent feeding*, the tube is flushed with 50 ml of water and the client remains in a sitting or right-side-lying position for 30–60 minutes.

When *continuous feedings* are administered, the tubing and container must be changed every 24 hours.

PALLIATIVE/COMFORT CARE

World Health Organization (WHO) definition of palliative/comfort care: “Approach which improves the quality of life of patients and their families facing life-threatening illness, through the prevention, assessment and treatment of pain and other physical, psychosocial, and spiritual problems.”

- The focus is on the whole person, relieving distressing symptoms and improving quality of life.
- It utilizes an interdisciplinary team approach.
- It is provided along with other medical treatments.

- It incorporates complimentary and alternative approaches.
- It is not just end-of-life care; it starts at the time of diagnosis.
- It does not hasten or delay death.
- It provides a support system for remaining as active as possible until death.
- It offers support to family during client’s illness and during grieving.

Refer to Chapter 16 for detailed discussion of relief of symptoms.

PERSONAL HYGIENE

- Factors that determine hygienic measures appropriate for a client include personal preferences (which may be culture-based), self-care ability, and skin condition
- Personal preferences of the client such as time and frequency of showering and/or bathing, type of oral care, usual hair and nail care, use of soaps, bath oils, lotions, powder, deodorant, etc., and products not used because of reactions such as dryness, itch, or rash

—When washing face, wash eyes first going from inner to outer canthus and using a different section of washcloth for each

—Rinse skin thoroughly to remove all soap residue

—Dry skin thoroughly but gently with special attention to skin fold areas such as under the breasts, groin, axilla, under the abdominal “apron” of overweight clients and between toes because bacteria grow best in warm, dark, and moist areas

- Check temperature of water carefully for clients who are confused or have poor circulation, as they may be unable to do so safely
- Do not leave children unattended in bathtub

BATHING AND CARE OF THE SKIN

- Skin is the body’s first line of defense so design and implementation measures with the goal of maintaining an intact, healthy skin
- Skin sensitivity is greatest in infants, young children, older adults, and in under- and overweight persons
 - Prevent/treat dry skin, which is easily damaged:
 - Limit bathing to once or twice per week
 - Limit or avoid use of soap; use cleansing cream
 - Avoid use of alcohol-based products
 - Apply lotions or creams
 - Prevent injury to skin:
 - Protect from friction and shearing forces
 - Prevent scratching
 - Protect from excessive pressure

Nursing Process Elements

- Prevent irritation and infection:
 - Wash from clean to dirty—for the perineum this means front to back

Nursing Intervention Alert

PEDS

Neonates should be immediately dried and wrapped after bathing to prevent heat loss because heat is lost rapidly as a result of body surface area being large relative to body mass and because their temperature-regulating mechanisms are immature.

FOOT CARE

Proper foot care is critical for diabetic clients and others with poor circulation to the feet.

NAIL CARE

- Soak hands or feet if needed to soften nails before cutting or filing.
- Cut nails straight across at end of fingers or toes; then use file to round corners.
- File, do not cut, nails of diabetic clients and other clients with poor circulation.
- Do not trim nails low in corners because of the risk of ingrown nails.

ORAL CARE

Nursing Process Elements

- Assess for clients at risk for oral health problems:
 - Those unable to maintain oral hygiene: comatose, confused, and depressed
 - Those with dry oral mucous membranes: anxious, dehydrated, heavy smokers, alcohol users, mouth breathers, for example, those with a NG tube, oxygen, nasal packing, those with salivary-gland damage from radiation to the head or neck, and those taking medications such as tranquilizers (chlorpromazine, diazepam), anticholinergics, diuretics, and chemotherapeutic agents
 - Those with poorly cared for teeth or improperly fitting dentures

Nursing Intervention Alert

Hyperplasia of the gums is a side effect of phenytoin (Dilantin) so regular flossing and brushing with a soft brush is critical.

- Monitor for dryness of mucous membrane and for signs of glossitis and stomatitis
- Provide/assist/teach oral hygiene to clients PRN
- Assess the gag reflex before giving or delegating oral care
- Prevent aspiration when giving oral care to unconscious clients: turn head to side and lower head if possible; when using syringe to rinse, inject fluid into mouth gently to avoid forcing it into the throat; make sure all fluid is removed from mouth
- Avoid long-term use of lemon and glycerine swabs because of their drying effect and effect on tooth enamel
- Use only a water-soluble lubricant for lips or nares because aspiration of an oil-based lubricant can cause lipid pneumonia
- Use hydrogen peroxide in the mouth with caution as it can irritate mucosa and alter normal flora
- If delegating oral care, instruct regarding correct positioning, use of oral suction catheter if needed, and remind to report any changes in mucosa

REST AND SLEEP

- Rest: Cessation of work that provides for a period of relaxation in which the person is awake.
- Sleep: Physiologic state of full or partial unconsciousness during which the body suspends voluntary actions while the body rests and restores itself. The sleep cycle consists of two major stages:
 - Rapid eye movement (REM) sleep during which people dream.
 - Nonrapid eye movement (NREM): sleep which consists of 4 stages:
 - Stage 1: very light sleep characterized by drowsiness and relaxation, eyes roll from side to side, and heart rate and respirations decrease; lasts only moments and the client is easily woken.
 - Stage 2: light sleep with continued slowing of body functions; decline in temperature; eyes are still. Lasts 10–15 minutes and represents 40–45% of the total time the client is asleep.
 - Stage 3: further slowing of the heart and respiratory rates along with other body systems due to dominance of the parasympathetic system; client not easily aroused; skeletal muscles are relaxed; reflexes are diminished and snoring is common.
 - Stage 4: deep sleep (delta sleep) that lasts up to 30 minutes; heart and respiratory rates are 20–30% below normal waking hour rates; client is difficult to arouse, very relaxed with little movement and occasional dreaming. Body replenishes itself during stage 4.
 - REM sleep (paradoxical sleep): lasts 5–30 minutes and occurs about every 90 minutes. Brain is very active with its metabolism increased by nearly 20% and dreaming occurs. Client is difficult to arouse

but may wake spontaneously. Muscle tone is depressed, gastric secretions increased, and irregularities in both heart and respiratory rates may occur.

- A complete sleep cycle for adults lasts 1.5 hours and most experience 4–6 cycles during a 7–8 hour sleep.

SLEEP REQUIREMENTS

- **PEDS** Newborns: 16 hours of sleep per day typically divided into seven sleep periods.
- **PEDS** Infants can sleep up to 22 hr/d though 10–12 hours of sleep may be adequate.
- **PEDS** Toddlers sleep 10–12 hr/d and spend approximately 20–30% of sleep in REM. Preschool child sleeps 11–12 hr/d with REM sleep being 20–30% that of an adult.
- **PEDS** School-age children: 8–12 hour sleep with REM sleep decreasing to 20% of the cycle.
- **PEDS** Adolescents: 8–10 hours of sleep prevents unnecessary fatigue and susceptibility to infection. REM sleep continues to be 20%. Nocturnal emissions are experienced by adolescent boys.
- Young adults do well with 7–8 hours of sleep and by mid-adulthood can feel adequately replenished with as little as 6 hours of sleep with REM remaining at 20%.
- Many elderly clients require as little as 6 hours of sleep with the first REM period being longer at 20–25% of the sleep cycle. However, stage-4 sleep is decreased or absent resulting in a less restorative sleep. Older persons tend to wake more frequently during the night and have more difficulty falling back to sleep. Some older people experience confusion at night (sundown syndrome), which may be the result of a decrease in stimulation, change in sleep–wake cycle (circadian rhythm), or Alzheimer's disease.

Nursing Process Elements

- Determine client's sleep activity pattern
- Provide food or fluid that would facilitate sleep, such as milk or protein
- Provide a quiet, dark environment
- Limit activities that could interrupt sleep, such as taking vital signs
- Provide a back massage to promote comfort and rest
- Administer sleep or pain medication as appropriate
- Position an immobile client to facilitate muscle relaxation

- Support pressure-prone areas of the body
- Provide loose-fitting clothing

Assessment Alert

Factors affecting the client's ability to achieve adequate rest and sleep include pain, respiratory conditions that affect breathing pattern, gastric or duodenal ulcers (increased gastric secretions during sleep), endocrine disturbances (hyperthyroidism increases presleep time, hypothyroidism decreases stage-4 sleep, low estrogen levels), elevated body temperature, need to urinate, environment (too hot/cold, too much light, noise), fatigue, shift work, emotional stress, stimulants (caffeine, nicotine), alcohol, diet, and medications that disrupt sleep cycle (amphetamines, antidepressants, beta blockers, bronchodilators, decongestants, narcotics, and steroids).

Clinical Alert

Milk and protein contain tryptophan, which is a precursor to serotonin and is thought to facilitate and maintain sleep.

Client teaching for self-care

Teach client

- that the five phases of sleep include REM (rapid eye movement, which is the time people dream) and NREM (non-rapid eye movement that includes two phases of deep sleep)
- to avoid or eliminate stressful situations prior to bedtime
- to void prior to going to bed
- to wear loose-fitting clothing
- to exercise regularly
- to avoid consuming alcohol, caffeine beverages, or a heavy meal at least 3 hours before bedtime
- to decrease fluid intake 2–3 hours prior to bedtime
- to maintain a regular bedtime and wakeup time always, including vacation and weekends
- when unable to sleep, to get up and do a nonstrenuous activity until sleepy

WORKSHEET

MATCHING QUESTIONS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all):

- | | |
|--|---------------------|
| 1. ____ A protein-sparing source of energy | a. Meditation |
| 2. ____ A complex carbohydrate that promotes peristalsis | b. Vitamin C |
| 3. ____ A fat which is filled with hydrogen atoms | c. Biofeedback |
| 4. ____ An important component of cell membranes | d. Massage |
| 5. ____ A fat-soluble vitamin | e. Saturated fat |
| 6. ____ The form in which carbohydrates are stored in muscles and the liver | f. Glycogen |
| 7. ____ Difficulty in swallowing | g. Black cohosh |
| 8. ____ A comprehensive accounting of foods selected and eaten | h. Fiber |
| 9. ____ A glycerol and three fatty acids | i. Atropine |
| 10. ____ The transferring of universal life energy | j. Reiki therapy |
| 11. ____ The improvement of blood flow secondary to muscle manipulation | k. Vitamin D |
| 12. ____ A herb that exhibits mild estrogen-like action | l. Citrucel |
| 13. ____ A complementary therapy that decreases respiratory rate and oxygen consumption | m. Diet history |
| 14. ____ A herb that enhances immune functioning | n. Garlic |
| 15. ____ A herb that decreases cholesterol and increases HDLs | o. Fecal impaction |
| 16. ____ A complementary therapy that is contraindicated in the presence of clotting disorders | p. Hesitancy |
| 17. ____ The decrease in muscle size associated with prolonged immobility | q. Tarry stools |
| 18. ____ The self-regulation of physiologic processes | r. Dysphagia |
| 19. ____ A common side effect of this medication is urinary retention | s. Acupuncture |
| 20. ____ The presence of hard, dry stool in the rectum | t. <i>Echinacea</i> |
| 21. ____ A bulk-forming laxative | u. Opioids |
| 22. ____ Difficulty in starting a urinary stream | v. Carbohydrate |

- | | |
|---|-------------------|
| 23. _____ A vitamin that acidifies urine | w. Triglyceride |
| 24. _____ An indication of upper GI bleeding | x. Cholesterol |
| 25. _____ A common side effect of this medication is constipation | y. Food intake |
| | z. Disuse atrophy |

FILL IN THE BLANKS

Fill in the blanks with the correct word or phrase to complete each statement.

- The client consumes a snack containing 15 g of carbohydrate, 5 g of protein, and 2 g of fat. The client has consumed _____ calories in this snack.
- Three benefits of a clear liquid diet are: _____, _____, and _____.
- A curved cane with a lower handgrip is useful in helping the client perform which activity of daily living? _____.
- A permanent shortening of muscle fibers, tendons, and ligaments is termed a _____.
- Four nonpharmacological comfort measures are
 - _____
 - _____
 - _____
 - _____
- A written record of all foods consumed in a 3-day time period is called a _____.
- The two nutritional deficiencies for which vegans are at greatest risk are _____ and _____.
- During which stage of sleep is the brain most active? _____.
- Three assistive devices that the nurse could recommend to a client who has difficulty bending at the waist are
 - _____
 - _____
 - _____
- A client seeking to restore energy (Qi) flow to a specific body part would go to a practitioner of _____.
- Four factors that the nurse would assess when determining a client's ability to achieve adequate rest and sleep are
 - _____
 - _____

(continued)

c. _____

d. _____

12. The nurse teaches the client that the minimum amount of fluid to consume daily is _____ ml.
13. Laxatives are contraindicated in the presence of _____.
14. List one nurse-initiated intervention that induces voiding. _____
15. An hourly urinary output of less than _____ ml must be reported to the physician immediately.
16. Vitamin _____ is manufactured by intestinal bacteria and is also found in green, leafy vegetables.
17. Vitamin _____ is essential for good eyesight.
18. Vitamin _____ protects essential fatty acids.
19. Clotting is impaired by a deficiency of vitamin _____.
20. Pernicious anemia results from a lack of vitamin _____.
21. The four factors that can contribute to disturbed sleep patterns are
 - a. _____
 - b. _____
 - c. _____
 - d. _____

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|------------|------------|
| 1. Complete proteins are found only in animal-based food sources. | _____ T | _____ F |
| 2. The total lymphocyte count decreases with protein depletion. | _____ T | _____ F |
| 3. Nasogastric tubes are used for long-term enteral nutrition. | _____ T | _____ F |
| 4. Older adults may require additional fiber in their diets. | _____ T | _____ F |
| 5. Clients receiving palliative care must stop all medical treatments except pain control. | _____ T | _____ F |
| 6. Lacto-ovo-vegetarians do not eat dairy or egg-containing foods. | _____ T | _____ F |
| 7. Vitamin C promotes the absorption of carbohydrates. | _____ T | _____ F |
| 8. Immobility is often accompanied by protein loss. | _____ T | _____ F |
| 9. Atelectasis occurs when retained secretions become infected with bacteria. | _____ T | _____ F |

| | | |
|--|------------------|------------------|
| 10. Transitional stool is passed by newborns within 24 hours of birth. | <u> </u> T | <u> </u> F |
| 11. Habit training for urinary incontinence requires placing the client on a planned voiding schedule. | <u> </u> T | <u> </u> F |
| 12. A client can be easily aroused from stage-3 sleep. | <u> </u> T | <u> </u> F |
| 13. Decreased stimulation is a cause of sundown syndrome. | <u> </u> T | <u> </u> F |
| 14. Milk and protein if taken before bedtime will facilitate sleep. | <u> </u> T | <u> </u> F |
| 15. The two age groups that require less than 8 hours of sleep are middle-aged adults and the elderly | <u> </u> T | <u> </u> F |

APPLICATION QUESTIONS

- Which statement made by a client following teaching about the importance of using only unsaturated fats when cooking indicates that information about which fats are unsaturated was understood?
 - “I will use butter when cooking.”
 - “I will use olive oil when cooking.”
 - “I will use lard when cooking.”
 - “I will use palm oil when cooking.”
- When caring for a client taking phenytoin (Dilantin), the nurse assesses the client’s mouth for which side effect of the drug?
 - Gum hyperplasia
 - Thrush
 - Dental caries
 - Glossitis
- When administering mouth care to an unconscious client, the nurse would place the client into which position?
 - Dorsal recumbent
 - High-Fowler’s
 - Supine
 - Side-lying
- Which data should the nurse review to most accurately assess a client’s protein stores?
 - Urinary protein
 - Triceps skinfold measurement
 - Plasma albumin
 - Height and weight
- Which nursing order related to nutrition should be included in the plan of care for a client with limited vision?
 - Assess for presence of the gag reflex
 - Orient to type and location of foods and utensils
 - Feed in the client’s preferred order of eating
 - Cut foods, then remove knife from tray
- By which route does the nurse administer parenteral nutrition?
 - Intravenous
 - Nasogastric
 - Intra-arterial
 - Nasoenteric
- The nurse performs range of motion exercises on an immobile client to avoid which complication associated with immobility?
 - Urinary stasis
 - Constipation
 - Dependent edema
 - Contractures
- Which nursing intervention should receive priority when caring for an immobile client?
 - Repositioning every 2 hours
 - Assessing for dependent edema each shift
 - Auscultating for bowel sounds daily
 - Administering a calcium supplement twice a day

(continued)

9. Which nursing intervention would best promote a client's psychospiritual comfort?
 - a. Offering a back rub
 - b. Maintaining a clean environment
 - c. Encouraging expression of feeling
 - d. Providing mouth and hair care
10. Use of a nasogastric tube is the method of choice for the administration of enteral feedings when the client is at risk for which problem?
 - a. Diarrhea
 - b. Infection
 - c. Aspiration
 - d. Hyperkalemia
11. When teaching how to maintain healthy, intact skin, which direction would the nurse include?
 - a. Bathe every day
 - b. Apply lubricating lotions
 - c. Briskly rub skin dry
 - d. Use an alcohol-based skin splash weekly
12. A client states he is self-medicating with St. John's wort for mild depression. To assess for a common side effect of this OTC herb, which question should the nurse ask?
 - a. "Have you experienced any abnormal bleeding?"
 - b. "Have you had a rash or any other skin problem?"
 - c. "How well do you sleep at night?"
 - d. "Do you have any problems with constipation?"
13. Which direction should be included in the teaching plan for a client with orthostatic hypotension?
 - a. Avoid use of the Valsalva maneuver
 - b. Self-monitor blood pressure daily
 - c. Limit use of table salt
 - d. Change position slowly
14. Which conditions place a client at risk for oral health problems? (Select all that apply.)
 - a. Coronary insufficiency
 - b. Confusion
 - c. Dehydration
 - d. Obesity
15. Which suggestion would the nurse give to an older client who reports frequent waking at night with difficulty in falling back to sleep? (Select all that apply.)
 - a. "Consume 5–10 oz of wine before bedtime."
 - b. "Maintain a regular schedule of exercise."
 - c. "Nap frequently during the day."
 - d. "Get out of bed and read until sleepy."
16. The nurse would be cautious about including the alternative therapy of imagery in the plan of care for a client with which health problems? (Select all that apply.)
 - a. Diabetes
 - b. Asthma
 - c. Psychosis
 - d. Seizures
17. When caring for an unconscious client, the nurse implements nursing interventions directed at preventing which problems associated with immobility? (Select all that apply.)
 - a. Pneumonia
 - b. Osteoporosis
 - c. Venous stasis
 - d. Pressure ulcers
18. Which actions would the nurse take prior to initiating a NG tube feeding? (Select all that apply.)
 - a. Check order for type and rate of feeding
 - b. Wash hands
 - c. Place client in the supine position
 - d. Aspirate stomach contents and check pH
19. Which information regarding nutrition over the lifespan is correct? (Select all that apply.)
 - a. Toddlers should be fed prepared toddler foods because they provide the best nutrition.
 - b. The older adult's diminished taste and smell requires dietary adjustments.
 - c. Menstruating females require additional daily iron.
 - d. Middle-aged adults require additional calories to meet energy needs.
20. When delegating feeding of a client on a full liquid diet to a nonlicensed assistant, which items would the nurse include on the list of permitted foods? (Select all that apply.)
 - a. Pudding
 - b. Oatmeal cereal
 - c. Yogurt
 - d. Ice cream
21. Which of these nursing interventions would be most appropriate when monitoring an elderly client taking MOM (milk of magnesia) for the treatment of constipation?
 - a. Assess serum electrolyte levels
 - b. Administer supplemental B and C vitamins
 - c. Instruct the client to limit physical activity
 - d. Encourage the client to wear an incontinent pad

22. When obtaining a health history from a client with a history of liver disease, which new complaint would the nurse recognize as most pertinent?
- Pruritus
 - Nausea
 - Clay-colored stools
 - Fatigue
23. When should the nurse plan to ambulate a client with constipation to the bathroom?
- As soon as the client wakes in the morning
 - After the client has finished eating breakfast
 - Immediately before eating dinner
 - Prior to going to bed
24. A client's urinary output is 450 ml in 24 hours. Which term could the nurse use when documenting about the client's urinary elimination status?
- Anuria
 - Oliguria
 - Dysuria
 - Nocturia
25. Which of the following statements, if made by a client, indicates correct understanding of self-care activities to decrease the likelihood of developing a urinary tract infection?
- "I will void every 6–8 hours."
 - "I will take baths rather than showers."
 - "I will perform pericare after each voiding."
 - "I will void before and after sexual intercourse."

ANSWERS & RATIONALES

MATCHING ANSWERS

Match the following (note that terms and/or descriptions may be used once, more than once, or not at all):

- | | |
|---|------------------|
| 1. <u>v</u> protein-sparing source of energy | a. Meditation |
| 2. <u>h</u> A complex carbohydrate that promotes peristalsis | b. Vitamin C |
| 3. <u>e</u> A fat which is filled with hydrogen atoms | c. Biofeedback |
| 4. <u>x</u> An important component of cell membranes | d. Massage |
| 5. <u>k</u> A fat-soluble vitamin | e. Saturated fat |
| 6. <u>f</u> The form in which carbohydrates are stored in muscles and the liver | f. Glycogen |
| 7. <u>r</u> Difficulty in swallowing | g. Black cohosh |
| 8. <u>m</u> A comprehensive accounting of foods selected and eaten | h. Fiber |
| 9. <u>w</u> A glycerol and three fatty acids | i. Atropine |
| 10. <u>j</u> The transferring of universal life energy | j. Reiki therapy |
| 11. <u>d</u> The improvement of blood flow secondary to muscle manipulation | k. Vitamin D |
| 12. <u>g</u> A herb that exhibits mild estrogen-like action | l. Citrucel |

(continued)

- | | |
|--|--------------------|
| 13. <u>a</u> A complementary therapy that decreases respiratory rate and oxygen consumption | m. Diet history |
| 14. <u>t</u> A herb that enhances immune functioning | n. Garlic |
| 15. <u>n</u> A herb that decreases cholesterol and increases HDLs | o. Fecal impaction |
| 16. <u>s</u> A complementary therapy that is contraindicated in the presence of clotting disorders | p. Hesitancy |
| 17. <u>z</u> The decrease in muscle size associated with prolonged immobility | q. Tarry stools |
| 18. <u>c</u> The self-regulation of physiologic processes | r. Dysphagia |
| 19. <u>i</u> A common side effect of this medication is urinary retention | s. Acupuncture |
| 20. <u>o</u> The presence of hard, dry stool in the rectum | t. Echinacea |
| 21. <u>l</u> A bulk-forming laxative | u. Opioids |
| 22. <u>p</u> Difficulty in starting a urinary stream | v. Carbohydrate |
| 23. <u>b</u> A vitamin that acidifies urine | w. Triglyceride |
| 24. <u>q</u> An indication of upper GI bleeding | x. Cholesterol |
| 25. <u>u</u> A common side effect of this medication is constipation | y. Food intake |
| | z. Disuse atrophy |

ANSWERS FOR FILL IN THE BLANKS

Fill in the blanks with the correct word or phrase to complete each statement.

- The client consumes a snack containing 15 g of carbohydrate, 5 g of protein, and 2 g of fat. The client has consumed 98 calories in this snack.
- Three benefits of a clear liquid diet are relieves thirst, prevents dehydration, and rests the GI tract.
- A curved cane with a lower handgrip is useful in helping the client perform which activity of daily living? Getting into and out of a sitting position.
- A permanent shortening of muscle fibers, tendons and ligaments is termed a contracture.
- Four nonpharmacological comfort measures are
 - back rub
 - mouth care
 - therapeutic touch
 - maintenance of a comfortable environment
- A written record of all foods consumed in a 3-day time period is called a food diary.

7. The two nutritional deficiencies for which vegans are at greatest risk are vitamin B12 and iron deficiency.
8. During which stage of sleep is the brain most active? REM sleep.
9. Three assistive devices that the nurse could recommend to a client who has difficulty bending at the waist are
 - a. soap on a rope
 - b. shoehorn with a long handle
 - c. long-handled bathing brush
10. A client seeking to restore energy (Qi) flow to a specific body part would go to a practitioner of acupuncture.
11. Four factors that the nurse would assess when determining a client's ability to achieve adequate rest and sleep are
 - a. pain
 - b. condition of the environment
 - c. stress level
 - d. alcohol use(Additional answers could be body temperature, medication taken, diet, endocrine, and respiratory status.)
12. The nurse teaches the client that the minimum amount of fluid to consume daily is 1500 ml.
13. Laxatives are contraindicated in the presence of nausea, cramps, colic, vomiting, or undiagnosed abdominal pain.
14. List one nurse-initiated intervention that induces voiding. Running water, pouring water over the perineum, stroking the inner thigh, etc.
15. An hourly urinary output of less than 30 ml must be reported to the physician immediately.
16. Vitamin K is manufactured by intestinal bacteria and is also found in green, leafy vegetables.
17. Vitamin A is essential for good eyesight.
18. Vitamin E protects essential fatty acids.
19. Clotting is impaired by a deficiency of vitamin K.
20. Pernicious anemia results from a lack of vitamin B12.
21. The four factors that can contribute to disturbed sleep patterns are
 - a. pain
 - b. respiratory conditions that affect breathing patterns
 - c. gastric or duodenal ulcers (increased gastric secretions during sleep)
 - d. endocrine disturbances (hyperthyroidism, hypothyroidism, low estrogen levels)

Answers may also include elevated body temperature, need to urinate, environment (too hot/too cold, too much light, noise), fatigue, shift work, emotional stress, stimulants (caffeine, nicotine), alcohol, diet, and medications that disrupt sleep cycle (amphetamines, antidepressants, beta blockers, bronchodilators, decongestants, narcotics, and steroids).

TRUE & FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. Complete proteins are found only in animal-based food sources. *False*
Complete proteins are found in animal-based food sources and soy.
2. The total lymphocyte count decreases with protein depletion. *True*
3. Nasogastric tubes are used for long-term enteral nutrition. *False*
Gastrostomy tubes are used for long-term enteral nutrition.
4. Older adults may require additional fiber in their diets. *True*
5. Clients receiving palliative care must stop all medical treatments except pain control. *False*
All medical treatments are provided for clients receiving palliative care.
6. Lacto-ovo-vegetarians do not eat dairy or egg-containing foods. *False*
Lacto-ovo-vegetarians do eat dairy products and eggs.
7. Vitamin C promotes the absorption of carbohydrates. *False*
Vitamin C promotes the absorption of iron.
8. Immobility is often accompanied by protein loss. *True*
9. Atelectasis occurs when retained secretions become infected with bacteria. *False*
Hypostatic pneumonia occurs when retained secretions become infected with bacteria.
10. Transitional stool is passed by newborns within 24 hours of birth. *False*
Meconium is passed by newborns within 24 hours of birth
11. Habit training for urinary incontinence requires placing the client on a planned voiding schedule. *True*
12. A client can be easily aroused from stage-3 sleep. *False*
A client can be easily woken in stage-1 of sleep.
13. Decreased stimulation is a cause of sundown syndrome. *True*
14. Milk and protein if taken before bedtime will facilitate sleep. *True*
15. The two age groups that require less than 8 hours of sleep are middle-aged adults and the elderly. *True*

APPLICATION ANSWERS

- Which statement made by a client following teaching about the importance of using only unsaturated fats when cooking indicates that information about which fats are unsaturated was understood?
 - “I will use butter when cooking.”
 - “I will use olive oil when cooking.”
 - “I will use lard when cooking.”
 - “I will use palm oil when cooking.”

Rationale

Correct answer: b.

Olive oil is an unsaturated fat.

Butter, lard, and palm oil are all saturated fats.

- When caring for a client taking phenytoin (Dilantin), the nurse assesses the client's mouth for which side effect of the drug?
 - Gum hyperplasia
 - Thrush
 - Dental caries
 - Glossitis

Rationale

Correct answer: a.

Gingival hyperplasia is a common side effect of the drug Dilantin.

- When administering mouth care to an unconscious client, the nurse would place the client into which position?
 - Dorsal recumbent
 - High-Fowler's
 - Supine
 - Side-lying

Rationale

Correct answer: d.

Placing the client in the side-lying position greatly decreases the risk of aspiration when performing oral hygiene on a comatose client.

- Which data should the nurse review to most accurately assess a client's protein stores?
 - Urinary protein
 - Triceps skinfold measurement
 - Plasma albumin
 - Height and weight

Rationale

Correct answer: c.

Albumin is manufactured by the liver from dietary proteins. In the absence of other diseases, clients with adequate protein intake should have normal serum albumin levels.

- Which nursing order related to nutrition should be included in the plan of care for a client with limited vision?
 - Assess for presence of the gag reflex
 - Orient to type and location of foods and utensils
 - Feed in the client's preferred order of eating
 - Cut foods, then remove knife from tray

Rationale

Correct answer: b.

Orienting the client to the food placement on the tray encourages independence in feeding and increases self-esteem in the client with limited vision.

- By which route does the nurse administer parenteral nutrition?
 - Intravenous
 - Nasogastric
 - Intra-arterial
 - Nasoenteric

Rationale

Correct answer: a.

Parenteral nutrition is the nutrition administered directly into a vein.

- The nurse performs range of motion exercises on an immobile client to avoid which complication associated with immobility?
 - Urinary stasis
 - Constipation
 - Dependent edema
 - Contractures

Rationale

Correct answer: d.

During periods of immobility, the muscle fibers shorten and atrophy, pulling the extremity into a position of flexion and fixation. Exercising the extremity can prevent this from occurring.

- Which nursing intervention should receive priority when caring for an immobile client?
 - Repositioning every 2 hours
 - Assessing for dependent edema each shift
 - Auscultating for bowel sounds daily
 - Administering a calcium supplement twice a day

Rationale

Correct answer: a.

Immobile clients are at a high risk for pressure ulcer development. Should this occur, the client is at an increased risk for infection and septicemia. Prevention of impaired skin integrity is a high priority.

(continued)

9. Which nursing intervention would best promote a client's psychospiritual comfort?
- Offering a back rub
 - Maintaining a clean environment
 - Encouraging expression of feeling
 - Providing mouth and hair care

Rationale

Correct answer: c.

Encouraging clients to identify and verbalize their feelings is therapeutic.

10. Use of a nasogastric tube is the method of choice for the administration of enteral feedings when the client is at risk for which problem?
- Diarrhea
 - Infection
 - Aspiration
 - Hyperkalemia

Rationale

Correct answer: c.

Nasogastric tubes deliver nutrients directly into the intestines, and therefore greatly reduce the risk for aspiration.

11. When teaching how to maintain healthy, intact skin, which direction would the nurse include?
- Bathe every day
 - Apply lubricating lotions
 - Briskly rub skin dry
 - Use an alcohol-based skin splash weekly

Rationale

Correct answer: b.

Applying moisturizers to the skin prevents fluid loss and drying of the skin. Hydrated, supple skin can resist damage from pressure and other potentially damaging conditions better than dry skin.

12. A client states he is self-medicating with St. John's wort for mild depression. To assess for a common side effect of this OTC herb, which question should the nurse ask?
- "Have you experienced any abnormal bleeding?"
 - "Have you had a rash or any other skin problem?"
 - "How well do you sleep at night?"
 - "Do you have any problems with constipation?"

Rationale

Correct answer: c.

Insomnia is a common side effect of St. John's wort.

13. Which direction should be included in the teaching plan for a client with orthostatic hypotension?
- Avoid use of the Valsalva maneuver
 - Self-monitor blood pressure daily

- Limit use of table salt
- Change position slowly

Rationale

Correct answer: d.

Clients with orthostatic hypotension experience a drop in blood pressure when changing positions. Changing positions slowly allows time for the blood pressure to equalize and reduces the occurrence of syncope.

14. Which conditions place a client at risk for oral health problems? (Select all that apply.)
- Coronary insufficiency
 - Confusion
 - Dehydration
 - Obesity

Rationale

Correct answers: b and c.

Clients with confusion may be unable to perform proper oral hygiene or may not be able to verbalize oral problems. Dehydrated clients have dry oral mucus membranes, which may no longer serve as an effective barrier and may lead to infection.

15. Which suggestion would the nurse give to an older client who reports frequent waking at night with difficulty in falling back to sleep? (Select all that apply.)
- "Consume 5–10 oz of wine before bedtime."
 - "Maintain a regular schedule of exercise."
 - "Nap frequently during the day."
 - "Get out of bed and read until sleepy."

Rationale

Correct answers: b and d.

These actions have been shown to be effective. Alcohol at bedtime may induce a sense of sleepiness initially but can interfere with the sleep cycle. Napping during the day makes one less sleepy at night and more likely to either have difficulty falling asleep or staying asleep.

16. The nurse would be cautious about including the alternative therapy of imagery in the plan of care for a client with which health problems? (Select all that apply.)
- Diabetes
 - Asthma
 - Psychosis
 - Seizures

Rationale

Correct answers: a, c, and d.

Imagery has been shown to alter blood glucose levels and brain-wave activity. Imagery is contraindicated in clients with psychosis.

17. When caring for an unconscious client, the nurse implements nursing interventions directed at pre-

venting which problems associated with immobility? (Select all that apply.)

- a. Pneumonia
- b. Osteoporosis
- c. Venous stasis
- d. Pressure ulcers

Rationale

Correct answers: a, b, c, and d.

Unconscious clients are at risk for developing pneumonia secondary to decreased respiratory movement and pooling of secretions, osteoporosis secondary to lack of weight bearing, venous stasis secondary to lack of skeletal muscle activity, and pressure ulcers secondary to a reduction in blood flow to tissues due to pressure.

18. Which actions would the nurse take prior to initiating a NG tube feeding? (Select all that apply.)
- a. Check order for type and rate of feeding
 - b. Wash hands
 - c. Place client in the supine position
 - d. Aspirate stomach contents and check pH

Rationale

Correct answers: a, b, and d.

The nurse must always determine that the correct feeding is being given by checking the order. Hand washing is necessary prior to any client care. Aspiration of stomach contents and checking the pH of the aspirate is necessary to determine tube placement. The head of the bed should be elevated 30–45 degrees to prevent aspiration during the feeding.

19. Which information regarding nutrition over the lifespan is correct? (Select all that apply.)
- a. Toddlers should be fed prepared toddler foods because they provide the best nutrition.
 - b. The older adult's diminished taste and smell requires dietary adjustments.
 - c. Menstruating females require additional daily iron.
 - d. Middle-aged adults require additional calories to meet energy needs.

Rationale

Correct answers: b and c.

Older adults have a diminished sense of taste and smell. Diseases and medications exacerbate the problem. Menstruating females lose iron in the menstrual flow, and therefore require dietary supplementation. Prepared toddler foods are not as nutritious as the fresh food prepared at home. Caloric requirement decreases with middle age and change in activity and metabolism.

20. When delegating feeding of a client on a full liquid diet to a nonlicensed assistant, which items would the nurse include on the list of permitted foods? (Select all that apply.)

- a. Pudding
- b. Oatmeal cereal
- c. Yogurt
- d. Ice cream

Rationale

Correct answers: a, c, and d.

Oatmeal cereal is the only food listed that is not permitted on a full liquid diet.

21. Which of these nursing interventions would be most appropriate when monitoring an elderly client taking MOM (milk of magnesia) for the treatment of constipation?
- a. Assess serum electrolyte levels
 - b. Administer supplemental B and C vitamins
 - c. Instruct the client to limit physical activity
 - d. Encourage the client to wear an incontinent pad

Rationale

Correct answer: a.

MOM is an osmotic laxative and can result in an electrolyte imbalance, particularly hypermagnesemia. MOM does not cause loss of B and C vitamins. Physical activity supports bowel function so limiting activity would tend to encourage constipation. MOM is a relatively gentle laxative and does not typically cause one to lose bowel control.

22. When obtaining a health history from a client with a history of liver disease, which new complaint would the nurse recognize as most pertinent?

- a. Pruritus
- b. Nausea
- c. Clay-colored stools
- d. Fatigue

Rationale

Correct answer: c

Clay-colored stools would indicate an obstruction to the flow of bile, a serious complication of liver disease.

23. When should the nurse plan to ambulate a client with constipation to the bathroom?

- a. As soon as the client wakes in the morning
- b. After the client has finished eating breakfast
- c. Immediately before eating dinner
- d. Prior to going to bed

Rationale

Correct answer: b.

(continued)

The gastrocolic reflex is strongest when food enters the stomach and is especially strong after breakfast. A bowel movement at this time is most likely a result of the stimulation of this reflex. Upon awakening, before dinner and at bedtime do not take advantage of this reflex.

24. A client's urinary output is 450 ml in 24 hours. Which term could the nurse use when documenting about the client's urinary elimination status?
- a. Anuria
 - b. Oliguria
 - c. Dysuria
 - d. Nocturia

Rationale

Correct answer: b.

Oliguria is defined as a urinary output less than 500 ml in 24 hours. Anuria is the absence of urinary output by the kidney. Dysuria is painful urination and nocturia is the need to get up more than one time at night to void.

25. Which of the following statements, if made by a client, indicates correct understanding of self-care activities to decrease the likelihood of developing a urinary tract infection?
- a. "I will void every 6–8 hours."
 - b. "I will take baths rather than showers."
 - c. "I will perform pericare after each voiding."
 - d. "I will void before and after sexual intercourse."

Rationale

Correct answer: d.

Voiding after sexual intercourse flushes out bacteria introduced into the urethra and bladder during intercourse. A normal adult voids every 3.5–4 hours. Taking a bath as opposed to a shower has the potential for introducing bacteria to the area of the urinary meatus. Pericare is not necessary; simply wiping front to back to avoid spreading *E. coli* or other organisms over the urinary meatus is sufficient.

DOSAGE CALCULATION

THE MEDICATION ORDER

- The nurse is legally responsible for ensuring that the correct client receives the right medication at the right dose, at the correct time and by the ordered route.
- Proper interpretation of the medication order is essential.

Abbreviations

- The nurse must follow the institution's policy regarding the use of abbreviations in the medical record.
- Medication errors may occur as a result of a misinterpretation of an abbreviation.

Metric System

- The major system of weights and measures used in medicine is the metric.
- Conversions between units in the system are accomplished by simply moving a decimal point.
- The three basic units of the metric system are
 - meter (length),
 - gram (weight), and
 - liter (volume).
- The same prefixes are used with all three measures listed above.

- The prefixes also change the value of each of the basic units by the same amount.
- Four main prefixes:
 - Kilo, which identifies a larger unit of measure than the basics.
 - Centi, which identifies a smaller unit than the basic.
 - Milli, which identifies a smaller unit than the basic.
 - Micro, which identifies a smaller unit than the basic.
- When administering medications, convert units of measure within the metric system, for example, g to mg, and mg to μg .
- Four metric weights commonly used in medicine (from highest to lowest value) are as follows:
 - k = kilogram
 - g = gram
 - mg = milligram
 - μg = microgram
- Two units of volume in the metric system are as follows:
 - l = liter
 - ml = milliliter
- Each of these units differs in value from the next by 1000.
 - 1 kg = 1000 g
 - 1 g = 1000 mg
 - 1 mg = 1000 μg
 - 1 l = 1000 ml (1000 cc)

Conversion Rules for Metric System

- Conversion between the units is a matter of moving the decimal point three places because each of the units differs from the next by 1000.
- If you are converting from a larger unit of measure to a smaller unit of measure, the quantity must get larger, so move the decimal three places to the right (Example: 0.5 g = 500 mg).
- In metric conversions from smaller units to larger units of measure, the quantity will get smaller. Move the decimal three places to the left (Example: 520 mg = 0.52 g).

Common conversions to remember

- 1 μg = 0.001 mg
- 1 mg = 0.001 g
- 1000 mg = 1 g
- In order to prevent medication errors, fractional dosages should be transcribed with a zero in front of the decimal point and unnecessary zeros are to be eliminated from dosages.

Examples:

- 125 μg = _____ mg (0.125)
- 0.25 mg = _____ μg (250)
- 100 mg = _____ g (0.1)

The Apothecary and Household Measures

- The apothecary and household are the oldest of the drug measurement systems

- If a drug label contains an apothecary dosage, it will usually also contain a metric dosage equivalent
- The apothecary system of weights is based upon the grain (gr), which is the smallest unit in the system
- Common medications that may be ordered or labeled in grains are nitroglycerin, atropine, codeine, morphine, and aspirin
- gr 1 = 60 mg
- gr 15 = 1000 mg

Apothecary measures

- There are three apothecary measures for volume:

Liquids:

—minim (m, min)

—dram (dr)

—ounce (oz)

1 ounce = 30 ml

1 dram = 4 ml

1 minim = 1 drop approximately or 0.06 ml (1/16 of a dram)

15 minim = 1 ml approximately

Household measures

- Common household measures which may be used in medication calculation are as follows:
 - Tablespoon (T or tbs) 1 T = 15 ml
 - Teaspoon (t or tsp) 1 tsp = 5 ml
 - Drop (gtt) 60 gtt = 1 tsp

Conversions from Apothecary to Metric

- When a medication dose is ordered using apothecary or household measures, it should be converted to metric.
- Use the equivalent: gr 1 = 60 mg.

Example:

gr 1/3 = _____ mg

$$\frac{\text{gr 1}}{60 \text{ mg}} = \frac{\text{gr 1/3}}{x \text{ mg}}$$

$$x = \frac{60}{3}$$

$$x = 20$$

- Remember, if you have less than 60 mg, the grain amount will be expressed as a fraction instead of a decimal number.

Example:

15 mg = gr _____

$$\frac{\text{gr 1}}{60 \text{ mg}} = \frac{\text{gr 1/3}}{x \text{ mg}}$$

$$60x = 15$$

$$x = \frac{15}{60}$$

$$x = \text{gr } \frac{1}{4}$$

Conversion from Household to Metric

- Examples to remember:
 - 1 T = _____ ml (Answer: 15)
 - 1 oz = _____ ml (Answer: 30)
 - 1 t = _____ ml (Answer: 5)

Dosage Calculation: Ratio and Proportion Method

- A ratio consists of two numbers, which have a significant relationship to each other.
- While a ratio is an expression of a significant relationship between two numbers, a proportion takes this one step further, and is used to show the relationship between two ratios.
- Example: The physician has ordered 10 mg of a medication. The nurse has a solution containing 8 mg/1 ml.

$$\frac{8 \text{ mg}}{1 \text{ ml}} = \frac{10 \text{ mg}}{x \text{ ml}} \quad \text{Check sequence of measurement units.}$$

$$\frac{8}{1} = \frac{10}{x} \quad \text{Drop the measurement units}$$

$$8x = 10 \quad \text{Cross-multiply, keeping } x \text{ on the left of the equation.}$$

$$x = \frac{10}{8} \quad \text{Remove the number on the left side of your equation by dividing 10 by the number in front of } x.$$

$$x = \frac{5}{4} \quad \text{Reduce the numbers by their highest common denominator—2. Divide the final fraction.}$$

$$x = 1.25 \text{ ml} \quad \text{The } x \text{ in the original proportion was ml, so the answer is 1.25 ml.}$$

The ordered dosage of 10 mg is contained in 1.25 ml.

- It should be routine to check your math twice in dosage calculations.
- It is also necessary to assess each answer to determine if it seems logical. If 1 ml contains 8 mg, you will need a *larger* volume than 1 ml to obtain 10 mg. The answer obtained, 1.25 ml is larger, and, therefore, it is logical.
- You can prove that the proportion is true and your calculation correct by substituting your answer for x in the original proportion.

Solve this dosage calculation problem:

The physician orders digoxin (Lanoxin) 0.125 mg p.o. daily. The medication available is digoxin (Lanoxin) 0.5 mg/2 ml. What is the quantity of medication that the nurse should administer?

Answer:

$$\frac{0.5 \text{ mg}}{2 \text{ ml}} = \frac{0.125 \text{ mg}}{x \text{ ml}}$$

$$0.5x = 0.25$$

$$x = 0.5 \text{ ml}$$

Dosage Calculation: Converting Different Units of Measure to One Unit of Measure

- Doctor's order: Give 0.15 g of medication. The dosage strength available is 200 mg/ml. You have to convert the different units of measure to one unit of measure.
- Convert the 0.15 g to mg by moving the decimal point three spaces to the right. $0.15 \text{ g} = 150 \text{ mg}$. Then solve for x . The ratio and proportion method can be used to solve all problems of fractional dosages. (Answer: 0.75 ml)

Solve this dosage calculation problem:

Remember to change to one unit of measure prior to calculating dose.

- The physician orders ampicillin (Principen) 0.5 g p.o. q 6 hour. The medication available is ampicillin (Principen) 125 mg/5 ml.
- What is the quantity of medication that the nurse should administer?

Change 0.5 g to 500 mg and then solve for x . (Answer: 20 ml)

Dosage Calculation: Converting pounds to kilograms

- There are 2.2 lbs in 1 kg
- To convert from lb to kg divide by 2.2
- Since you are dividing, the answer in kg will be smaller than the lb you are converting
- Answers are expressed to the nearest 10th.

Solve this dosage calculation problem:

Convert the weight of a 150-lb adult to kg.

Answer: $150/2.2 = 68.18 \cong 68.2 \text{ kg}$

Dosage Calculation Based on Body Weight

- Individual dosages may be calculated in terms of $\mu\text{g/kg}$, mg/kg , or mg/lb/d
- The total daily dosage may be administered in divided doses, for example every 6 hours (4 doses), every 8 hours (3 doses) or every 12 hours (2 doses).

Dosage Calculation: Recommended Daily Dosage Range

Two-step procedure

- Calculate the total daily dosage range
- Divide the total daily dosage by the number of doses per day to obtain the actual dose administered at one time.
- Dosage discrepancies are much more critical if the dosage range is low, for example 4–6 mg, as opposed to high, for example 250 mg.
- To check the safeness of a dose ordered by the physician, calculate the correct dosage and compare it with the dosage ordered.

Solve this dosage calculation problem:

The physician orders amoxicillin (Amoxil) for a 50-lb child. The child is to receive this medicine p.o. tid. The usual dose range is 20–40 mg/kg/d in divided doses.

- 50 lb = _____ kg
- What is the lower daily dosage? _____
- What is the upper daily dosage? _____
- What is the lower dose for one dose? _____
- What is the upper dose for one dose? _____
- The dosage range is _____ mg to _____ mg per dose q 8 hours.
- If the order is to give 400 mg q 8 hour, is this a safe dose? Why?

Answer:

- First, determine how many kg the client weighs: 50 lb/2.2 kg = 22.7 kg.
- Second, use 20 mg as your lower daily dosage and multiply that by 22.7 kg = 454 mg/d.
- Third, use 40 mg as your upper daily limit and multiply that by 22.7 kg = 908 mg/d.
- Fourth, using the 454 mg/d, divide by 3 to obtain the lower limit for one dose = 151.3 mg per dose.
- Fifth, using the 908 mg/d, divide by 3 to obtain the upper limit for one dose = 302.6 mg per dose.
- Sixth, you have determined that 151.3–302.6 mg is the safe dose range for this client.
- Seventh, 400 mg/8 hours is *not* a safe dose range for this client.

Dosage Calculation: Temperature Conversion

- To convert Celsius to Fahrenheit: multiply by 1.8 and add 32. (Or multiply by 9/5 and add 32)
- To convert Fahrenheit to Celsius: subtract 32 and divide by 1.8 (Or subtract 32, and multiply by 5/9).

Solve these problems:

$$37^{\circ}\text{C} = \text{_____}^{\circ}\text{F} \quad (\text{Answer: } 98.6)$$

$$34^{\circ}\text{C} = \text{_____}^{\circ}\text{F} \quad (\text{Answer: } 93.2)$$

$$107.6^{\circ}\text{F} = \text{_____}^{\circ}\text{C} \quad (\text{Answer: } 42)$$

$$105.8^{\circ}\text{F} = \text{_____}^{\circ}\text{C} \quad (\text{Answer: } 41)$$

Steps to Decrease Interpretation Errors

- Always place a zero before a decimal expression less than one.
- Never place a decimal point and zero after a whole number, because the decimal may not be seen and result in a 10-fold overdose.
- Avoid using decimals whenever whole numbers can be used as alternatives. Example: 0.3 g should be expressed as 300 mg
- Whenever possible, use the metric system rather than grains, drams, or minims.

Dosage Calculation: IV Flow Rate

- Most institutions require the use of an infusion controller or pump to assist with the delivery of intravenous infusions.
- However, there will be many times when the nurse will be responsible for calculating ml/hr or ml/min to safely administer intravenous medications or fluids.
- The size of the fluid drop is determined by the specific intravenous set being used.
- Macro drip sets will vary among manufacturers and will deliver between 10–20 gtt/ml.
- Micro drip sets deliver 60 gtt/ml.

Information Needed to Calculate Intravenous Flow Rate

- The volume of solution to be infused
- The length of time of the infusion: converted to minutes: i.e., 1 hour = 60 minutes
- The drop factor of the infusion set being used: i.e., 15 gtt/ml

Formula to Calculate Flow Rates

$$\text{gtts/min} = \frac{\text{Volume (ml)} \times \text{Drop factor (gtt/ml)}}{\text{Time (min)}}$$

Solve this rate calculation problem:

- The physician orders an IV to infuse at 150 ml/hr. Calculate the drops per minute rate for a set with a drop factor of 10 gtt/ml.
- Do not forget to convert the hour to minutes.

Answer:

$$\frac{150 \text{ ml} \times 10 \text{ gtt/ml}}{60 \text{ min}}$$

$$\text{Answer} = 25 \text{ gtt/min}$$

Solve this rate calculation problem:

- The physician orders 1000 ml D5 ½ NS to infuse over 8 hours.
- The nurse has an infusion set that delivers 15 gtt/ml.
- How many milliliters should the nurse administer per hour?
- How many drops per minute should the nurse administer?

Answer:

$$1000 \text{ ml} / 8 \text{ hours} = 125 \text{ ml/hour}$$

$$\text{Flow rate} = \frac{125 \text{ ml} \times 15 \text{ gtts/ml}}{60 \text{ min}}$$

$$\text{Answer} = 31 \text{ gtt/min}$$

PHARMACOTHERAPY

BASIC CONCEPTS

- **Pharmacology:** The study of the physical and chemical properties of drugs, their origin, history, sources, and the ways in which drugs affect living organisms.
- **Pharmacodynamics:** Study of drugs and their mechanisms of action on living organisms.
- **Pharmacokinetics:** Study of the absorption, distribution, metabolism, and excretion of drugs.
- **Pharmacodynamics:** Mechanism of drug action.
 - Drugs form chemical bonds with specific receptors within the body. This is the most common way in which drugs exert their action. A lock and key concept demonstrates the drug and receptor relationship. The bound drug elicits or blocks physiologic responses. Drugs that bind to the receptor and create a physiologic response are agonists. Drugs that bind to a receptor but do not elicit a response are called antagonists.
 - Drugs may interact with enzymes by inhibiting the action of a specific enzyme.
 - Drugs alter cellular functions. For example, an antibiotic slows or completely stops the growth and/or reproduction of microbial organisms.
 - Drugs alter the chemical composition of body fluid. For example, antacids are designed to alter the acidity of the stomach contents.

Sources of Drugs

- Drugs may be derived from natural sources such as animals and plants.
- Drugs may be semisynthetically or synthetically produced in the laboratory to form pure products.
- Biotechnology plays an important role in mass-producing hormones and vaccines.

Factors Affecting Responses to a Drug

- **Age of client:** Variations in drug absorption, distribution, metabolism, and elimination may occur among all clients, but in particular, the pediatric and the geriatric.
- **Body weight:** Body surface area is a useful measure to determine if a specific dose of a drug would be appropriate for a specific client.
- **Basal metabolic rate:** Clients with high BMR may absorb, distribute, metabolize, and eliminate drugs more rapidly than clients with normal metabolic rates. In addition, clients with lower metabolic rates may be at risk for toxicity due to a slower absorption, distribution, metabolism, and excretion of drugs from their body.
- **Disease States:** Underlying disease states may affect a client's response to a drug by modifying factors such as, absorption, distribution, biotransformation, and excretion.
- **Tolerance:** May account for the need to increase dosage to maintain therapeutic effect.

Assessment Alert

The very young and the very old clients are at a higher risk for drug toxicity.

Adverse drug effects

- Drugs may interact with other drugs, foods, and other substances.
- Over-the-counter drugs, herbal products, home remedies, and prescription drugs all may pose a threat.
- The nurse must be aware of all substances that a client may encounter and monitor the client for possible interactions.

- Side effects are undesirable effects resulting from the action of the drug. This is the most common type of adverse drug effects. Examples may include N&V, diarrhea, and rash. Side effects are generally predictable and manageable.
- Allergic reactions or hypersensitivity reactions are a response of the client's immunological system to the presence of that specific drug. Reactions may vary from mild (rash, hives, itching) to severe (difficulty breathing and shock).
- Drug toxicity may occur with any client. All drugs are capable of producing toxic effects. In monitoring the client, the nurse needs to be aware that sometimes drugs may accumulate faster than they are metabolized or eliminated. In addition, the very young and the older client are more susceptible to toxicity reactions.
- An idiosyncratic reaction is a genetically determined abnormal reaction to a normal dose of a drug. It can manifest as toxic, accelerated, or as an unusual response to a therapeutic dose.
- A teratogenic effect is one that will cause a structural defect in the unborn fetus whose mother took the drug. Drugs that cross the placenta may cause a teratogenic effect. The FDA requires that all prescription drugs absorbed systemically or known to be potentially harmful to the fetus be classified accordingly to five pregnancy categories (A, B, C, D, and X).
- Drug tolerance means that a client develops a resistance to the effects of the drug, thereby requiring an increased dose or increased frequency of administration.

Drug interactions

- A drug interaction occurs when the pharmacological effects of one drug are altered by another drug. This can cause an increase or a decrease in the actions of the drug.
- Synergistic interaction occurs if the administration of two or more drugs produces a pharmacological response that is greater than that which would be expected by the individual effects of either drug.
- Antagonistic interaction when the combination of two drugs results in effects that are less than if the two drugs had been given separately.
- Incompatibilities occur when two or more drugs or solutions are mixed together and an undesired chemical reaction occurs causing a precipitate, color change, or other physical deterioration to occur.

Measurement of drug concentrations in the body

- Peak drug level is the highest plasma concentration achieved by the administration of a drug at a specific time. Peak levels are drawn according to the type of drug and the route of administration. If the drug is an oral medication, it may be drawn within 1–3 hours after the drug was administered. If the drug was administered intravenously, the level may need to be drawn 10–30 minutes after administration.
- Trough drug level is the lowest plasma concentration of a drug. Trough levels are drawn immediately before the next dose of the drug is given.
- Minimum effective concentration—the minimum level required to elicit the desired effect.
- Minimum toxic concentration—minimum plasma level at which toxic effects of the drug are observed.
- Half-life is the time required by the body to metabolize half of the amount of the dose of the drug.

Controlled substances

- The manufacturing, prescribing, dispensing, and administration of controlled substances are regulated by the government as outlined in the Controlled Substance Act.
- The drugs identified as controlled substances are assigned to Schedules I–V according to their potential for abuse and dependence.

Controlled substances schedules

- Schedule I—High potential for abuse, no currently accepted medical use in the United States, and safety has not been established. Example: LSD.
- Schedule II—High potential for abuse, and may lead to severe psychological and physical dependence. Examples include oxycodone (OxyContin) and methylphenidate (Ritalin).
- Schedule III—Lower potential for abuse than Schedule I and Schedule II drugs, but abuse may cause moderate physical dependence or severe psychological dependence. Examples include hydrocodone/acetaminophen combination drugs (Vicodin), and hydrocodone/aspirin (Lortab).
- Schedule IV—Lower potential for physical or psychological dependence when compared with Schedule III drugs. Examples include alprazolam (Xanax) and diazepam (Valium).
- Schedule V—Lowest potential for physical and psychological dependence when compared with Schedule I–IV drugs. Examples include codeine/guaifenesin combination cough suppressants (Robitussin A-C) and diphenoxylate/atropine (Lomotil).

Think Smart/Test Smart

Remember, a peak is the pointed top of a mountain, thus a drug's peak is when the serum level is the highest. A trough is a depression; therefore the lowest serum level of a drug is the trough.

MEDICATION ADMINISTRATION

ASSESSMENT

Assessing the Client

- Medication history—The client should be asked for names of all medications he/she is taking (prescription, over-the-counter, herbals, home remedies, and alcohol). Ask client about adverse drug effects or allergies.
- Assess clients' understanding of their medications and the relationship of the medications to their illness.
- Conduct a physical assessment of the client. Obtain client's weight, height, BP, temperature, pulse rate, and respiratory rate. Assess general health, nutrition, and ability to perform activities of daily living.
- Assess growth and development issues related to the client's age. Explore emotional, cognitive, cultural, and socioeconomic concerns related to drug therapy.
- Obtain information about social networks and resources to assist with self-care.

Assessing the Drug

- Know the drug's classification, mechanism of action, indications, contraindications, safe dosages, adverse effects, S&S of toxicity, antidotes, and nursing implications.
- Understand how to prepare the dose using correct administration techniques.

Analyze the Information

- Obtain all relevant information regarding the client and the drug, evaluate the information, and make judgments and decisions to assist in formulating a nursing diagnosis.

NURSING DIAGNOSES

- Based upon the assessment and analysis of the data, the nurse will be able to make a conclusion regarding actual client needs and the risk for problems.

Planning

- Identify goals and outcome criteria.
- Goals should be client oriented, measurable, and realistic.
- Outcome criteria should be client oriented, apply to medications the client will receive, and assist in directing safe medication administration.
- Outcome criteria may address issues with drug preparation such as making sure all supplies are available, and providing for a clean and safe work area.

Implementation

- During the implementation phase, the nurse will put into effect the nursing care plan.
- The nurse needs to know the client information and the medication profile data in order to provide safe care.
- The nurse should always use the basic "Five Rights" of medication administration when implementing care for a client receiving medications.
- Remember to check the order, the label and the "Five Rights" at least three times before administration of the medication.

Evaluation

- After the nursing care plan has been implemented and the medication has been administered, the evaluation process continues as an ongoing part of the nursing process.
- The nurse is responsible for monitoring the client's responses to drug therapy at every part of the process.
- Identification of therapeutic responses, unexpected responses, adverse effects, and the need for continued client education are important nursing observations and judgments.

Five Rights of Medication Administration

Right drug

- After carefully checking the order and the drug label, select the correct medication.
- Safe administration requires that the nurse be familiar with the drug's mechanism of action, indications, and contradictions for use, usual dosage, and side effects.

Right dose

- The nurse must check the dose and its safety in relation to the weight and age of the client.
- The nurse is responsible for correct dosage calculation and must be familiar with household measures, the apothecary system, and the metric system and be able to convert from one system to another.
- The nurse must have skills in using measuring devices, such as medicine cups, oral syringes, and parenteral syringes.

Right client

- Always compare the client's name and number on his/her identification band to the name and number on the medication administration record.
- Request that the client state his/her name.
- Remember to ask about allergies.
- If the client questions the appearance, dosage, or route, always recheck the order and medication before administering the dose.

Right time

- The nurse should always be aware of the institution's policy regarding routine medication times.
- The physician's order will specify the number of times a day the medication is to be given.
- The order may state the exact hours of administration or give general guidelines such as before or after meals.
- Take into consideration the drug's action, characteristics of the drug, possible interactions with other drugs or food, and the clients' daily schedule.
- At most institutions, the policy states that medication is administered within 30 minutes of the time it is ordered to be given.

Right route

- If the medication order did not specify the route, the nurse must clarify this with the physician. Remember, the route is part of a correctly written medication order.

**Nursing Intervention Alert**

Always document the administration of medications immediately after you give them.

MEDICATION DOSAGE FORMS

- **Tablet:** A mixture of active and inactive ingredients pressed into a solid.
- **Buccal tablet:** A tablet that is placed in the mouth and held between the cheek and gum until dissolved and absorbed by the buccal mucosa.
- **Sublingual (SL):** Tablets are placed under the client's tongue until fully absorbed. Remind the client not to chew the tablet.

Sublingual and Buccal Routes:

- Medications are absorbed through the oral mucous membranes for rapid systemic effect.
- Instruct the client *not* to swallow these medications.
- Wear clean gloves if you place the medication in the client's mouth.
- **Chewable tablets:** These tablets are often used with children or adults who have difficulty swallowing. Remember that the drug may be absorbed faster than the oral tablet form that is designed to be swallowed.
- **Enteric-coated tablets:** Tablets are coated with a substance that prevents the tablet from dissolving in the stomach where gastric acid is present, but permits it to dissolve in the small intestine. Remind the client *not* to chew enteric-coated tablets.
- **Timed or sustained-release tablets:** Tablets are designed to release contents at specific timed intervals. Do not crush these tablets. Remind the client not to chew timed or sustained-release tablets.

- **Capsules:** The drug is enclosed in either a hard or soft soluble shell, usually made of gelatin. This gelatin shell dissolves in the stomach within 10–20 minutes.
- **Lozenges:** This solid dose form should always be dissolved slowly in the mouth. Often this form is ordered for the soothing effect it exerts on the oral mucus membranes.
- **Oral solutions:** A solution is a clear liquid preparation that contains one or more dissolved substances. The solution may have flavorings and color additives.
- **Suspensions:** Solutions that have solid drug particles mixed with, but not dissolved in, the fluid. Always shake suspensions thoroughly immediately prior to administration.

Nonoral Solutions

- **Douche:** Instillation of a medicated or nonmedicated solution into a body orifice.
- **Injection:** Instillation of a sterile solution administered intramuscular, intravenous, subcutaneous, intradermal, and epidural.
- **Ophthalmic solution:** Medicated or nonmedicated solution instilled onto the conjunctiva.
- **Otic solution:** Instillation of a medicated or nonmedicated solution into the ear.

Mouth Rinses

- After rinsing, some medications are expectorated but other medications may be swallowed
- Local anesthetic rinse agents are indicated for painful mouth lesions
- “Swish and swallow”: After rinsing mouth with medication, the client then swallows the medication
- Example of swish and swallow is an antifungal medication for a fungal infection of the mouth
- Always administer the mouth rinse and swish and swallow medications last

Topical Dosage Forms

- **Ointments and creams:** Most are used for the treatment of skin disorders.
- **Transdermal therapeutic systems (Patches):** A drug delivery system that allows for the drug to be absorbed through the skin and into the bloodstream.
- **Implants:** Medication filled pellets or capsules are surgically implanted under the skin.
- **Lotions:** Protect, soften, and provide relief from itching
- **Liniments**
 - applied by rubbing
 - provide relief from tight aching muscles
- **Powders:** applied for their soothing, drying action
- **Aerosol foam:** spreads drug over wide area

- Application of topical medication
 - Use clean gloves to apply medication to unbroken skin
 - Use sterile gloves to apply medication if the skin is open
 - Use cotton tipped applicators for small areas
 - Do not use tongue blades to apply medication
 - Use correct technique to apply medications from a tube
 - Use correct technique to apply medications from a jar
- Suppositories: This drug form is a semisolid substance and is usually inserted into the rectum, vagina, or urethra where it dissolves slowly to release the medication.

Nursing Intervention Alert

Always use a water-soluble lubricate on the suppository prior to insertion.

- Parenteral Products: Sterile solutions or suspensions packaged for use as an injection.
 - Ampules
 - Prefilled syringes
 - Vials

Administration of Medications to Client with Swallowing Difficulties

- Place client in high-Fowler's or a sitting position
- Provide sufficient fluid for swallowing
- Use special medicine and water glass which dispenses tablet and water at same time
- Use tablet divider to split the solid tablet into one or more pieces
- Use tablet crusher to reduce tablets to a powder and mix with juice, pudding, applesauce, etc.
- Empty powdered contents of regular capsules into a plastic medicine cup and mix with juice, pudding, or applesauce
- Obtain medications in liquid form
- Never divide or crush
 - Enteric-coated products
 - Sustained-action forms
 - Products that contain encapsulated beads or a wax matrix
 - Sublingual or buccal products
- Many sustained release (SR) preparations have time-release beads and can be sprinkled onto food, but the beads should never be chewed or bitten into.
- Some soft gelatin capsules can have a pinhole pricked in one end and the liquid squeezed out.

Parenteral Drug Administration: Advantages and Disadvantages

Definition

- Any route other than gastrointestinal
- Commonly used to indicate subcutaneous, intramuscular, intradermal, and intravenous routes

Advantages of parenteral routes

- Rapid, almost complete absorption of medication
- Gastric disturbances do not affect the medication
- Client does not have to be conscious to receive the medication

Disadvantages of parenteral routes

- Penetration of the skin increasing risk for infection
- Nerve damage
- Painful
- Potential for abscesses

Standard Precautions

- Wash hands before and after procedures, and between clients
- Wear gloves when performing any injection
- Carefully dispose of used gloves, needles, and syringes according to facility's policy.
- *Never* recap, remove, bend, or break needle after giving an injection.
- If accidentally exposed to body fluid by needle stick, always seek immediate treatment.
- Follow agency's procedures for care of clients with communicable diseases

Nursing Intervention Alert

Proper hand washing is the single most important intervention in the prevention of the spread of organisms.

Calibration Scale of Syringes

- Tuberculin syringe: hundredths
- 3 cc syringe: tenths
- 5 cc, 6 cc, 10 cc, and 12 cc: two 10ths
- Syringes larger than 12 cc: full cc measures
- Minim scale
- First long calibration indicates zero
- Read calibrations from the top, or front ring, of the plungers suction tip

Needles for Injection: Gauge and Length

Intradermal

- 26 or 27 gauge
- $\frac{1}{4}$ – $\frac{3}{8}$ in. length
- Diagnostic purposes

Subcutaneous

- 25–28 gauge
- $\frac{1}{2}$ – $\frac{5}{8}$ in. length
- Frequently used for administration of insulin and heparin

Intramuscular

- 21–23 gauge
- 1–1 1/2 in. length
- Use the longer needles for medications that are irritating to tissues
- Use the larger diameter (smaller gauge) needle for viscous products

Intramuscular Injection

Sites

- Deltoid
- Dorsogluteal
- Ventrogluteal
- Vastus Lateralis

Considerations for site selection

- Muscle mass
- Adequate circulation
- Free of infection, breakdown, and scars
- Rotation of site
- Volume and type of medication

Subcutaneous Injection

Sites

- Middle lateral aspect of upper arm
- Abdomen: either side of umbilicus

- Upper posterior aspect of hips
- Middle and outer areas of thigh

Considerations for site selection

- Subcutaneous tissue mass
- Adequate circulation
- Free of infection, breakdown, and scars
- Rotation of site
- Type of medication

Intradermal Injection

Sites

- Inner aspect of forearm
- Upper chest
- Shoulder blades

Procedures for Administering Medications

Step-by-step procedures for the administration of oral, rectal, subcutaneous, intramuscular, intradermal, otic, and ophthalmic medications are given in Tables 14-1 through 14-12. Also included are procedures for medication administration via metered dose inhaler, and administration of nitroglycerine ointment, heparin, and various forms of insulin.

(This helps relax the sphincter muscles.) ◦ Using a gloved, lubricated finger, insert the suppository into the client's rectum, tip first. ◦ Advance the suppository past the anal sphincter. ◦ Withdraw your finger and press the client's buttocks together for a few minutes. ◦ Instruct the client not to push the suppository out. ◦ Wipe excess lubricant from the client's anus. ◦ Remove gloves and wash your hands. • Document on the MAR. • Leave the client in a comfortable position. | | |

PHARMACOLOGICAL AGENTS

Think Smart/Test Smart

As you review drugs and their classes, remember that the NCLEX-RN® is written in terms of nursing process. That means that you would not expect questions that ask: what is the action of Digoxin, what is a major side effect of digoxin, or what is a sign of digoxin toxicity. Phrased in terms of nursing process, these questions could be phrased as:

A client asks what digoxin will do for his heart. Which fact should serve as the basis for the nurse's response? (Way of asking for the therapeutic action of digoxin.) An alternate way of asking about the expected action of the drug is a question such as "When evaluating the effectiveness of digoxin for a client with congestive heart failure, which assessment data would the nurse gather?"

When teaching a client about her newly prescribed digoxin, which S&S would be correctly described as potential side effects of the medication?

Which symptoms should a client on digoxin be instructed to report immediately? (Way of asking what are signs of toxicity?)

Cardiac Glycosides

Example: digoxin (Lanoxin)

Drug Effects on Cardiac Action

- Positive inotropic: drugs that increase the force of contraction
- Negative inotropic: drugs that decrease the force of contraction
- Positive chronotropic: drugs that increase heart rate
- Negative chronotropic: drugs that decrease heart rate
- Positive dromotropic: drugs that increase the rate of electrical conduction through the myocardium
- Negative dromotropic: drugs that decrease the rate of electrical conduction through the myocardium

Mechanisms of Action

- Positive inotropic effect: increases the force of myocardial contraction
- Negative chronotropic effect: decreases the heart rate
- Negative dromotropic: decreases the rate of electrical conduction through the atrioventricular node

Common Uses

- Congestive heart failure
- Atrial fibrillation
- Atrial flutter
- Paroxysmal atrial tachycardia

Toxicity

- Gastrointestinal distress
 - Nausea
 - Vomiting
 - Anorexia
 - Diarrhea
- Neurological effects
 - Restlessness and confusion
 - Headache
 - Weakness
 - Lethargy
 - Blurred vision, double vision, and decreased visual acuity
 - Colored vision and halo visual changes

- Cardiac effects
 - Bradycardia (heart rate <60)
 - Atrioventricular block
 - Extrasystole (extra heart beats)

Monitoring Effects of Cardiac Glycoside

Nursing Process Elements

- Be familiar with client's baseline VS, electrolyte levels, and general health
- Assess the following before administering digoxin (Lanoxin)
 - Check serum digoxin, potassium, magnesium, and calcium levels
 - Take *apical* pulse for one full minute noting rate, rhythm, and quality.
 - Assess for toxicity
- Withhold digoxin (Lanoxin) and notify physician if:
 - Pulse rate <60
 - Significant change in pulse rate or rhythm
 - S&S of digoxin toxicity
 - Serum potassium level is less than 4 mEq/l
 - Serum digoxin level > 2 ng/ml (therapeutic range = 0.8–2 ng/ml)
- Monitor client's fluid intake and urinary output
- Monitor client's weight, signs of edema, lung, and heart sounds

Assessment Alert

Take apical pulse for one minute prior to administering digoxin. Withhold digoxin and call physician if heart rate is less than 60 bpm.

Nursing Diagnoses

- Cardiac output: decreased
- Tissue perfusion: ineffective
- Knowledge deficit related to medications and disease

**Client teaching for self-care**

- Instruct how to count pulse
- Instruct to call physician if pulse < 60 or > 110
- Instruct to call physician if heart rhythm irregular
- Review S&S of toxicity and instruct to report them to physician
- Weigh each day and report > 2 lb gain per day
- Take digoxin (Lanoxin) as prescribed at same time each day

ANTIARRHYTHMICS**Mechanisms of Action**

Varies depending on the antiarrhythmic class used

- Decreases the automaticity of cardiac tissue
- Alters the rate of conduction of electrical impulses
- Alters the refractory period

Common Uses

Suppression of arrhythmias

Common Adverse Effects

Differs among the different drugs

Monitoring Effects of Antiarrhythmics**Nursing Process Elements**

- Assess heart rate and rhythm and BP prior to administration and throughout therapy
- Monitor ECG
- Monitor for adverse effects

Nursing Diagnoses

- Cardiac output is decreased
- Knowledge deficit related to medication and disease

**Client teaching for self-care**

- Instruct in how to obtain pulse rate, and to report changes in rate and rhythm to physician
- Instruct to take doses round the clock and what to do regarding missed doses and over-the-counter medications
- Advise regarding importance of follow-up appointments with health care provider

**Assessment Alert**

Take BP and heart rate prior to administering antiarrhythmic medications.

NITRATE VASODILATORS

Example: nitroglycerin (Nitrocot)

Mechanism of Action

- Relaxes smooth muscle
- Dilates venous and arterial blood vessels
- Reduces peripheral resistance
- Decreases venous return to the heart
- Reduces myocardial oxygen consumption
- Decreases BP
- Relieves and prevents angina (chest pain)

Common Uses

- Prophylaxis, treatment, and management of angina pectoris (chest pain)
- Congestive heart failure

Common Adverse Effects

- Hypotension
- Headache
- Dizziness
- Syncope

Forms of Nitrate Vasodilators

- Sublingual tablet
 - Place tablet under tongue to dissolve within 5 minutes
- Extended-release buccal tablet
 - Place tablet between lip and gum or between cheek and gum to dissolve over 3–5 hours
- Oral sustained-release tablet or capsule
- Translingual spray
 - Do not shake canister
 - Spray under tongue
 - Do not inhale spray
- Transdermal ointment
 - Use dose-determining applicator supplied with ointment
 - Nurse should wear gloves
- Transdermal Unit (patch)
 - Nurse should wear gloves
- Parenteral (IV)

Monitoring Effects of Nitroglycerin

Nursing Process Elements

- Be familiar with clients baseline VS
- Obtain BP, heart rate prior to administering medication
- Check BP and heart rate after administration (hypotension may occur)
- Assess chest pain using pain scale, and assess for associated symptoms: dyspnea, shortness of breath, jaw, arm, neck pain, nausea, and diaphoresis
- Assess for blurred vision, headache, and dry mouth
- Assess for topical reactions when using the ointment or transdermal unit

Assessment Alert

Take BP prior to and after administering nitroglycerin.

Nursing Diagnoses

- Pain: acute
- Tissue perfusion: ineffective
- Knowledge deficit related to medications and disease

Client teaching for self-care

- Instruct that sublingual tablets may be taken prophylactically 5–10 minutes prior to exercise or other stimulus known to trigger angina.
- Remind them to keep record of number of angina attacks, amount of medication taken, and precipitating factors.
- Instruct that contact with water (bathing, swimming) does not affect transdermal unit.
- Inform that the sublingual form can be taken while transdermal unit or ointment is in place.
- When chest pain occurs, take one nitroglycerine tablet as prescribed; if chest discomfort is not relieved in 3 minutes, call 911.
- Remind to report blurred vision, dry mouth, faintness, dizziness, flushing, or increase in frequency or severity of pain to physician.
- Explain to change positions slowly and avoid prolonged standing (postural hypotension)
- Inform that SL tablets should be kept in their original container and tablets need to be replaced every 6 months to assure potency.

- Advise to take medication as directed, avoid alcohol, and not to take over-the-counter medications without approval of physician.
- Encourage to keep follow-up appointments with health care provider.

ANTIHYPERTENSIVES

Diuretics

Mechanisms of Action

Thiazide diuretics

Example: hydrochlorothiazide (HCTZ)

- Inhibits sodium reabsorption in the distal tubule, thereby increasing excretion of water and sodium.
- Enhances excretion of magnesium, chloride, and potassium.

Loop diuretics

Example: furosemide (Lasix)

- Inhibits the reabsorption of sodium and chloride in the ascending loop of Henle
- Increases risk of hypokalemia (low potassium level)
- Reduces the ability of the kidneys to concentrate urine
- More potent than the thiazides in promoting sodium and fluid excretion

Potassium-sparing diuretics

Example: spironolactone (Aldactone)

- Promotes sodium and chloride excretion without concomitant loss of potassium
- Inhibits the action of the hormone aldosterone thereby causing diuresis
- Lowers BP by unknown mechanism
- Increases risk of hyperkalemia (increased potassium levels)

Common Uses

- Congestive heart failure
- Hypertension
- Renal failure
- Edema

Common Adverse Effects

- Hypokalemia (except potassium sparing diuretics)
- Hyponatremia
- Dehydration
- Postural hypotension
- Hyperglycemia

Monitoring Effects of Diuretics

Nursing Process Elements

- Be familiar with client's baseline VS
- Obtain BP and heart rate prior to administering medication
- Check BP and heart rate before and after administration
- Monitor for signs of hypokalemia
- Fatigue
- Muscle weakness and cramps
- Rapid irregular pulse
- Vomiting
- Shortness of breath
- Monitor fluid intake and urinary output
- In hospital, weigh client daily
- Monitor for
 - edema
 - abnormal lung sounds
 - extra heart sounds
- Assess for postural hypotension
- Monitor serum levels
 - Potassium
 - Sodium
 - Chloride
 - Glucose
 - Blood urea nitrogen (BUN)
- Assess for digoxin (Lanoxin) toxicity if dehydration or hypokalemia exists

Assessment Alert

Take BP prior to and after administering diuretics. Always monitor electrolytes prior to administering diuretics.

Nursing Diagnoses

- Fluid volume: excess
- Knowledge deficit related to medications, disease, and nutrition

Client/family teaching

- Instruct regarding weighing at least once per week
- Remind to have BP monitored weekly
- Advise to follow dietary guidelines, especially regarding potassium and sodium
- Encourage to change positions slowly to avoid a decrease in BP (postural hypotension)

- Instruct to notify health care provider if experiencing muscle weakness or cramping, fatigue, or dizziness
- Advise to take medication as directed and to not take over-the-counter drugs unless approved by physician
- Encourage to keep follow-up appointments with health care provider

BETA-ADRENERGIC BLOCKING AGENTS

Example: propranolol (Inderal)

Think Smart/Test Smart

The generic names for the beta-blockers end in “lol,” therefore, you will be able to identify the beta-blockers from a list of drugs.

Mechanisms of Action

- Reduction in heart rate
- Reduces force of cardiac contraction
- Slows electrical conduction
- Reduces myocardial irritability

Common Uses

- Management of cardiac arrhythmias
- Hypertension
- Tachyarrhythmias associated with digitalis toxicity
- Angina Pectoris

Common Adverse Effects

- Weakness: fatigue
- Impotence
- Concerns for use: Precautions
 - It may cause bronchoconstriction; therefore, its use may be contraindicated in clients with chronic pulmonary diseases
 - It may promote congestive heart failure therefore use cautiously in clients with risk for heart failure.

Monitoring Effects of Beta-Adrenergic Blocking Agents

Nursing Process Elements

- Assess heart rate and rhythm, BP prior to administration and throughout therapy

- Assess location, intensity, and duration of anginal pain and associated symptoms
- Monitor ECG
- Monitor for adverse effects

Assessment Alert

Always take BP and heart rate prior to administering beta-blockers.

Nursing Diagnoses

- Cardiac output, decreased
- Pain: acute
- Tissue perfusion: ineffective
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct in how to obtain pulse rate, and to report changes in rate and rhythm to physician
- Instruct to take doses round the clock and what to do regarding missed doses and over-the-counter medications
- Advise to report chest pain to health care provider immediately
- Advise regarding importance of follow-up appointments with health care provider

CALCIUM CHANNEL ANTAGONISTS

Example: nifedipine (Procardia)

Mechanisms of Action

- Relaxation of vascular smooth muscle and lowered BP
- Prevents or reverses spasms of coronary blood vessels
- Dilates coronary arteries and arterioles resulting in an antianginal effect
- Reduces myocardial oxygen consumption
- Slows electrical impulse conduction (supraventricular tachycardia)

Common Uses

- Prevention and treatment of angina pectoris
- Hypertension

Common Adverse Effects

- Hypotension
- Peripheral edema

- Dizziness
- Headache

Monitoring Effects of Calcium Channel Antagonists Agents

Nursing Process Elements

- Assess heart rate and rhythm, BP prior to administration and throughout therapy
- Assess location, intensity, and duration of anginal pain
- Monitor ECG
- Monitor for adverse effects

Assessment Alert

Always take the client's BP and heart rate before and after administering calcium channel antagonists.

Nursing Diagnoses

- Cardiac output, decreased
- Pain: acute
- Tissue perfusion: ineffective
- Knowledge deficit related to medication, disease

Client teaching for self-care

- Instruct in how to obtain pulse rate, and to report changes in rate and rhythm to physician
- Instruct to take doses around the clock and what to do regarding missed doses and over-the-counter medications
- Advise to report chest pain to health care provider immediately
- Advise regarding importance of follow-up appointments with health care provider

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITORS

Example: captopril (Capoten)

Think Smart/Test Smart

The generic names of the ACE inhibitors end in "pril," therefore, you will be able to identify them from a list.

Mechanism of Action

- Dilates peripheral arterioles
- Relaxes vascular smooth muscles
- Reduces peripheral resistance
- Interferes with conversion of angiotensin I to angiotensin II
- Dilates peripheral vessels thereby reducing BP

Common Uses

- Hypertension
- Congestive heart failure
- Arrhythmias (irregular heart rhythm)
- Angina Pectoris (chest pain)

Common Adverse Effects

- Hypotension
- Postural hypotension
- Dizziness, fainting, and headaches
- Drug-specific

Monitoring Effects of ACE Inhibitors

Nursing Process Elements

- Be familiar with client's baseline VS
- Obtain BP and pulse rate prior to administering medication
- Check BP and pulse rate after administration
- Monitor weight, edema, lung, heart sounds, and I&O
- Assess for postural hypotension
- Encourage client to rise slowly from lying to sitting position

Assessment Alert

Always take the client's BP and heart rate prior to and after administering ACE inhibitors.

Nursing Diagnoses

- Tissue perfusion: ineffective
- Knowledge deficit related to medications and disease

Client teaching for self-care

- Instruct on monitoring BP weekly
- Remind to change positions slowly to prevent rapid decrease in BP
- Encourage to follow dietary restrictions: low sodium
- Instruct regarding reporting weight changes, edema, and dizziness to physician

- Emphasize importance of follow-up appointments with health care provider

ANTIMICROBIAL AGENTS

Classification of Antimicrobial Agents

- Bactericidal and bacteriostatic
 - Bactericidal agents have a killing action on the bacteria
 - Bacteriostatic agents inhibit the growth of bacteria permitting the host's immunological defenses to destroy the organism

Site of Action

- Agents that inhibit cell wall synthesis
- Agents that inhibit protein synthesis
- Agents that interfere with the permeability of the bacterial cell membrane
- Agents with antimetabolite action block or alter steps essential for the normal growth of the bacteria

Narrow or Broad Spectrum of Action

- Narrow spectrum
 - Effective against a limited number of organisms
 - Use when identity of organism and susceptibility of the antibiotic is known
 - Usually do not disrupt normal bacterial flora
- Broad spectrum
 - Act on a wide variety of organisms
 - Useful in treating infections when the identity and susceptibility to antimicrobial treatment of the infecting organism is unknown
 - However, they destroy the body's normal microbes and may permit superinfection and diarrhea

Adverse Effects

- Hypersensitivity reactions
 - Rash
 - Urticaria
 - Fever
 - Bronchospasm
 - Anaphylactic shock
- Organ toxicity
 - High doses and/or over long periods of time
 - Can involve liver, kidneys, central nervous system, etc
- Ototoxicity (detrimental effect on eighth nerve or organs of hearing)
- Hematological disorders
 - Anemia
 - Increased bleeding time

Major Classes

- Penicillins (beta-lactams)

Example: ampicillin (Polycillin)

- Bactericidal agents
- Inhibit the synthesis of the bacterial cell wall
- Narrow and broad-spectrum agents

- Cephalosporins

- Chemically and pharmacologically related to the penicillins
- Bactericidal or bacteriostatic effect
- Interferes with bacterial cell wall syntheses
- Four “generations” of cephalosporins
- Use caution when client has allergy to penicillins

- Tetracyclines:

Example: tetracycline (Tetracycl)

- Bacteriostatic
- Broad-spectrum agents
- Inhibits protein synthesis in the bacterial cell
- May interfere with normal calcification of temporary and permanent teeth and discolor developing teeth
- May interfere with bone growth
- Clients more susceptible to sunburn

- Macrolides:

Example: erythromycin (Ery-Tab)

- Bacteriostatic
- May be bactericidal in high concentrations
- Inhibits protein synthesis in the bacterial cell

- Aminoglycosides:

Example: gentamicin (Garamycin)

- Bactericidal or bacteriostatic
- Inhibits protein synthesis in the bacterial cell
- May produce nephrotoxicity and ototoxicity

Monitoring Effects of Antibiotics

- Take a careful medication history before administering antibiotics
- Know exactly why your client is receiving antibiotics
- If ordered, obtain specimen for culture and susceptibility *before* administering the antibiotic
- Know what a therapeutic response to antibiotic treatment would include for each specific client situation
- Administer oral doses of antibiotics on empty stomach or with food as specified
- Be aware of food–drug and drug–drug interactions, for example, penicillin can interfere with effectiveness of oral contraceptives.
- Monitor VS and S&S of infection

- Monitor WBC count, BUN, creatinine, and other laboratory values
- Observe for adverse effects
- Observe for S&S of superinfections

Nursing Intervention Alert

If cultures are ordered by the physician, always obtain the specimen prior to administering the first dose of antibiotic.

Nursing Diagnoses

- Infection: risk for
- Knowledge deficit related to medication or disease

Client teaching for self-care

- Advise to call health care provider if symptoms do not improve
- Remind to take all doses of the medication even if their symptoms are no longer present, and to follow instructions regarding taking medication with or without food
- Instruct to inform health care provider if diarrhea, vomiting occur, black, hairy growth develops on tongue, and vaginal irritation occurs
- Advise to keep all follow-up appointments with health care provider

ANTICOAGULANTS

Mechanism of Action

Parenteral anticoagulants

Example: heparin (Heparin Lock); enoxaparin (Lovenox)

- Exerts direct effect on blood coagulation (clotting) by enhancing the inhibitory actions of antithrombin III on several factors essential to normal blood clotting, thereby blocking the conversion of prothrombin to thrombin and fibrinogen to fibrin.
- Does not lyse existing thrombi but may prevent their extension
- Inhibits formation of new clots

Oral anticoagulant

Example: warfarin sodium (Coumadin)

- Indirectly interferes with blood clotting by depressing hepatic synthesis of vitamin K dependent coagulation factors: II, VII, IX, and X.

- Deters further extension of existing thrombi and prevents new clots from forming.
- Has no effect on platelets.
- Unlike heparin, action is cumulative and more prolonged.

Common Uses

Heparin and Lovenox

- Prophylaxis and treatment of venous thrombosis and pulmonary embolism (blood clot to leg or lung)
- Prevent thromboembolic complications arising from cardiac surgery and vascular surgery
- During acute stages of myocardial infarction (heart attack)

Coumadin

- Prophylaxis and treatment of deep venous thrombosis and pulmonary embolism (blood clot in leg or lung)
- Treatment of atrial fibrillation with embolization (irregular heart beat that may cause blood clots).
- An adjunct in treatment of coronary occlusion, cerebral transient ischemic attacks (heart attacks, near strokes)
- Prophylactic treatment for clients with prosthetic cardiac valves

Common Adverse Effects

- Bleeding
- Hematuria
- Tarry stools
- Excessive vaginal bleeding
- Abdominal, flank, or joint pain
- Headaches
- Changes in neurological status, restlessness
- Hematoma or bruising
- Vomiting blood
- Bleeding from the nose or gums
- Weak, rapid pulse rate
- Hypotension

Monitoring Effects of Heparin

Nursing Process Elements

- Before administration check coagulation tests, hemoglobin, hematocrit, and platelet counts.
- In general, the goal is to keep the activated partial thromboplastin time (aPTT) at 1.5–2.5 times its normal value of 35–45 seconds.
- Safely administer heparin via ordered route, i.e., subcutaneous injection, continuous intravenous infusion, or intermittent intravenous infusion.

- No intramuscular injections
- Observe for S&S of bleeding
- No aspirin containing products
- Use soft toothbrush and electric razor

Nursing Intervention Alert

Always check the aPTT prior to administering heparin.

Monitoring Effects of Coumadin

- Before administration check coagulation tests, hemoglobin, hematocrit, and platelet counts
- In general, the goal is to maintain a prothrombin time (PT) of 1.5–2 times the control or reference value and maintain the international normalized ratio (INR) at a value of 2–3. The PT control value is generally 11–15 seconds
- The daily oral dose is based on the PT and INR results until maintenance dosage is established
- Observe for S&S of bleeding
- No intramuscular injections
- No aspirin containing products
- Medic alert identification
- Use soft toothbrush and electric razor

Nursing Intervention Alert

Always check the PT and INR prior to administering Coumadin.

Antidotes

- Heparin and Lovenox: Protamine sulfate
- Coumadin: Vitamin K (Aqua Mephyton)

Nursing Diagnoses

- Injury: risk for
- Tissue perfusion: ineffective
- Knowledge deficit related to medications, disease

Client teaching for self-care

- Instruct to use a soft toothbrush, electric razor, avoid contact sports
- Inform not to take medications containing aspirin or aspirin-like products without approval of physician

- Instruct about foods high in vitamin K (broccoli, collards, kale, spinach, cabbage, yogurt, milk, and green tea) and importance of not significantly increasing or decreasing daily intake of them
- Remind to report signs of bleeding to physician immediately: bleeding gums, bruising, blood in urine, feces, abdominal, joint or head pain, weak, rapid pulse, low BP, weakness, and restlessness
- Encourage to keep laboratory appointments to monitor coagulation factors and follow-up appointments with health care provider
- Request that a medical identification describing the anti-coagulation medications be carried at all times

Assessment Alert

For clients receiving anticoagulation medications, always assess for S&S of bleeding.

ANTIDIABETIC AGENTS

Mechanisms of Action

Sulfonylureas

Example: glyburide: (DiaBeta)

- Directly stimulates functioning pancreatic beta cells to secrete insulin
- Increases sensitivity of peripheral insulin receptors resulting in increased insulin binding

Biguanide

Example: metformin (Glucophage, Glucophage XR)

- Increases glucose transport across cell membrane, with enhanced glucose utilization in skeletal muscles
- Increases the binding of insulin to its receptor and potentiating insulin action

Meglitinides

Example: repaglinide (Prandin)

- Stimulates release of insulin from the pancreatic islets

Thiazolidinediones

Example: rosiglitazone (Avandia)

- Improves target cell response to insulin
- Reduces cellular insulin resistance
- Decreases hepatic glucose output

Alpha-Glucosidase Inhibitors

Example: acarbose (Precose)

- Inhibits or delays the absorption of sugars from the intestinal tract

Mechanism of Action

Regular insulin

Example: (Humulin R)

- Enhances transmembrane passage of glucose across cell membranes
- Promotes conversion of glucose to glycogen

Common Uses

Oral hypoglycemic agent

- Noninsulin-dependent, type 2 diabetes mellitus

Insulin

- Insulin-dependent, type 1 diabetes mellitus

Common Adverse Effects

- Hypoglycemia

Rapid Acting Insulin

Example: insulin lispro (Humalog)

- Onset of action: within 15 minutes
- Peak action: 30–90 minutes
- Duration: 3–4 hours

Short-Acting Insulins

Example: Regular insulin (Humulin R)

- Onset of action: 30–60 minutes
- Peak action: 2–3 hours
- Duration: 3–6 hours

Intermediate-Acting Insulins

Example: NPH (Humulin N)

- Onset of action: 2–4 hours
- Peak Action: 6–10 hours
- Duration: 10–16 hours

Long-Acting Insulins

Example: Insulin glargine (Lantus), Insulin detemir (Levemir)

- Onset of action: 2 hours
- Peakless
- Duration: 24 hours

Fixed Combinations of N and R

Example: 1. 70/30 = 70% N and 30% R

- Onset of action: 30–60 minutes
- Peak action: Refer to N, R
- Duration: 10–16 hours

Fixed Combinations

Example: Humalog Mix 75/25 = 75% insulin lispro protamine and 25% insulin lispro

- Onset of action: within 15 minutes
- Peak action: 1–6.5 hours (average 2.5 hours)
- Duration: Refer to N and insulin lispro

Inhalation Agents

- Insulin human inhalation powder

Mechanism of Action: Incretin mimetics (Byetta)

- Enhances glucose-dependent insulin secretion
- Suppresses elevated glucagon secretion
- Slows gastric emptying

Monitoring Effects of Hypoglycemic Agents

Nursing Process Elements

- Be familiar with client's baseline blood glucose levels
- Monitor for S&S of hypoglycemia
 - Fatigue, restlessness
 - Cool, moist skin
 - Weakness and dizziness
 - Headache
 - Confusion, slurred speech
- Monitor for S&S of hyperglycemia
 - Flushed, dry skin
 - Increased urine output
 - Increased thirst
 - Increased appetite
 - Drowsiness
- Monitor blood glucose results as ordered

Assessment Alert

Assess the lower extremities and feet of clients with diabetes. Provide foot care and assure that client has shoes to wear while in the hospital.

Nursing Diagnoses

- Noncompliance
- Knowledge deficit related to medication, diet, and disease
- Nutrition: imbalanced

Client teaching for self-care

- Instruct in signs of hyperglycemia and hypoglycemia
- Instruct in actions to take for hyperglycemia and hypoglycemia
- Inform to carry a quick acting sugar product at all times
- Instruct in proper use of equipment for blood glucose testing
- Review the proper use of insulin syringes and pens, as well as proper technique for injection, storage and disposal of syringes
- Remind to rotate injection sites
- Review diet modifications, food item selections and substitutions, and alcohol restrictions
- Encourage to follow diet, medication, and exercise plan and to follow-up with regular appointments with health care provider

BRONCHODILATORS

Mechanisms of Action

Sympathomimetic agents

Example: albuterol (Proventil) and xanthine derivatives (theophylline [Uniphyll])

- Relax smooth muscle of bronchi and pulmonary vessels producing bronchodilation
- Increase vital capacity

Leukotriene receptor antagonists

Example: montelukast (Singulair)

- Decreases bronchial edema and inflammation
- Causes bronchodilation

Common Uses

- Prophylaxis and symptomatic relief of bronchial asthma
- Relieve bronchospasm associated with bronchitis and emphysema

Common Adverse Effects

- Tremor
- Tachycardia
- Nausea

Monitoring Effects of Bronchodilators

- Be familiar with client's baseline VS
- Monitor client's lung sounds, respiratory effort, and oxygen saturation percentages via pulse oximetry
- Monitor for cyanosis of lips, ear lobes, mucous membranes, and nailbeds

- Monitor theophylline plasma levels, if ordered. Therapeutic range is 10–20 $\mu\text{g/ml}$.
- Observe client for adverse effects
- Ensure that client uses metered dose inhaler correctly

Nursing Diagnoses

- Breathing pattern: ineffective
- Airway clearance: ineffective
- Knowledge deficit related to medications and disease

Client teaching for self-care

- Instruct in proper use of metered-dose inhaler and spacer. Remind to use the short-acting bronchodilator inhaler 5 minutes prior to the steroid dose inhaler
- Instruct in proper mouth care and cleansing of inhalers
- Inform to avoid smoke and all other respiratory irritants
- Remind to allow for rest periods before or between periods of activity
- Encourage to follow all medication and respiratory exercise regimes and keep appointments with health care provider

Assessment Alert

Inquire about the client's activities of daily living and modifications in their activities they have made as a result of frequent shortness of breath.

AGENTS AFFECTING GASTROINTESTINAL FUNCTION

Mechanisms of Action

Laxatives

Stimulant laxative:

Example: bisacodyl (Dulcolax)

- Increases motility of gastrointestinal tract by chemical irritation of the intestinal mucosa
- Increases the secretion of water into large and small intestines

Saline laxatives:

Example: magnesium hydroxide (milk of magnesia)

- Draws water through the intestinal wall by osmotic action increasing the fluidity of the stool and stimulates greater intestinal motility

Bulk-forming laxatives:

Example: psyllium hydrophilic (Metamucil)

- Absorbs fluid and the compound swells in the intestine, stimulating peristaltic action.

Lubricant laxatives:

Example: mineral oil

- Act as lubricant to facilitate passage of fecal mass through the intestines

Stool softeners:

Example: docusate sodium (Colace)

- Permits water and fat to penetrate and soften stool
- Detergent action lowers surface tension

Common Uses for Laxatives

- Prevent or treat constipation
- Prepare clients for a lower gastrointestinal X-ray series or surgery
- Reduce the strain of defecation in clients with cardiovascular disease or in postoperative clients
- Diagnose and treat parasitic infestations of the gastrointestinal tract
- Help remove unabsorbed poisons from the gastrointestinal tract

Guidelines for Laxatives

- Always assess the effectiveness of laxatives
- In selecting a laxative, consider the age and general condition of client
- In general, avoid use of stimulant laxatives in the elderly
- Follow bulk-forming laxatives with at least one glass of fluid to prevent gastrointestinal obstruction
- Never administer laxatives to clients experiencing abdominal pain, nausea, or vomiting until after consulting with physician
- Be aware of specific drug–drug and drug–food interactions
- Monitor frequent and prolonged laxative use

Mechanisms of Action

Histamine receptor antagonists

Example: famotidine (Pepcid)

- Inhibits the action of histamine at the histamine-sensitive H_2 receptor site of the parietal cells in the stomach
- Results in reduction in acid secretion

Proton pump inhibitors

Example: lansoprazole (Prevacid)

- Suppresses gastric acid secretion by inhibiting the gastric acid pump in the parietal cells of the stomach

Common Uses for Histamine Receptor Antagonists and Proton Pump Inhibitors

- Treatment of duodenal ulcer
- Treatment of gastric ulcer
- Gastroesophageal reflux disease
- Gastritis
- Erosive esophagitis

Adverse Effects of Histamine Receptor Antagonists and Proton Pump Inhibitors

- Diarrhea
- Headache

Monitoring Effects of Therapy

Nursing Process Elements

- Monitor symptoms of gastrointestinal distress:
 - Heartburn
 - Fullness in stomach and throat
 - Pain in abdomen or chest
- Monitor for signs of gastrointestinal bleeding:
 - Blood in stool
 - Vomiting dark-colored substance

—Decrease in hemoglobin

- Be aware of drug–drug and drug–food interactions
- Monitor for adverse effects

Nursing Diagnoses

- Pain: acute
- Injury: risk for bleeding
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Inform to avoid spicy foods, alcohol, aspirin, NSAIDs, and smoking
- Advise to continue taking medications even if symptoms are no longer present
- Instruct to call health care provider for any signs of bleeding: tarry stools, increase in abdominal or back pain

Assessment Alert

Obtain information about client's diet and modifications in food selection based on their frequent symptoms of heartburn or gastrointestinal distress.

PHARMACOLOGICAL PAIN MANAGEMENT

ANALGESIC, ANTIPYRETIC, AND ANTI-INFLAMMATORY AGENTS

Mechanisms of Action

Opioid analgesics

Example: morphine (Roxanol)

- Opioid and opioid-like agents bind onto opioid receptors found in the central nervous system and act to inhibit the transmission of pain impulses and alter pain perception
- Suppresses medullary cough centers
- Suppresses the motility of the gastrointestinal tract

Assessment Alert

Always assess client's respiratory rate prior to and after administering morphine. Many institutional policies state that the nurse should not administer morphine to a client with a respiratory rate of less than 10 breaths per minute.

Salicylates

Example: aspirin (Ecotrin)

- Anti-inflammatory action: Inhibits prostaglandin synthesis (nonsteroidal anti-inflammatory drug (NSAID))
- Analgesic action: Acts peripherally to interfere with action of prostaglandins
- Antipyretic action: In addition to inhibiting prostaglandin synthesis, it lowers body temperature in fever by causing centrally mediated peripheral vasodilation and sweating
- Antiplatelet action: Aspirin (but not other salicylates) inhibits platelet aggregation, therefore, aspirin helps prevent strokes and myocardial infarction (heart attack)

Nonnarcotic analgesic and antipyretic

Example: acetaminophen (Tylenol)

- Produces analgesia by unknown mechanism, perhaps by action on peripheral nervous system
- Reduces fever by direct action on hypothalamus, peripheral vasodilation, and sweating

Nonsalicylates

Example: celecoxib (Celebrex)

- Newer NSAIDs inhibit prostaglandin synthesis by inhibiting COX-2
- Provides analgesic and anti-inflammatory effects
- Less adverse effects on the gastrointestinal system and less antiplatelet activity

Corticosteroids

Example: prednisone (Pred-Pak)

- Synthetic steroid used primarily for its glucocorticoid effects—anti-inflammatory agent
- Reduces the severity of inflammatory symptoms

Common Uses**Opioid analgesics**

- Moderate to severe pain
- Cough suppressant
- Suppressing the motility of the gastrointestinal tract (diarrhea)

Salicylates

- Low to moderate pain
- Rheumatoid arthritis
- Osteoarthritis
- Reduction of fever
- Reduce incidence of stroke and myocardial infarction (heart attack)

Nonnarcotic analgesic and antipyretic

- Mild to moderate pain
- Reduction of fever
- Often a substitute for aspirin when aspirin is not tolerated

Nonsalicylates (NSAIDs)

- Osteoarthritis
- Mild to moderate pain
- Primary dysmenorrhea
- Reduction of fever

Corticosteroids

- Bronchial asthma
- Osteoarthritis
- Dermatitis
- Inflammatory conditions

Common Adverse Effects**Opioid analgesics**

- N&V
- Constipation
- Pruritus (itching)

- Decrease in respiratory rate (Naloxone [Narcan] is opioid antagonist and reverses respiratory depression)

Salicylates

- Nausea
- Heartburn and stomach pain

Nonnarcotic analgesic and antipyretic

- Negligible with recommended dosage

Nonsalicylates (NSAIDs)

- Heartburn
- Nausea

Corticosteroids

- Insomnia
- Fluid retention
- Hyperglycemia
- Altered fat deposition causing “moon face”
- Weight gain
- Hypertension

Monitoring Effects of Therapy**Nursing Process Elements****Opioid analgesics**

- Be familiar with client's pain history
- Be familiar with client's baseline VS
- Monitor for respiratory depression, sedation, and orthostatic hypotension
- Assist client with ambulation activities
- Monitor for constipation and other adverse effects
- Evaluate level of pain relief

Salicylates

- Be familiar with client's pain history and baseline VS
- Do not administer aspirin to clients taking anticoagulants, those with gastric ulcers, pregnant women, or children with fever
- Observe for signs of bleeding (bleeding gums, bruising, bloody or dark stools, cloudy or bloody urine)
- If taking aspirin for prevention of stroke or heart attack, then observe for S&S of stroke or heart attack
- Evaluate for reduction of symptoms for which medication prescribed.

Nonnarcotic analgesics and antipyretics

- Be familiar with client's pain history and baseline VS
- Do not administer greater than 4 g of Tylenol in 24 hours to an adult because of risk of liver damage
- Evaluate for reduction of pain or fever after administration

Nonsalicylates (NSAIDs)

- Be familiar with client's pain history and baseline VS
- Monitor for S&S of gastrointestinal distress or bleeding
- Do not administer aspirin or acetaminophen concurrently with ibuprofen
- Evaluate for reduction of symptoms (relief of pain and stiffness, improved joint flexion)

Corticosteroids

- Be familiar with client's history and VS
- Be aware of exactly why the client is receiving a steroid medication
- Administer medication with food, and before 0900 if possible
- Monitor BP, fluid intake, urinary output, weight, and sleep pattern
- Monitor blood glucose, serum potassium levels as ordered
- Administer calcium supplements as ordered
- Observe for masked infection and delayed healing
- Inspect client's mouth for white patches, black furry tongue, painful membranes
- Assist client to plan a reasonable and safe range of activities
- Watch for changes in mood and behavior
- Do not abruptly discontinue medication
- Evaluate for reduction of symptoms for which medication was ordered

Nursing Diagnoses

- Pain: acute
- Body temperature: imbalance
- Knowledge deficit related to medications and disease

**Client teaching for self-care**

- Instruct that analgesics should be taken with food and may cause drowsiness.
- Inform that steroids may mask signs of infection, need to be taken with food, and calcium with vitamin D needs to be taken as long as steroids are prescribed.
- Instruct to take steroids exactly as directed by health care provider and to not abruptly stop taking medication.
- Advise to eat a diet high in protein, calcium, and potassium, but low in sodium while taking steroid medications.
- Instruct regarding assessing oral mucus membranes for redness and soreness while taking steroids.
- Remind parents not to administer aspirin to children with viral illnesses due to Reye's syndrome.
- Inform that aspirin and NSAIDs may cause an increase in bruising and bleeding and to report symptoms to health care provider. Must be discontinued 1 week before elective surgery.

ANTI-ALZHEIMER'S AGENTS**Cholinesterase Inhibitors**

Example: donepezil (Aricept)

Mechanism of Action

- Enhances cholinergic function by increasing levels of acetylcholine

Common Uses

- Mild to moderate dementia associated with Alzheimer's disease

Common Adverse Effects

- Headache
- Diarrhea
- Nausea

Monitoring Effects of Therapy

- Assess memory, attention, language, and ability to follow directions or perform simple tasks.
- Assess for dizziness, headache, weight loss, diarrhea, nausea, and change in color of stools.

Nursing Diagnoses

- Injury: risk for
- Thought processes: disturbed
- Knowledge deficit related to medication and disease

**Client teaching for self-care**

- Advise to notify health care provider if symptoms worsen, if new symptoms appear or if adverse effects such as diarrhea, nausea, or headache occur
- Instruct in safe environment measures, and to be aware that dizziness may occur
- Encourage to keep follow-up appointments with health care provider

**Assessment Alert**

A home safety survey may need to be conducted in order to provide a safe, therapeutic environment.

ANTIANSXIETY AGENTS

Example: alprazolam (Xanax)

Mechanisms of Action

Benzodiazepine group

- Slows nerve impulses by enhancing the activity of GABA

Common Uses

- Anxiety
- Panic attacks

Common Adverse Effects

- Dizziness
- Fatigue
- Drowsiness

Monitoring Effects of Antianxiety Agents

- Assess level of anxiety before and throughout therapy
- Monitor CBC, liver panel, BUN, and creatinine (Cr)
- Monitor for adverse effects: dizziness, drowsiness, and fatigue
- Assess coping mechanisms and resources available

Nursing Diagnoses

- Anxiety
- Injury: risk for
- Knowledge deficit related to medications and disease

Client teaching for self-care

- Instruct to not drive if drug causes drowsiness or dizziness
- Inform to avoid alcohol and other CNS depressants, and consult health care provider prior to changing medication regimen

Nursing Intervention Alert

Always place call bell within client's reach, and keep bed in lowest position.

ANTICONSULSANTS

Example: phenytoin (Dilantin)

Mechanisms of Action

- Alters ion transport thereby limiting seizure propagation
- Improves AV conduction thus reducing incidents of arrhythmias

Common Uses

- Treatment and prevention of tonic-clonic seizures and complex partial seizures
- Treatment and prevention of arrhythmias

Common Adverse Effects

- Hypotension
- Nausea
- Rashes
- Diplopia
- Gingival hyperplasia
- Ataxia

Monitoring Effects of Anticonvulsants

- Assess type, duration, frequency, and characteristics of seizure activity
- Assess for adverse effects of medication: signs of gingival hyperplasia, rashes, fever, and vision changes
- Monitor serum phenytoin, CBC, platelet count, liver panel, calcium, and urinalysis
- Administer medications round the clock
- Implement seizure precautions

Nursing Diagnoses

- Injury: risk for
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to follow the medication regime closely, and not consume alcohol
- Advise to carry medical identification at all times
- Instruct in proper oral hygiene practices and express need to have regular dental exams
- Advise that medication may cause drowsiness and should not drive until physician indicates that the seizures and the medication have provided a safe condition for such activities

ANTIDEPRESSANTS

There are two major classes: tricyclic antidepressants and selective serotonin reuptake inhibitors (SSRIs)

Examples: nortriptyline (Aventyl), paroxetine (Paxil)

Mechanisms of Action

Tricyclic antidepressants

- Potentiates the effect of norepinephrine and serotonin
- Possesses anticholinergic action

Selective serotonin reuptake inhibitors

- Inhibits uptake of serotonin in the CNS

Common Uses

- Treatment of depression

Common Adverse Effects

- Fatigue
- Drowsiness
- Blurred vision and dry eyes
- Dry mouth and constipation
- Hypotension

Monitoring Effects of Antidepressants**Nursing Process Elements**

- Assess mental status, mood changes, and signs of suicide thoughts
- Monitor BP and heart rate
- Monitor serum drug levels, CBC, liver panel, and glucose

Nursing Diagnoses

- Injury: risk for
- Coping: ineffective
- Knowledge deficit related to medication and disease

**Client teaching for self-care**

- Inform family to observe for changes in mental status and notify physician
- Inform that medication should be taken as prescribed and not to abruptly discontinue medication, add any other CNS depressants or consume alcohol
- Instruct to inform physician if adverse effects occur
- Caution of teratogenic effect and notify physician immediately if pregnancy is planned or suspected
- Encourage to keep all follow-up appointments with health care providers

ANTIDIARRHEALS

Example: bismuth subsalicylate (Kaopectate)

Mechanisms of Action

- Increases intestinal absorption of fluids
- Decreases synthesis of prostaglandins in the intestines

Common Uses

- Diarrhea
- Indigestion: ulcer disease

Common Adverse Effects

- Constipation

Monitoring Effects of Antidiarrheals**Nursing Process Elements**

- Assess frequency, amount, and consistency of stools
- Assess for nausea, abdominal pain, and indigestion
- Assess for electrolytes and fluid imbalance symptoms (dry mucous membranes, poor skin turgor, decrease urine output, fatigue, muscle weakness)
- Monitor serum electrolyte levels

Nursing Diagnoses

- Diarrhea
- Fluid volume deficit
- Knowledge deficit related to medication and disease

**Client teaching for self-care**

- Advise that medication may cause stools to change to a gray–black color while taking medication
- Instruct to contact health care provider if diarrhea continues or if experiencing muscle weakness, tremors, or dizziness

ANTIEMETIC AGENTS

Example: promethazine (Phenergan)

Mechanisms of Action

- Inhibits the chemoreceptor trigger zone in the medulla

Common Uses

- Treatment and prevention of N&V
- Allergic conditions
- Motion sickness
- Sedation

Common Adverse Effects

- Sedation
- Disorientation

Monitoring Effects of Antiemetic Agents**Nursing Process Elements**

- Assess for N&V, and abdominal pain
- Assess for fluid volume deficit (dry mucous membranes, poor skin turgor, decreased urine output, and thirst)

- Monitor I&O
- Implement safety precautions to prevent falls

Nursing Diagnoses

- Fluid volume deficit
- Injury: risk for
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Inform that medication may cause sedation and to take safety precautions to prevent accidents
- Instruct to take only sips of liquids and small meals to prevent nausea
- Advise to inform health care provider if condition continues

ANTIFUNGUAL AGENTS

Example: fluconazole (Diflucan)

Mechanisms of Action

- Inhibits synthesis of fungal sterols
- Affects the permeability of the fungal cell membrane or protein synthesis within the cell

Common Uses

- Treatment of fungal infections
- Prevention of fungal infections

Common Adverse Effects

- abdominal discomfort

Monitoring Effects of Antifungal Agents

Nursing Process Elements

- Assess area of infection and document findings
- Obtain cultures, if ordered, prior to first dose
- Monitor CBC, liver function tests, BUN, and Cr

Nursing Diagnoses

- Infection: risk for
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to take full course of medication even if symptoms are no longer present
- Advise to notify health care provider if symptoms do not improve, or if fever, pain, fatigue, or N&V occur

ANTIHISTAMINE AGENTS

Example: fexofenadine (Allegra)

Mechanisms of Action

- Blocks the effects of histamine at peripheral histamine-1 receptors

Common Uses

- Relief of allergic rhinitis
- Urticaria

Common Adverse Effects

- No common adverse effects

Monitoring Effects of Antihistamine Agents

Nursing Process Elements

- Assess allergy symptoms
- Maintain fluid intake of 2000 ml/d to provide hydration and decrease viscosity of secretions
- Provide an environment free of allergens

Nursing Diagnoses

- Airway clearance, ineffective
- Injury: risk for
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct in methods to reduce allergens in the environment
- Advise to take medication as directed and to call health care provider if symptoms do not improve

Nursing Intervention Alert

Apple, orange, and grapefruit juice will decrease the absorption of fexofenadine (Allegra).

ANTINEOPLASTIC AGENTS

Mechanisms of Action

Depends on specific agent used

- Interferes with folic acid metabolism resulting in inhibition of cell reproduction
- Competes with estrogen for binding sites

- Damages DNA before mitosis resulting in death of cells
- Inhibits DNA and RNA synthesis resulting in death of replicating cells

Common Uses

- Treatment of cancer
- Treatment of rheumatoid arthritis

Common Adverse Effects

- Nausea
- Alopecia
- Fatigue

Monitoring Effects of Antineoplastic Agents

Nursing Process Elements

- Assess for symptoms of original tumor/disease
- Assess for signs of infection, bone marrow depression, stomatitis
- Monitor VS, I&O, weight, and fatigue
- Monitor CBC, platelet count, BUN, Cr, liver panel, and serum drug levels
- Encourage adequate oral intake and nutrition

Nursing Diagnoses

- Infection: risk for
- Nutrition: imbalanced, less than body requirements
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to take medication as prescribed
- Advise to observe for signs of infection (fever, chills), cough, increased fatigue, increased pain, sore throat, gout, bleeding, red and sore oral mucous membranes, and difficulty breathing and to notify physician immediately
- Inform to avoid crowds and people with signs of illness
- Discuss options available in case hair loss occurs
- Encourage to schedule follow-up appointments with health care providers
- Advise to have laboratory tests done as prescribed
- Discuss community resources available

ANTIPARKINSON AGENTS

Mechanisms of Action

Anticholinergics

- Blocks cholinergic activity in the central nervous system and restores the balance of neurotransmitters

Dopamine agonists

- Converts levodopa to dopamine

Antiviral

- Increases the action of dopamine in the CNS

Catechol-O-methyltransferase Inhibitors

- Prevents the breakdown of levodopa

Common Uses

- Treatment of Parkinson's disease

Common Adverse Effects: Varies with specific drugs

- Blurred vision, dry eyes, and dry mouth
- Constipation
- Dizziness

Monitoring Effects of Anti-Parkinson Agents

Nursing Process Elements

- Assess for symptoms of Parkinson's disease (rigidity, tremors, movement difficulty, pill rolling, and shuffling gait)
- Monitor VS, assess for postural hypotension, assess oral mucus membranes
- Assess bowel and bladder function; maintain I&O record
- Assess for dizziness and implement safety precautions to prevent accidents

Nursing Diagnoses

- Mobility: impaired
- Injury: risk for
- Knowledge deficit related to medication, disease

Client teaching for self-care

- Encourage to take medication as prescribed
- Instruct to change position slowly so as to avoid a decrease in BP
- Advise to increase oral fluids, use gum, hard candy, or a saliva substitute to prevent dry mouth
- Encourage to keep appointments with health care providers

ANTIPLATELET AGENTS

Mechanisms of Action

- Glycoprotein IIb/IIIa inhibitors: eptifibatide (Integrilin)
- Platelet Aggregation Inhibitors: dipyridamole (Persantine)
- Platelet Adhesion Inhibitors: clopidogrel (Plavix)

Common Uses

- Prevention of myocardial infarction or stroke
- Treatment of acute coronary syndromes

Common Adverse Effects

- Dizziness
- Headache
- Bruising

Monitoring Effects of Antiplatelet Agents

Nursing Process Elements

- Assess VS
- Assess for signs of stroke or myocardial infarction
- Assess for signs of bleeding (venous and arterial access sites, hypotension, weak, rapid pulse, bruising)
- Monitor CBC, platelet count, coagulation studies, and Cr

Nursing Diagnoses

- Tissue perfusion: ineffective
- Injury: risk for
- Pain: acute
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to take medication as prescribed and to avoid using over-the-counter medication containing aspirin or NSAIDs without prior approval from physician
- Advise to avoid using alcohol and tobacco products due to the vasoconstriction action
- Instruct to notify physician if signs of bleeding (bruising, headache, blood in urine, dark stools, headache, weakness)
- Encourage to keep appointments with health care providers

ANTIPSYCHOTICS

Example: risperidone (Risperdal)

Mechanisms of Action

- Alters dopamine and serotonin in the CNS

Common Uses

- Treatment of schizophrenia
- Acute manic episodes

Common Adverse Effects

- Dizziness, headache, sleep disturbances, and extrapyramidal reactions
- Visual changes, rhinitis, and rash
- Constipation, diarrhea, nausea, and dry mouth
- Dysmenorrhea

Monitoring Effects of Antipsychotic Agents

Nursing Process Elements

- Assess mental status, mood changes, and signs of suicidal thoughts
- Monitor for orthostatic hypotension, hypotension, hypertension, elevated temperature, respiratory distress, and ECG changes
- Monitor for extrapyramidal symptoms such as rigidity, muscle spasms, tremors, drooling, restlessness, and for facial twitching
- Monitor laboratory values: CBC, AST, and ALT

Nursing Diagnoses

- Injury: risk for
- Thought processes: disturbed
- Noncompliance
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to take medication as directed and avoid alcohol and other CNS agents unless directed by physician
- Inform of adverse effects and importance of reporting them to the physician immediately
- Advise to change position slowly; avoid driving until approved by physician, and use sun protective products and clothing
- Instruct to use hard candy, gum, or mouth rinses to help prevent dry mouth
- Encourage to keep all follow-up appointments with health care providers

Nursing Intervention Alert

Advise client to use sunscreen and protective clothing to prevent photosensitivity reaction.

ANTIRETROVIRALS

Mechanisms of Action

- Protease Inhibitors: amprenavir (Agenerase)
—Inhibits the action of HIV-I protease
- Nucleoside reverse transcriptase inhibitors: abacavir (Ziagen)
—Converted to carbovir triphosphate which inhibits the activity of HIV-I reverse transcriptase
- Nonnucleoside reverse transcriptase inhibitors: delavirdine (Rescriptor): Binds to reverse transcriptase and inhibits viral DNA synthesis

Common Uses

- Treatment of HIV infection in combination with other drugs

Common Adverse Effects

- Diarrhea and N&V
- Mood changes
- Rash

Monitoring Effects of Antiretroviral Agents

Nursing Process Elements

- Assess for changes in HIV symptoms or opportunistic infections
- Monitor for adverse effects
- Monitor laboratory values: viral load, CD4 cell count, glucose, CBC, and cholesterol levels
- Be aware of serious drug–drug interactions among the antiretroviral agents.

Nursing Diagnoses

- Infection: risk for
- Knowledge deficit related to medications and disease
- Noncompliance

Client teaching for self-care

- Instruct to take medication round the clock exactly as directed and to maintain dosing schedule
- Inform that these medications do not cure HIV or reduce the risk of spreading virus to others
- Instruct to use condom, do not share needles, and do not donate blood
- Inform not to use over-the-counter medication unless approved by physician

- Review adverse effects of all drugs and emphasize the importance of notifying physician if experiencing any of these
- Advise to keep all follow-up appointments with physician

Antirheumatic Agents

Example: etanercept (Enbrel)

Mechanisms of Action

- Binds to tumor necrosis factor (TNF) and blocks its interaction with cell surface TNF receptors

Common Uses

- Moderate to severe rheumatoid arthritis

Common Adverse Effects

- Respiratory tract infection
- Rhinitis, headache

Monitoring Effects of Antirheumatic Agents

Nursing Process Elements

- Assess joint swelling, redness, heat, pain, and range of motion
- Rotate injection sites and observe site for redness, heat, and swelling
- Assess S&S of upper respiratory infection, and chest pain

Nursing Diagnoses

- Pain: acute
- Mobility: impaired
- Knowledge deficit related to medication, disease

Client teaching for self-care

- Instruct regarding dilution of solution, proper injection technique, site rotation, and disposal of equipment
- Advise not to receive live vaccine immunizations while taking this medication
- Instruct to report signs of infection, dizziness, shortness of breath, chest pain, or other adverse effects to health care provider immediately
- Encourage to keep all follow-up appointments with health care providers

Nursing Intervention Alert

Latex allergy: Needle cover of diluent syringe contains latex.

ANTITUBERCULAR AGENTS

Example: rifampin (Rifadin)

Mechanisms of Action

- Suppresses RNA synthesis by preventing attachment of the enzyme to DNA and blocking RNA transcription in susceptible organisms

Common Uses

- Treatment of tuberculosis

Common Adverse Effects

- Red-orange discoloration of all body fluids
- Diarrhea, abdominal pain, N&V

Monitoring Effects of Antitubercular Agents

Nursing Process Elements

- Assess respiratory rate, pattern and effort, lung sounds, and amount and character of sputum
- Monitor CBC, liver and renal function studies, PPD test results, and sputum cultures
- Monitor for red–orange discoloration of body fluids

Nursing Diagnoses

- Infection: risk for
- Gas Exchange: impaired
- Airway clearance: ineffective
- Knowledge deficit related to medication and disease
- Noncompliance

Client teaching for self-care

- Inform to take medication as directed for the entire course of therapy even if symptoms have subsided and to avoid alcohol
- Instruct regarding red–orange discoloration of body fluids
- Advise of adverse effects and to report symptoms to physician
- Instruct to report fatigue, increase in cough, shortness of breath, fever, and chills to physician
- Encourage to keep follow-up appointments with physician

ANTIVIRAL AGENTS

Example: acyclovir (Zovirax)

Mechanisms of Action

- Inhibits viral DNA replication

Common Uses

- Treatment of herpes zoster (shingles)
- Treatment of herpes simplex virus types 1 and 2
- Treatment of genital herpes infections

Common Adverse Effects

- Headache and dizziness
- Nausea, vomiting, and diarrhea

Monitoring Effects of Antiviral Agents

Nursing Process Elements

- Assess skin lesions for redness, pain, edema, and exudates
- Monitor CBC, electrolytes, and liver function studies

Nursing Diagnoses

- Infection: risk for
- Skin integrity: impaired
- Pain: acute
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Instruct to take medication as directed for the entire course of therapy.
- Advise that drug is not a cure, but will help manage symptoms.
- Explain methods to prevent spread of infection to others: Adequately cover lesions; wear loose fitting, cotton underwear for genital lesions and use a condom for sexual intercourse; wash hands after touching lesions; and apply ointment using a glove.
- Advise female clients to have annual pap smear due to increased risk of cervical cancer.
- Advise to avoid contact with children who have not had chicken pox, and avoid pregnant women.
- Encourage to keep all follow-up appointments with health care providers.

Nursing Intervention Alert

Monitor BUN and serum creatinine before and during treatment.

HORMONE AGENTS

Example: estrogens, conjugated (Premarin)

Mechanisms of Action

- Replacement of estrogen to promote normal development of female sex organs and secondary sex characteristics

Common Uses

- Hormone replacement therapy for moderate to severe vasomotor symptoms of menopause
- Prophylaxis of postmenopausal osteoporosis

Common Adverse Effects

- Edema, weight gain
- Hypertension, headache
- Breast tenderness, dysmenorrhea, or amenorrhea
- Nausea

Monitoring Effects of Estrogen Therapy

Nursing Process Elements

- Assess blood VS, edema, and weight gain
- Monitor I&O
- Monitor liver and lipid panels

Nursing Diagnoses

- Body image, disturbed
- Sexual dysfunction
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Advise to take oral dose with food and follow the dosing schedule
- Instruct to report shortness of breath, vaginal bleeding, headache, pain, swelling in legs, weight gain, and visual changes to physician immediately
- Instruct to wear protective products during exposure to sunlight
- Review instructions for application of vaginal medication if prescribed: Emphasize to administer the medication at bedtime, remaining recumbent for at least 30 minutes after inserting drug
- Encourage to keep follow-up appointments with health care providers

CONTRACEPTIVE AGENTS

Example: norgestimate/ethinyl estradiol (Ortho Tri-Cyclen)

Mechanisms of Action

- Suppression of FSH and LH inhibits ovulation

Common Uses

- Prevention of pregnancy
- Regulation of menstrual cycle

Common Adverse Effects

- Weight changes

Monitoring Effects of Contraceptive Agents

Nursing Process Elements

- Assess BP, edema, and weight gain
- Assess for pain and swelling in extremities, headache, and abnormal vaginal bleeding
- Assess for high-risk sexual practices

Nursing Diagnoses

- Knowledge deficit related to medication
- Noncompliance

Client teaching for self-care

- Instruct to take medication as directed and keep oral medications in original container
- Advise to report pain in legs or chest, cough, and respiratory distress to physician immediately
- Advise to report edema, weight gain, mood changes, and fatigue to physician
- Inform to limit caffeine consumption and avoid tobacco products
- Remind client that this medication does not provide any protection against STD and to use appropriate barrier protection
- Encourage to keep follow-up appointments with health care provider

IMMUNOSUPPRESSANT AGENTS

Example: azathioprine (Imuran)

Mechanisms of Action

- Inhibits synthesis of DNA, RNA, and proteins

Common Uses

- Prevention of renal transplant rejection
- Treatment of rheumatoid arthritis

Common Adverse Effects

- Anemia, leukopenia, thrombocytopenia, and pancytopenia
- N&V and anorexia
- Chills and fever

Monitoring Effects of Immunosuppressant Agents

Nursing Process Elements

- Assess for signs of infection
- Assess joints for pain, heat, redness, edema, and limited mobility for clients with rheumatoid arthritis
- Monitor CBC, renal, and liver studies
- Protect client from visitors with risk for infecting client

Nursing Diagnoses

- Infection: risk for
- Knowledge deficit related to medication, disease

Client teaching for self-care

- Instruct to take medication as prescribed by physician. Emphasize importance of not stopping medication abruptly, and not taking over-the-counter medications without prior approval.
- Advise to report adverse effects to physician immediately: increase in fatigue, fever, chills, diarrhea, tarry stools, back or side pain, and cough.
- Advise to avoid crowds and contact with people who are sick.
- Encourage to keep follow-up appointments with health care provider

Assessment Alert

Report leukocyte counts of less than 3000 to physician and anticipate a dose reduction or drug to be temporarily discontinued.

Lipid Lowering Agents

Example: HMG-CoA Reductase Inhibitors: rosuvastatin (Crestor)

Mechanisms of Action

- Reduces total cholesterol, LDL, and triglycerides and increases HDL

Common Uses

- Reduce lipids/cholesterol in order to decrease risk for myocardial infarction and stroke

Common Adverse Effects

- Indigestion, diarrhea, and constipation
- Rash

Monitoring Effects of Lipid-Lowering Agents

Nursing Process Elements

- Assess risk factors for stroke and myocardial infarction
- Obtain dietary history as well as food preferences
- Monitor serum cholesterol and triglyceride levels, and liver function tests
- Provide resources and suggestions for approved exercise activities

Nursing Diagnoses

- Knowledge deficit related to diet, medication, and disease risk factors
- Noncompliance

Client teaching for self-care

- Instruct in low cholesterol diet and appropriate exercise plan
- Advise to take medication as directed
- Advise to report adverse effects to physician: leg pain, muscle tenderness, weakness, fatigue, and fever
- Have regular eye examinations because of the risk of cataracts
- Encourage to keep follow-up appointments with health care provider

Nursing Intervention Alert

Grapefruit juice increases blood levels of most drugs in this class.

SEDATIVE/ HYPNOTIC AGENTS

Example: flurazepam (Dalmane)

Mechanisms of Action

- Depression of CNS, may be mediated by neurotransmitter GABA

Common Uses

- Management of insomnia

Common Adverse Effects

- Lethargy and daytime sedation
- Drowsiness

Monitoring Effects of Sedative/Hypnotic Agents

Nursing Process Elements

- Assess sleep history as well as daytime napping
- Assess for previous drug use for insomnia
- Monitor for postural hypotension
- Monitor daytime drowsiness and napping
- Implement safety precautions to prevent falls: bed in low position, call bell within reach, and supervised ambulation

Nursing Diagnoses

- Injury: risk for
- Sleep pattern: disturbed
- Knowledge deficit related to medication and safety
- Noncompliance

Client teaching for self-care

- Advise to take medication as directed
- Discuss relaxation techniques, cool, dark bedroom, quiet environment, avoiding caffeine, alcohol, and nicotine products
- Advise regarding safety measures: night light, phone, and glasses within reach
- Instruct to keep a sleep diary to help determine specific cause of insomnia
- Encourage to keep follow-up appointment with health care providers

SKELETAL MUSCLE RELAXANT AGENTS

Example: carisoprodol (Soma)

Mechanisms of Action

- Relaxation of skeletal muscles by depression of CNS

Common Uses

- Treatment of muscle spasm

Common Adverse Effects

- Dizziness and weakness
- Drowsiness

Monitoring Effects of Skeletal Muscle Relaxant Agents

Nursing Process Elements

- Assess muscle stiffness, tenderness, pain, and range of motion
- Assess for idiosyncratic reaction within first few minutes to one hour of dose: weakness, disorientation, blurred vision. Such reaction is temporary
- Implement safety measures to prevent falls

Nursing Diagnoses

- Mobility: impaired
- Injury: risk for
- Pain: acute
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Advise to take medication as directed, and avoid driving until response to medication is established
- Instruct in safety measures to prevent falls: change positions slowly to prevent orthostatic hypotension
- Instruct to avoid alcohol and other CNS depressants
- Inform regarding adverse effects and to notify physician if symptoms occur
- Encourage to continue with other prescribed measures to prevent muscle spasms: heat or cold therapy, physical therapy, exercise, and relaxation techniques

THROMBOLYTIC AGENTS

Example: reteplase (Retavase)

Mechanisms of Action

- Activates plasminogen to degrade clot

Common Uses

- Acute coronary thrombosis

Common Adverse Effects

- Reperfusion arrhythmias

Monitoring Effects of Thrombolytic Agents

Nursing Process Elements

- Assess for bleeding at venous and arterial access catheters, check neurological status, abdominal and joint pain, hypotension, and weak and rapid pulse
- Assess for angina, nausea, pain radiating down arm or to jaw, and diaphoresis
- Monitor VS throughout therapy and maintain bed rest
- Monitor ECG continuously and assess for reperfusion arrhythmias
- Assess for hypersensitivity reaction (fever, dyspnea, wheezing, rash, and facial swelling)
- Monitor CBC, coagulation studies, cardiac enzymes, and liver panel.

Nursing Diagnoses

- Tissue perfusion: ineffective
- Pain: acute
- Injury: risk for
- Knowledge deficit related to medication and disease

Client teaching for self-care

- Inform of the goals of therapy and the monitoring routine
- Instruct to report any adverse effects immediately
- Explain the importance of maintaining complete bed rest during therapy

Nursing Intervention Alert

To prevent harm to the client, request that another RN check the physician's order, dosage calculations, and electronic infusion device settings.

IMMUNE GLOBULIN AGENTS

Example: RhoGAM

Mechanisms of Action

- Suppresses immune response of nonsensitized Rh negative clients who are exposed to Rh-positive blood

Common Uses

- Administered to a female client who is Rh negative after she gives birth to a child who is Rh-positive

Common Adverse Effects

- Anemia

Monitoring Effects of Immune Globulin Agents

Nursing Process Elements

- Assess VS throughout therapy
- Determine Rh factor of mother and baby
- Monitor for signs of intravascular hemolysis (chills, back pain, anemia)

Nursing Diagnoses

- Knowledge deficit related to medication

Client teaching for self-care

- Explain purpose and importance of medication: preventing hemolytic disease of the newborn

DRUG THERAPY FOR GERIATRIC CLIENTS

Anatomic and Physiological Factors

- Drug absorption
 - Reduced gastric acidity may affect the way tablets dissolve
 - Gastric emptying may be prolonged
 - Rate of passage of drugs through the lower gastrointestinal tract may be slowed
 - Elderly may use laxatives, which increase the passage of drugs, foods, and liquids through the intestines
 - General reduction in blood flow to the intestines
 - Topical absorption may be quicker because of thinner skin
- Drug Distribution
 - Total body water is decreased in the older adult, which may increase the blood concentration of drugs and diminish the distribution of water-soluble drugs.
 - Age-related loss of muscle tone due to atrophy, alters medications administered intramuscularly
 - Total body fat content is increased in the older adult. Sedatives may be absorbed by the fatty tissue prolonging the effects of the drugs
 - A decrease in protein-binding capability may be present in the older adult, therefore, drugs may accumulate rather than being excreted

- Drug metabolism
 - Blood flow to liver diminishes with age, which affects the rate of metabolism of drugs that are primarily metabolized by the liver
- Drug Excretion
 - Reduced blood flow to kidneys of older adults and the loss of nephrons reduces the ability of the elderly to excrete drugs and metabolites

Age Related Changes and Health Issues

- Sensory losses
- Vision loss
 - Difficulty reading instructions, directions, and labels
 - Difficulty distinguishing prescription bottles
- Hearing loss makes it difficult to hear directions and information given to them verbally
- Recent memory loss
 - Forget directions given by health care providers
 - Forget to stay on medication schedule
- Multiple medications due to chronic health problems
- More than one pharmacy filling the prescriptions
- Using over-the-counter medications and home remedies
- Failing to discard old medications
- Sharing medications with another person
- Economics
 - Not getting prescriptions filled
 - Ask physician for a sample of the drug
 - Ask pharmacist for a short-term supply

General Guidelines

- Obtain baseline measures
 - VS
 - Height
 - Weight
- Take a history of allergies and current use of prescription and nonprescription drugs
- Obtain information on
 - disabilities of client or others in the home,
 - home environment and safety,
 - social and family life, and
 - economic concerns.
- Make sure that clients responsible for self-medication are able to follow dosing schedule, open containers and obtain their prescriptions
- Follow the “Five Rights” of medication administration
- When giving oral medications, position client in an upright position
- Use liquid dosage forms if client has difficulty swallowing tablets or capsules
- Allow adequate time for client to take medication and fluids

Table 14–13 Class, Action, and Side effects of 75 Commonly Prescribed Medications*

| Medication | Action | Side Effects |
|--|---|---|
| Accupril (quinapril) | ACE inhibitor used to treat hypertension and to decrease risk of CV disease | Rash, loss of taste, swelling of mouth, face, hands, feet, dizziness, fainting, chest pain, fast or irregular heartbeat, confusion nervousness, numbness and tingling in hands and feet, diarrhea, headache, tiredness, cough |
| Actonel (risedronate sodium) | Bisphosphonate used to treat postmenopausal osteoporosis | Stomach pain, bone or muscle pain, nausea, diarrhea, constipation, gas, leg cramps, bloated feeling, anxiety, depression, throat pain, heartburn, dysphagia, headache, weak muscles |
| Afedital CR (nifedipine sustained-action—oral) | Calcium channel blocker used to treat hypertension, sometimes angina | Headache, dizziness, nausea, flushing, constipation, leg/muscle cramps, or sexual problems, edema of the ankles/feet, dyspnea, unusual weakness/tiredness, new or worsening chest pain, allergic reaction |
| Allopurinol | Xanthine oxidase inhibitor used to treat gout, high levels of uric acid in the body caused by certain cancer medications, and kidney stones | Rash, hives, itch, jaundice, drowsiness, diarrhea, N&V, stomach pain, headache |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|-------------------------------|---|---|
| Altace (ramipril) | ACE inhibitor used to treat hypertension and decrease cardiovascular risk | Rash, loss of taste, swelling of mouth, face, hands, feet, dizziness, fainting, chest pain, fast or irregular heartbeat, confusion nervousness, numbness and tingling in hands and feet, diarrhea, headache, tiredness, cough |
| Ambien (zolpidem) | Sedative/hypnotic used to treat insomnia | Daytime drowsiness, light-headedness, dizziness, clumsiness, headache, diarrhea, nausea, dry mouth, muscle aches or pain, tiredness, indigestion, joint pain, memory problems |
| Aricept (donepezil) | Cholinesterase inhibitor used to treat Alzheimer's disease | N&V, diarrhea, lack of coordination, rash, indigestion, headache, muscle aches, anorexia, stomach pain, chills, dizziness, drowsiness, dry or itching eyes, increased sweating, joint pain, runny nose, sore throat, lower extremity edema, insomnia, weight loss, facial flushing, unusual tiredness or weakness. |
| Avapro (irbesartan) | Angiotensin II receptor antagonist used to treat hypertension | Headache, dizziness, fever or sore throat (upper respiratory tract infection), diarrhea, back pain, cough, fatigue, stuffy nose |
| Cartia XT (diltiazem) | Calcium Channel Blocker used to treat hypertension, angina, and certain arrhythmias | Tiredness, brady or tachyarrhythmia, wheezing, cough, dyspnea, dizziness, numbness or tingling in hands or feet, swollen feet, ankles or legs, difficult urination, nausea, constipation |
| Celebrex (celecoxib capsules) | NSAID used to treat osteoarthritis, rheumatoid arthritis, and acute pain | Headache, indigestion, upper respiratory tract infection, diarrhea, sinus inflammation, stomach pain, nausea, gastric bleeding, kidney damage, liver damage, fluid retention |
| Cozaar (losartan) | Angiotensin II receptor antagonist used to treat hypertension | Headache, dizziness, fever or sore throat (upper respiratory tract infection), diarrhea, back pain, cough, fatigue, stuffy nose |
| Zestril (lisinopril) | ACE inhibitor used to treat hypertension and heart failure | Rash, loss of taste, swelling of mouth, face, hands, feet, dizziness, fainting, chest pain, fast or irregular heartbeat, confusion nervousness, numbness and tingling in hands and feet, diarrhea, headache, tiredness, cough |
| Tenormin (Atenolol) | Beta-adrenergic blocking agent used to treat angina, hypertension and to improve survival post MI | Bradycardia, drowsiness, fatigue, numbness and tingling of fingers or toes, dizziness, nausea, diarrhea, weakness, cold hands or feet, dry skin, eyes, mouth, hallucinations, nightmares, insomnia, headache, dyspnea, joint pain, confusion, reduced alertness, depression, impotence, abdominal pain, constipation, (life threatening: CHF, severe dyspnea, tachyarrhythmia, severe asthma) |
| Detrol (tolterodine) | Antispasmodic used to treat overactive bladder (OAB) | Change in vision, difficult, burning, or painful urination, frequency, bloody or cloudy urine, chest pain, dizziness, dry mouth, vomiting, abdominal pain, constipation, diarrhea, N&V, headache, flu-like symptoms, drowsiness, dry eyes, flatulence |
| Digoxin (Brand name: Lanoxin) | Cardiac glycoside used to treat heart failure, atrial fibrillation/flutter | Anorexia, diarrhea, extreme drowsiness, lethargy, disorientation, headache, fainting, vision changes |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|--|--|---|
| Diovan (valsartan) | Angiotensin II receptor antagonist used to treat hypertension | Headache, dizziness, fever or sore throat (upper respiratory tract infection), diarrhea, back pain, cough, fatigue, stuffy nose |
| Diovan HCT (valsartan) (See Diovan) | | |
| Doxazosin mesylate (Brand name: Cardura) | Alpha-adrenergic receptor blocker used for the control of hypertension and for benign prostatic hyperplasia | Headache, drowsiness, rash or pruritus, blurred vision, shortness of breath, dyspnea, chest pain, tachycardia, anorexia, constipation or diarrhea, abdominal pain, N&V, edema, joint or muscle aches, tiredness, orthostatic hypotension, headache, irritability, depression, dry mouth, stuffy nose, increased urination, drowsiness |
| Lisinopril (Brand names: Zestril, Prinivil) (See Zestril) | | |
| Enalapril maleate (Brand names: Vasotec, Lexxel) | ACE inhibitor used to treat hypertension | Headache, dizziness, light-headedness, weakness, nausea, dry cough or blurred while adjusting to medication, fainting, decreased sexual ability, signs of infection (fever, chills, persistent sore throat), liver problems (jaundice, dark urine, stomach/abdominal pain, persistent fatigue, persistent nausea), allergic reaction |
| Evista (raloxifene) | Selective estrogen receptor modulator (SERM) used to treat and prevent osteoporosis | Thrombi, chest pain, bloody or cloudy urine, dysuria, frequency, infection, cold or flu-like symptoms, leg cramps, rash, edema of hands, ankles or feet, vaginal itching, joint or muscle pain, joint swelling, flatulence, upset stomach, vomiting, hot flashes, insomnia, white vaginal discharge, depression, unexplained weight gain, sweating, abdominal pain, diarrhea, anorexia, nausea, weakness, migraine, dyspnea, fever, congestion |
| Flomax (tamsulosin) | Alpha-1 antagonist with specificity to alpha-1A subtype receptors used in the management of BPH | Light-headedness, dizziness, headache, drowsiness, weakness, lethargy, nausea, palpitations |
| Fluoxetine HCL (Brand name: Prozac) | Selective serotonin reuptake inhibitor used to treat major depression, obsessive–compulsive disorder, panic disorder, posttraumatic stress disorder, bulimia nervosa | Allergic reaction: rash, pruritus, dyspnea, chest pain, drowsiness, nausea, cough or hoarseness, lower back or side pain, sores on lips or mouth, constipation or diarrhea, headache, anxiety, changed sexual desire or function, insomnia, dry mouth, unusual weakness or tiredness, vision changes, confusion, apathy, dyspnea, chills, black or tarry stools, fever, lymphadenopathy, arrhythmias, vomiting, skin rash, itching, abdominal pain, anorexia, yawning, tingling, skin burning or prickling, stuffy nose, changes in taste, tooth grinding, increased saliva, gas, heartburn, urinary changes, muscle or joint pain, menstrual changes, weight changes, loss of hair |
| Folic Acid (vitamin B 9) | | Large amounts of yellow urine |
| Fosamax (alendronate) | A bisphosphonate (affects normal and abnormal bone resorption) used to treat and prevent osteoporosis | Abdominal pain, musculoskeletal pain, flatulence, acid regurgitation, esophageal ulcer, abdominal distention, gastritis, headache, fever |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|---|--|--|
| Furosemide (Brand name Lasix) | Loop diuretic used to relieve peripheral edema from CHF, hepatic, and renal disease; relieve pulmonary edema; manage hypertension | Dizziness, mood change, fatigue, anorexia, diarrhea, arrhythmia, muscle cramps, hypotension, abdominal pain, weakness |
| Gemfibrozil (Brand name: Lopid) | Antihyperlipidemic drug used to treat hypertriglyceridemia and reduce risk of CAD | Indigestion, chest pain, SOB, arrhythmia, N&V, diarrhea, stomach pain |
| Glucophage XR (metformin) | A nonsulfonylurea antidiabetic agent of the class biguanide, which improves the action of insulin | Stomach pain, diarrhea, vomiting, decreased appetite, gas, changes in taste, headache, weight loss, feeling of fullness, nausea |
| Glucotrol XL (glipizide) | Sulfonylurea, oral antidiabetic agent used in the management of type 2 diabetes | Dizziness, diarrhea, anorexia, stomach pain, heartburn, low blood sugar (hunger, anxiety, cold sweats, rapid pulse, shortness of breath) |
| Glyburide (Brand name: DiaBeta) | Sulfonylurea, oral antidiabetic agent, used in the management of type 2 diabetes | Dizziness, diarrhea, anorexia, stomach pain, heartburn, constipation, low blood sugar (hunger, anxiety, cold sweats, rapid pulse, shortness of breath) |
| Hydrochlorothiazide (Brand name: HydroDIURIL) | Thiazide diuretic used to treat hypertension and edema | Muscle cramps, blurred vision, severe abdominal pain, N&V, arrhythmia, weak pulse; dizziness, mood changes, headache, weakness, tiredness, weight changes, decreased sex drive, diarrhea, dry mouth, thirst |
| Hyzaar (losartan and hydrochlorazide) | Combination of losartan an angiotensin II receptor blocker and hydrochlorothiazide, a thiazide diuretic used to treat hypertension | (See losartan and hydrochlorothiazide for side effects) |
| Isosorbide dinitrate (Brand name: Isordil) | Nitrate used to prevent and treat angina pectoris | Headache, flushed face and neck, dry mouth, N&V, fainting, tachycardia, restlessness, blurred vision, dizziness |
| Klor-Con (potassium supplement) | | Skin rash, swollen salivary glands, diarrhea, nausea, abdominal pain, bone and joint pain, numbness or tingling in hands or feet, vomiting, dizziness |
| Lescol (fluvastatin) | CoA reductase inhibitor used to reduce serum cholesterol and triglyceride levels | Aching muscles, fever, blurred vision, constipation, nausea, tiredness, weakness, dizziness, skin rash, headache, diarrhea, heartburn |
| Lescol XL (fluvastatin) | CoA reductase inhibitor used to reduce serum cholesterol and triglyceride levels | Aching muscles, fever, blurred vision, constipation, nausea, tiredness, weakness, dizziness, skin rash, headache, diarrhea, heartburn |
| Levothyroid (levothyroxine) | | Tremor, headache, irritability, insomnia, appetite changes, diarrhea, leg cramps, menstrual irregularities, fever, heat sensitivity, unusual sweating, weight loss, nervousness, hives, rash, vomiting, chest pain, rapid and irregular heartbeat, SOB |
| Proventil (albuterol) | Bronchodilator used in the prevention and treatment of asthma symptoms | Nervousness, tremors, headache, insomnia, nausea |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|--|---|---|
| Lisinopril-HCTZ | ACE inhibitor plus a thiazide diuretic used to treat hypertension, heart failure and edema | Rash, loss of taste, swelling of mouth, face, hands, feet, dizziness, fainting, chest pain, fast or irregular heartbeat, confusion nervousness, numbness and tingling in hands and feet, diarrhea, headache, tiredness, cough. Also muscle cramps, blurred vision, severe abdominal pain, N&V, arrhythmia, weak pulse; dizziness, mood changes, headache, weakness, tiredness, weight changes, decreased sex drive, diarrhea, dry mouth, thirst |
| Lotrel (benazepril and amlodipine) | ACE inhibitor and calcium channel blocker used to manage hypertension | Headache, dizziness, nausea, flushing, constipation, leg/muscle cramps, or sexual problems, edema of the ankles/feet, dyspnea, unusual weakness/tiredness, new or worsening chest pain, allergic reaction, rash, loss of taste, swelling of mouth, face, hands, feet, dizziness, fainting, chest pain, fast or irregular heartbeat, confusion, nervousness, numbness and tingling in hands and feet, diarrhea, cough |
| Lovastatin (Brand name: Mevacor) | Antihyperlipidemic CoA reductase inhibitor used to reduce serum cholesterol level | Aching muscles, fever, blurred vision, constipation, nausea, tiredness, weakness, dizziness, skin rash, headache, diarrhea, heartburn |
| Metoprolol (Brand names: Lopressor, Toprol XL) | Cardio-selective oral beta adrenergic blocking agent used to treat hypertension, angina, cardiac arrhythmias, myocardial infarction, migraine and pheochromocytoma among other problems | Tiredness, dizziness, diarrhea, depression, shortness of breath, bradycardia, itching, rash, other GI symptoms including vomiting |
| Miacalcin (calcitonin) | Calcium regulator drug used to treat PTH excess or high serum calcium levels | Allergic reaction/nasal inflammation, dryness, crusting, sores, irritation, itching, redness; swollen, runny, stuffy nose; small amount of nasal bleeding, discomfort tenderness, back and joint pain, headache, mild nose bleed, flushing, nausea, sinus infection |
| Nexium (esomeprazole) | Proton pump inhibitor used to treat GERD | Diarrhea, stomach pain, nausea, anorexia, headache, heartburn, muscle pain, skin rash, drowsiness |
| Norvasc (amlodipine) | Non-antiarrhythmic calcium channel blocker used to treat angina and essential hypertension | Constipation, dizziness, light-headedness, headache, nausea, hypotension, peripheral edema, bradycardia, AV block, pulmonary edema, shortness of breath, asthenia |
| Plavix (clopidogrel) | Platelet inhibitor used to prevent stroke, MI, or vascular death in clients with arteriosclerosis and in those who have had a stroke or MI. Also used for those undergoing CABG or PCI | Severe bleeding, chest pain, general body pain, red or purple spots on skin, diarrhea, stomach ache, back pain, dizziness, heartburn, muscle aches, symptoms of a cold, unusual bleeding or bruising, arrhythmia, shortness of breath, pedal edema, hematemesis, fainting, menometrorrhagia, headache, joint pain, mild weakness |
| Potassium chloride (Brand names: K-Dur, K-Lor, Slow-K) | Potassium supplement | Nausea, vomiting, diarrhea, rash, tingling in hands or feet, anxiety |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|--|--|---|
| Pravachol (pravastatin) | Antihyperlipidemic used to lower serum cholesterol and triglyceride levels | Aching muscles, fever, blurred vision, constipation, nausea, tiredness, weakness, dizziness, skin rash, headache, diarrhea, heartburn |
| Premarin (conjugated estrogen) | Estrogen used to treat female hypogonadism, primary ovarian failure, menopausal symptoms, abnormal uterine bleeding associated with hormone imbalance and with no organic cause, vaginal dryness and dyspareunia. It is also used as palliative treatment for prostatic cancer, male breast cancer, and nonestrogen dependent female breast cancer | Profuse bleeding, painful or swollen breasts, pedal edema, rapid weight gain, anorexia, nausea, stomach cramps or bloating, breast lumps or discharge, changes in vaginal bleeding (more, less spotting, prolonged), migraine, dizziness, contact lens intolerance, vomiting, mild diarrhea, headache, change in sex drive, slow weight gain |
| Prevacid (lansoprazole) | Proton pump inhibitor used to treat active duodenal ulcer, erosive esophagitis, GERD, H pylori, hypersecretory disorders | Headache and diarrhea |
| Propoxy-N/APAP | Narcotic analgesic with acetaminophen used for mild to moderate pain | Irregular or slow heartbeat, dyspnea, wheezing, dizziness, drowsiness, tiredness, headache, lightheadedness, N&V, stomach cramps, overexcitement, black tarry stools, bloody or cloudy urine, painful or frequent urination, fast, slow or pounding heartbeat; hallucinations; dyspnea, wheezing; back or side pain, tinnitus, rash, sore throat, facial edema, fever, oliguria; trembling; uncontrolled muscle movements, unusual bleeding or bruising, jaundice, feeling depressed, pale stools |
| Proscar (finasteride) | 5-alpha reductase inhibitor used to shrink the prostate in symptomatic BPH and in much smaller doses is used to treat male pattern baldness | Decreased volume of ejaculation, back or stomach pain, headache |
| Ranitidine (Brand name: Zantac) | Histamine 2 receptor antagonist used in the management of peptic ulcer disease, GERD, and erosive esophagitis | Dizziness, headache, diarrhea, decreased sex drive, unusual milk flow in women, hair loss |
| Triamterene/HCTZ (Brand name: Diazide) | Potassium sparing diuretic and hydrochlorothiazide used | Nausea or mild vomiting, anorexia, stomach cramps, mild diarrhea- dizziness, muscle cramps, headache, skin sensitive to sun, dry mouth, decreased sex drive |
| Verapamil (Brand name: Calan) | Calcium channel blocker used to treat hypertension, angina, and certain arrhythmias | Tiredness, bradyarrhythmia or tachyarrhythmia, wheezing, cough, dyspnea, dizziness, numbness or tingling in hands or feet, swollen feet, ankles or legs, difficult urination, nausea, constipation |
| Viagra (sildenafil) | Oral erectile dysfunction agent taken an hour before sexual activity, a major contraindication of which is the concurrent use of nitrates | Headache, flushing, stomach upset, stuffy or runny nose, back pain, muscle aches, urination problems, blurred vision, changes in color perception, light sensitivity, rash, dizziness, prolonged erection, diarrhea |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|--------------------------------------|---|--|
| Warfarin | Oral anticoagulant used after heparin therapy in the treatment of thrombosis and embolism; used prophylactically for clients at risk for thrombosis or embolism, e.g., those with venous stasis, atrial fibrillation or prosthetic heart valves | Bloating, flatulence, rash, hives, itch, blurred vision, sore throat, easy bruising, bleeding, hematuria, back pain, jaundice, fever, chills, fatigue, weakness, dysuria, oliguria, bleeding gums, menometrorrhagia |
| Xalatan (latanoprost) | Antiglaucoma prostaglandin | Eye itch, mild pain, redness, feeling of something in the eye, decreased vision, dryness or tearing, lid crusting, sensitivity to light, discharge, color or other vision changes, increased hair growth |
| Anagrelide (Brand name: Agrylin) | Antiplatelet agent used to reduce platelet counts in clients with essential thrombocytopenia | Headache, palpitations, diarrhea, asthenia, edema, nausea and abdominal pain |
| Azathioprine (Brand name: Imuran) | IV immunosuppressant antimetabolite to prevent rejection of renal transplants and to treat rheumatoid arthritis unresponsive to other therapy | Infection, GI distress, secondary malignancies |
| Azithromycin (Brand name: Zithromax) | Macrolide antibiotic used to treat lower respiratory tract infection, nongonococcal urethritis and cervicitis, skin infections, acute otitis media, pharyngitis, tonsillitis, helicobacter pylori infection | Nausea, vomiting, abdominal pain, diarrhea (GI effects less than with erythromycin), allergic reactions |
| Clindamycin (Brand name: Cleocin) | Very toxic lincosamide antibiotic active against a wide range of aerobic, gram-positive cocci and several anaerobic gram positive and gram-negative organisms | Nausea, vomiting, abdominal pain, maculopapular rash, erythema, pruritus, hypersensitivity reactions, thrombocytopenia, eosinophilia, neutropenia, which may be heralded by sore throat or fever |
| Atomoxetine (Brand name: Strattera) | Selective norepinephrine reuptake inhibitor used in the management of Attention deficit hyperactive disorder (ADHD) | Risk of suicide. In children: suppression of normal weight and height patterns, dyspepsia, nausea, vomiting, fatigue; in adults: constipation, dry mouth, nausea, anorexia, dizziness, insomnia, sexual dysfunction, urinary hesitation or retention, dysmenorrhea |
| Paxil (paroxetine) | SSRI used for depression, OCD, panic disorder, anxiety | Central nervous system: asthenia, dizziness, headache, insomnia, somnolence, tremor, nervousness, suicidal behavior, anxiety, paresthesia, confusion, agitation; cardiovascular: palpitations, vasodilation, orthostatic hypotension; EENT: sensation of lump or tightness in the throat; gastrointestinal: dry mouth, nausea, constipation, diarrhea, flatulence, vomiting, dyspepsia, dysgeusia, increased or decreased appetite, abdominal pain; musculoskeletal: myopia, myalgia, myasthenia; genitourinary: ejaculatory disturbance, sexual dysfunction, urinary frequency; skin: diaphoresis, rash and pruritus; and yawning |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|---|---|---|
| Lexapro (escitalopram) | SSRI used in the management of major depressive disorder | Nausea, dry mouth, trouble sleeping, loss of appetite, weakness, tiredness, drowsiness, dizziness, increased sweating, or yawning, nervousness, unusual high energy/excitement, suicidal thoughts, tremor, decreased interest in sex, changes in sexual ability |
| Xanax (alprazolam) | Benzodiazepine used to control anxiety | Respiratory depression, drowsiness, hallucinations, confusion, agitation, rash, itching and sensitivity to sunlight |
| Cymbalta (duloxetine hydrochloride) | Selective serotonin and norepinephrine reuptake inhibitor used to treat major depressive disorders and neuropathic pain related to diabetic peripheral neuropathy | Nausea, which improves in a few weeks, dry mouth, constipation, decreased appetite, fatigue, sleepiness, increased sweating |
| Zoloft (sertraline) | Selective serotonin reuptake inhibitor used to treat depression | Nausea, anorexia, diarrhea, sweating, insomnia, nervousness, anxiety, drowsiness, fatigue, dizziness, headache, suicidal thoughts and behavior |
| Oxycodone hydrochloride (Brand names: OxyContin (timed release preparation), OxyIR (rapid release preparation), Roxicodone) | Oral opioid analgesic used for moderate to severe pain | Clouded sensorium, dizziness, euphoria, light-headedness, physical dependence, sedation, somnolence, bradycardia, hypotension, constipation, nausea, vomiting, urinary retention, respiratory depression, diaphoresis, pruritus |
| Effexor (venlafaxine) | Newer generation antidepressant chemically unrelated to all other available antidepressants | Asthenia, headaches, somnolence, dizziness, nervousness, insomnia, suicidal behavior, anxiety, tremor, abnormal dreams, paresthesias, agitation, hypertension, tachycardia, blurred vision, nausea, constipation, dry mouth, anorexia, vomiting, diarrhea, dyspepsia, flatulence, abnormal ejaculation, impotence, urinary frequency, urinary retention, diaphoresis, rash, weight loss, yawning, chills, infection |
| Terazosin (Brand name: Hytrin) | Alpha-adrenergic blocking agent used in the management of hypertension and benign prostatic hypertrophy (BPH) | Light-headedness, dizziness, headache, drowsiness, weakness, lethargy, nausea, palpitations, reflex tachycardia, orthostatic hypotension, nasal congestion, inhibition of ejaculation |
| Timolol (Brand name: Blocadren) | Nonselective beta-adrenergic blocking agent used to treat hypertension, angina, and arrhythmias. Also used post-myocardial infarction, to prevent migraine headaches; and as an ophthalmic preparation to treat glaucoma by lowering intraocular pressure (IOP) | Cognitive dysfunction, depression, hallucinations and psychosis with high doses; hypoglycemia in clients with Type I diabetes; diarrhea, weight gain and with abrupt withdrawal, risk of MI, ventricular arrhythmias, severe hypertension |
| Zyrtec (cetirizine) | Antihistamine used in the management of seasonal and perennial allergy and for hives | Drowsiness, fatigue, headache, nausea, abdominal pain |
| Gabapentin (Brand name: Neurontin) | Anticonvulsant used to control seizures and to relieve post herpetic neuralgia | Drowsiness, dizziness, unsteadiness, fatigue, vision changes, weight gain, nausea, dry mouth, constipation |

(continued on next page)

Table 14–13 (continued from previous page)

| Medication | Action | Side Effects |
|---|--|--|
| Amoxicillin (Brand names: Amoxil, Biomox) | Antibiotic in the penicillin group used to treat infections due to <i>H. influenzae</i> , <i>N. gonorrhoeae</i> , <i>E. coli</i> , pneumococci, streptococci, and certain strains of staphylococci | Nausea, vomiting, mild diarrhea, irritation of the mouth or throat |

*Medications in this table are listed by either generic or brand name depending on how they are most often ordered based on lists prepared by Blue Cross and Blue Shield of Texas, AARP and the American Pharmaceutical Association.

If the listed name is generic, it is followed by one or more brand names identified as such in parentheses. If the listed name is a brand name, the generic name follows in parentheses and can be identified as such by its lower case first letter. Side effects are listed in general order of frequency.

WORKSHEET

Solve the following calculation problems:

1. gr 1/100 = _____ mg
2. 0.25 mg = gr _____
3. 100 mg = _____ g
4. 0.01 mg = _____ μ g
5. 95°F = _____ °C
6. 40°C = _____ °F
7. 6 oz = _____ ml
8. ½ oz = _____ ml
9. 1 half-pint carton of milk = _____ ml
10. 1 dr = _____ ml
11. 1 T = _____ ml
12. A 2-liter bottle of 7 Up = _____ ml
13. 1 T = _____ t
14. 1 l = _____ qt (approx.)
15. Order: promethazine (Phenergan) 20 mg p.o.
Stock: 10 mg scored tablets
Dose: _____

(continued)

16. Order: furosemide (Lasix) 0.04 g p.o. every day
Stock: 20 mg scored tablets
Dose: _____
17. Order: levothyroxine (Levothroid) 100 μg p.o. qid
Stock: scored tablets 200 μg
Dose: _____
18. The physician orders cefazolin (Ancef) 750 mg. The nurse has Ancef 330 mg/ml. How many ml should the nurse administer? Answer: _____
19. The physician orders digoxin (Lanoxin) 0.125 mg p.o. every day. The nurse has digoxin 0.25 mg per tablet. How many tablet(s) should the nurse administer? Answer: _____

Convert the kilograms to pounds or pounds to kilograms.

20. 150 lb _____
21. 130 lb _____
22. 114 lb _____
23. 99.2 kg _____
24. 71.8 kg _____
25. The physician orders 1000 ml D5 $\frac{1}{4}$ NS to be infused over 6 hours. The nurse will be using a 20 gtt/ml infusion set.
a. At how many milliliters per hour will the nurse infuse the solution? Answer: _____
b. At how many drops per minute will the nurse set the flow rate? Answer: _____
26. The physician orders morphine (MS Contin) gr $\frac{1}{4}$ p.o. q 6 hour p.r.n. The medication available is morphine 30 mg per scored tablet. How many tablets will the nurse administer? Answer: _____
27. The physician orders amoxicillin (Trimox) 7.5 ml q 8 hour. The amoxicillin on hand is 125 mg/5 ml.
How many mg will the client receive per dose? Answer: _____
How many mg will the client receive per day? Answer: _____
28. The physician orders Amoxicillin (Amoxil) for a 70-lb child. The child is to receive this medicine p.o. 4 times per day. The usual dose range is 20 to 40 mg/kg/d in divided doses.
a. 70 lb = _____ Kg
b. What is the lower daily dosage? _____
c. What is the upper daily dosage? _____
d. What is the lower dose for one dose? _____
e. What is the upper dose for one dose? _____
f. The dosage range is _____ mg to _____ mg per dose q 8 hours.
g. If the order is to give 450 mg q 6 hr, is this a safe dose? _____ Why? _____
29. The physician orders theophylline (Uniphyll) 20 mg/kg/24 hours to be administered p.o. every 6 hours. How many milligrams would you administer per dose to a client weighing 126 lb? Answer: _____
30. The physician orders cephapirin (Cefadyl) 400 mg IM every 6 hr. The 500-mg vial of powdered medication reads: "To prepare solution add 2 ml sterile water. Provides an approximate volume of 2.2 ml of a 225 mg/ml solution." How many milliliters will you administer for one dose? Answer: _____

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. The physician orders digoxin (Lanoxin) 0.25 mg p.o. stat. You have digoxin 0.125 mg scored tablet. How many tablet(s) should you administer? Answer: _____
2. Prior to administering digoxin, the nurse checks the serum level. What is the therapeutic range for the digoxin serum level for a client receiving digoxin? Answer: _____
3. Prior to administering digoxin, the nurse checks the serum potassium level. What is the normal range for the serum potassium level? Answer: _____
4. The nurse has a vial of heparin (Calcilean) 10,000 unit/ml. The client is to receive 7000 units sc bid. How many ml(s) should the client receive per dose? Answer: _____
5. What type of syringe will the nurse use to administer heparin subcutaneously? Answer: _____
6. What is the normal range for a serum PTT level for a client who has NOT received an anticoagulant? Answer: _____
7. The client is to receive morphine sulfate 8 mg intramuscular for pain. The nurse has Morphine Sulfate 10 mg/ml. How many ml(s) will the nurse administer? Answer: _____
8. What size needle would the nurse use to administer this intramuscular injection for a client who is 5 ft 6 in. tall and weighs 125 lb?
Gauge: _____, length: _____
9. The physician orders Lasix (furosemide) 30 mg p.o. every day. You have Lasix 20 mg scored tablets. How many tablet(s) will you give? Answer: _____
10. Name the primary laboratory test that you would closely monitor prior to administering Lasix. Answer: _____
11. The client may receive nitroglycerin tablets (Nitrostat) gr 1/100 sublingual for chest pain. How many mg = gr 1/100? Answer: _____
12. Which one VS would you monitor closely before and after the administration of nitroglycerin? Answer: _____
13. The nurse is to administer insulin lispro (Humalog) and NPH insulin (Humulin N) at 0730.
(a) Which insulin should be drawn into the syringe first? Answer: _____
(b) What is the onset of action of Humalog? Answer: _____
(c) What is the onset of action of NPH insulin? Answer: _____
14. List the five rights of medication administration.
a. _____
b. _____
c. _____
d. _____
e. _____
15. The client is to receive regular insulin (Humulin R) subcutaneous before each meal. The physician has written an order to administer the insulin using this formula: $\frac{\text{BG} - 120}{40}$
Your client's blood glucose is 368. How many units of insulin will you administer? Answer: _____

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|--|-------------|-------------|
| | <u> </u> | <u> </u> |
| | T | F |
| 1. Pharmacokinetics is the study of the absorption, distribution, metabolism, and excretion of drugs. | <u> </u> | <u> </u> |
| | T | F |
| 2. The rate of drug absorption, distribution, metabolism, and elimination for each specific class of drug is basically the same for all clients. | <u> </u> | <u> </u> |
| | T | F |
| 3. The nurse should always take into consideration the drug's action, characteristics of the drug, possible interactions with other drugs or food, and the client's daily schedule prior to administering medications. | <u> </u> | <u> </u> |
| | T | F |
| 4. If the client questions the appearance, dosage, or route, the nurse should fully explain the process of checking the drug three times, assure the client that it is the correct medication, and request that the client speak to the physician if they are uncomfortable with the medication routines. | <u> </u> | <u> </u> |
| | T | F |
| 5. When administering medications to a client with difficulty swallowing, the nurse may reduce the risk of aspiration by placing the client in a high-Fowler's or a sitting position if condition allows, provide sufficient fluid for swallowing, divide or crush tablets which are not enteric coated or sustained release, or obtain medications in liquid form when available. | <u> </u> | <u> </u> |
| | T | F |
| 6. Always assess the client's respiratory rate prior to and after administering morphine. Many institutional policies state that the nurse should not administer morphine to a client a respiratory rate of less than 10 breaths per minute. | <u> </u> | <u> </u> |
| | T | F |
| 7. Aspirin—a member of the salicylate drug classification—possesses the actions of anti-inflammatory, analgesic, antipyretic, and antiplatelet, and, therefore, may be administered for many different reasons. | <u> </u> | <u> </u> |
| | T | F |
| 8. The drug donepezil (Aricept), a member of the cholinesterase inhibitor classification, acts by enhancing cholinergic function by decreasing the levels of acetylcholine. | <u> </u> | <u> </u> |
| | T | F |
| 9. When advising clients about the drug, fexofenadine (Allegra), the nurse should inform them to take it with 6–8 oz of orange juice daily. | <u> </u> | <u> </u> |
| | T | F |
| 10. When monitoring the effects of antineoplastic agents, the nurse should assess for signs of infection, monitor VS and WBC count, encourage adequate oral intake and nutrition, inform client to avoid crowds and people with signs of illness, and explore options with client for possible loss of hair. | <u> </u> | <u> </u> |
| | T | F |
| | <u> </u> | <u> </u> |
| | T | F |
| 11. When providing education to a client who is taking the antipsychotic medication, risperidone (Risperdal), the nurse should instruct the client to change positions slowly, drink alcohol in moderate amounts only, use sun protective products and clothing, and to use hard candy, gum, or mouth rinses to help prevent dry mouth. | <u> </u> | <u> </u> |
| | T | F |

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. List three instructions to include in client/family teaching for a client who is taking the antiretroviral medication, amprenavir (Agenerase).
 - a. _____
 - b. _____
 - c. _____
2. List two possible nursing diagnoses for a client taking the antirheumatic agent, etanercept (Enbrel).
 - a. _____
 - b. _____
3. Describe three nursing interventions the nurse should include in a care plan for a client taking the antitubercular agent, rifampin (Rifadin).
 - a. _____
 - b. _____
 - c. _____

MATCHING QUESTIONS

Match the following:

Drug Classification

1. ____ Immunosuppressant agents: azathioprine (Imuran)
2. ____ Lipid lowering agents: rosuvastatin (Crestor)
3. ____ Sedative/hypnotic agents: flurazepam (Dalmane)
4. ____ Thrombolytic agents: reteplase (Retavase)
5. ____ Immune globulin agents: RhoGAM
6. ____ Tricyclic antidepressants: nortriptyline (Aventyl)
7. ____ Corticosteroid: prednisone (Pred-Pak)
8. ____ Antidiabetic agents: Biguanide (Glucophage)

Drug Action

- a. Using its glucocorticoid effects, reduces inflammation
- b. Activates plasminogen to degrade clot
- c. Inhibits DNA, RNA, and proteins
- d. Potentiates the effects of norepinephrine and serotonin
- e. Reduces total cholesterol, LDL, and triglycerides and increases HDL
- f. Suppresses immune response of nonsensitized Rh negative clients who are exposed to Rh positive blood
- g. Increases the binding of insulin to its receptors and potentiates the action of insulin
- h. Management of insomnia

MATCHING QUESTIONS

Match the following:

- | | |
|-------------------------------------|------------------------------|
| 1. _____Carisoprodol (Soma) | a. Alzheimer's Disease |
| 2. _____Fluconazole (Diflucan) | b. Prevention of stroke |
| 3. _____Amprenavir (Agenerase) | c. N&V |
| 4. _____Phenytoin (Dilantin) | d. Acute coronary thrombosis |
| 5. _____Naloxone (Narcan) | e. Asthma |
| 6. _____Promethazine (Phenergan) | f. Muscle spasm |
| 7. _____Albuterol (Proventil) | g. Depression |
| 8. _____Retepase (Retavase) | h. Anxiety |
| 9. _____Risperidone (Risperdal) | i. Seizure disorders |
| 10. _____Donepezil (Aricept) | j. HIV |
| 11. _____Nortriptyline (Aventyl) | k. Fungal infection |
| 12. _____Alprazolam (Xanax) | l. Respiratory depression |
| 13. _____Dipyridamole (Persantine) | m. Schizophrenia |

APPLICATION QUESTIONS

- A physician has prescribed enteric-coated tablets for the client. The nurse knows the following is true about enteric-coated tablets:
 - The tablets should be administered with antacids.
 - The tablets are designed to carry drugs that may irritate the stomach.
 - The tablets are designed to dissolve in the stomach.
 - The tablets should be crushed.
- The nurse is providing care for a client with mild liver damage due to hepatitis. The nurse is aware that this client may need reduced dosages of medications because
 - the client's kidneys cannot eliminate medications at the usual rate.
 - the drugs may accumulate in the client's body and produce toxicity.
 - the rate of absorption will increase allowing more of the drug to enter the bloodstream.
 - liver damage may cause drugs to bind to plasma proteins.
- Which of the following oral dosage forms should not be disrupted?
 - Enteric-coated and sustained-action medications
 - Sustained-action and intravenous medications

- c. Products containing a wax matrix and subcutaneous medications
- d. Enteric-coated tablets and all capsules
4. The physician has ordered nitroglycerin gr 1/200 for a client experiencing angina. How many milligrams of nitroglycerin (Nitrostat) are in one tablet of gr 1/200?
- 0.05 mg
 - 0.005 mg
 - 3 mg
 - 0.3 mg
5. A client is to receive Synthroid (levothyroxine) 100 μg p.o. every day. The medication label states: Synthroid 0.05 mg per scored tablet. How many tablet(s) should the nurse administer?
- $\frac{1}{2}$ tablet
 - 1 tablet
 - 2 tablets
 - 3 tablets
6. The physician orders meperidine (Demerol) for a postoperative client weighing 145 lb. If the recommended dose for meperidine (Demerol) is 6 mg/kg/24 hours, how much should be administered as a single dose four times daily?
- 220 mg
 - 98.8 mg
 - 22.6 mg
 - 65 mg
7. The physician orders Lasix (furosemide) 40 mg p.o. for a client who has fluid volume excess. The medication label states: Lasix 20 mg per scored tablet. How many tablet(s) should the nurse administer?
- $\frac{1}{2}$ tablet
 - 1 tablet
 - 2 tablets
 - 3 tablets
8. The physician orders gentamicin (Garamycin) for a child weighing 88 lb. If the dose range is 6–7.5 mg/kg/d, and the child is to receive the medication tid, what is the therapeutic range for a single dose for this child?
- 20–40 mg
 - 50–70 mg
 - 80–100 mg
 - 110–130 mg
9. The physician ordered penicillin (Penicillin G) 250,000 units intravenously. The nurse has on hand penicillin 20,000,000 units in 20 ml. How many ml contains the ordered dose?
- 0.25 ml
 - 4 ml
 - 16 ml
 - 25 ml
10. The physician ordered digoxin (Lanoxin) 0.125 mg p.o. every day. The nurse has digoxin 0.25 mg scored tablets. How many tablet(s) should the nurse administer?
- $\frac{1}{2}$ tablet
 - 1 tablet
 - $1\frac{1}{2}$ tablet
 - 2 tablets
11. Which of the following classes of drugs would most likely predispose a client to digitalis toxicity?
- Salicylate analgesics
 - Tetracycline antibiotics
 - Diuretics
 - Barbiturates
12. The nurse is providing care for a client who is receiving digoxin (Lanoxin). Which of the following symptoms should the nurse recognize as digoxin (Lanoxin) toxicity?
- Hyperkalemia
 - Increased hunger
 - Constipation
 - Visual disturbances
13. A client comes to the clinic complaining of unexplained black and blues and bloody appearing urine. Which type of medication is it most important to find out if the client is taking?
- Antibiotic
 - Antipruritic
 - Antianemic
 - Anticoagulant
14. A client was admitted to the hospital with pneumonia. The physician ordered “Zinacef, (a second generation cephalosporin) 2 g IV q 8 hour.” While preparing to administer the first dose of Zinacef, the nurse notices that this client has a penicillin allergy. The best action by the nurse is to
- administer the Zinacef as ordered but watch the client carefully for any signs of an allergic reaction.
 - ask the pharmacist if another antibiotic can be substituted for the Zinacef.
 - administer the Zinacef as ordered.
 - hold the Zinacef and notify the physician of the client’s allergy to penicillin.

(continued)

15. The physician prescribes an antihypertensive medication for your client. As a nurse, you would instruct the client to
 - a. limit fluid intake to 1200 ml daily.
 - b. increase activities, but limit foods high in magnesium.
 - c. take a laxative along with the antihypertensive medication.
 - d. change positions slowly, and sit up for a few minutes before rising from a lying position.
16. A client, who is 6-months pregnant, comes to the physician asking for a prescription for a tetracycline type medication to treat her acne. Your response should be
 - a. "Tetracycline, if taken during pregnancy, may be deposited in the bones and teeth of the fetus."
 - b. "The effect of tetracycline is decreased during pregnancy."
 - c. "Tetracycline may cause renal failure if taken during pregnancy."
 - d. "Taking tetracycline during pregnancy may cause your teeth to discolor."
17. You have just finished instructing your client on measures to help the body fight infections. Which of the following statements by your client would lead you to believe he needs additional instruction regarding the antibiotics?
 - a. "I will make sure I get adequate rest."
 - b. "I know I must continue to eat a balanced diet and drink lots of fluids."
 - c. "I will take my medicine until I no longer have a fever."
 - d. "I will wash my hands often."
18. The nurse should provide client education as an integral component of client care. Clients taking captopril (Capoten) should be informed that they may experience a common adverse effect of the angiotension-converting enzyme inhibitors (ACE inhibitors) such as
 - a. Persistent cough
 - b. Increased appetite
 - c. Hypertension
 - d. Sedation
19. A client was prescribed both heparin (Calcilean) and warfarin (Coumadin) by the physician. When preparing to administer both of these anticoagulants, what rationale would the nurse consider appropriate?
 - a. It takes 12–24 hours before the action of oral anticoagulants is evident.
 - b. Heparin (Calcilean) is more effective when used with warfarin sodium (Coumadin).
 - c. By administering an oral anticoagulant with heparin (Calcilean), the client needs less frequent administration of heparin.
 - d. The client is less likely to experience adverse effects
20. The nurse needs to administer two types of insulin to the client. Which of the following is the correct procedure for mixing two types of insulin in the same syringe?
 - a. Withdraw the regular insulin prior to any other type of insulin.
 - b. Withdraw the regular insulin after other types of insulin.
 - c. Draw each of the insulin medications in a separate syringe then combine the two.
 - d. Withdraw one half dose of the regular insulin prior to the other insulin, and then withdraw the remaining dose of the regular insulin.
21. A client was diagnosed with a thrombus in her left leg. The physician has ordered Coumadin (warfarin) 7.5 mg p.o. every day. The client's prothrombin time (PT) is 20 and the International Normalized Ratio (INR) is 2.4. The nurse has Coumadin (warfarin) 5 mg scored tablets. What should the nurse plan to do?
 - a. Administer 1/2 tablet because the PT and the INR are in a safe range.
 - b. Administer one tablet because the PT and the INR are in a safe range.
 - c. Administer 1 1/2 tablets because the PT and the INR are in a safe range.
 - d. Do not administer Coumadin because the PT and the INR are too high.
22. The physician orders digoxin (Lanoxin) 0.25 mg p.o. every day. The nurse has digoxin 0.125 mg scored tablets. The client's serum digoxin level is 1.4 and his potassium level is 4.2. What should the nurse plan to do?
 - a. Administer 1/2 tablet.
 - b. Administer 2 tablets
 - c. Do not administer the digoxin because the client's digoxin level is too high.
 - d. Do not administer the digoxin because the client's potassium is too low.
23. If the nurse is to administer both an inhalation bronchodilator and an inhalation corticosteroid, which of the following is true?
 - a. The bronchodilator should be used first.

- b. The corticosteroid should be used first.
 - c. The order of use does not matter.
 - d. It is a good idea to alternate which product is used first.
24. When the nurse is monitoring the effects of bronchodilators, which of the following should be included?
- a. Monitor for cyanosis of lips, earlobes, nail beds and mucous membranes, and monitor theophylline levels.
 - b. Be familiar with client's VS, and monitor their bowel sounds and respiratory effort.
 - c. Observe client for cyanosis, rapid respiratory rate, and monitor magnesium levels.
 - d. Observe client for adverse effects and ensure that he uses metered-dose inhalers correctly every hour.
25. When administering medication using a metered-dose inhaler the nurse should
- a. require the client to rinse mouth before using inhaler.
 - b. monitor client's respiratory rate and bowel sounds.
 - c. observe client's oral mucosa and tongue for redness and white patches
 - d. encourage client to use a hard bristle toothbrush.
26. The bulk-forming laxatives should always be taken with
- a. 30 ml orange juice.
 - b. 45 ml milk.
 - c. 4 oz of any liquid.
 - d. 240–300 ml of water or juice.
27. When administering proton pump inhibitors to a client, the nurse understands that they act by
- a. suppressing gastric acid secretion by inhibiting the gastric pump in the parietal cells of the stomach.
 - b. reducing gastric acid production by inhibiting the leukotriene activity in the stomach.
 - c. increasing gastric acid secretion by increasing the gastric pump output.
 - d. increasing gastric acid production by inhibiting the gastric pump in the stomach.
28. Client teaching regarding long-term corticosteroid therapy should include:
- a. the need for periodic blood glucose assessment
 - b. the need to take the medication late in the day to avoid insomnia
 - c. the possibility of enhanced wound healing
 - d. the need for a diet low in iron
29. Clients receiving long-term corticosteroid therapy may require dietary modifications. Which of the following statements is true about special diets for long-term corticosteroid therapy?
- a. A potassium-restricted diet may be needed due to sodium and water retention.
 - b. A low-protein, low-carbohydrate diet may be needed to correct negative nitrogen balance.
 - c. A potassium-restricted diet may be needed due to potassium retention.
 - d. Increased calcium is encouraged to help prevent osteoporosis.
30. Anatomic and physiological factors that affect drug absorption in the elderly include
- a. Increased rate of passage of drugs through the lower gastrointestinal tract.
 - b. Decreased gastric emptying, thus increasing the time medications remain in stomach.
 - c. Increased gastric acidity affects the way tablets dissolve.
 - d. Thinner skin surface delays absorption of topical drugs.
31. Factors that may place elderly people at risk for medication related problems include
- a. vision loss, hearing loss, and using the same pharmacy so accurate profiles may be kept.
 - b. memory loss, hearing loss, and using the same pharmacy so that prescriptions errors may be caught easily.
 - c. recent memory loss, vision loss, and taking multiple medications due to chronic health problems.
 - d. maintaining accurate profile at the pharmacy, asking physician for a sample of the prescription to assess the medications effects, and following the pharmacist's instructions.
32. A serious concern in health care is the development of increasing numbers of antibiotic-resistant strains of bacteria. To help prevent this problem, clients should be taught to
- a. complete the entire prescription of antibiotics
 - b. share their antibiotic prescription with other family members with the same symptoms
 - c. stop taking their antibiotic medications when they begin to feel better
 - d. request a prescription for antibiotics from the physician when they have a viral infection

(continued)

33. The nurse monitors the client for adverse effects of medications. What is a major disadvantage of using broad-spectrum antibiotics to treat infections?
- They are only effective against a small number of microorganisms.
 - They destroy normal flora, enabling superinfections to develop.
 - They are not effective against viruses.
 - They are more likely to cause an allergic reaction.
34. The nurse receives a medication order with no route specified. What is the best action by the nurse?
- Give the medication orally because that is the most common route.
 - Ask the client how he usually takes the medication.
 - Call the physician to clarify the order.
 - Ask another nurse which route to use.
35. The physician orders nitroglycerin (Nitro Bid) 0.4 mg SL now. Which of the following options would indicate that the nurse correctly administered the medication?
- Tablet placed under the client's tongue and client instructed to allow medication to dissolve.
 - Tablet given to the client with 8 oz of water after checking BP and heart rate.
 - Tablet given to the client with 4 oz of juice to assist with masking bitter flavor.
 - Tablet placed under client's tongue and client instructed to chew slowly to assist with absorption.
36. When administering intramuscular medication to a client who is 5 ft 6 in. tall and weighs 118 oz, which of the following needles should the nurse select?
- 27 gauge, 1 in.
 - 23 gauge, 2 in.
 - 25 gauge, 1½ in.
 - 22 gauge, 1 in.
37. Which of the following rights do clients have in regard to medication? The right to
- know the names of the other clients on the hall.
 - refuse medication and know the names of their medication.
 - information concerning side effects of the medications they are taking at home only.
 - know all of the medication that the nurse administers to all the clients.
38. What direction should the nurse give to a client in regard to the use of NSAIDs prior to scheduled surgery?
- Take as usual as long as recommended dose is not exceeded.
 - Do not take after midnight the day of surgery.
 - Gradually taper to zero during the week prior to surgery.
 - Discontinue 7 days prior to elective surgery.
39. The nurse should instruct the client taking an antilipemic about the regular need for which type of examination?
- Colonoscopy
 - Dental
 - Ophthalmic
 - Hearing
40. Which question should be asked of a young adult female for whom penicillin has been ordered?
- Do you drink milk?
 - Are you allergic to shellfish?
 - Do you take birth control pills?
 - Have you ever had vaginitis?

ANSWERS & RATIONALES

Answers for the calculation problems:

- $\text{gr } 1/100 = \underline{0.6} \text{ mg}$
- $0.25 \text{ mg} = \text{gr } \underline{1/240}$
- $100 \text{ mg} = \underline{0.1} \text{ g}$
- $0.01 \text{ mg} = \underline{10} \mu\text{g}$

5. $95^{\circ}\text{F} = \underline{35^{\circ}\text{C}}$
 6. $40^{\circ}\text{C} = \underline{104^{\circ}\text{F}}$
 7. 6 oz = 180 ml
 8. $\frac{1}{2}$ oz = 15 ml
 9. 1 half-pint carton of milk = 240 ml
 10. 1 dr = 4 ml
 11. 1 T = 15 ml
 12. A 2-liter bottle of 7 Up = 2000 ml
 13. 1 T = 3 t
 14. 1 L = 1 qt (approx.)
 15. Order: promethazine (Phenergan) 20 mg p.o.
Stock: 10 mg scored tablets
Dose: 2
 16. Order: furosemide (Lasix) 0.04 g p.o. every day
Stock: 20 mg scored tablets
Dose: 2
 17. Order: levothyroxine (Levothroid) 100 μg p.o. qid
Stock: scored tablets 200 μg
Dose: $\frac{1}{2}$
 18. The physician orders cefazolin (Ancef) 750 mg. The nurse has Ancef 330 mg/ml. How many ml should the nurse administer? Answer: 2.3
 19. The physician orders digoxin (Lanoxin) 0.125 mg p.o. every day. The nurse has digoxin 0.25 mg per tablet. How many tablet(s) should the nurse administer? Answer: $\frac{1}{2}$
- Convert the kilograms to pounds or pounds to kilograms.
20. 150 lb 68.2 kg
 21. 130 lb 59.1 kg
 22. 114 lb 51.8 kg
 23. 99.2 kg 218.2 kg
 24. 71.8 kg 158 kg
 25. The physician orders 1000 ml D5 $\frac{1}{4}$ NS to be infused over 6 hours. The nurse will be using a 20 gtt/ml infusion set.
 - a. At how many milliliters per hour will the nurse infuse the solution? Answer: 167 ml/hr
 - b. At how many drops per minute will the nurse set the flow rate? Answer: 56 gtt/min

(continued)

26. The physician orders morphine (MS Contin) gr $\frac{1}{4}$ p.o. q 6 hour p.r.n. The medication available is morphine 30 mg per scored tablet. How many tablets will the nurse administer? Answer: $\frac{1}{2}$
27. The physician orders amoxicillin (Trimox) 7.5 ml q 8 hour. The amoxicillin on hand is 125 mg/5 ml.
 a. How many mg will the client receive per dose? Answer: 187.5
 b. How many mg will the client receive per day? Answer: 562.5
28. The physician orders Amoxicillin (Amoxil) for a 70-lb child. The child is to receive this medicine p.o. 4 times per day. The usual dose range is 20–40 mg/kg/d in divided doses.
 a. 70 lb = 31.8 kg
 b. What is the lower daily dosage? 636 mg
 c. What is the upper daily dosage? 1272 mg
 d. What is the lower dose for one dose? 159 mg
 e. What is the upper dose for one dose? 318 mg
 f. The dosage range is 159 mg to 318 mg per dose q 8 hours.
 g. If the order is to give 450 mg q 6 hour, is this a safe dose? Answer: No. Why? Too high of a dose.
29. The physician orders theophylline (Uniphyll) 20 mg/kg/24 hours to be administered p.o. every 6 hours. How many milligrams would you administer per dose to a client weighing 126 lb? Answer: $126/2.2 = 57.3$ kg $\Rightarrow 57.3 \Rightarrow 20 = 1146$ mg/day $\Rightarrow 1146/4 = 286.5$ mg.
30. The physician orders cephapirin (Cefadyl) 400 mg IM every 6 hours. The 500-mg vial of powdered medication reads: “To prepare solution add 2-ml sterile water. Provides an approximate volume of 2.2 ml of a 225-mg/ml solution.” How many milliliters will you administer for one dose? Answer: 3.9

ANSWERS FOR FILL IN THE BLANKS

- The physician orders digoxin (Lanoxin) 0.25 mg p.o. stat. You have digoxin 0.125 mg scored tablet. How many tablet(s) should you administer? Answer: Two tablets.
- Prior to administering digoxin, the nurse checks the serum level. What is the therapeutic range for the digoxin serum level for a client receiving digoxin? Answer: 0.8–2.0 ng/ml.
- Prior to administering digoxin, the nurse checks the serum potassium level. What is the normal range for the serum potassium level? Answer: 3.5–5.3 mEq/L.
- The nurse has a vial of heparin (Calcilean) 10,000 unit/ml. The client is to receive 7000 units sc bid. How many ml(s) should the client receive per dose? Answer: 0.7 ml.
- What type of syringe will the nurse use to administer heparin subcutaneously? Answer: Tuberculin.
- What is the normal range for a serum PTT level for a client who has NOT received an anticoagulant? Answer: 25–45 seconds.
- The client is to receive morphine sulfate 8 mg intramuscular for pain. The nurse has Morphine Sulfate 10 mg/ml. How many ml(s) will the nurse administer? Answer: 0.8 ml.

8. What size needle would the nurse use to administer this intramuscular injection for a client who is 5 ft. 6 in. tall and weighs 125 lb?
Answer: Gauge: 21–23 , length: 1 in.
9. The physician orders Lasix (furosemide) 30 mg p.o. every day. You have Lasix 20 mg scored tablets. How many tablet(s) will you give? Answer: 1½ tablets.
10. Name the primary laboratory test that you would closely monitor prior to administering Lasix.
Answer: Serum potassium level.
11. The client may receive nitroglycerin tablets (Nitrostat) gr 1/100 sublingual for chest pain. How many mg = gr 1/100?
Answer: 0.6 mg.
12. Which one VS would you monitor closely before and after the administration of nitroglycerin? Answer: Blood pressure.
13. The nurse is to administer insulin lispro (Humalog) and NPH insulin (Humulin N) at 0730.
(a) Which insulin should be drawn into the syringe first? Answer: lispro (Humalog).
(b) What is the onset of action of Humalog? Answer: Within 15 minutes.
(c) What is the onset of action of NPH insulin? Answer: Within 2–4 hours.
14. List the five rights of medication administration.
a. Client
b. Drug
c. Dose
d. Route
e. Time
15. The client is to receive regular insulin (Humulin R) subcutaneous before each meal. The physician has written an order to administer the insulin using this formula: $\frac{BG - 120}{40}$
Your client's blood glucose is 368. How many units of insulin will you administer? Answer: 6.2 (say 6) units.

TRUE & FALSE ANSWERS

1. Pharmacokinetics is the study of the absorption, distribution, metabolism, and excretion of drugs. *True*
2. The rate of drug absorption, distribution, metabolism, and elimination for each specific class of drug is basically the same for all clients. *False*
The rate of drug absorption, distribution, metabolism, and elimination may be affected by underlying disease states, age, body weight, or basal metabolic rate.
3. The nurse should always take into consideration the drug's action, characteristics of the drug, possible interactions with other drugs or food, and the client's daily schedule prior to administering medications. *True*

(continued)

4. If the client questions the appearance, dosage, or route, the nurse should fully explain the process of checking the drug three times, assure the client that it is the correct medication, and request that the client speak to the physician if they are uncomfortable with the medication routines. *False*
The nurse should recheck the physician's orders, reevaluate the medication record, perform the "five rights" and "three checks" again, and obtain more information from client if needed prior to making a decision to administer the medication.
5. When administering medications to a client with difficulty swallowing, the nurse may reduce the risk of aspiration by placing the client in a high-Fowler's or a sitting position if condition allows, provide sufficient fluid for swallowing, divide or crush tablets which are not enteric coated or sustained release, or obtain medications in liquid form when available. *True*
6. Always assess the client's respiratory rate prior to and after administering morphine. Many institutional policies state that the nurse should not administer morphine to a client with a respiratory rate of less than 10 breaths per minute. *True*
7. Aspirin—a member of the salicylate drug classification—possesses the actions of anti-inflammatory, analgesic, antipyretic, and antiplatelet, and, therefore, may be administered for many different reasons. *True*
8. The drug donepezil (Aricept), a member of the Cholinesterase Inhibitor classification, acts by enhancing cholinergic function by decreasing the levels of acetylcholine. *False*
Donepezil acts by increasing the levels of acetylcholine.
9. When advising clients about the drug, fexofenadine (Allegra), the nurse should inform them to take it with 6–8 oz of orange juice daily. *False*
Apple, orange, and grapefruit juice will decrease the absorption of fexofenadine (Allegra).
10. When monitoring the effects of antineoplastic agents, the nurse should assess for signs of infection, monitor VS and WBC count, encourage adequate oral intake and nutrition, inform client to avoid crowds and people with signs of illness, and explore options with client for possible loss of hair. *True*
11. When providing education to a client who is taking the antipsychotic medication, risperidone (Risperdal), the nurse should instruct the client to, change positions slowly, drink alcohol in moderate amounts only, use sun protective products and clothing, and to use hard candy, gum, or mouth rinses to help prevent dry mouth. *False*
Clients taking risperidone should avoid drinking alcohol.

ANSWERS FOR FILL IN THE BLANKS

1. List three instructions to include in client/family teaching for a client who is taking the antiretroviral medication, amprenavir (Agenerase).
Answers may include: Instruct to take medication round the clock exactly as directed to maintain dosing schedule. Inform that these medications do not cure HIV or reduce the risk of spreading virus to others. Instruct to use condom, not to share needles, and not to donate blood. Inform not to use over-the-counter medication unless approved by physician. Review adverse effects such as diarrhea, N&V, mood changes, and rash. Advise to keep all follow-up appointments with health care providers.

2. List two possible nursing diagnoses for a client taking the antirheumatic agent, etanercept (Enbrel).
Answers may include: Pain: acute, mobility: impaired, deficient knowledge related to medication and disease.
3. Describe three nursing interventions the nurse should include in a care plan for a client taking the antitubercular agent, rifampin (Rifadin).
Answers may include: Assess respiratory rate, pattern and effort, lung sounds, and amount and character of sputum before and after administration of medication. Monitor CBC, liver and renal function studies, PPD test results, and sputum cultures. Assess for common adverse effects of the medication such as diarrhea, abdominal pain, nausea, vomiting, and red–orange discoloration of body fluids. Instruct client to report increase in fatigue, cough, shortness of breath, fever, and chills to health care provider.

MATCHING ANSWERS

Drug Classification

1. c Immunosuppressant agents: azathioprine (Imuran)
2. e Lipid lowering agents: rosuvastatin (Crestor)
3. h Sedative/hypnotic agents: flurazepam (Dalmane)
4. b Thrombolytic agents: reteplase (Retavase)
5. f Immune globulin agents: RhoGAM
6. d Tricyclic antidepressants: nortriptyline (Aventyl)
7. a Corticosteroid: prednisone (Pred-Pak)
8. g Antidiabetic agents: Biguanide (Glucophage)

Drug Action

- a. Using its glucocorticoid effects, reduces inflammation
- b. Activates plasminogen to degrade clot
- c. Inhibits DNA, RNA, and proteins
- d. Potentiates the effects of norepinephrine and serotonin
- e. Reduces total cholesterol, LDL, and triglycerides and increases HDL
- f. Suppresses immune response of nonsensitized Rh negative clients who are exposed to Rh positive blood
- g. Increases the binding of insulin to its receptors and potentiates the action of insulin
- h. Management of insomnia

MATCHING ANSWERS

1. f Carisoprodol (Soma)
 2. k Fluconazole (Diflucan)
 3. j Amprenavir (Agenerase)
 4. l Phenytoin (Dilantin)
- a. Alzheimer's Disease
 - b. Prevention of stroke
 - c. N&V
 - d. Acute coronary thrombosis

(continued)

- | | |
|--|---------------------------|
| 5. <u>l</u> Naloxone (Narcan) | e. Asthma |
| 6. <u>c</u> Promethazine (Phenergan) | f. Muscle spasm |
| 7. <u>e</u> Albuterol (Proventil) | g. Depression |
| 8. <u>d</u> Reteplase (Retavase) | h. Anxiety |
| 9. <u>m</u> Risperidone (Risperdal) | i. Seizure disorders |
| 10. <u>a</u> Donepezil (Aricept) | j. HIV |
| 11. <u>g</u> Nortriptyline (Aventyl) | k. Fungal infection |
| 12. <u>h</u> Alprazolam (Xanax) | l. Respiratory depression |
| 13. <u>b</u> Dipyridamole (Persantine) | m. Schizophrenia |

APPLICATION ANSWERS

- A physician has prescribed enteric-coated tablets for the client. The nurse knows the following is true about enteric-coated tablets:
 - The tablets should be administered with antacids.
 - The tablets are designed to carry drugs that may irritate the stomach.
 - The tablets are designed to dissolve in the stomach.
 - The tablets should be crushed.

Rationale

Correct answer: b.

Answer (b) is correct; the coating prevents the tablet from dissolving in the stomach where gastric acid is present and allows these more irritating medications to be carried to the small intestines to dissolve. Answer (a) is incorrect because the antacids may change the pH of the stomach to a more neutral or alkaline environment and allow the tablet to dissolve in the stomach. Answers (c) and (d) are incorrect because the tablet is designed to dissolve in the small intestine, and should never be crushed.

- The nurse is providing care for a client with mild liver damage due to hepatitis. The nurse is aware that this client may need reduced dosages of medications because
 - the client's kidneys cannot eliminate medications at the usual rate.
 - the drugs may accumulate in the client's body and produce toxicity.

- the rate of absorption will increase allowing more of the drug to enter the bloodstream.
- liver damage may cause drugs to bind to plasma proteins.

Rationale

Correct answer: b.

Answer (b) is correct because clients with liver damage may experience a decrease in the ability to metabolize drugs, thus the drugs accumulate in the body and may cause toxicity. Answer (a) does not relate to liver failure. Answer (c) is incorrect because absorption occurs prior to metabolism in the liver. Answer (d) is incorrect because the chemical properties of a drug are what determine how the drug is bound or distributed.

- Which of the following oral dosage forms should not be disrupted?
 - Enteric-coated and sustained-action medications
 - Sustained-action and intravenous medications
 - Products containing a wax matrix and subcutaneous medications
 - Enteric-coated tablets and all capsules

Rationale

Correct answer: a.

Answer (a) is correct because enteric-coated and sustained action drugs should not be divided or crushed. Answers (b), (c), and (d) all have one option that may be disrupted, thus making them the incorrect choice.

(continued)

4. The physician has ordered nitroglycerin gr 1/200 for a client experiencing angina. How many milligrams of nitroglycerin (Nitrostat) are in one tablet of gr 1/200?
- 0.05 mg
 - 0.005 mg
 - 3 mg
 - 0.3 mg

Rationale

Correct answer: d.

Answer (d) is correct:

$$\frac{\text{gr } 1/200}{x \text{ mg}} = \frac{\text{gr } 1}{60 \text{ m}}$$

$$1 x = 60/200$$

$$x = 0.3 \text{ mg}$$

5. A client is to receive Synthroid (levothyroxine) 100 μg p.o. every day. The medication label states: Synthroid 0.05 mg per scored tablet. How many tablet(s) should the nurse administer?
- $\frac{1}{2}$ tablet
 - 1 tablet
 - 2 tablets
 - 3 tablets

Rationale

Correct answer: c.

Answer (c) is correct: Change the 100 μg to 0.1 mg, then set up your ratio.

$$0.1 \text{ mg}/x \text{ tablet} = 0.05 \text{ mg}/1 \text{ tablet}$$

$$0.05 x = 0.1$$

$$x = 2 \text{ tablets}$$

6. The physician orders meperidine (Demerol) for a postoperative client weighing 145 lb. If the recommended dose for meperidine (Demerol) is 6 mg/kg/24 hours, how much should be administered as a single dose four times daily?
- 220 mg
 - 98.8 mg
 - 22.6 mg
 - 65 mg

Rationale

Correct answer: b.

Answer (b) is correct. Determine the client's weight in kg: 145 lb/2.2 = 65.9 kg, then work the problem. 65.9 kg \times 6 mg = 395.4 mg per 24 hours. Divide 395.4 by 4 doses per day = 98.8 mg per single dose.

7. The physician orders Lasix (furosemide) 40 mg p.o. for a client who has fluid volume excess. The medication label states: Lasix 20 mg per scored tablet. How many tablet(s) should the nurse administer?

- $\frac{1}{2}$ tablet
- 1 tablet
- 2 tablets
- 3 tablets

Rationale

Correct answer: c.

Answer (c) is correct: 40 mg/x tablet = 20 mg/1 tablet

$$20 x = 40$$

$$x = 2 \text{ tablets}$$

8. The physician orders gentamicin (Garamycin) for a child weighing 88 lb. If the dose range is 6–7.5 mg/kg/d, and the child is to receive the medication tid, what is the therapeutic range for a single dose for this child?
- 20–40 mg
 - 50–70 mg
 - 80–100 mg
 - 110–130 mg

Rationale

Correct answer: c.

Answer (c) is correct: Determine the client's weight in kg: 88 lb/2.2 kg = 40 kg

To determine the range, take the dose range and multiply it by the client's weight: 6 mg \times 40 kg = 240 mg/kg/d is the lower range. For the upper range: 7.5 mg \times 40 kg = 300 mg/kg/d. To find a single dose, divide each of the doses by 3 because it was ordered tid. 240 mg/3 = 80 mg per dose. 300 mg/3 = 100 mg per dose. Therefore, the single dose range is 80–100 mg.

9. The physician ordered penicillin (Penicillin G) 250,000 units intravenously. The nurse has on hand penicillin 20,000,000 units in 20 ml. How many ml contains the ordered dose?
- 0.25 ml
 - 4 ml
 - 16 ml
 - 25 ml

Rationale

Correct answer: a.

Answer (a) is correct:

$$250,000 \text{ units}/x \text{ ml} = 20,000,000/20 \text{ ml}$$

$$20,000,000x = 5,000,000$$

$$x = 0.25 \text{ ml}$$

10. The physician ordered digoxin (Lanoxin) 0.125 mg p.o. every day. The nurse has digoxin 0.25 mg scored tablets. How many tablet(s) should the nurse administer?
- $\frac{1}{2}$ tablet
 - 1 tablet
 - $1\frac{1}{2}$ tablet
 - 2 tablets

(continued)

Rationale

Correct answer: a.

Answer (a) is correct: $0.125 \text{ mg}/x \text{ tablet} = 0.25 \text{ mg}/1 \text{ tablet}$

$$0.25x = 0.125$$

$$x = \frac{1}{2} \text{ tablet}$$

11. Which of the following classes of drugs would most likely predispose a client to digitalis toxicity?
- Salicylate analgesics
 - Tetracycline antibiotics
 - Diuretics
 - Barbiturates

Rationale

Correct answer: c.

Answer (c) is correct because many diuretics increase the excretion of potassium from the body and a decreased level of potassium increases the risk of digoxin toxicity. Answers (a),(b), and (d) do not predispose a client to digoxin toxicity.

12. The nurse is providing care for a client who is receiving digoxin (Lanoxin). Which of the following symptoms should the nurse recognize as digoxin (Lanoxin) toxicity?
- Hyperkalemia
 - Increased hunger
 - Constipation
 - Visual disturbances

Rationale

Correct answer: d.

Answer (d) is correct because it is a common symptom of digoxin toxicity. Other symptoms include fatigue, anorexia, blurred or double vision, nausea, confusion, and bradycardia. Answers (a), (b), and (c) are not symptoms of digoxin toxicity.

13. A client comes to the clinic complaining of unexplained black and blues and bloody appearing urine. Which type of medication is it most important to find out if the client is taking?
- Antibiotic
 - Antipruritic
 - Antianemic
 - Anticoagulant

Rationale

Correct answer: d.

Answer (d) is correct because a side effect of anticoagulant therapy is abnormal bleeding, which can manifest in many ways two of which are as gross blood in the urine and easy bruising.

14. A client was admitted to the hospital with pneumonia. The physician ordered "Zinacef, (a second generation cephalosporin) 2 g IV q 8 hour." While preparing to administer the first dose of Zinacef, the nurse notices that this client has a penicillin allergy. The best action by the nurse is to
- administer the Zinacef as ordered but watch the client carefully for any signs of an allergic reaction
 - ask the pharmacist if another antibiotic can be substituted for the Zinacef
 - administer the Zinacef as ordered
 - hold the Zinacef and notify the physician of the client's allergy to penicillin

Rationale

Correct answer: d.

Answer (d) is the best answer. Often, a client who has an allergy to Penicillin will experience an adverse effect to the cephalosporin class of antibiotics because they are chemically and pharmacologically similar. Therefore, for the safety of the client, the nurse should always call the physician. The answers of (a), (b), and (c) are not appropriate actions for the nurse to take with this client situation.

15. The physician prescribes an antihypertensive medication for your client. As a nurse, you would instruct the client to
- limit fluid intake to 1200 ml daily.
 - increase activities, but limit foods high in magnesium.
 - take a laxative along with the antihypertensive medication.
 - change positions slowly, and sit up for a few minutes before rising from a lying position.

Rationale

Correct answer: d.

Answer (d) is correct. Many of the antihypertensive medications cause orthostatic hypotension. Therefore, the nurse should instruct the client regarding sudden movements and about rising slowly to prevent a decrease in BP and prevent client injury. Answers (a), (b), and (c) are not appropriate instructions in regards to medications for hypertension.

16. A client, who is 6-months pregnant, comes to the physician asking for a prescription for a tetracycline type medication to treat her acne. Your response should be
- "Tetracycline, if taken during pregnancy, may be deposited in the bones and teeth of the fetus."
 - "The effect of tetracycline is decreased during pregnancy."

- c. "Tetracycline may cause renal failure if taken during pregnancy."
- d. "Taking tetracycline during pregnancy may cause your teeth to discolor."

Rationale

Correct answer: a.

Answer (a) is correct because the tetracycline medications are contraindicated during pregnancy because the drugs may interfere with normal calcification of temporary and permanent teeth and discolor developing teeth of the fetus. The drug may also interfere with bone growth of the fetus. Answers (b) and (c) are incorrect. Answer (d) is incorrect because the medication affects the developing teeth of the fetus and children younger than 8 years of age, not the adult.

17. You have just finished instructing your client on measures to help the body fight infections. Which of the following statements by your client would lead you to believe he needs additional instruction regarding the antibiotics?
- a. "I will make sure I get adequate rest."
 - b. "I know I must continue to eat a balanced diet and drink lots of fluids."
 - c. "I will take my medicine until I no longer have a fever."
 - d. "I will wash my hands often."

Rationale

Correct answer: c.

Answer (c) is correct. The question is asking how the nurse would know the client needs additional instruction or that the client does not understand. If the client thinks he should stop taking his antibiotics when he no longer has a fever, then he needs additional education. Answers (a), (b), and (d) are all good measures to help fight or prevent infection, therefore, these do not indicate he needs more instruction.

18. The nurse should provide client education as an integral component of client care. Clients taking captopril (Capoten) should be informed that they may experience a common adverse effect of the angiotension-converting enzyme inhibitors (ACE inhibitors) such as
- a. Persistent cough
 - b. Increased appetite
 - c. Hypertension
 - d. Sedation

Rationale

Correct answer: a.

Answer (a) is correct. A persistent cough is a common adverse effect of ACE Inhibitors. Answers (b), (c), and (d) are not common adverse effects of ACE Inhibitors.

19. A client was prescribed both heparin (Calcilean) and warfarin (Coumadin) by the physician. When preparing to administer both of these anticoagulants, what rationale would the nurse consider appropriate?
- a. It takes 12–24 hours before the action of oral anticoagulants is evident.
 - b. Heparin (Calcilean) is more effective when used with warfarin sodium (Coumadin).
 - c. By administering an oral anticoagulant with heparin (Calcilean), the client needs less frequent administration of heparin.
 - d. The client is less likely to experience adverse effects

Rationale

Correct answer: a.

Answer (a) is correct. In many situations the client is receiving heparin intravenously and the physician prescribes the addition of Coumadin for several days prior to discontinuing the heparin. For oral anticoagulants, their effect is usually not evident for 12–24 hours after therapy has begun. Therefore, the client is receiving the heparin while the effects of the Coumadin are beginning to become evident. After the laboratory work shows evidence that the oral anticoagulants are effective, then the physician will discontinue the heparin therapy. Answers (b),(c), and (d) are not correct.

20. The nurse needs to administer two types of insulin to the client. Which of the following is the correct procedure for mixing two types of insulin in the same syringe?
- a. Withdraw the regular insulin prior to any other type of insulin.
 - b. Withdraw the regular insulin after other types of insulin.
 - c. Draw each of the insulin medications in a separate syringe then combine the two.
 - d. Withdraw one half dose of the regular insulin prior to the other insulin, and then withdraw the remaining dose of the regular insulin.

Rationale

Correct answer: a.

Answer (a) is correct. The nurse withdraws the regular (clear) insulin first so as to not contaminate the regular insulin vial with the other types of insulin. Answers (b) and (d) risk the chance to contaminate the regular insulin vial. Answer (c) indicates that the nurse is wasting time and supplies, as well as the insulin syringes do not have a detachable needle, thus, the nurse can not add solution from one syringe to another syringe.

21. A client was diagnosed with a thrombus in her left leg. The physician has ordered Coumadin (warfarin)

(continued)

7.5 mg p.o. every day. The client's prothrombin time (PT) is 20 and the international normalized ratio (INR) is 2.4. The nurse has Coumadin (warfarin) 5 mg scored tablets. What should the nurse plan to do?

- Administer $\frac{1}{2}$ tablet because the PT and the INR are in a safe range.
- Administer one tablet because the PT and the INR are in a safe range.
- Administer $1\frac{1}{2}$ tablets because the PT and the INR are in a safe range.
- Do not administer Coumadin because the PT and the INR are too high.

Rationale

Correct answer: c.

Answer (c) is correct. The PT and the INR values are in a normal range for a client who is receiving oral anticoagulant therapy. Therefore, you need to determine the dose the nurse will administer. $7.5 \text{ mg}/x \text{ tablet} = 5 \text{ mg}/1 \text{ tablet}$

$$5x = 7.5$$

$$x = 1\frac{1}{2} \text{ tablet}$$

22. The physician orders digoxin (Lanoxin) 0.25 mg p.o. every day. The nurse has digoxin 0.125 mg scored tablets. The client's serum digoxin level is 1.4 and his potassium level is 4.2. What should the nurse plan to do?

- Administer $\frac{1}{2}$ tablet.
- Administer 2 tablets
- Do not administer the digoxin because the client's digoxin level is too high.
- Do not administer the digoxin because the client's potassium is too low.

Rationale

Correct answer: b.

Answer (b) is correct. The serum digoxin level of 1.4 is within normal limits for a client taking digoxin (0.8–2.0). The potassium level of 4.2 is within normal limits (3.5–5.3). Therefore, you need to determine the dose the client will receive.

$$0.25 \text{ mg}/x \text{ tablet} = 0.125 \text{ mg}/1 \text{ tablet}$$

$$0.125x = 0.25$$

$$x = 2 \text{ tablets}$$

23. If the nurse is to administer both an inhalation bronchodilator and an inhalation corticosteroid, which of the following is true?

- The bronchodilator should be used first.
- The corticosteroid should be used first.
- The order of use does not matter.
- It is a good idea to alternate which product is used first.

Rationale

Correct answer: a.

Answer (a) is correct. The nurse should administer the bronchodilator inhaler first so that the medication can dilate the bronchioles prior to the administration of the inhalation corticosteroid medication. It is best to wait 5–10 minutes after the administration of the bronchodilator inhaler before administering any other inhaled medications.

24. When the nurse is monitoring the effects of bronchodilators, which of the following should be included?
- Monitor for cyanosis of lips, earlobes, nail beds and mucous membranes, and monitor theophylline levels.
 - Be familiar with client's VS, and monitor their bowel sounds and respiratory effort.
 - Observe client for cyanosis, rapid respiratory rate, and monitor magnesium levels.
 - Observe client for adverse effects and ensure that he uses metered-dose inhalers correctly every hour.

Rationale

Correct answer: a.

Answer (a) is correct. When the nurse is monitoring the effects of medications, the S&S of the disorder that these medications are treating are included in the assessment. With bronchodilators, the S&S of the disorder are respiratory system related. Theophylline is a medication that promotes bronchodilation, and the physician often orders serum theophylline levels to be drawn. Answers (b) and (c) have distracters such as bowel sounds and magnesium levels which are not associated with monitoring the effects of bronchodilators. Answer (d) is incorrect because the nurse would not administer the inhaler every hour as this would be an overdose.

25. When administering medication using a metered-dose inhaler the nurse should

- require the client to rinse mouth before using inhaler.
- monitor client's respiratory rate and bowel sounds.
- observe client's oral mucosa and tongue for redness and white patches
- encourage client to use a hard bristle toothbrush.

Rationale

Correct answer: c.

Answer (c) is correct. Some of the inhaled medications are steroids and may cause irritation or oral candidiasis. Answer (a) would not be the best answer, although there may be situations where the nurse may need the client to rinse their mouth before using the inhaler. Answer (b) is incorrect because the bowel sounds are not a component of

this assessment. Answer (d) is incorrect because if there is a situation that may cause oral irritation, the client should be instructed to use a soft bristle toothbrush.

26. The bulk-forming laxatives should always be taken with
- 30 ml orange juice.
 - 45 ml milk.
 - 4 oz of any liquid.
 - 240–300 ml of water or juice.

Rationale

Correct answer: d.

Answer (d) is correct. The nurse should administer a bulk-forming laxative with 240–300 ml of water or juice to prevent gastrointestinal obstruction. Answers (a), (b), and (c) are not enough volume.

27. When administering proton pump inhibitors to a client, the nurse understands that they act by
- suppressing gastric acid secretion by inhibiting the gastric pump in the parietal cells of the stomach.
 - reducing gastric acid production by inhibiting the leukotriene activity in the stomach.
 - increasing gastric acid secretion by increasing the gastric pump output.
 - increasing gastric acid production by inhibiting the gastric pump in the stomach.

Rationale

Correct answer: a.

Answer (a) is the correct action of medications in the drug classification of proton pump inhibitors. Answer (b) is incorrect because leukotriene activity is not an action of these medications. Answers (c) and (d) are incorrect because gastric acid is decreased, not increased with this classification.

28. Client teaching regarding long-term corticosteroid therapy should include
- the need for periodic blood glucose assessment
 - the need to take the medication late in the day to avoid insomnia
 - the possibility of enhanced wound healing
 - the need for a diet low in iron

Rationale

Correct answer: a.

Answer (a) is correct because an adverse effect of corticosteroid therapy is hyperglycemia. Answer (b) is incorrect because it is generally recommended that a client on long-term corticosteroid therapy take their medication early in the day to help prevent insomnia. Answer (c) is incorrect because one of the adverse effects is delayed wound healing and masking of infections. Answer (d) is incorrect because there are no recommendations to decrease iron intake.

29. Clients receiving long-term corticosteroid therapy may require dietary modifications. Which of the following statements is true about special diets for long-term corticosteroid therapy?
- A potassium-restricted diet may be needed due to sodium and water retention.
 - A low-protein, low-carbohydrate diet may be needed to correct negative nitrogen balance.
 - A potassium-restricted diet may be needed due to potassium retention.
 - Increased calcium is encouraged to help prevent osteoporosis.

Rationale

Correct answer: d.

Answer (d) is correct. Clients on long-term corticosteroid therapy are at risk for osteoporosis due to an increased excretion of calcium. Therefore, calcium supplements are very important. Answers (a), (b), and (c) are incorrect as the client may need a high-carbohydrate, high-protein diet and foods high in potassium to maintain adequate nutrition.

30. Anatomic and physiological factors that affect drug absorption in the elderly include
- increased rate of passage of drugs through the lower gastrointestinal tract.
 - decreased gastric emptying, thus increasing the time medications remain in stomach.
 - increased gastric acidity affects the way tablets dissolve.
 - thinner skin surface delays absorption of topical drugs.

Rationale

Correct answer: b.

Answer (b) is correct. In older adults gastric emptying is slowed and takes a longer time, therefore the medication remains in the stomach longer. Answers (a) and (c) are incorrect due to drugs taking longer to absorb in older adults, and gastric acid production is decreased in the older adult. Answer (d) is incorrect because thinner skin surfaces actually increase absorption of topical medications.

31. Factors that may place elderly people at risk for medication related problems include
- vision loss, hearing loss, and using the same pharmacy so accurate profiles may be kept.
 - memory loss, hearing loss, and using the same pharmacy so that prescriptions errors may be caught easily.

(continued)

- c. recent memory loss, vision loss, and taking multiple medications due to chronic health problems.
- d. maintaining accurate profile at the pharmacy, asking physician for a sample of the prescription to assess the medications effects, and following the pharmacist's instructions.

Rationale

Correct answer: c.

Answer (c) is correct. These changes may occur in the older adult and many older clients are on eight or more medications per day. Answers (a) and (b) are incorrect, even though the cognitive and sensory changes are possible, using the same pharmacy for all the prescriptions helps prevent medication related problems. Answer (d) is incorrect because these are examples of methods that help prevent medication related problem.

32. A serious concern in health care is the development of increasing numbers of antibiotic-resistant strains of bacteria. To help prevent this problem, clients should be taught to
- a. complete the entire prescription of antibiotics
 - b. share their antibiotic prescription with other family members with the same symptoms
 - c. stop taking their antibiotic medications when they begin to feel better
 - d. request a prescription for antibiotics from the physician when they have a viral infection

Rationale

Correct answer: a.

Answer (a) is correct. Nurses should instruct clients to complete the entire course of therapy of antibiotics. Answer (b) is incorrect. Clients should be instructed not to share any of their medications with another individual. Answer (c) is incorrect. Clients should be instructed to take the full course of therapy and not to stop taking their antibiotics when they feel better. Answer (d) is incorrect. Antibiotics are not the correct treatment for viral infections.

33. The nurse monitors the client for adverse effects of medications. What is a major disadvantage of using broad-spectrum antibiotics to treat infections?
- a. They are only effective against a small number of microorganisms.
 - b. They destroy normal flora, enabling superinfections to develop.
 - c. They are not effective against viruses.
 - d. They are more likely to cause an allergic reaction.

Rationale

Correct answer: b.

Answer (b) is correct. Broad-spectrum antibiotics may destroy normal flora in the client's mouth and gastrointestinal tract, causing oral candidiasis and diarrhea. Answer (a) is incorrect. Broad-spectrum antibiotics are effective against a large number of organisms. Answer (c) is not the best answer to the question because antibiotics are not effective against viruses. Answer (d) is not accurate information.

34. The nurse receives a medication order with no route specified. What is the best action by the nurse?
- a. Give the medication orally because that is the most common route.
 - b. Ask the client how he usually takes the medication.
 - c. Call the physician to clarify the order.
 - d. Ask another nurse which route to use.

Rationale

Correct answer: c.

Answer (c) is correct. The nurse should always call the physician to verify the route. Answers (a), (b), and (d) are incorrect and do not constitute safe nursing practice.

35. The physician orders nitroglycerin (Nitro Bid) 0.4 mg SL now. Which of the following options would indicate that the nurse correctly administered the medication?
- a. Tablet placed under the client's tongue and client instructed to allow medication to dissolve.
 - b. Tablet given to the client with 8 oz of water after checking BP and heart rate.
 - c. Tablet given to the client with 4 oz of juice to assist with masking bitter flavor.
 - d. Tablet placed under client's tongue and client instructed to chew slowly to assist with absorption.

Rationale

Correct answer: a.

Answer (a) is correct. The order is for the tablet to be administered SL (sublingual). Answers (b), (c), and (d) indicate that the client is to swallow the medication.

36. When administering intramuscular medication to a client who is 5 ft 6 in. tall and weighs 118 lb, which of the following needles should the nurse select?
- a. 27 gauge, 1 in.
 - b. 23 gauge, 2 in.
 - c. 25 gauge, 1½ in.
 - d. 22 gauge, 1 in.

Rationale

Correct answer: d.

Answer (d) is correct. The client is 5 ft 6 in. tall and only weighs 118 lb, which indicates that the client is probably slender without excess body fat. A 22-gauge needle is the normal size gauge for medications that are not viscous, and a 1-in. needle should be the correct length for the client's body built. Answer (a) is incorrect because the 27 gauge is too small for an intramuscular injection. Answer (b) is incorrect because the length of 2 in. is too long for this client's height and weight indicators. Answer (c) is incorrect because the gauge is too small for an intramuscular injection and the length is too long for this client's height and weight indicators.

37. Which of the following rights do clients have in regard to medication? The right to
- know the names of the other clients on the hall.
 - refuse medication and know the names of their medication.
 - information concerning side effects of the medications they are taking at home only.
 - know all of the medication that the nurse administers to all the clients.

Rationale

Correct answer: b.

Answer (b) is correct. Clients have the right to know the names, doses, adverse effects, contraindications, indications, etc. of all their medications and they have the right to refuse medication. Answer (a) is incorrect because it violates client confidentiality in most institutions. Answer (c) is incorrect only because it indicates "at home only" in the answer. Answer (d) is incorrect because it violates the rights of other clients.

38. What direction should the nurse give to a client in regard to the use of NSAIDs prior to scheduled surgery?
- Take as usual as long as recommended dose is not exceeded.

- Do not take after midnight the day of surgery.
- Gradually taper to zero during the week prior to surgery.
- Discontinue 7 days prior to elective surgery.

Rationale

Correct answer: d.

Answer (d) is correct. NSAIDs should be discontinued 1 week prior to elective surgery because of their anticlotting effect.

39. The nurse should instruct the client taking an antilipemic about the regular need for which type of examination?
- Colonoscopy
 - Dental
 - Ophthalmic
 - Hearing

Rationale

Correct answer: c.

Answer (c) is correct. An association has been found between the use of antilipemics and the development of cataracts so regular eye examinations are recommended. Antilipemics are not known to affect the large bowel, teeth, or hearing.

40. Which question should be asked of a young adult female for whom penicillin has been ordered?
- Do you drink milk?
 - Are you allergic to shellfish?
 - Do you take birth control pills?
 - Have you ever had vaginitis?

Rationale

Correct answer: c.

Answer (c) is correct. Penicillin can inhibit the effectiveness of oral contraceptives so a backup form of birth control is needed when taking penicillin.

Test Plan Category:

Physiological Integrity

Sub-category: Pharmacological and Parenteral Therapies—Part 2

Topics: Parenteral/Intravenous Therapy
Central Venous Access Devices
Blood and Blood Products
Total Parenteral Nutrition

| | | | |
|----------------------------|-----|---------------------------|-----|
| ▸ Blood and Blood Products | 445 | ▸ Parenteral Nutrition | 444 |
| ▸ Intravenous Therapy | 439 | ▸ Vascular Access Devices | 440 |

INTRAVENOUS THERAPY

INDICATIONS FOR INTRAVENOUS THERAPY

- Administer intravenous medications
- Maintain fluid volume and electrolyte balance
- Replace fluid volume and electrolyte losses
- Provide nutritional support

ADVANTAGES OF INTRAVENOUS THERAPY

- Faster absorption and distribution of drugs and fluids
- Provision of access route for a client who is unconscious, NPO
- Provision of access route for delivery of medications and fluids in an emergency
- Administration of medications that are only available in intravenous parenteral form

DISADVANTAGES OF PARENTERAL THERAPY

- Potential for local and systemic complications
- Allergic reaction to a medication, fluid product
- Hypervolemia
- Painful for client

LOCAL COMPLICATIONS OF INTRAVENOUS THERAPY

- Phlebitis: inflammation of vein causing pain at site, redness, and heat along the length of vein
- Thrombosis: blood clot inside vein causing the infusion to slow or stop, swelling, tenderness, redness, and heat along the vein
- Infiltration: leaking of intravenous fluid or medication into the extravascular tissue causing edema and coolness at or above the insertion site

- Infection of site: caused by invasion of microorganisms and site may be warm, red, swollen, and painful
- Extravasation: caused by the leakage of a vesicant substance into the extravascular tissue. Edema and coolness are signs of extravasation at or above the insertion site

Think Smart/Test Smart

In the above list of local complications of intravenous therapy, signs and symptoms of the complications are presented with slightly different, but interchangeable wordings, any of which might be used as part of an NCLEX-RN test question. For example, it states that “infiltration causes edema and coolness at or above the insertion site.” This could have been stated as “edema and coolness are signs of infiltration” or “edema and coolness occur at or above the site.”

When testing knowledge of these facts, ways to ask questions include

When assessing an IV site for infiltration, for which signs would the nurse observe?

When assessing an IV site, the nurse notes the area above the site is swollen and cool. How should the nurse interpret this assessment data?

SYSTEMIC COMPLICATIONS OF INTRAVENOUS THERAPY

- Circulatory overload: Excess circulating fluid caused by fluids infusing at a faster rate than client can accommodate.
 - Assess for shortness of breath, increased respiratory and heart rate, elevated blood pressure, edema, and distended jugular veins.
- Allergic reaction: Client may be allergic to medication, intravenous solution, or intravenous catheter.
- Sepsis: Caused by microorganisms entering the circulatory system.
 - Assess for chills, fever, tachycardia, hypotension, change in level of consciousness, and leukocytosis.
- Catheter embolism caused by a piece of the catheter breaking off and entering the circulation.
 - Assess for pain along the vein, hypotension, weak, rapid pulse, a change in level of consciousness.

VASCULAR ACCESS DEVICES

SHORT PERIPHERAL CATHETER

- It is inserted into veins of the hand and forearm of adults: dorsal, and basilic, cephalic
- Three fourths of an inch to 1¼ inch in length, 14–26 gauge
- Rotation to different sites after 72 hours
- Use 18 gauge for blood administration

MIDLINE CATHETER

- It is inserted through the basilic vein at the antecubital area, with catheter tip located in the upper arm at the axilla level
- 6–8 inch in length, single, double, and triple lumens
- Rotation to different sites after 3–4 weeks
- It is used for clients who will receive intravenous medications over several weeks

PERIPHERALLY INSERTED CENTRAL VENOUS ACCESS DEVICE

- It is inserted through the basilic or cephalic veins with the catheter tip located in the superior vena cava
- 40–60 cm in length
- Chest X-ray is required prior to use
- Rotation to different sites may not be necessary for months/year
- It is used for clients who receive intravenous medications over a long period of time, and parenteral nutrition

NONTUNNELED CENTRAL VENOUS ACCESS DEVICE

- It is inserted through the jugular or subclavian veins, with the catheter tip located in the superior vena cava

- 15–20 cm in length, double or triple lumens
- Chest X-ray is required prior to use
- It is used for short term, acute situation, not for home care

TUNNELED CENTRAL VENOUS ACCESS DEVICE

- It is surgically inserted with the distal catheter tip located in the superior vena cava and the proximal end is tunneled subcutaneously to an exit site on the client's trunk
- It is used when intravenous therapy is long term and will be used frequently

IMPLANTED PORTS

- Implanted ports are surgically placed in the upper chest or upper arm area with the catheter inserted into the subclavian or internal jugular veins
- Nurse accesses the port using a noncoring needle, therefore, the client may experience discomfort with each access
- It is used when intravenous therapy needs will be long term

CLIENT PREPARATION FOR INTRAVENOUS THERAPY PROCEDURES

Client teaching for self-care

Preinsertion of Catheter

Provide information to the client about

- the physician's order for infusion therapy
- rationale for infusion therapy
- specific type of therapy ordered
- expected time frame therapy may be needed
- validate allergy information with client
- type of catheter, tubing, dressing, and rate controlling device required
- expected location of venipuncture and insertion of catheter
- postinsertion X-ray if a central venous catheter is inserted
- specific type of activity limitations
- signs or symptoms the client should report to the health care provider

Initiation of Intravenous Therapy Using a Peripheral Vascular Access Device

- Review physician's order for intravenous therapy.
- Review client's allergies.
- Review type of fluid and medication to be administered.
- Assess client for history of CVA, mastectomy, orthopedic injuries or surgery, lymphedema, or impaired circulation in area of expected venipuncture. Avoid these areas.
- Introduce yourself to client.
- Identify the correct client by checking the armband against the physician's order and use a second agency approved method of client identification.
- Conduct client education regarding the venipuncture and infusion therapy.
- Gather necessary equipment: vascular access device, tourniquet and dressing kit, intravenous solution and administration tubing if ordered, rate-controlling device if needed.
- Wash hands using approved agency procedure.
- Explain to client what you are doing throughout procedure.
- Provide privacy.
- Assess venipuncture locations and note areas of edema, previous venipunctures, veins that are sclerotic or phlebotic, or any areas of inflammation.
- Apply tourniquet 3–4 inches above the expected insertion site and tighten enough so that only venous, not arterial, blood flow is impeded. Release tourniquet within 4 minutes of application and wait at least 2 minutes before reapplying.
- Use other interventions to locate appropriate vein when needed. Place extremity below the level of the client's heart and apply warm compress, ask client to make a fist or open and close his hand several times.
- After locating an acceptable vein, release tourniquet, prepare supplies and equipment and prep insertion site for venipuncture. Remember to be aware of tape, latex, iodine, or shell fish allergies.
- Set up all the necessary supplies on the overbed table, cut tape to a desired length, open packages of alcohol, povidone-iodine or aqueous chlorhexidine gluconate, gauze, and transparent dressing.
- Apply gloves.
- Reapply the tourniquet to client's extremity.
- Remove the needle cover of over-the-needle catheter and inspect the catheter.
- Anchor the selected vein below the intended insertion site using your thumb and pull the skin taut.
- Hold the vascular access device by the needle hub flash chamber, with the bevel up and insert the needle into the skin at an angle of approximately 20 degrees.

- Observe the flash chamber for a blood return.
- Upon entering the vein and seeing the blood return, lower the device flush to the skin and advance the catheter tip further into the vein.
- Release the tourniquet.
- Remove the needle, and connect the vascular access device to the selected intravenous tubing.
- Secure the catheter and tubing to prevent dislodgement.
- Open the flow clamp to the intravenous solution or flush the catheter with saline solution to check for infiltration.
- Dress the insertion site per agency protocol.
- Discard the needle in the sharps container.
- Remove gloves, discard them properly, and wash hands.
- Label the insertion site with date, time, type and size of device, and your initials.
- Remind client of any activity restrictions, and to report signs and symptoms.
- Inquire if client has any questions or concerns.
- Document on client's medical record: insertion date and time of insertion, the extremity and vein used, type and size of device, the type and rate of solution administered, rate controlling device in use, as well as the client response.

Administration and Monitoring of Intravenous Therapy Using a Peripheral Vascular Access Device

- Review physician's order and select correct solution using the "5 Rights" of medication administration.
- Observe solution for clarity and note integrity of container; do not use if cloudy or otherwise not clear or if seals on container have been broken.
- Accurately calculate and set infusion rate.
- Use electronic infusion device as institution designates, especially important for infants and other clients at risk for fluid overload.
- Apply time-tape to fluid container to assist in monitoring flow rate accuracy.
- Assess flow rate every hour.
- Assess the catheter site for early signs of local reactions: infiltration, phlebitis, thrombosis, infection, and extravasation.
- Assess client for systemic reactions: allergic reactions, circulatory overload, sepsis, and catheter embolism
- Use aseptic techniques when performing venipuncture, applying or changing dressing, changing or accessing tubing, and accessing catheter
- Determine patency of catheter prior to injection of intravenous medications
- Document type of fluid and medication infusions, infusion rate, site assessment, I&O, and client's reaction.
- Document central venous access infusion rate/type/and I&O.

Nursing Intervention Alert

Always monitor intravenous flow rate and infusion site at least every hour.

Assessment Alert

Monitor client for sign of infection at catheter insertion site: redness, swelling, heat, pain, and drainage.

Removal of a Peripherally Inserted Vascular Access Device

- Review physician's order to discontinue intravenous therapy
- Review client's allergies
- Introduce yourself to client
- Identify the correct client by checking the armband against the physician's order and use a second agency approved method of client identification
- Provide information to the client regarding removing the catheter
 - The physician's order to discontinue infusion therapy
 - Rationale for discontinuing the infusion therapy
 - Procedure used to remove the dressing and catheter
 - Expected discomfort associated with procedure
 - Site care after catheter is removed: keep site clean and dry
 - Signs or symptoms the client should report to the health care provider: redness, warmth, discomfort, and drainage
 - Specific type of activity limitations
- Gather necessary supplies
- Wash hands using approved agency procedure
- Explain to client what you are doing throughout procedure
- Provide privacy
- Assess venipuncture location and note areas of edema, veins that are sclerotic or phlebotic, or any areas of inflammation
- Turn off rate controlling device, and clamp intravenous tubing
- Prepare dressing supplies
- Don gloves
- Remove tape, and loosen edges of transparent dressing carefully, using alcohol or adhesive remover if necessary
- Stabilize catheter while removing dressing completely
- Hold gauze over the insertion site while gently removing the catheter: do not pull on catheter if resistance is met
- Inspect catheter to ensure entire catheter has been removed
- Apply pressure to insertion site for 1 minute or until there is no bleeding

- Assess site and apply dressing per agency protocol
- Dispose of device in sharps container
- Remove gloves, discard them properly, and wash hands
- Inquire if client has any questions or concerns
- Document on client's medical record: date and time of removal, the extremity and vein used, type and size of device, condition of catheter upon removal, as well as the client response

Initiation of Intravenous Therapy Using a Centrally Inserted Vascular Access Device

- Review physician's order for intravenous therapy.
- Review client allergies.
- Review type of fluid and medication to be administered.
- Introduce yourself to client.
- Identify the correct client by checking the armband against the physician's order and use a second agency approved method of client identification.
- Conduct client education regarding the venipuncture and infusion therapy. Instruct client that physician may request that he/she perform a Valsalva maneuver at a point during the procedure. Instruct client that he/she will need to take a deep breath, hold it and bear down for 10 seconds when instructed to do so by the physician.
- Gather necessary equipment: central venous access device, insertion and dressing kit, sterile gown, masks, sterile gloves, intravenous solution and administration tubing if ordered, rate-controlling device. Wash hands using approved agency procedure.
- Explain to client what the physician and nurse are doing throughout procedure.
- Provide privacy.
- Apply mask, cap, goggles, gown, and gloves.
- Assist physician during procedure as needed.
- Monitor client's condition during and after catheter insertion.
- Apply dressing per agency protocol.
- Inquire if client has questions or concerns.
- Document the insertion date and time, type, size and length of catheter, the name of physician who inserted the catheter, and the client's response to the procedure.
- Follow physician orders regarding obtaining a preinfusion chest X-ray.
- Monitor client's condition and report results of chest X-ray to the physician.

Administration and Monitoring of Intravenous Therapy Using a Centrally Inserted Vascular Access Device

- Review physician's order and select correct solution using the "5 Rights" of medication administration.

- Explain therapy to client and family.
- Assess client's vital signs, I&O, weight.
- Observe expiration date and clarity of solution.
- Accurately calculate and set infusion rate.
- Administer using an electronic infusion device and monitor rate of infusion every hour. Maintain accurate rate of flow.
- Assess client for systemic reactions: allergic reactions, sepsis, and catheter embolism.
- Identify potential misconnections through risk assessment of all existing catheters.
- As part of the handoff communication, follow standardized "line reconciliation" process.
- Educate all clinical and nonclinical staff about the hazards of misconnecting tubing and devices.
- Maintain aseptic techniques when changing solution, accessing tubing, and dressing.
- Inspect catheter insertion site for redness, swelling, heat, drainage.
- Assess for signs of infection: elevated temperature and WBC, chills, redness at catheter site.
- Document fluid and medication infusions, I&O, and client's reaction.

Removal of a Centrally Inserted Nontunneled Vascular Access Device

- Obtain certification by your agency to perform procedure
- Review physician's order to discontinue the centrally inserted vascular access device intravenous therapy
- Review client allergies
- Introduce yourself to client
- Identify the correct client by checking the armband against the physician's order and use a second agency approved method of client identification
- Conduct client education regarding removing the catheter. Review the Valsalva maneuver with client
- Gather necessary supplies: dressing kit, mask, gloves, suture removal kit
- Wash hands using approved agency procedure
- Explain to client what you are doing throughout the procedure
- Provide privacy
- Assess venipuncture location and note areas of edema, redness, or warmth
- Turn off rate controlling device, and clamp intravenous tubing
- Prepare dressing supplies
- Position the bed in Trendelenburg or flat position, according to agency protocol and client condition
- Don gloves and mask
- Remove tape, and loosen edges of transparent dressing carefully, using alcohol or adhesive remover if necessary

- Stabilize catheter while removing dressing completely
- Cleanse the insertion site and surrounding area with alcohol and povidone-iodine (if client is not allergic)
- Carefully remove sutures
- Hold gauze over the insertion site and ask the client to perform the Valsalva maneuver while gently removing the catheter: do not pull on catheter if resistance is met
- Ask client to breathe normally
- Apply pressure to insertion site for 2 minutes or until there is no bleeding
- Apply dressing per agency protocol, making sure that air can not enter the site area
- Observe catheter for length, integrity, drainage
- Dispose of device in sharps container if catheter is intact and no signs of infection are present
- Remove gloves, discard them properly, and wash hands
- Inquire if client has any questions or concerns
- Document on client's medical record: date and time of removal, type and size of device, condition of catheter upon removal, as well as the client response

RATE-CONTROLLING DEVICES

General Principles for Properly Using a Rate-Controlling Device

- Monitor the client's infusion rate and insertion site carefully during intravenous therapy.
- Be aware that rate-controlling devices may malfunction, therefore, always monitor the client and assess the functioning of the device often.
- Know how to correctly operate the device.
- Understand that controllers use a sensor to count drops, and monitor the flow of the fluid, and they rely on gravity to create fluid flow.

- Be aware that pumps create fluid flow under pressure, and are more accurate than controllers.
- Always respond quickly to an alarm from a rate-controlling device. Never silence the alarm and do not follow up on why the alarm is occurring. Always troubleshoot the device and determine the specific problem quickly.

PARENTERAL FLUIDS

- Normal plasma osmolarity is approximately 290 mOsm/l
- Parenteral fluids with similar characteristics are isotonic
- Parenteral fluids with less than 250 mOsm/l are hypotonic
- Parenteral fluids with greater than 350 mOsm/l are hypertonic

Isotonic Solutions

- 0.9% saline (normal saline)
- 5% dextrose in water (D5W)
- Ringer's lactate
- 5% dextrose in 0.225% saline (D5¹/₄ NS)

Hypotonic Solutions

- 0.45% Saline (¹/₂ NS)

Hypertonic Solutions

- 5% dextrose in 0.9% normal saline (D5NS)
- 5% dextrose in 0.45% normal saline (D5 ¹/₂ NS)
- 5% dextrose in Ringer's lactate (D5 RL)
- 10% dextrose in water (D10W)

PARENTERAL NUTRITION

TOTAL PARENTERAL NUTRITION

Solutions may contain

- Dextrose
- Amino acids
- Trace elements
- Vitamins and minerals
- Emulsified fats
- Heparin, insulin, and other medications specific for client

TYPES OF PARENTERAL NUTRITION

Peripherally Administered Parenteral Nutrition

- It is infused through a peripheral venous catheter
- Ten percent dextrose solution with vitamins, minerals, trace elements, and electrolytes added
- 10% or 20% lipid emulsions

Centrally Administered Parenteral Nutrition

- It is infused through a central venous access device
- Greater than 10% dextrose solution with vitamins, minerals, trace elements, electrolytes, and insulin added
- 10–20% lipid emulsions

INDICATIONS FOR TOTAL PARENTERAL NUTRITION (TPN THERAPY)

- Inadequate oral intake or need for NPO status for extended period of time
- Increased metabolic needs
- Bowel obstruction
- Inflammatory bowel disease and related intestinal disorders
- Radiation enteritis
- Preterm or newborn infants who require surgery
- Severe malnutrition disorders

MONITORING EFFECTS OF TOTAL PARENTERAL NUTRITION THERAPY: NURSING IMPLICATIONS

- Explain therapy to client and family.
- Assess nutritional status, daily weights, vital signs, and I&O.
- Assess for signs of infection: elevated temperature and WBC, chills, redness, edema, warmth, and drainage at catheter site.
- Monitor electrolyte levels/assess for signs of electrolyte imbalances.
- Assess oral mucosa and provide frequent mouth care.
- Compare solution contents with those listed in the physician's order.
- Check expiration date and clarity of TPN solution; do not use if expired or cloudy.

- Administer using an electronic infusion device and monitor rate of infusion every hour. Maintain accurate rate of flow. Do not try to “catch up” solution if infusion rate was slower than intended.
- Keep solution cold, warm to room temperature before administering.
- Discontinue use of any solution not infused within 24 hours.

Assessment Alert

Monitor client's blood glucose levels every 6 hours, or as designated by the institutional policy.

- Administer insulin as ordered; may be needed because of the large amount of glucose in the TPN solution.
- Do not stop TPN suddenly due to high glucose content; if TPN administration is interrupted, give 5–10% dextrose to prevent hypoglycemia.
- Maintain aseptic technique when changing solution and tubing every 24 hours and dressing every 24 hours if using gauze or every 48–72 hours per agency policy.
- Position client flat when changing dressing and tubing.
- Tape connections securely.
- Assess for symptoms of hyperglycemia: weakness, headache, thirst, nausea, and fast respirations.
- Assess for complications: fluid overload, especially in the elderly, air embolism, osmotic diuresis or shifts of electrolytes caused by high glucose formulas.
- Monitor for pneumothorax, hemothorax or injury to brachial plexus due to insertion of central venous catheter.
- Encourage client activities.
- If needed, teach client/caregiver about administration of TPN, for example, hand washing, care of equipment, aseptic technique and provide a 24-hour phone number to call for any problems.

BLOOD AND BLOOD PRODUCTS

WHOLE BLOOD

- It is administered in incidents such as acute hemorrhage where a client has lost greater than 25% of their total blood volume
- Volume for transfusion is approximately 450–500 ml

PACKED RED BLOOD CELLS (PRBCs) AND FROZEN RED CELLS

- PRBCs and frozen RBCs are administered to clients with decreased hemoglobin (usually less than 7) from loss of blood related to trauma or surgery or to clients with con-

ditions that affect red blood cell production who are symptomatic

- Volume of component for transfusion is 250–325 ml per bag
- These are infused within 2–4 hours

PLATELETS

- Platelets are administered to clients with bleeding due to thrombocytopenia or platelet dysfunction, platelet counts less than 20,000 (normal = 150,000–350,000)
- Volume of component for transfusion ranges from 200–300 ml per bag
- Platelets are infused over 15–30 minutes using the designated administration set

FRESH FROZEN PLASMA

- Fresh frozen plasma is administered to clients with clotting disorders who are actively bleeding or at high risk for bleeding
- Volume of component for transfusion is approximately 200 ml
- It is infused immediately after thawing over a 15–30 minute time frame

CRYOPRECIPITATE

- Cryoprecipitate is administered to clients with a decreased fibrinogen levels of less than 100 mg/dl
- Volume of component for transfusion is 10–20 ml per unit
- It is infused in a 15–30 minute time frame

COAGULATION FACTOR CONCENTRATES

Factor VIII

—Factor VIII is administered to clients with hemophilia A (congenital factor VIII deficiency) or von Willebrand's disease who are bleeding or preparing for an invasive procedure

Factor IX

—Factor IX is administered to clients with hemophilia B (Christmas disease), factor IX deficiency who are bleeding or preparing for an invasive procedure

Antithrombin III

—Antithrombin III is administered to clients with a congenital antithrombin III deficiency who have an acute risk of a venous thrombo-embolic event

IMMUNE SERUM GLOBULINS

- Nonspecific immune serum globulins are administered to prevent infection in clients with
 - poorly functioning immune systems: HIV infection
 - chronic lymphocytic leukemia
 - following bone marrow transplantation
- Specific immune serum globulins are administered to provide immunity prior to or following exposure to disease specific antigens
 - Hepatitis B immune globulin
 - Varicella-zoster immune globulin
 - Rh immune globulin
 - Cytomegalovirus immune globulin
 - Lymphocyte immune globulin

GRANULOCYTES (WHITE CELL)

- Granulocytes are administered to replace WBCs in clients with severe neutropenia and a life threatening infection.
- Volume of component for transfusion is approximately 400 ml of plasma
- These are infused within a 50–60-minute time frame.
- Severe reactions may occur. Monitor vital signs, level of consciousness, and respiratory status every 15 minutes throughout transfusion.

ALBUMIN

- Albumin is administered to clients as an expansion of plasma volume to correct fluid volume deficit
- Replacement of albumin is done for clients with renal or liver disease
- It mobilizes fluid from extravascular tissues back into the intravascular space

BLOOD TYPING AND CROSSMATCHING PRIOR TO TRANSFUSION OF BLOOD

General Principles

- Blood typing and crossmatching must be completed prior to a blood transfusion
- The physician will order the client's blood to be typed and crossmatched and a specimen will be drawn from the client and sent to the lab for testing and comparison with donor blood
- Typing is a process that determines the blood type (A, B, AB, O)

- Crossmatching is a process that correctly matches compatibilities between the blood types of the recipient and the donor
- Individuals with type O blood are considered “universal donors”, but may only receive type O blood
- Clients with type A should only receive type A blood, but may receive type O in an emergency
- Clients with type B should only receive type B blood, but may receive type O in an emergency
- Clients with type AB blood are “universal recipients: and should only receive type AB blood but may, in an emergency, receive all four types of blood.
- Clients who have Rh-positive blood may receive a transfusion from an Rh-positive or Rh-negative donor
- Clients with Rh-negative blood should not receive Rh-positive blood
- Blood is also tested for the Rh determination, antibodies, HIV, hepatitis, and other viruses

TRANSFUSION REACTIONS

Allergic Transfusion Reaction

- Allergic transfusion reaction is caused by foreign plasma proteins
- Its signs and symptoms may include urticaria, itching, bronchospasm, and anaphylaxis.
- It occurs at anytime during infusion and up to 24 hours after transfusion
- Treatment may include stopping transfusion temporarily and administering antihistamines.

Hemolytic Transfusion Reaction

- Hemolytic transfusion reaction is caused by ABO or Rh incompatibility.
- Its signs and symptoms may include chest or back pain, fever, chills, shortness of breath, headache, change in level of consciousness, and hypotension.
- Treatment includes stopping infusion, send blood component and administration set to the lab, follow the institution’s transfusion reaction protocol for follow-up lab samples, monitoring vital signs and observing client for shock.

Circulatory Overload

- Circulatory overload is caused by fluid volume excess and may be precipitated if blood product is infused too rapidly. Older adults are a high-risk population group for this problem.
- Its signs and symptoms include dyspnea, hypertension, tachycardia, distended jugular veins, and a change in level of consciousness.

- Treatment includes slowing or stopping infusion, administering diuretics, monitoring I&O.

Febrile Transfusion Reaction

- Febrile transfusion reaction is caused by recipient antibodies reacting with white cell antigens in the blood component
- Its signs and symptoms include fever, chills, nausea, vomiting, tachycardia, and hypotension
- Treatment may include stopping the infusion and managing the symptoms

Bacterial Transfusion Reaction

- Bacterial transfusion reaction is caused by bacteria introduced into the component at the time of collection or during processing or storage
- Its signs and symptoms include fever, chills, hypotension, and tachycardia
- Treatment includes immediately stopping the transfusion, following the protocol for transfusion reaction at the institution, blood cultures and broad spectrum antimicrobial agents may be prescribed

Nursing Intervention Alert

Always follow the institution’s policy if a transfusion reaction occurs. There will be a step-by-step protocol to implement.

MONITORING EFFECTS OF BLOOD AND BLOOD PRODUCT ADMINISTRATION: NURSING IMPLICATIONS

Pretransfusion Care

- Assess vital signs, laboratory values.
- Review physician’s order for blood products.
- Perform venipuncture and insert an 18-Ga catheter if peripheral line is required.
- Obtain blood products from blood bank.
- Follow institutional policy for verifying product with another RN, verify client’s name and blood type, and compare product with transfusion record, client’s chart and identification band. Check the expiration date on the component.

Transfusion Care

- Prime the appropriate blood product administration set. Use only 0.9% Normal saline if dilution or piggyback solution is required. Use standard precautions.
- Do not administer any medications using the blood administration tubing while blood is infusing.
- Assess vital signs before beginning the transfusion.
- Determine the infusion rate per hour and gtt/min. During the first 15 minutes, administer the blood component slowly.
- Remain with client during the first 15 minutes of the transfusion and obtain another set of vital signs.
- Place call bell within client's reach and instruct to call if experiencing pain at infusion site, back or chest pain, chills, fever, shortness of breath, or any other concern.
- Document blood component type and unit number, time infusion started, and vital signs.
- Monitor client every 30 minutes throughout transfusion for adverse reactions and obtain vital signs.

Posttransfusion Care

- Assess vital signs
- Assess for adverse reactions
- Discontinue the transfusion using standard precautions
- Document transfusion stop time, vital signs, and assessment finding related to adverse reactions
- Continue to monitor client for delayed adverse reactions

Client Controlled Analgesia (CCA)

Analgesic administered from a pump-controlled syringe attached to an IV line.

Patterns of administration

- Basal rate: small amount of drug administered continually without client action
- Client controlled dosing only: Medication administered only when the client pushes button
- Basal rate plus client dosing: small amount of analgesic administered continually with additional amount given when client pushes the button

Dose

- Total amount of analgesic that can be delivered to the client in a set period of time is determined by the health care provider.
- A "lockout" period prevents the client from getting too much medication too soon even if the button is repeatedly pushed.

Use

Control of acute pain postoperatively or posttrauma; control of chronic pain related to diseases such as cancer and sickle cell crisis.

Nursing Process Elements

- Explain PCA to clients.
- Caution others not to push button for client.
- Allay fears of becoming addicted. Explain that often less medication is taken because medication is given when needed without a wait and pain does not have a chance to become severe.
- Assess for sleepiness and bradypnea, which are signs of overmedication.
- Assess for restlessness and complaints of discomfort, which are signs of insufficient medication.
- Assess for medication side effects including nausea, pruritus, and difficulty urinating.
- Assist client as needed with activities such as changing clothes or getting out of bed.
- Instruct client to report:
 - Excessive sleepiness
 - Vomiting
 - Unmanageable pain
 - Pain, warmth, redness, edema or bleeding of the IV site.
 - Increased blood in the tube going to the pump.
 - No more medication in the pump.

EPIDURAL INFUSION

- Delivery of a local anesthetic and a narcotic analgesic via a computer-controlled pump directly into the epidural space at either a steady rate or in response to client-controlled dosing.
- Blocks impulse transmission in sensory nerves thereby blocking pain as well as heat, cold, and pressure without affecting movement.
- Client may experience transient mild weakness, tingling, or numbness in the tissues below the level of the block.

Use

- Postoperative pain management
- Chronic pain management

Advantages of Epidural Infusion

- Provides more consistent pain management
- Reduces amount of opioid requirement overall

- Decreases client sedation
- Increases client's ability to be active, cough, and deep breathe after surgery

Contraindication

Bleeding problems

Complications of Epidural Infusion

- Infection
- Bleeding at catheter site
- Leakage of cerebral spinal fluid
- Opioid related adverse effect such as respiratory depression, hypotension, urinary retention, constipation

Nursing Process Elements

- Review physician's order and select correct solution using the "5 Rights" of medication administration.
 - Explain therapy to client and family.
 - Assess client's pain level, vital signs, I&O: pain level should be checked on coughing or moving to judge effectiveness of block.
 - Monitor client's respiratory rate and pattern frequently.
 - Assess for signs of urinary retention and constipation.
 - Assess motor power and sedation level.
 - Observe expiration date and clarity of solution.
 - Accurately calculate and set infusions rate.
 - Administer using an electronic infusion device and monitor rate of infusion every hour. Maintain accurate rate of flow.
- Assess client for systemic reactions: allergic reactions, sepsis, and catheter embolism.
 - Identify potential misconnections through risk assessment of all existing catheters.
 - As part of the handoff communication, follow standardized "line reconciliation" process.
 - Educate all clinical and nonclinical staff about the hazards of misconnecting tubing and devices.
 - Maintain aseptic techniques when changing solution, accessing tubing, and dressing.
 - Inspect catheter insertion site for redness, swelling, heat, and drainage.
 - Assess for signs of infection: elevated temperature and WBC, chills, redness at catheter site.
 - Document fluid and medication infusions, I&O, pain assessment, and client's reaction.
 - Position/reposition as needed to prevent skin damage related to impaired sensation.
 - Change position slowly in relation to gravity because of the risk of hypostatic hypotension.
 - Have naloxone (Narcan), sodium chloride 0.9% diluent and injection equipment immediately available (Cox, 2001).

Nursing Intervention Alert

Nurses should follow the "line reconciliation" process by rechecking tubing and catheter connections, tracing all client tubes and catheters to their sources for correct route, and labeling all tubes and catheters at the point(s) of connection.

WORKSHEET

MATCHING QUESTIONS

Match the types of blood product with the specific client condition requiring an infusion of a blood product.

Blood Product

Condition

1. _____ Whole blood

a. Thrombocytopenia

2. _____ Packed red blood cells

b. Client lost > 25% of total blood volume

3. _____ Platelets

c. Fibrinogen levels < 100

4. _____ Cryoprecipitate

d. Hemoglobin < 7

MATCHING QUESTIONS

Match the types of parenteral fluids with the specific category of osmolarity.

| Parenteral Fluid | Category of Osmolarity |
|------------------------------|------------------------|
| 5. _____ D5W | a. Hypertonic |
| 6. _____ 0.45% Normal saline | b. Hypotonic |
| 7. _____ D51/2 Normal saline | c. Isotonic |
| 8. _____ Ringer's lactate | |

MATCHING QUESTIONS

Match the types of intravenous catheters with the site of insertion.

| Types of Catheters | Insertion Sites |
|---|--|
| 9. _____ Midline catheter | a. Surgically inserted with the distal catheter tip located in the superior vena cava and the proximal end tunneled subcutaneously to an exit site on the client's trunk |
| 10. _____ Peripherally inserted central venous catheter | b. Ports are surgically placed in the upper chest or upper arm area with the catheter inserted into the subclavian or internal jugular veins |
| 11. _____ Nontunneled central venous access device | c. Inserted through the basilic vein at the antecubital area, with catheter tip located in the upper arm at the axilla level. |
| 12. _____ Tunneled central venous access device | d. Inserted through the basilic or cephalic veins with the catheter tip located in the superior vena cava |
| 13. _____ Implanted ports | e. Inserted through the jugular or subclavian veins, with the catheter tip located in the superior vena cava. |

MATCHING QUESTIONS

Match the blood types with the blood transfusion products.

| Client's Blood Type | Blood Product for Transfusion |
|---------------------|-------------------------------|
| 14. _____ A | a. B |
| 15. _____ B | b. Rh-negative donor |

- | | |
|-----------------------|----------------------|
| 16. _____ AB | c. O |
| 17. _____ O | d. A |
| 18. _____ Rh-positive | e. Rh-positive donor |
| 19. _____ Rh-negative | f. AB |

MATCHING QUESTIONS

Signs & Symptoms

20. _____ dyspnea, cough
21. _____ chills, fever
22. _____ edema, restlessness
23. _____ nausea, vomiting
24. _____ urticaria
25. _____ bronchospasm

Type of Reaction

- a. Circulatory overload
- b. Pyrogenic (febrile)
- c. Allergic

TRUE & FALSE QUESTIONS

Mark each statement True or False on the line provided. Correct each false statement in the space provided.

- | | | |
|---|----------|----------|
| 1. When inserting a peripheral IV access device, the tourniquet should be applied tightly enough to dilate the vein and suppress arterial blood flow. | _____ | _____ |
| | T | F |
| 2. When entering the skin and cannulating a vein with a vascular access device, the position of the needle is bevel up. | _____ | _____ |
| | T | F |
| 3. For a client who has an allergy to shell fish, the nurse should not use iodine to cleanse the skin prior to an intravenous catheter insertion. | _____ | _____ |
| | T | F |
| 4. When removing an intravenous catheter, the nurse should cover the venipuncture site with an alcohol swab and hold pressure on the site until the bleeding stops. | _____ | _____ |
| | T | F |
| 5. The nurse should monitor the client receiving intravenous fluid every hour or more frequently if needed. | _____ | _____ |
| | T | F |
| 6. Line reconciliation procedure is used when clients have an epidural infusion. | _____ | _____ |
| | T | F |

(continued)

- | | | |
|---|---|---|
| 7. Development of chest and back pain in a client receiving a blood transfusion are symptoms of circulatory overload. | T | F |
| 8. If TPN administration must be interrupted, an infusion of normal saline should be immediately begun. | T | F |
| 9. When priming a blood administration set, 0.9% normal saline should be used if dilution is required. | T | F |
| 10. Clients with type A, B or AB blood may receive type O in an emergency. | T | F |

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. The nurse is preparing to administer an intravenous medication, the best method to correctly identify the client is to _____.
2. The single most important method of preventing the spread of nosocomial infections is _____.
3. Common indications for epidural infusions include _____ and _____.
4. Three advantages of epidural infusions include _____, _____, and _____.
5. Three complications of epidural infusions include _____, _____, and _____.
6. The nurse is documenting the care provided to a client who has an epidural infusion. What type of information would the nurse include in the documentation? _____
7. The physician ordered an intravenous infusion of 1000 ml of D5 1/2 NS to infuse over 8 hours. The drop factor for the administration set is 10 gtt/ml. Calculate the gtt/min. _____
8. The nurse is preparing to administer an intravenous infusion of 500 ml D5W with 20,000 units of heparin. The physician ordered the delivery of 1200 units of heparin per hour. How many milliliters per hour will the nurse administer in order to deliver 1200 units of heparin per hour to the client?
9. After insertion of a central venous access device, the physician will order a _____ prior to beginning infusion of fluid via the catheter.
10. The nurse should follow the "line reconciliation" process by performing the following checks and assessments: _____

11. For how long should the nurse remain with a client when a blood transfusion is started? _____
12. Client preparation for a peripherally inserted vascular access device includes assessing for conditions or situations which may lead to complications. Identify three areas of concern: _____

13. Describe the information the nurse should include in the documentation after removing a peripheral vascular access device. _____

14. How often should blood glucose levels be checked when a client is started on TPN? _____
15. A client receiving a blood transfusion has a shaking chill and complains of back pain. What should be the nurse's first action? _____

APPLICATION QUESTIONS

1. The nurse is preparing to insert a peripheral access device in a client's right lower arm. In order to dilate the veins of that extremity, the nurse asks the client to (Check all that apply)
 - a. elevate his hand above his heart
 - b. open and close his fist several times
 - c. lower his arm below the level of his heart
 - d. remain seated or lying in bed with warm compresses on area for 5–10 minutes
 - e. allow the tourniquet to remain in place for 4 minutes while the nurse examines the arm
2. The client who is receiving an opioid analgesic via an epidural infusion becomes heavily sedated and has a respiratory rate of eight breaths per minute. The nurse anticipates the physician ordering which of the following medications?
 - a. Abacavir (Ziagen)
 - b. Bupivacaine (Marcaine)
 - c. Naloxone (Narcan)
 - d. Oxymorphone (Numorphan)
3. The nurse is preparing to administer morphine sulfate to the client for complaints of postoperative pain. The most important nursing assessment to perform prior to administering the medication would be to
 - a. Assess respiratory rate and pattern
 - b. Assess for urinary output and edema
 - c. Assess capillary refill and skin color
 - d. Assess pain level and cranial nerve # 1
4. The nurse is transcribing the physician orders and has difficulty reading one of the entries. The best action of the nurse is to
 - a. clarify the order with another nurse
 - b. call the physician who wrote the order and ask for clarification
 - c. ask the pharmacist for clarification
 - d. refer the matter to the Charge Nurse
5. The physician orders an infusion of 1000 ml of D5 1/4 NS to be infused at 50 ml/hr. The nurse begins the infusion at 0700. What time will the infusion be completed?
 - a. 1100
 - b. 1700
 - c. 0100
 - d. 0300
6. The physician ordered an antibiotic to be administered to the client and the pharmacy prepared the medication in a solution of 50 ml NS. The medication solution should be administered over a 20-minute period of time. The rate controlling device the nurse
 - a. Assess respiratory rate and pattern
 - b. Assess for urinary output and edema
 - c. Assess capillary refill and skin color
 - d. Assess pain level and cranial nerve # 1

(continued)

- will be using has to be programmed in ml/hr. At how many milliliters per hour will the nurse set the rate-controller device in order to administer the medication in 20 minutes?
- 50 ml/hr
 - 100 ml/hr
 - 150 ml/hr
 - 200 ml/hr
7. The client is receiving an intravenous solution and may be experiencing a hypersensitivity reaction. Which of the following actions by the nurse is correct?
- Stop the infusion, discontinue the IV, and observe the client carefully
 - Slow the infusion to 30 ml/hr, assess the client, and call the physician
 - Slow the infusion to 30 ml/hr, administer an antihistamine, and call the physician
 - Stop the infusion, keep the vein open with NS at 30 ml/hr, assess the client, and call the physician.
8. When monitoring clients who are receiving intravenous infusions, the nurse should include which of the following interventions in the plan of care? (Check all that apply)
- Monitor all clients receiving intravenous solutions for circulatory overload: assess for rapid heart rate, dyspnea, cough, restlessness, and edema
 - Monitor all client receiving intravenous fluids for pyrogenic reactions: chills, fever, nausea, and vomiting
 - Throughout the infusion, monitor client for signs of infiltration and phlebitis
 - Monitor vital signs every 4 hours or more frequently, noting signs of orthostatic hypotension
 - Assess jugular vein distention, capillary refill, and heart and lung sounds
 - Monitor urinary output, daily weight, trends in weight loss or gain, edema, or signs of dehydration
9. When preparing a client for a blood transfusion, the nurse should consider for which of the following? (Check all that apply)
- Blood typing and crossmatching must be completed prior to a blood transfusion
 - Clients with type A should only receive type A blood, but may receive type O in an emergency
 - Clients with type B should only receive type B blood, but may receive type A in an emergency
 - Clients with type AB blood are “universal recipients: and should only receive type AB blood but may, in an emergency, receive all four types of blood
10. The nurse is preparing to remove a central venous catheter and identifies which of the following interventions as appropriate care: (Check all that apply)
- Position the bed in Trendelenburg or flat position, according to agency protocol and client condition
 - Review the Valsalva maneuver with client
 - Cleanse the insertion site and surrounding area with alcohol and povidone-iodine (if client is not allergic)
 - Carefully remove sutures
 - Document on client’s medical record: date and time of removal, type and size of device, condition of catheter upon removal, as well as the client response
11. The physician orders fluconazole (Diflucan) 100 mg per mouth. The oral solution has 200 mg/5 ml. How many milliliters should the nurse administer?
- 2.5 ml
 - 5 ml
 - 7.5 ml
 - 10 ml
12. Digoxin (Lanoxin) 0.125 mg by the intravenous route has been ordered for a client with atrial fibrillation. The client’s potassium level is 3.1. The digoxin (Lanoxin) is available in a dose of 0.5 mg/2 ml. Which of the following actions by the nurse is appropriate?
- Administer 0.5 ml and call the physician about the hyperkalemia
 - Administer 1 ml and call the physician about the hypokalemia
 - Administer 0.125 ml and call the physician about the hyperkalemia
 - Hold the digoxin and call the physician about the client’s hypokalemia
13. Indications for Intravenous Therapy include: (Check all that apply)
- Administer intravenous medications
 - Maintain fluid volume and electrolyte balance
 - Replace fluid volume and electrolyte losses
 - Provide nutritional support
14. Which of the following is correct about the administration of whole blood?
- Administered in incidents such as acute hemorrhage where a client has lost greater than 25% of total blood volume

- b. Volume of component for transfusion is 250–325 ml per bag
 - c. Administered to clients with bleeding due to thrombocytopenia or platelet dysfunction, platelet counts less than 20,000 (normal = 150,000–350,000)
 - d. Administered to clients with clotting disorders who are actively bleeding or at high risk for bleeding
15. Which of the following is correct with regards to the administration of cryoprecipitate?
- a. Administered to clients with a decreased fibrinogen level of less than 100 mg/dl
 - b. Administered to clients with hemophilia A (congenital factor VIII deficiency) or von Willebrand's disease who are bleeding or preparing for an invasive procedure
 - c. Administered to clients with hemophilia B (Christmas disease), factor IX deficiency who are bleeding or preparing for an invasive procedure
 - d. Administered to clients with a congenital antithrombin III deficiency who have an acute risk of a venous thrombo-embolic event
16. A hemolytic transfusion reaction is caused by
- a. Fluid volume excess and may be precipitated if blood product is infused too rapidly.
 - b. ABO or Rh incompatibility
 - c. Recipient antibodies reacting with white cell antigens in the blood component
 - d. Bacteria introduced into the component at the time of collection or during processing or storage
17. The nurse should monitor the client every hour or more frequently when the client is receiving an intravenous infusion. The complication of circulatory overload may cause the following symptoms:
- a. Less than 2 second capillary refill, headache, and hypertension
 - b. Edema, decreased urinary output, increased respiratory rate, and hypotension
 - c. Shortness of breath, increased respiratory and heart rate, hypertension, edema, and distended jugular veins
 - d. Decreased level of consciousness, edema, hypotension, and dilated pupils
18. When providing care for a client with a tunneled central venous access device, the nurse is aware that the catheter is
- a. inserted through the jugular or subclavian veins, with the catheter tip located in the superior vena cava
 - b. surgically inserted with the distal catheter tip located in the superior vena cava and the proximal end tunneled subcutaneously to an exit site on the client's trunk
 - c. inserted through the basilic or cephalic veins with the catheter tip located in the superior vena cava
 - d. inserted through the basilic vein at the antecubital area, with catheter tip located in the upper arm at the axilla level
19. Indications for TPN therapy include which of the following conditions? (Check all that apply)
- a. Inadequate oral intake or need for NPO status for extended period of time
 - b. Increased metabolic needs
 - c. Bowel obstruction
 - d. Inflammatory bowel disease and related intestinal disorders
 - e. 2-day episode of nausea, vomiting, and diarrhea
 - f. Preterm or newborn infants who require surgery
 - g. Severe malnutrition disorders
20. Peripherally administered parenteral nutrition may be
- a. infused through a peripheral venous catheter and contain 10% dextrose solution with vitamins, minerals, trace elements, and electrolytes added
 - b. infused through a central venous access device and contain greater than 10% dextrose solution with vitamins, minerals, trace elements, electrolytes, and insulin added
 - c. infused through a venous access device and contain greater than 20% dextrose solution with vitamins, trace elements, and insulin added
 - d. infused through a 20-Ga angiocath in the basilic vein and contain 5% dextrose solution and potassium 20 mEq
21. The physician orders 1000 ml D5 $\frac{1}{4}$ NS with Potassium 40 mEq to be administered over 8 hours. The administration set has a drop factor of 15 gtt/ml. How many milliliters per hour and drops per minute should the nurse administer this infusion?
- a. 100 ml/hr, 25 gtt/min
 - b. 100 ml/hr, 31 gtt/min
 - c. 125 ml/hr, 38 gtt/min
 - d. 125 ml/hr, 31 gtt/min
22. The physician orders ampicillin (Ampicin) 500 mg in 100 ml D5W to infuse over 30 minutes. The nurse sets the rate controller device to deliver the medication

(continued)

- over 30 minutes. The rate controller device must be set at how many milliliters per hour?
- 50 ml/hr
 - 100 ml/hr
 - 150 ml/hr
 - 200 ml/hr
23. When providing care for a client who is receiving peripherally administered parenteral nutrition, the nurse includes which of the following in the plan of care: (Check all that apply)
- Assess the catheter insertion site for redness, swelling, heat, and drainage.
 - Assess nutritional status, daily weights, vital signs, and intake and output ratio
 - Administer 20% dextrose solution with vitamins, minerals, trace elements, and electrolytes added
 - Assess for signs of infection: elevated temperature and white blood cell count, chills, and redness at catheter site
 - Maintain accurate rate of flow and complete entire infusion on time increasing rate to “catch up” if necessary
 - Maintain aseptic techniques when changing solution and tubing every 24 hours
24. The physician has ordered a transfusion of packed red blood cells to your client. Which of the following actions should be included to provide safe care during the transfusion? (Check all that apply)
- Use only 0.45% normal saline to prime the tubing or dilute the blood products
 - Assess vital signs before beginning the transfusion, 15 minutes after beginning the infusion, and every 30 minutes to 1 hour during transfusion.
 - Flush tubing with normal saline to administer intravenous medications throughout transfusion
 - Place call bell within client’s reach, instruct client to call if experiencing shortness of breath, and request that the nurse aide remain with the client during the first 15 minutes of the transfusion
 - Monitor client every 30 minutes throughout transfusion for adverse reactions and assessment of vital signs
25. The client has had a peripheral intravenous device in the left hand for three days. The nurse’s assessment for local complications of intravenous therapy includes which of the following? (Check all that apply)
- Phlebitis
 - Thrombosis
 - Circulatory overload
 - Allergic reaction to medications
 - Infiltration
 - Infection at catheter site
 - Extravasation

ANSWERS & RATIONALES

MATCHING ANSWERS

Blood Product

- b Whole blood
- d Packed red blood cells
- a Platelets
- c Cryoprecipitate

Parenteral Fluid

- c D5W

Condition

- Thrombocytopenia
- Client lost > 25% of total blood volume
- Fibrinogen levels < 100
- Hemoglobin < 7

Category of Osmolarity

- Hypertonic

6. b 0.45% normal saline

7. a D51/2 normal saline

8. a Ringer's lactate

Types of Catheters

9. a Midline catheter

10. d Peripherally inserted central venous catheter

11. e Nontunneled central venous access device

12. a Tunneled central venous access device

13. b Implanted ports

Client's Blood Type

14. d, c A

15. a, c B

16. a, f, c, d AB

17. c O

18. b, e Rh-positive

19. b Rh-negative

Signs & Symptoms

20. a dyspnea, cough

21. b chills, fever

22. a edema, restlessness

23. b nausea, vomiting

24. c urticaria

25. c bronchospasm

b. Hypotonic

c. Isotonic

Insertion Sites

a. Surgically inserted with the distal catheter tip located in the superior vena cava and the proximal end tunneled subcutaneously to an exit site on the client's trunk

b. Ports are surgically placed in the upper chest or upper arm area with the catheter inserted into the subclavian or internal jugular veins

c. Inserted through the basilic vein at the antecubital area, with catheter tip located in the upper arm at the axilla level.

d. Inserted through the basilic or cephalic veins with the catheter tip located in the superior vena cava

e. Inserted through the jugular or subclavian veins, with the catheter tip located in the superior vena cava.

Blood Product for Transfusion

a. B

b. Rh-negative donor

c. O

d. A

e. Rh-positive donor

f. AB

Type of Reaction

a. Circulatory overload

b. Pyrogenic (febrile)

c. Allergic

TRUE & FALSE ANSWERS

1. When inserting a peripheral IV access device, the tourniquet should be applied tightly enough to dilate the vein and suppress arterial blood flow. *True*
2. When entering the skin and cannulating a vein with a vascular access device, the position of the needle is beveled up. *True*
3. For a client who has an allergy to shell fish, the nurse should not use iodine to cleanse the skin prior to an intravenous catheter insertion. *True*
4. When removing an intravenous catheter, the nurse should cover the venipuncture site with an alcohol swab and hold pressure on the site until the bleeding stops. *False*
When removing an intravenous catheter, the nurse should cover the venipuncture site with a gauze pad and hold pressure on the site until the bleeding stops.
5. The nurse should monitor the client receiving intravenous fluid every hour or more frequently if needed. *True*
6. Line reconciliation procedure is used when clients have an epidural infusion. *True*
7. Development of chest and back pain in a client receiving a blood transfusion are symptoms of circulatory overload. *False*
Development of chest and back pain in a client receiving a blood transfusion are symptoms of a hemolytic reaction; signs and symptoms of circulatory overload include dyspnea, hypertension, tachycardia, distended jugular veins, and a change in level of consciousness.
8. If TPN administration must be interrupted, an infusion of normal saline should be immediately begun. *False*
If TPN administration must be interrupted, an infusion of 5–10% dextrose is given to prevent hypoglycemia.
9. When priming a blood administration set, 0.9% normal saline should be used if dilution is required. *True*
10. Clients with type A, B, or AB blood may receive type O in an emergency. *True*

ANSWERS FOR FILL IN THE BLANKS

1. The nurse is preparing to administer an intravenous medication, the best method to correctly identify the client is to compare the name and number on client's identification band with the name and number on his medical record.
2. The single most important method of preventing the spread of nosocomial infections is proper hand washing.
3. Common indications for epidural infusions include postoperative pain management and chronic pain management.
4. Three advantages of epidural infusions include: provides more consistent pain management, reduces amount of opioid requirement overall, decreases client sedation, and increases client's ability to be active, cough, and deep breathe after surgery.
5. Three complications of epidural infusions include: infection, bleeding at catheter site, and leakage of cerebral spinal fluid, opioid related adverse effect such as respiratory depression, hypotension, urinary retention, constipation.

6. The nurse is documenting the care provided to a client who has an epidural infusion. What type of information would the nurse include in the documentation?
Document fluid and medication infusions, i& o, pain assessment, and client's reaction.
7. The physician ordered an intravenous infusion of 1000 ml of D5 1/2 NS to infuse over 8 hours. The drop factor for the administration set is 10 gtt/ml. Calculate the gtt/min. Answer: 21 gtt/min.
8. The nurse is preparing to administer an intravenous infusion of 500 ml D5W with 20,000 units of heparin. The physician ordered the delivery of 1200 units of heparin per hour. How many milliliters per hour will the nurse administer in order to deliver 1200 units of heparin per hour to the client? Answer: 30 ml/hr.
9. After insertion of a central venous access device, the physician will order a chest X-ray prior to beginning infusion of fluid via the catheter.
10. The nurse should follow the “line reconciliation” process by performing the following checks and assessments: rechecking tubing and catheter connections, tracing all client tubes and catheters to their sources for correct route, and labeling all tubes and catheters at the point(s) of connection.
11. For how long should the nurse remain with a client when a blood transfusion is started? Answer: 15 minutes.
12. Client preparation for a peripherally inserted vascular access device includes assessing for conditions or situations which may lead to complications. Identify three areas of concern: Assess client for history of cva, mastectomy, orthopedic injuries or surgery, lymphedema, or impaired circulation in area of expected venipuncture.
13. Describe the information the nurse should include in the documentation after removing a peripheral vascular access device: Document on client's medical record: date and time of removal, the extremity and vein used, type and size of device, condition of catheter upon removal, as well as the client response.
14. How often should blood glucose levels be checked when a client is started on TPN? Answer: Every 6 hours or as required by agency policy.
15. A client receiving a blood transfusion has a shaking chill and complains of back pain. What should be the nurse's first action? Answer: Discontinue the transfusion keeping the line open with normal saline.

APPLICATION ANSWERS

1. The nurse is preparing to insert a peripheral access device in a client's right lower arm. In order to dilate the veins of that extremity, the nurse asks the client to: (Check all that apply)
 - a. elevate his hand above his heart
 - b. open and close his fist several times
 - c. lower his arm below the level of his heart
 - d. remain seated or lying in bed with warm compresses on area for 5–10 minutes
 - e. allow the tourniquet to remain in place for 4 minutes while the nurse examines the arm

Rationale

Correct answers: b, c, d, and e.

These answers are interventions used to dilate veins. Answer a is incorrect because raising the hand above the heart will not dilate the veins.

2. The client who is receiving an opioid analgesic via an epidural infusion becomes heavily sedated and has a respiratory rate of eight breaths per minute. The nurse anticipates the physician ordering which of the following medications?
 - a. abacavir (Ziagen)

(continued)

- b. bupivacaine (Marcaine)
- c. naloxone (Narcan)
- d. oxymorphone (Numorphan)

Rationale

Correct answer: c.

Answer c is correct because Narcan is an antidote for opioids and reverses CNS depression and respiratory depression related to opioid overdosage. a, b, and d are not opioid reversal agents.

3. The nurse is preparing to administer morphine sulfate to the client for complaints of postoperative pain. The most important nursing assessment to perform prior to administering the medication would be to
- a. assess respiratory rate and pattern
 - b. assess for urinary output and edema
 - c. assess capillary refill and skin color
 - d. assess pain level and cranial nerve # 1

Rationale

Correct answer: a.

Answer a is correct because morphine sulfate is an opioid analgesic which depresses respiratory rate. Answers b, c, and d are not assessment findings which are directly related to the effects of morphine sulfate.

4. The nurse is transcribing the physician orders and has difficulty reading one of the entries. The best action of the nurse is to
- a. clarify the order with another nurse
 - b. call the physician who wrote the order and ask for clarification
 - c. ask the pharmacist for clarification
 - d. refer the matter to the Charge Nurse

Rationale

Correct answer: b.

Answer b is correct. Always clarify the orders with the physician who wrote the orders. Answers a, c, and d are incorrect—these people did not write the order and thus are not the best people to clarify the order.

5. The physician orders an infusion of 1000 ml of D5 1/4 NS to be infused at 50 ml/hr. The nurse begins the infusion at 0700. What time will the infusion be completed?
- a. 1100
 - b. 1700
 - c. 0100
 - d. 0300

Rationale

Correct answer: d.

Answer d is because 1000 ml of solution will take 20 hours to infuse at 50 ml/hour.

6. The physician ordered an antibiotic to be administered to the client and the pharmacy prepared the medication in a solution of 50 ml NS. The medication solution should be administered over a 20 minute period of time. The rate controlling device the nurse will be using has to be programmed in ml/hr. At how many milliliters per hour will the nurse set the rate-controller device in order to administer the medication in 20 minutes?
- a. 50 ml/hour
 - b. 100 ml/hour
 - c. 150 ml/hour
 - d. 200 ml/hour

Rationale

Correct answer: c.

Answer c is correct. The solution will have to infuse at a rate of 150 ml/hour to instill 50 ml over the 20 minutes.

7. The client is receiving an intravenous solution and may be experiencing a hypersensitivity reaction. Which of the following actions by the nurse is correct?
- a. Stop the infusion, discontinue the IV, and observe the client carefully
 - b. Slow the infusion to 30 ml/hr, assess the client, and call the physician
 - c. Slow the infusion to 30 ml/hr, administer an antihistamine, and call the physician
 - d. Stop the infusion, keep the vein open with NS at 30 ml/hr, assess the client, and call the physician.

Rationale

Correct answer: d.

Answer d is correct. The client may be experiencing a reaction to the solution, therefore, the nurse stops that solution, but maintains intravenous access with an infusion of NS. Assessing the client and calling the physician are standard procedures for safe care.

8. When monitoring clients who are receiving intravenous infusions, the nurse should include which of the following interventions in the plan of care? (Check all that apply)
- a. Monitor all clients receiving intravenous solutions for circulatory overload: assess for rapid heart rate, dyspnea, cough, restlessness, and edema
 - b. Monitor all client receiving intravenous fluids for pyrogenic reactions: chills, fever, nausea, and vomiting
 - c. Throughout the infusion, monitor client for signs of infiltration and phlebitis
 - d. Monitor vital signs every 4 hours or more frequently, noting signs of orthostatic hypotension

- e. Assess jugular vein distention, capillary refill, and heart and lung sounds
- f. Monitor urinary output, daily weight, trends in weight loss or gain, edema, or signs of dehydration

Rationale

Correct answer: All answers are correct..

All answers are correct. All of these assessments are important when providing care for a client receiving intravenous therapy.

9. When preparing a client for a blood transfusion, the nurse should consider for which of the following? (Check all that apply)
- a. Blood typing and crossmatching must be completed prior to a blood transfusion
 - b. Clients with type A should only receive type A blood, but may receive type O in an emergency
 - c. Clients with type B should only receive type B blood, but may receive type A in an emergency
 - d. Clients with type AB blood are “universal recipients: and should only receive type AB blood but may, in an emergency, receive all four types of blood

Rationale

Correct answers: a, b, and d.

Answers a, b, d are correct. Answer c is incorrect because clients with type B blood may only receive types B and O.

10. The nurse is preparing to remove a central venous catheter and identifies which of the following interventions as appropriate care: (Check all that apply)
- a. Position the bed in Trendelenburg or flat position, according to agency protocol and client condition
 - b. Review the Valsalva maneuver with client
 - c. Cleanse the insertion site and surrounding area with alcohol and povidone-iodine (if client is not allergic)
 - d. Carefully remove sutures
 - e. Document on client's medical record: date and time of removal, type and size of device, condition of catheter upon removal, as well as the client response

Rationale

Correct answer: All answers are correct..

11. The physician orders fluconazole (Diflucan) 100 mg per mouth. The oral solution has 200 mg/5 ml. How many milliliters should the nurse administer?
- a. 2.5 ml
 - b. 5 ml

- c. 7.5 ml
- d. 10 ml

Rationale

Correct answer: a.

Answer a is correct. The ratio of 200 mg per 5 ml yields a dose of 100 mg per 2.5 ml

12. Digoxin (Lanoxin) 0.125 mg by the intravenous route has been ordered for a client with atrial fibrillation. The client's potassium level is 3.1. The digoxin (Lanoxin) is available in a dose of 0.5 mg/2 ml. Which of the following actions by the nurse is appropriate?
- a. Administer 0.5 ml and call the physician about the hyperkalemia
 - b. Administer 1 ml and call the physician about the hypokalemia
 - c. Administer 0.125 ml and call the physician about the hyperkalemia
 - d. Hold the digoxin and call the physician about the client's hypokalemia

Rationale

Correct answer: d.

Answer d is correct. The potassium level is too low to administer digoxin. Hypokalemia places the client at a higher risk for digoxin toxicity.

13. Indications for Intravenous Therapy include: (Check all that apply)
- a. Administer intravenous medications
 - b. Maintain fluid volume and electrolyte balance
 - c. Replace fluid volume and electrolyte losses
 - d. Provide nutritional support

Rationale

Correct answers: a, b, c, and d.

Answers a, b, c, and d are correct.

14. Which of the following is correct about the administration of whole blood?
- a. Administered in incidents such as acute hemorrhage where a client has lost greater than 25% of total blood volume
 - b. Volume of component for transfusion is 250–325 ml per bag
 - c. Administered to clients with bleeding due to thrombocytopenia or platelet dysfunction, platelet counts less than 20,000 (normal = 150,000–350,000)
 - d. Administered to clients with clotting disorders who are actively bleeding or at high risk for bleeding

(continued)

Rationale

Correct answer: a.

Answer a is correct. Answer b is incorrect because the volume is not enough. Whole blood is usually about 450–500 ml. Answer c is incorrect because it is describing the purpose of platelet administration. Answer d is incorrect because it is describing when it is appropriate to administer fresh frozen plasma.

15. Which of the following is correct with regard to the administration of cryoprecipitate?
- Administered to clients with a decreased fibrinogen level of less than 100 mg/dl
 - Administered to clients with hemophilia A (congenital factor VIII deficiency) or von Willebrand's disease who are bleeding or preparing for an invasive procedure
 - Administered to clients with hemophilia B (Christmas disease), factor IX deficiency who are bleeding or preparing for an invasive procedure
 - Administered to clients with a congenital antithrombin III deficiency who have an acute risk of a venous thrombo-embolic event

Rationale

Correct answer: a.

Answer a is correct. Answer b is incorrect because it describes the conditions for administering Factor VIII. Answer c is incorrect because it describes conditions to administer Factor IX, d is incorrect because it describes the conditions to administer Antithrombin III

16. A hemolytic transfusion reaction is caused by
- Fluid volume excess and may be precipitated if blood product is infused too rapidly.
 - ABO or Rh incompatibility
 - Recipient antibodies reacting with white cell antigens in the blood component
 - Bacteria introduced into the component at the time of collection or during processing or storage

Rationale

Correct answer: b.

Answer b is correct. Answer a is the cause of circulatory overload. Answer c is the cause of febrile transfusion reaction. Answer d is the cause of bacterial transfusion reaction.

17. The nurse should monitor the client every hour or more frequently when the client is receiving an intravenous infusion. The complication of circulatory overload may cause the following symptoms:
- Less than 2 second capillary refill, headache, and hypertension

- Edema, decreased urinary output, increased respiratory rate, and hypotension
- Shortness of breath, increased respiratory and heart rate, hypertension, edema, and distended jugular veins
- Decreased level of consciousness, edema, hypotension, and dilated pupils

Rationale

Correct answer: c.

Answer c is correct. It describes the symptoms associated with circulatory overload.

18. When providing care for a client with a tunneled central venous access device, the nurse is aware that the catheter is
- inserted through the jugular or subclavian veins, with the catheter tip located in the superior vena cava
 - surgically inserted with the distal catheter tip located in the superior vena cava and the proximal end tunneled subcutaneously to an exit site on the client's trunk
 - inserted through the basilic or cephalic veins with the catheter tip located in the superior vena cava
 - inserted through the basilic vein at the antecubital area, with catheter tip located in the upper arm at the axilla level

Rationale

Correct answer: b.

Answer b is correct. Answer a is location for a nontunneled central VAD. Answer c is the location for a peripherally inserted central VAD. Answer d is the location for a midline catheter.

19. Indications for TPN therapy include which of the following conditions? (Check all that apply)
- Inadequate oral intake or need for NPO status for extended period of time
 - Increased metabolic needs
 - Bowel obstruction
 - Inflammatory bowel disease and related intestinal disorders
 - 2 day episode of nausea, vomiting, and diarrhea
 - Preterm or newborn infants who require surgery
 - Severe malnutrition disorders

Rationale

Correct answers: a, b, c, d, f, and g.

Answers a, b, c, d, f, g are correct. Answer e usually does not necessitate TPN, only oral hydration or basic intravenous therapy replacement fluids.

20. Peripherally administered parenteral nutrition may be
- infused through a peripheral venous catheter, and contain 10% dextrose solution with vitamins, minerals, trace elements, and electrolytes added
 - infused through a central venous access device, and contain greater than 10% dextrose solution with vitamins, minerals, trace elements, electrolytes, and insulin added
 - infused through a venous access device and contain greater than 20% dextrose solution with vitamins, trace elements, and insulin added
 - infused through a 20 Ga angiocath in the basilic vein and contain 5% dextrose solution and potassium 20 mEq

Rationale

Correct answer: a.

Answer a is the correct answer. Answer b is describing a centrally administered parenteral nutrition. Answer c contains too high of a concentration of dextrose. d is describing a solution which can be administered via a peripheral venous access device.

21. The physician orders 1000 ml D5 $\frac{1}{4}$ NS with Potassium 40 mEq to be administered over 8 hours. The administration set has a drop factor of 15 gtt/ml. How many milliliters per hour and drops per minute should the nurse administer this infusion?
- 100 ml/hr, 25 gtt/min
 - 100 ml/hr, 31 gtt/min
 - 125 ml/hr, 38 gtt/min
 - 125 ml/hr, 31 gtt/min

Rationale

Correct answer: d.

Answer d is correct. $1000 \text{ ml} / 8 \text{ hr} = 125 \text{ ml/hr}$. $125 \text{ ml} / 60 \text{ min} \times 15 = 31 \text{ gtt/min}$.

22. The physician orders ampicillin (Ampicin) 500 mg in 100 ml D5W to infuse over 30 minutes. The nurse sets the rate controller device to deliver the medication over 30 minutes. The rate controller device must be set at how many milliliters per hour?
- 50 ml/hr
 - 100 ml/hr
 - 150 ml/hr
 - 200 ml/hr

Rationale

Correct answer: d.

Answer d is correct answer. $100 \text{ ml} : 30 \text{ minutes} :: X \text{ ml} : 60 \text{ minutes}$

23. When providing care for a client who is receiving peripherally administered parenteral nutrition, the nurse includes which of the following in the plan of care: (Check all that apply)
- Assess the catheter insertion site for redness, swelling, heat, and drainage.
 - Assess nutritional status, daily weights, vital signs, and intake and output ratio
 - Administer 20% dextrose solution with vitamins, minerals, trace elements, and electrolytes added
 - Assess for signs of infection: elevated temperature and white blood cell count, chills, and redness at catheter site
 - Maintain accurate rate of flow and complete entire infusion on time increasing rate to “catch up” if necessary
 - Maintain aseptic techniques when changing solution and tubing every 24 hours

Rationale

Correct answers: a, b, d, and f.

Answers a, b, d, and f are correct. All of these answers should be included in care planning for this client. Answer c is incorrect because the nurse should not administer greater than a 10% dextrose solution peripherally. Answer e is incorrect because the nurse should not increase the rate or “catch up” the solution as this may cause fluid overload or hyperglycemia.

24. The physician has ordered a transfusion of packed red blood cells to your client. Which of the following actions should be included to provide safe care during the transfusion? (Check all that apply)
- Use only 0.45% normal saline to prime the tubing or dilute the blood products
 - Assess vital signs before beginning the transfusion, 15 minutes after beginning the infusion, and every 30 minutes to 1 hour during transfusion.
 - Flush tubing with normal saline to administer intravenous medications throughout transfusion
 - Place call bell within client's reach, instruct client to call if experiencing shortness of breath, and request that the nurse aide remain with the client during the first 15 minutes of the transfusion
 - Monitor client every 30 minutes throughout transfusion for adverse reactions and assessment of vital signs

Rationale

Correct answers: b and e.

Answers b and e are correct. These are appropriate interventions to use when administering blood products.

(continued)

Answer a is incorrect because the nurse should only use 0.9% normal saline solution when administering blood products. Answer c is incorrect because the nurse should start an additional intravenous infusion if the client needs intravenous medications throughout the administration of blood products. Answer d is incorrect because the nurse should remain with the client during the first 15–30 minutes of the transfusion.

25. The client has had a peripheral intravenous device in the left hand for three days. The nurse's assessment for local complications of intravenous therapy includes which of the following? (Check all that apply)

- a. Phlebitis
- b. Thrombosis
- c. Circulatory overload
- d. Allergic reaction to medications
- e. Infiltration
- f. Infection at catheter site
- g. Extravasation

Rationale

Correct answers: a, b, e, f, and g.

Answers a, b, e, f, and g are correct. These answers are all local complications. Answers c and d are examples of systemic complications of intravenous therapy.

Test Plan Category:

Physiological Integrity

| ▸ Laboratory Values | 479 | | |

DIAGNOSTIC TESTS

CARDIOVASCULAR SYSTEM

Electrocardiogram (ECG, EKG)

- Recording of the electrical activity of the heart
- Standard EKG is 12-lead EKG

Indications: To assess for dysrhythmias, myocardial ischemia, and myocardial infarction

Preparation: Shaving the skin may be required to allow adequate adhesion of the electrodes.

Nursing Intervention Alert

Remind the client not to speak or move during the recording to avoid the occurrence of artifact on the EKG strip.

Procedure: Monitoring electrodes are placed on the left arm, right arm, and left leg; a grounding electrode is placed on the right leg, and six electrodes are positioned across the chest.

Echocardiogram

- A type of ultrasound, which focuses on cardiac structures.

Indications: To evaluate heart muscle and valves and to calculate ejection fraction of the heart

Preparation: No preparation is needed. Inform the client the test is not painful.

Nursing Intervention Alert

Remind client to remain still during the test to ensure clear imaging.

Procedure: A water-based gel is applied to the chest wall. The transducer is placed on the skin and moved to provide clear images of the cardiac structures. Recordings of images are made with the client supine and when turned on the left side (which brings the heart closer to the chest wall).

Cardiac Nuclear Scan (Myocardial Perfusion Scan)

- Involves the use of a radiopharmaceutical to perform diagnostic imaging examinations on the heart.
- In a thallium scan healthy cardiac tissue absorbs the thallium first, ischemic tissue absorbs it more slowly, and infarcted tissue does not absorb it at all. Similar testing can be done using other radioisotopes (Cardiolite, Myoview).
- It may be done in conjunction with an exercise stress test on a treadmill (exercise electrocardiography).
- For clients unable to exercise, the heart can be stimulated through the use of medications such as adenosine and dipyridamole, thus effectively simulating the effects of exercise on the heart.

Indications: To assess for ischemic heart disease, cardiac vessel patency, and cardiac wall functioning

Preparation: No solid food for 6 hours before the test. No nicotine on the day of the test.

Nursing Intervention Alert

For exercise testing with adenosine: No caffeine for 12–24 hours prior to the test and no theophylline medications (such as Theo-Dur, aminophylline) for 24–48 hours before the test.

Procedure: A radioactive isotope is injected into a vein. Radioactive isotopes attach to red blood cells and pass through the heart in the circulating blood. The radioactive isotope can be traced through the heart using a special scanner. The images may be combined with an electrocardiogram. There are generally two phases to this test: exercise scan and resting scan. During the exercise portion of the test, the client will be injected with the isotope when 85–90% of maximum heart rate has been reached. The client will continue exercising for 1–2 minutes to distribute the isotope and is then immediately scanned. The client will be rescanned 3–4 hours after resting.

Nursing Intervention Alert

Bronchospasm may occur during exercise testing with adenosine or dipyridamole. This may be reversed with administration of aminophylline.

Nursing Process Elements

Special Considerations

- Have the client dress in comfortable clothes and wear walking shoes if an exercise stress test is going to be done.
- Educate the client concerning where the test will be performed and that he will have an IV, EKG monitor, and blood pressure cuff on during the testing.
- Obtain an accurate weight and baseline EKG.

Clinical Alert

Nuclear medicine procedures are generally contraindicated for pregnant women and lactating mothers.

Cardiac Catheterization

- Involves the injection of a contrast medium through a catheter in the femoral or brachial artery
- Abnormalities of the coronary arteries or valves may be able to be treated during the cardiac catheterization
 - Percutaneous Transluminal Coronary Angioplasty (PTCA):* A balloon is inflated at the area of arterial narrowing
 - Stenting:* A metal mesh tube placed over the balloon will expand during angioplasty and lock into place to hold the artery open

Indications: To evaluate congenital disorders, coronary arteries, and function of heart muscle and valves

Preparation: The client is to fast for 8 hours prior to the procedure. A complete blood count and coagulation studies such as PT and PTT are obtained. Allergies to iodine, shellfish, or contrast medium dye must be reported. Any medications which might prolong bleeding must also be reported. Signed informed consent is obtained, and preprocedure sedation is administered as ordered.

Nursing Intervention Alert

Inform the client that intense flushing may be experienced for 15–30 seconds during injection of the contrast medium.

Nursing Intervention Alert

Clients who are taking metformin should discontinue the medication 2 days prior to the cardiac catheterization to avoid the possibility of lactic acidosis occurring. After the procedure, renal function should be assessed for adequacy prior to resuming the medication.

Procedure: An IV is started and EKG monitor applied. The puncture site is cleansed and anesthetized. The needle puncture is made; a guide wire is inserted through the needle; and the catheter is then inserted over the guide wire into the artery. Fluoroscopy is used to view the position of the catheter, and when in the correct position, contrast dye is injected. Images are taken as the dye moves through the vasculature and chambers of the heart. If abnormalities such as narrowing of a coronary artery are noted, treatment such as PTCA or stenting may be done.

Clinical Alert

Generally contraindicated for those allergic to iodine, shellfish, or contrast medium dye, those with bleeding disorders, those with renal failure, and pregnant women.

Nursing Process Elements

Special Considerations

- Pressure must be maintained on the entry site and the affected extremity immobilized for 8–12 hours, unless a metal clip is used to seal the site. In this situation, ambulation is allowed in 1 hour.
- Vital signs, urinary output, and condition of the affected extremity (color, movement, temperature, sensation, and pulses) are monitored frequently per institutional protocol.

HEMATOLOGIC/IMMUNOLOGIC SYSTEM

Bone Marrow Biopsy

- Removal of a sample of bone marrow from the iliac crest or sternum

Indications: To investigate abnormal blood counts and to assess for the presence of systemic disease in the bone marrow

Preparation: No fasting is required prior to the test. The client is provided information about the procedure, noting discomfort occurs primarily when the puncture site is anesthetized and during removal of the marrow sample. Baseline coagulation laboratory studies are completed. A signed informed consent is obtained, and preprocedure sedation is administered as ordered.

Procedure: The client is assisted into a prone or lateral position. The puncture site is cleansed and anesthetized. A small incision is often made, and a large bore needle is inserted into the bone. Samples of liquid and other bone marrow are

Clinical Alert

Generally contraindicated for clients with bleeding disorders, and for those unable to cooperate during the procedure.

obtained. The needle is removed and pressure applied to the site for 10–15 minutes.

Nursing Process Elements

Special Considerations

- Assess the client for signs of hemorrhage (change in vital signs, bleeding from puncture site, and pain)
- If possible, the client should remain on bedrest for 1 hour postprocedure.

RESPIRATORY SYSTEM

Pulse Oximetry

- A noninvasive study of arterial blood oxygen saturation using a probe or clip attached to a sensor site, most commonly the fingertips or ear lobe.
- Normal oxygen saturation is 95–100%

Indications: Often used to monitor the oxygen saturation of arterial blood during surgical procedure, diagnostic testing, and mechanical ventilation

Nursing Process Elements

- Assess for interfering factors such as excessive light, excessive pigmentation, nail polish, peripheral vascular disease, hypothermia, hypotension, and vasoconstriction.
- Place the transducer over the finger so that the light beams and sensors are opposite each other.
- Assess the site for skin irritation at least every 4 hours; check transducer site as needed.

ARTERIAL BLOOD GASES

Pulmonary Function Test

- Uses a spirometry device to measure pulmonary volumes and capacities
 - Tidal volume:* normal volume of air inspired/expired during normal respiration
 - Vital capacity:* maximum amount of air exhaled after a maximal inspiration

Indications: To evaluate ventilatory function, to determine cause of dyspnea, to assess effectiveness of medication, and to rule out obstructive or restrictive disease process

Nursing Process Elements

- Perform test before meals
- Explain the position: may be upright with a nose clip or in a plethysmograph or an airtight box (no need for nose clip). Reassure the client that although he/she may experience claustrophobia, he will be able to communicate with the technician
- Discuss with the client that he may receive bronchodilators

- Explain the importance of following directions so that the test can be done faster
- Instruct the client to keep tight seal around the mouth-piece to ensure accurate result.

Nursing Intervention Alert

Instruct the client to use no bronchodilators and not to smoke for 6 hours prior to the test. If the client receives bronchodilators during the test then ask the client to take his/her normal dose after 4 hours.

Purified Protein Derivatives (PPD) Test

- Intradermal injection of purified protein derivatives to detect tuberculosis (TB) infection or to detect any previous sensitization of tubercle bacillus

Indications: To detect previous exposure to TB. If positive result, diagnosis of TB includes client history and presentation, chest X-ray, and sputum for AFB (acid-fast bacilli)

Nursing Process Elements

- Make sure to mark the area after administration of the test
- Document site of administration in the chart
- Result is read within 48–72 hours
- Measure induration (raised area) not erythema (redness)
 - 5 mm or above is considered positive if the client is immunocompromised.
 - 10 mm or above is considered positive for client who has other risk factors such as health care workers, people living in crowded areas, BCG vaccinated clients, teachers, and clients with lower economic status.
 - 15 mm or above is considered for clients with no known risk factors.

Sputum Culture

Indications: To identify and differentiate causative organism and to identify effective antibiotics

Nursing Process Elements

- Advise the client to cough deeply to produce specimen
- Avoid sending saliva
- Avoid mouthwashes before specimen is obtained.

Sputum Cytology

Indication: To identify abnormal cells

Nursing Process Elements

- Send the specimen in formalin or as ordered.

Chest X-ray

Indications: To evaluate gross lung presentation, and to aid in diagnosis of pneumonia, tuberculosis, and carcinoma

Nursing Process Elements

- Assess for pregnancy
- Protect radiation sensitive areas such as thyroid and reproductive organs

Clinical Alert

Assess for pregnancy. X-rays are generally contraindicated for clients who are pregnant.

Lung CT Scan

- Provides cross-sectional view of the lung segments by passing an X-ray beam from a computerized scanner through the lung at different angles and depth.

Indication: To assess abnormalities including masses or lesions

Preparation:

- Obtain an informed signed consent
- The client is to fast for 4 hours prior to the test
- Assess for allergy to contrast medium dye
- Explain to the client that the equipment may make him feel claustrophobic. He/she should not move during the procedure, relax, and breathe normally during the procedure.

Nursing Intervention Alert

Clients who are taking metformin should discontinue the medication 2 days prior to the CT scan to avoid the possibility of lactic acidosis occurring. After the procedure, renal function should be assessed for adequacy prior to resuming the medication.

Bronchoscopy

- Involves direct visualization of larynx, trachea, and bronchi through the use of a fiberoptic bronchoscope

Indications: To view abnormalities seen on X-ray, to obtain specimens for examination, and for foreign body removal

Preparation:

- Obtain signed informed content
- The client is to fast for 12 hours prior to the procedure
- Dentures are removed.
- Preprocedure medication includes an anticholinergic to decrease bronchial secretions and a medication such as midazolam for sedation and relief of anxiety
- Explain that a local anesthetic will be sprayed in the throat

Nursing Process Elements

- Place client in supine or semi-Fowler position as ordered
- Observe for complications such as hemorrhage, subcutaneous emphysema and dyspnea, bronchospasm, pneumothorax, and laryngeal edema
- Discourage coughing, talking, and smoking for a few hours
- Administer oxygen as ordered
- Inform the client that sore throat and hoarseness of the voice may occur temporarily after the procedure

Nursing Intervention Alert

After the procedure, withhold fluids and food until the gag reflex returns.

Clinical Alert

Generally contraindicated for clients with severe respiratory failure and clients who cannot tolerate interruption of high-flow oxygen.

GASTROINTESTINAL SYSTEM

Gastric Analysis

- Examination of stomach contents

Indications: Most often done to check for presence and amount of HCl (high in peptic ulcer disease, absent in pernicious anemia, should be decreased after vagotomy); can also document presence of occult blood, malignant cells, and parasites

Preparation: Light meal or fluids evening before then NPO after MN; no smoking in the morning of test because it stimulates HCl secretion

Procedure: Stomach contents aspirated via NG tube using a syringe and gentle suction; if production of HCl is being measured, this is the baseline amount. Subsequently, aspirations are repeated every 15–20 minutes for 1–2 hours usually after a stimulus such as a carbohydrate meal, 50 ml of caffeine or alcohol, or an injection of histamine is given.

Assessment Alert

Check for history of allergies; may contraindicate use of histamine.

Whenever histamine is used, monitor pulse and blood pressure; expect client to experience a hot, flushing sensation.

Upper GI Series/Lower GI Series (Barium Enema)

- Fluoroscopic examination of the GI tract through the use of barium sulfate
 - Upper GI: visualizes the esophagus, stomach, and small intestine
 - Lower GI: visualizes the large intestine

Indications:

- *Upper GI:* To evaluate dysphagia, regurgitation, epigastric pain, and hematemesis
- *Lower GI:* To evaluate lower abdominal pain, changes in bowel habits, and blood in stools

Preparation:

- *Upper GI:* Fasting for 8 hours required prior to test.
- *Lower GI:* A liquid diet for 24 hours prior to test, use of stool softeners, laxatives, and enemas as ordered the evening before and morning of the test, and NPO for 8 hours prior to the test.

Nursing Intervention Alert

If both upper and lower GI series are to be done, the lower GI series should be done first so that barium from the upper GI series does not obscure lower GI images.

Procedure:

- *Upper GI:* The client drinks a milkshake-type solution containing barium sulfate. Movement of the barium is

viewed fluoroscopically and spot films are taken throughout the passage of the barium from the pharynx through the small intestine.

- *Lower GI:* A preliminary film is taken with the client supine to check for adequacy of bowel prep. If adequate, the client is turned to the side and a rectal tube is inserted. Barium is allowed to flow slowly into the large intestine until it is full. Movement of the barium is viewed fluoroscopically and spot films are taken throughout the passage of the barium to the ileocecal valve.

Clinical Alert

Generally contraindicated for intestinal obstruction, perforated GI tract (a water-soluble contrast medium [Gastrografin] would be needed), and pregnant women.

Nursing Process Elements

Special Considerations

- Encourage fluid intake to promote excretion of the barium.
- Reinforce to client the need to evacuate all of the barium. A cathartic may be ordered. Instruct the client to check all stools for barium and to notify the health care provider if the barium is not expelled within 2–3 days.

Oral Cholecystogram

- X-ray visualization of the gallbladder

Indications: To evaluate gallbladder function; to diagnose gallstones or other disease

Preparation: Ingest usual amount of dietary fat in days preceding test to empty bile from gallbladder. Fat free supper and Telepaque tablets containing contrast medium are taken the night before. Observe NPO after midnight. The fat free supper prevents contraction of gallbladder and allows dye to accumulate.

Nursing Intervention Alert

Give the Telepaque tablets 5 minutes apart with small amounts of water to minimize nausea. There are usually six or more tablets (dose is calculated according to body weight).

Procedure: X-ray is taken; if gallbladder with stones is seen, procedure is over. Otherwise a fatty meal is given to stimulate gallbladder contraction and more films are taken in 15–20 minutes.

Clinical Alert

Complications include severe diarrhea and vomiting with dehydration; anaphylaxis if client is allergic to iodine in dye, liver and kidney damage if dye is not properly excreted.

Cholangiogram

- Visualization of bile ducts through the use of a contrast medium.

Indications: To detect obstruction of bile ducts, tumors, cysts of common bile duct, biliary sclerosis, and sclerosing cholangitis; to evaluate between obstructive and nonobstructive jaundice. There are three types:

- *Percutaneous transhepatic cholangiogram:* Contrast dye is injected directly into the bile duct. It is performed in jaundiced clients since they cannot process dye given orally or intravenously.
- *Operative cholangiogram:* It is done while client is undergoing a cholecystectomy to check common bile duct for stones.
- *T-Tube cholangiogram:* Dye is injected through the T-tube to check for patency of the common bile duct prior to removal of the T-tube.

Preparation: Low fat diet 24 hours before procedure, NPO 8 hours before, laxative evening before, and enema the morning of examination; obtain signed informed consent; preprocedure medication may include a sedative, analgesic, and antibiotic if ordered. Coagulation studies need to be within normal limits.

Procedure: For the percutaneous transhepatic cholangiogram, the client is placed supine on a tilting X-ray table, right upper abdomen is cleansed with povidone-iodine solution and surgically draped. With fluoroscopy guidance, needle is inserted into liver; placement in bile duct is confirmed by return flow of bile; contrast medium is injected; X-rays taken with client in various positions; dry sterile dressing to puncture site, may use sand bag to apply pressure.

Clinical Alert

Contraindicated in clients with iodine or shellfish allergies, with prolonged clotting time, cholangitis, when client cannot remain still, and pregnant women.

Nursing Process Elements

- Assess vital signs before and after procedure
- Monitor for bleeding, increased pulse and decreased blood pressure
- bile extravasation, sepsis, and bacteremia after procedure
- Maintain NPO for a few hours after examination and bedrest for several hours
- Instruct to immediately report any adverse reactions to contrast as nausea, vomiting, headache, dizziness, or urticaria
- Inform client when diet can be resumed
- Teach to report signs of bleeding abdominal discomfort, drainage from puncture site or fever and chills
- Instruct to increase fluid intake to help excrete dye

Endoscopic GI Procedures: Direct visualization of upper GI tract with a flexible fiberoptic scope

- *Esophagogastroduodenoscopy (EGD)/Gastroscopy:* Visualizes esophagus, stomach, and upper duodenum
- *Sigmoidoscopy:* Visualizes anus, rectum, and sigmoid colon
- *Colonoscopy:* Visualizes entire large intestine

Indications:

- *EGD:* To view organ linings, aspirate fluid, removal foreign bodies, obtain tissue biopsies, and control bleeding
- *Sigmoidoscopy:* Can be diagnostic or therapeutic; detects polyps, ulcerative colitis, diverticular disease, granulomas or irritable bowel syndrome; used as screening test for colon cancer
- *Colonoscopy:* To detect tumors; to detect and remove polyps; to diagnose inflammatory bowel disease; to obtain biopsies; to dilate strictures; used as screening test for colon cancer

Preparation:

- *EGD:* Obtain signed informed consent. Fasting for 8–12 hours. Remove dentures. Preoperative medication includes an anticholinergic (atropine) to decrease secretions and a medication (such as midazolam) for sedation and relief of anxiety.
- *Sigmoidoscopy:* Usually clear fluids 24 hours before procedure, oral cathartics such as fleets phosphate soda, given on evening of examination and an enema in the morning.
- *Colonoscopy:* Clear liquid diet for 1–3 days and NPO for 8 hours; laxatives 1–3 days before and enemas night before or saline cathartic or 1 gallon Golytely or Colyte taken as an 8-oz glass every 10 minutes.

Procedure:

- *EGD:* Topical anesthetic applied to the pharynx to numb the gag reflex, a flexible scope is passed through the mouth to esophagus, air is insufflated to distend the area to clearly view GI organs, may take a biopsy or brushings for cytological specimens or remove polyps.

- *Sigmoidoscopy:* Client is sedated; positioned in left lateral or knee chest or lithotomy position; a flexible scope is placed into rectum up to about 25 inches, air is insufflated to aid with visualization; polyps may be removed or a biopsy taken
- *Colonoscopy:* Client is sedated, positioned in left lateral position. a flexible scope is placed into rectum and advanced to the ileocecal valve. Air is insufflated to aid with visualization; polyps may be removed or a biopsy taken

Clinical Alert

Complications

- *EGD:* Bleeding, cardiac arrhythmias, pulmonary aspiration or perforation
- *Sigmoidoscopy:* Bleeding from colon or rectum due to biopsy or polyp removal, perforation, cardiac arrhythmias, peritonitis
- *Colonoscopy:* Rectal bleeding, perforation

Nursing Process Elements

Special Considerations

- *EGD:* Monitor vital signs until fully awake. Inform client to resume eating once the gag reflex returns; instruct to use a soothing mouthwash for sore throat; call physician for any difficulty breathing or abdominal pain.
- *Sigmoidoscopy:* Monitor vital signs until fully awake. Inform client that slight bleeding may occur if biopsy taken or polyp removed. Instruct client to report bleeding, elevated temperature and abdominal pain to physician. Explain about occurrence of gas pains and flatulence after procedure.
- *Colonoscopy:* Monitor vital signs until fully awake. Observe for rectal bleeding if biopsy or polypectomy done. Assess for signs of perforation (malaise, abdominal distention, and tenesmus). Inform client that abdominal cramping may occur.

Clinical Alert

Colonoscopy is contraindicated for clients with acute diverticulitis, peritonitis, ischemic bowel disease, or fulminant ulcerative colitis and suspected perforation of the colon.

Liver Biopsy

- Sampling of liver tissue for histopathologic evaluation

Indications: To aid in diagnosis of cirrhosis, hepatitis, neoplasm; to monitor course of liver disease

Preparation: Check coagulation status (PT, clotting, or bleeding time). Check for type and x-match. Obtain signed informed consent. Obtain baseline vital signs. Explain position and breathing. NPO for 6 hours prior to the test.

Procedure: Puncture site is cleansed and local anesthetic is administered. Conscious sedation may be used. Client lies supine with right arm over head. He/she exhales fully and holds breath; needle is inserted between anterior right 6 and 7 or 8 and 9 ribs, and sample of liver tissue is aspirated.

Complications: Bile peritonitis, shock, pneumothorax

Nursing Process Elements

Monitor vital signs q 15 minutes $\times 2$, q 30 minutes $\times 4$, q 1 hour $\times 4$; position client on right side to keep pressure on area of needle insertion for minimum of 2 hours; keep flat for 12–14 hours.

Clinical Alert

Generally contraindicated for clients with bleeding disorders, decreased platelet count, platelet dysfunction, extrahepatic obstruction, infection, and when there is difficulty locating the liver due to ascites or obesity.

NEUROLOGICAL SYSTEM

Cerebral Angiography

Traditional method

- It uses injected contrast medium and X-ray to visualize the cerebral, carotid and vertebral circulation.

Indications: To identify AV malformations, aneurysms, and blocked or leaking vessels

Preparation: NPO for 8–12 hours; preprocedure sedative, analgesic or hypnotic

Procedure: Head will be immobilized and client must lie still, contrast medium injected and serial X-rays taken

Complications: Allergic reaction; vasospasm which can be severe enough to occlude blood flow and cause permanent effects such as paresis or paralysis depending on the area of the brain affected.

Nursing Process Elements

- Tell client to expect a sensation of heat when the contrast media is injected.
- Administer antihistamines before and/or after if prescribed for clients with allergies.
- Check for allergy to iodine, shellfish, and contrast media.

- Obtain baseline vital signs and neurological assessment.
- After the procedure monitor vital signs and neurological signs every 15 minutes for first hour and then at increasing intervals.
- Monitor neurovascular signs in extremity distal to the site of contrast media injection (ability to feel and move, color, temperature, pulse, and capillary refill).
- Maintain bedrest for several hours with injected extremity straight and immobilized.
- Monitor injection site for bleeding.
- Encourage fluids when allowed to aid excretion of contrast material over next 24 hours.

Digital subtraction method

- It is less invasive and involves less risk of vasospasm.
- Angiocatheter is threaded into the brachial vein and into the superior vena cava near the right atrium; an initial reference X-ray is taken and loaded into a computer. The contrast medium is then injected. Subsequent pictures are computer compared to the original.
- There is no fluid restriction, but food restricted for 2 hours.
- There is no activity restriction postprocedure; otherwise care same as in traditional method.

Computerized Tomography (CT) Scan

- May be done with or without contrast medium
- Food withheld for 4 hours if contrast used; no fluid restriction

Indications: To identify tumors, infarctions, hemorrhage, hydrocephalus, and bone malformations

Nursing Process Elements

- Ensure wigs, hairpins, and the like are removed.
- Monitor for delayed allergic reaction if contrast used.

Magnetic Resonance Imaging (MRI)

- May use noniodine contrast substance, gadolinium
- No special preparation or follow up care.
- Contraindicated for confused, agitated, or pregnant clients and those with unstable vital signs or implanted ferromagnetic devices or tattoos. Also contraindicated for those on continuous life support.

Positron Emission Computed Tomography Scan (PET)

- It is different from CT scan and MRI because it shows function (glucose and oxygen metabolism and cerebral blood flow), not structure.

- Deoxyglucose tagged with a radioisotope is injected intravenously and is taken up in varying amounts by different areas of the brain depending on their activity. The greater the activity, the greater is the amount taken up. Areas with different amounts show different colors on the resultant films.
- Allows areas of metabolic alteration to be identified that are associated with seizure, dementia, etc.
- Client may wear earplugs and be blindfolded during the test.
- Client will be asked to perform different mental functions during the test to show activity in different areas of the brain.

Nursing Process Elements

- Keep client NPO for 6–12 hours before the test.
- Hold insulin, glucose solutions or any other drugs that alter glucose metabolism.
- Encourage fluids after the procedure; the isotope is excreted in urine but no special precautions are needed.

Lumbar Puncture

Insertion of a spinal needle between the third and fourth or fourth and fifth lumbar vertebrae into the subarachnoid space.

Indications: To obtain CSF for laboratory analysis; to obtain pressure readings; to check for obstruction; or inject medications

Clinical Alert

LP is generally contraindicated for clients with signs of increased ICP because of the risk of herniation of brain tissue through the uncus if the pressure is suddenly decreased and also for those with infection near the entry site because of the risk of introducing pathogens into the CSF.

Procedure: Once the needle is in place, pressure readings are obtained and samples collected and numbered sequentially.

Nursing Process Elements

- Have client empty bladder.
- Assist into side lying fetal position (chin on chest, back flexed, knees flexed on trunk and held in place with arms and hands) at side of bed or table.
- Hold client in place with hands behind knees and neck.

- After the procedure, maintain bedrest in a flat position if ordered for up to 4–8 hours.
- Encourage increased fluid intake up to 3000 ml/day for 2 days to encourage production of replacement CSF.
- Give analgesics for headache, which may be severe and throbbing as a result of the decrease in CSF.
- Monitor for complications: CSF leakage, infection and hematoma formation.

Electroencephalography

Indications:

- Determine general activity of the cerebral cortex; identify origin of seizure activity; monitor brain activity during anesthesia; diagnose sleep problems; diagnose brain death.
- May be done as a sleep deprived test; client is awakened at 2 or 3 a.m. and kept awake until after the test.
- Withhold CNS stimulant or depressant foods or medications for 24 hours before test.
- Test is done in a stimulus free environment
- Hair needs to be washed before test and after to remove gel.
- Client may be asked to hyperventilate; may be exposed to bright light; or may be put to sleep.

GENITOURINARY SYSTEM

KUB Plain Film

- Plain radiographic visualization of the abdomen (kidneys, ureters, and bladder).

Indications: To delineate size, shape, and position of kidneys; to aid in diagnosis of hydronephrosis, cysts, tumors, or displacement; to identify intra-abdominal diseases such as intestinal obstruction, masses, ruptured organs, abnormal gas accumulation, and ascites

Preparation: It should precede intravenous pyelogram (IVP) or other GI diagnostic studies. Remove all metal from X-ray field. Client teaching: Hold breath as instructed when images are taken.

Procedure: With client supine on examination table, abdominal X-ray films are obtained. For portable examination, head of bed is elevated to a high Fowler's position.

Nursing Process Elements

Reinforce information given regarding further testing, treatment, or referral.

Pyelogram

- Radiographic visualization of the kidney, ureters, bladder, and renal pelvis using contrast medium.

Indications: To aid in diagnosis of renovascular hypertension, determine cause of hematuria, assess for presence of

renal calculi, cyst, tumor, or ureteral obstruction; to evaluate urinary tract function, congenital anomalies, or trauma

Preparation: Obtain signed informed consent, complete history and physical conditions (rule out pregnancy, dehydration, renal insufficiency, multiple myeloma, perforation of ureters or bladder, and allergy to shellfish and iodinated dye), baseline BUN and creatinine, pretest laxative, fasting for 8 hours, steroid/antihistamine prep for known iodine allergy; remove all metal from X-ray field.

Nursing Intervention Alert

Clients who are taking metformin should discontinue the medication 2 days prior to the pyelogram to avoid the possibility of lactic acidosis occurring. After the procedure, renal function should be assessed for adequacy prior to resuming the medication.

Procedure: Radiopaque contrast medium administered intravenously (IVP or excretory urogram) or through ureteral catheters, which have been passed into the renal pelvis by cystoscopic manipulation (retrograde pyelogram). X-ray exposures made at 1, 5, 10, 15, 20, and 30 minutes and postvoiding to follow course and timing of contrast medium through urinary system.

Clinical Alert

Complications include renal failure, IV or catheter related infections, allergic reaction.

Clinical Alert

Failure to discontinue Glucophage may result in lactic acidosis.

Nursing Process Elements

Monitor for decreased urinary output, S&S of allergic response. Resume diet, medications, and activity (see alert regarding metformin). Increase fluid intake to assist with excretion of dye.

Renal Ultrasound

- Use of ultrasound to produce an image of an organ or tissue.

Indications: To evaluate size, shape, and position of kidney; to aid in diagnosis of tumors, malformations, or

obstructions; to guide renal biopsy or nephrostomy tube insertion

Preparation: Client teaching: The client may be asked to inhale deeply and hold breath during examination.

Procedure: With client supine, conduction gel is applied to the skin and a transducer passes high frequency sound waves into the body, which are reflected back, electronically processed, and displayed as an image.

Nursing Process Elements

Test should precede CT or endoscopic examinations. There should be no barium studies for 2 days prior to ultrasound.

Renal Scan

- Assesses flow and rate of radionuclide through kidney. Does not use iodinated contrast medium, therefore, procedure considered safe for clients with allergy or compromised renal function.

Indications: To aid in diagnosis of renal artery disease, to detect renal infection or inflammatory diseases, abscess, trauma, calculi, obstructive uropathy, tumors, or congenital disorders

Preparation: Obtain signed informed consent. No fasting is required. Client needs to be well hydrated.

Procedure: Radioisotopes injected intravenously. Gamma camera detects emitted rays, tracks the rate of flow, plots the times on a graph, and stores the information in a computer. Delayed images are taken at 2–24 hours (may leave the nuclear medicine department and return later for delayed imaging)

Nursing Process Elements

Wear gloves when discarding urine. Wash gloved hands with soap and water before removing, then wash again after gloves removed. Radionuclide excreted within 6–24 hours.

Cystoscopy

- Direct endoscopic visualization of the bladder and urethra.

Indications: To aid in diagnosis of tumor, stone, ulcer, and obstruction; to allow insertion of ureteral catheters, removal of calculi, electrocautery of bleeding sites, dilation of urethra, and attainment of biopsy specimen

Preparation: Obtain signed, informed consent. No fasting is required if local anesthesia is to be used; 8-hour fast if general anesthesia planned. Client teaching: The client may be told that he/she may experience an urge to urinate during the procedure.

Procedure: Urethra cleansed, local anesthetic applied, and rigid or flexible cystoscope inserted through urethra into the bladder. Optical lens system provides magnified, illuminated

view; water or saline inserted via the scope's attached irrigation system to aid in bladder visualization.

Clinical Alert

Complications include bleeding, infection, post-catheter urinary retention, and bladder rupture.

Nursing Process Elements

Monitor for UTI, urinary retention, or hemorrhage. Anticipate blood-tinged urine. Warm sitz bath and mild analgesics may relieve discomfort. Report burning on voiding, heavy bleeding, or decreased urine output; force fluids.

Cystourethrogram

- Radiographic visualization of the urethra and bladder during urination using contrast medium.

Indications: To identify injuries, tumors, strictures, vesicoureteric reflux, neurogenic bladder, or structural abnormalities; to evaluate emptying problems or incontinence.

Preparation: Obtain signed informed consent, steroid/antihistamine prep for known iodine allergy. Client teaching: The client may be told that he/she may experience pressure and an urge to urinate during procedure.

Nursing Intervention Alert

Cystourethrogram should be completed prior to any tests involving barium

Procedure: With client supine, urinary catheter inserted, radiopaque contrast medium injected and catheter clamped. X-ray images taken in various positions with the bladder full of contrast and while the bladder is being emptied.

Complications: Renal failure, catheter related UTI, and allergic reaction.

Clinical Alert

Failure to discontinue Glucophage may result in lactic acidosis.

Nursing Process Elements

Monitor for decreased urinary output, allergic reactions, infection, bleeding, or urinary retention. Resume diet and

medications. Force fluids. Report fever, chills, urinary difficulty, or bleeding.

Cystometrogram

- Manometric study measuring bladder pressure and volume characteristics during filling and storage.

Indications: To evaluate motor and sensory causes of incontinence and monitor effects of treatment

Preparation: Obtain signed informed consent. No fasting is needed. Inform client that the urge to void may be felt as fluid or gas fills the bladder. Instruct client to report sensations during procedure.

Procedure: Client is observed during pretest voiding and the following data is recorded: start time, force and continuity of stream, volume voided, presence of dribbling, straining, or hesitancy, and stop time. With client supine, a urinary catheter is inserted and residual urine measured. The catheter is connected to a cystometer and pressure and volume readings are recorded and graphed for response to heat, full bladder, urge to void, and ability to inhibit voiding.

Complications: UTI and bleeding

Clinical Alert

Procedure is contraindicated if UTI is present or patient is experiencing diarrhea.

Nursing Process Elements

Monitor for infection, bleeding, and urinary retention. Encourage client to increase fluid intake. Administer analgesics and antibiotics as ordered. Warm tub baths may aid in comfort. Instruct client to report pain, frank bleeding, and dysuria.

Renal Biopsy

- Excision of tissue sample from the kidney for microscopic analysis

Indications: To confirm diagnosis of cancer or renal disease; to determine extent of involvement in systemic lupus erythematosus; to monitor progression of nephrotic syndrome; to monitor renal function after transplantation

Preparation: Obtain signed informed consent, obtain baseline chest X-ray and coagulation studies. NPO for 8 hours, withhold anticoagulant therapy for 7 days prior to test.

Procedure: Sandbag placed under abdomen with client in prone position. Following local anesthesia, client instructed to take a deep breath, exhale forcefully, and hold breath while percutaneous needle inserted through renal tissue with ultrasound guidance and rotated to obtain renal tissue.

May also be performed by open biopsy through a small flank incision under general anesthesia.

Complications: Bleeding, infection, and delayed allergic response

Clinical Alert

Obesity and spinal deformities make percutaneous approach impossible.

Nursing Process Elements

Client assisted to supine position. Bedrest for 24 hours. Monitor vital signs and dressing. Encourage fluid intake. Monitor output and observe for frank bleeding. Strenuous activity should be avoided for 2 weeks.

Nursing Intervention Alert

Observe for indications of hemorrhage (vital sign changes, back, flank or shoulder pain, lightheadedness). Observe for signs of punctured bowel or liver (abdominal pain/tenderness, decreased bowel sounds, and abdominal rigidity)

Clinical Alert

Generally contraindicated in clients with renal tumors, hydronephrosis, abscess, advanced renal failure, urinary tract infection, or if have only one kidney.

REPRODUCTIVE SYSTEM

Mammogram

- Radiographic imaging of the breast

Indications: To detect nonpalpable lesions and assist in diagnosing palpable masses; to evaluate nipple discharge, breast pain, nipple retraction, and dimpling of skin of breast

Preparation: Explain to client the need to avoid use of powders, lotions, or deodorant prior to examination as they may interfere with results

Procedure: Two views are taken of each breast; a craniocaudal view and a mediolateral oblique view; the breast is compressed from top to bottom and from side to side; the procedure takes about 20 minutes.

Nursing Intervention Alert

Inform clients of screening guidelines from the American Cancer Society which recommend a mammogram each year after reaching the age 40; screening for women who are high-risk is to begin 10 years before the age of the diagnosis of breast cancer in a family member.

Nursing Process Elements

Explain that there is a false-positive rate ranging between 5 and 10%, generally greater in younger women with greater breast density tissue

Colposcopy

- Direct visualization of the cervix and vagina via a colposcope

Indications: To identify area of cellular dysplasia following abnormal cervical Pap results

Preparation: Instruct client to avoid douching and sexual intercourse for 24 hours prior to the test. Obtain a signed informed consent.

Procedure: The client empties her bladder and is assisted into lithotomy position. External genitalia are cleansed and a vaginal speculum is inserted. The cervix is swabbed with 3% acetic acid solution to remove secretions/medications and to highlight abnormal areas. The areas are illuminated by the colposcope and biopsies taken of suspicious areas. The vagina is rinsed with sterile saline or water to remove the acetic acid.

Nursing Process Elements

Inform client that mild cramping, vaginal discomfort, and vaginal discharge may occur following the procedure. Discharge may continue for 1 week. Instruct client to avoid strenuous exercise for 24 hours. Tampons, douching, and intercourse should be avoided for 2 weeks. Instruct client to report abdominal pain, fever or frank vaginal bleeding, or if bleeding lasts for more than 2 weeks.

Pelvic Ultrasound

- Ultrasound imaging of structures in the pelvic region

Indications: To identify stones, tumors, and other disorders in urinary bladder; to evaluate ovaries, uterus, cervix, and fallopian tubes of women; to assess fetal development; to evaluate prostate, seminal vesicles, and bladder in men

Preparation: No fasting is required. A full bladder is needed during the examination. Instruct the client to drink 1 liter of water 1 hour before the test.

Procedure: The client is assisted to a supine position. A water-based gel is applied to the abdominal and pelvic area and a transducer is placed on the skin and moved as needed to provide good images. The examination can also be done transvaginally for women (bladder is emptied prior to this examination) and transrectally for men

Nursing Process Elements

Special Consideration

- Allow the client to void immediately after the examination is completed.

Nonstress Test (NST)

- A noninvasive test used to evaluate the status of the fetus

Indications: Used with pregnant clients who have diabetes or hypertension, when fetal development is abnormal, and in postterm pregnancy

Preparation: Instruct client to eat prior to the test to ensure a high maternal serum glucose level, which enhances fetal activity.

Nursing Intervention Alert

Explain to client that a nonreactive NST does not mean there is a problem with the fetus. The fetus may have been in a sleep cycle during the test.

Procedure: The client voids and is then assisted into a Sims' position. An external fetal monitor is applied. The client is instructed to push a button whenever fetal movement is felt. This is then correlated to fetal heart rate. If there is no fetal movement in 20 minutes, external stimulation is done (rubbing the abdomen or producing loud noise near abdomen).

Clinical Alert

If there is no fetal movement for 40 minutes, the test is nonreactive, and the client is scheduled for a contraction stress test.

Amniocentesis

- An invasive diagnostic procedure involving transabdominal needle aspiration of amniotic fluid

Indications: To detect chromosomal abnormalities, to determine fetal maturity, and to detect Rh incompatibility

Preparation: No fasting is required. Obtain a signed informed consent. If client has full bladder due to having ultrasound

prior to the amniocentesis, the client needs to void prior to the amniocentesis to avoid accidental puncture.

Nursing Intervention Alert

If the mother's blood is Rh negative and that of the fetus is Rh positive, obtain order for RhoGAM to be administered.

Procedure: The client is assisted to a supine position. The skin of the lower abdomen is cleansed, draped, and anesthetized. A spinal needle is inserted into the amniotic cavity and a fluid sample is aspirated. The needle is withdrawn and a dressing is applied. The sample is protected from light and transported to the laboratory.

Clinical Alert

Possible complications include amniotic fluid embolism, fetal injury, hemorrhage, infection, premature labor, Rh sensitization, and spontaneous abortion.

Nursing Process Elements

Special Considerations

- Monitor fetal heart rate and maternal vital signs every 15 minutes until stable
- Monitor dressing for drainage
- Instruct client to report abdominal pain, cramping, chills, fever, vaginal bleeding, fetal hyperactivity, or lethargy

Hysterosalpingography

- An X-ray of the uterus and Fallopian tubes using fluoroscopy and a contrast medium

Indications: Used primarily as part of infertility workup to detect blocked fallopian tubes and uterine abnormalities

Preparation: Best performed 1 week after menstruation but before ovulation to make sure client is not pregnant. No fasting is required. Client may be asked to take a laxative or an enema to empty her bowels so that the uterus and surrounding structures can be seen clearly. Antibiotics and sedative may be given. Client needs to inform physician of any allergies and/or reactions, especially to contrast material.

Procedure: The client voids and is assisted into lithotomy position. A plain abdominal X-ray may be done to ensure adequacy of bowel prep. A vaginal speculum is inserted. The cervix is cleansed and a cannula is inserted into the cervix.

Contrast dye is injected through the cannula, and the flow of the dye is viewed fluoroscopically. Films are taken throughout the procedure.

Nursing Process Elements

Inform client that she may experience minor discomfort during and after the procedure but it should not last long. Shoulder pain may be experienced as the contrast medium leaks into the peritoneal cavity and irritates the diaphragm. Observe for allergic reaction to dye. Inform client bloody discharge may be present for 1–2 days. Client should report any fever, chills, abdominal pain, or frank bleeding.

Clinical Alert

Possible complications include allergic reaction, infection, and uterine perforation. The test is contraindicated in clients who are pregnant, in their menses, with undiagnosed vaginal bleeding, or with pelvic inflammatory disease or untreated sexually transmitted disease.

MUSCULOSKELETAL SYSTEM

Arthrogram

- Visualization of joints of the elbow, knee, wrist, hip, and temporomandibular area

Indications: To aid in diagnosis of tears of the menisci, ligament disruption, and synovial cysts

Preparation: Assess the client for allergies to iodine, seafood, or local anesthetics. Obtain signed informed content.

Procedure: Skin is injected with local anesthetic. Needle is inserted into the joint space. Fluid may be aspirated for analysis prior to injecting radiopaque dye, air or both into the joint cavity. The needle is removed and the joint is manipulated to disperse the dye throughout the joint. X-rays are taken with the joint in various positions.

Clinical Alert

Clients who are or may be pregnant should not have this procedure due to the risk of radiation exposure.

Nursing Process Elements

- Observe for allergic reaction to dye.
- Apply ice and elastic wrap and administer analgesics. Encourage rest of injected joint for 12 hours. Teach client

to report edema, redness, or unusual pain following the procedure.

Arthrocentesis (Synovial Fluid Aspiration)

- Removal of fluid from the joint for analysis.

Indications: To relieve edema and provide joint fluid sample for diagnosing gout, infection, or rheumatoid arthritis

Preparation: Obtain signed informed consent.

Procedure: With skin cleansed and anesthetized, sterile needle is inserted into the joint and fluid is aspirated.

Nursing Process Elements

Client teaching: Apply ice on joint for 20–30 minutes every 3–4 hours to relieve pain; take medication to relieve pain as prescribed by physician; avoid stressing the joint; apply an elastic bandage to support joint.

Bone Scan

- Visualization of abnormalities in bone or joint through the use of radioisotope

Indications: To aid in diagnosis of metastatic disease, tumors, osteomyelitis, trauma, arthritis, metabolic diseases, bone marrow hyperplasia, and Paget's disease

Preparation: No fasting is required. Obtain a signed informed consent. Radioisotope is injected intravenously 2 hours prior to the scan being performed. The client is to drink 4–6 glasses of water during the time between injection and scanning to help clear body of excess radionuclide.

Clinical Alert

Clients who are or may be pregnant should not have this procedure due to the risk of radiation exposure.

Procedure: Client voids and is then assisted to supine position. Client lies quietly on examination table during scanning, which may take 1 hour.

Nursing Process Elements

Encourage increased fluid intake following examination to ensure excretion of isotope. No other radionuclide tests should be scheduled for 24–48 hours.

PULMONARY SYSTEM

Arterial Blood Gases

- Measure the pH (acidity), oxygen content, and carbon dioxide content of the blood.

LABORATORY VALUES

Tables 16-1 to 16-7 summarize important information about the major laboratory tests used in the assessment of each body system. Table 16-8 lists laboratory tests and values

that are identified in the NCLEX-RN test plan as those the nurse “must know” or “must recognize when deviating from normal.”

Table 16–1 Cardiovascular System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---|---|--|------------------------------------|--|---|
| Creatinine Kinase (CK) Creatinine Phosphokinase | Enzyme found in higher concentrations in the heart and skeletal muscle and in the brain. | To identify injury to heart and skeletal muscle and the brain | 50–325 mU/ml | With MI it begins to rise in 4–6 hrs, peaks in 24 and returns to normal in 48–72 hrs | Decreased values have no diagnostic meaning |
| (CPK) CK-MB (CK-MB ₂) | Isoenzyme specific for cardiac muscle. | To identify cardiac injury | 0–6% | With MI it rises within 3–8 hrs, peaks in 18–24 hrs | Serial blood samples are drawn every 6–8 hrs, three times |
| Aspartate Transaminase (AST) | Enzyme present in tissues of high metabolic activity. | To identify liver and heart muscle damage | 7–40% | With MI it rises and peaks in 24 hrs | AST curve in MI parallels that of CK |
| Lactate Dehydrogenase (LDH) | Enzyme that is widely distributed in the tissues of the body. | Useful in diagnosis of MI when viewed in relation to other laboratory tests | 140–280 U/l | Elevates in 36–55 hrs after an MI | |
| LDH ₁ | One of five isoenzyme of fractions of LDH. It is present in cardiac tissues. | Useful in diagnosis of cardiac damage | 17–27% of total LDH | Released into the blood stream when cardiac tissue necrosis (MI) occurs | |
| LDH ₂ | One of five isoenzyme of fractions of LDH. It is present in cardiac tissues. | Useful in diagnosis of cardiac damage | 29–39% of total LDH | Released into the blood stream when cardiac tissue necrosis (MI) occurs. LDH flip is very helpful in diagnosing MI | LDH flip occurs when LDH ₁ levels are higher than LDH ₂ |
| Troponin I | Protein found only in cardiac muscle. | Useful in diagnosis of cardiac damage | <0.35 ng/ml | Rises with in 3–6 hrs of cardiac damage Peaks 12–16 hrs | |
| Cardiac troponin T | Protein which displays significant amino acid differences in cardiac and skeletal tissue. | Useful in diagnosis of cardiac damage | <0.2 ng/ml | Rises with in 4–8 hrs of cardiac damage Peaks 12–48 hrs | |
| Ischemia modified albumin (IMA) | Is a sensitive marker of myocardial ischemia, Acute Coronary Syndrome. | It was found that ischemia modified albumin rises so rapidly that it is present in the blood within 6–10 min after the ischemic episode. | | It occurs more rapidly than any other indicator. It also clears fairly rapidly, in about 6 hrs from the blood | Must be used in conjunction with other cardiac markers (e.g., troponin). |
| High density lipoprotein cholesterol (HDL-C) “the good cholesterol” | Lipoprotein which removes cholesterol from the arteries and transports it to the liver. | Used to assess CAD risk | Men: >40 mg/dl Women: >50 mg/dl | Decreased levels of HDL-C are considered atherogenic | Requires a 9–12-hr fast before the test and no alcohol for 24 hrs before test |

(continued on next page)

Table 16–1 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---|---|---|---|---|---|
| Low-Density Lipoprotein (LDL) “the bad cholesterol” | Lipoprotein which carries cholesterol to the arteries. | Used to assess CAD risk | Desirable <130 mg/dl Borderline high risk >140–159 High risk >160 mg/dl | Increased levels are considered atherogenic | Requires a 9–12-hr fast before the test and no alcohol for 24 hrs before test |
| Very low density lipoprotein (VLDL) | Lipoprotein which is a major carrier of triglycerides in the blood. VLDL degradation is a major source of HDL. | Used to assess CAD risk | 10–15% of total cholesterol | Increased levels are considered atherogenic | |
| High sensitivity c-reactive protein-hs (CRP) | A specific abnormal protein that appears in the blood during an inflammatory process. | Used to determine risk for coronary event | Normal: <0.8 mg/dl | The higher the value the greater the risk of a coronary event | Requires a 9–12-hr fast before the test and no alcohol for 24 hrs before test |
| Apolipoprotein B (Apo B) plaque | Measures the level of lipoprotein phospholipase A2 (Lp-PLA2). Lp-PLA2 generates oxidized molecules within the blood vessel wall that are more prone to lead to both atherosclerosis and irritability of the atherosclerotic plaque. | Used to determine risk for coronary event | Normal 50–100 mg/dl | High levels of Apo B are indicative of increased risk for heart attack and stroke even when LDL is not in the high-risk range | Requires a 12-hr fast |
| Brain natriuretic peptide (BNP) test | Measures the amount of the BNP in the blood and is a marker for ventricular dysfunction. | Used to diagnose CHF | Normal <100 ng/l | Elevated levels indicate worsening of CHF. Decreased levels indicate improvement of CHF | Requires a 12-hr fast |

Table 16–2 Hematologic/Immunologic System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|-----------------------------------|---|---|--|---|---|
| Complete Blood Count (CBC) | | | | | |
| Red blood cell (RBC) count | RBCs are produced in the bone marrow and live 80–120 d. | Important for oxygen carried on Hgb molecules | Female $4.2 \times 10^6/\text{mm}^3$ to $5.4 \times 10^6/\text{mm}^3$ Male $4.7 \times 10^6/\text{mm}^3$ to $6.1 \times 10^6/\text{mm}^3$ | Decreased in anemia, leukemia, and renal disease Increased in polycythemia | |
| Hemoglobin (Hgb) | Hgb is composed of <i>heme</i> (containing iron and porphyrin) and <i>globin</i> (protein). | Measures oxygen-carrying capacity of blood | Female 12–16 g/dl Male 13–18 g/dl | Decreased in anemia, leukemia, and renal disease Increased in polycythemia | |
| Hematocrit (Hct) | Proportion of RBCs to plasma within a sample of blood. | Assesses the extent of a client’s blood loss | Female 37–48% Male 42–52% | A drop of 3% in Hct equals approx. 1 unit of blood | With normal hydration, RBC count and Hgb, the Hct is normally 3 times the Hgb |
| Mean corpuscular volume (MCV) | Measurement of average RBC size. | Aids in diagnosis of type of anemia | 86–98 mm^3 | Elevated = macrocytic anemia Decreased = microcytic anemia | Microcytic/hypochromic anemia = Iron deficiency anemia |

(continued on next page)

Table 16–2 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|--|--|--|---------------------------------|--|--|
| Mean corpuscular hemoglobin concentration (MCHC) | Hemoglobin content relative to the size of the RBC. | Aids in diagnosis of type of anemia | 32–36 g/dl | Increased = hyperchromic Decreased = hypochromic | Macrocytic/hyperchromic anemia = Folic acid and Vitamin B12 deficiencies |
| Platelet count | Formed in the bone marrow, lifespan of 8–12 d, removed from circulation by spleen. | Assesses hemostasis and blood clotting | 150,000–400,000/mm ³ | Increased = thrombocytosis Decreased = thrombocytopenia | Spontaneous bleeding occurs with platelet count < 20,000/mm ³ Concern of clot formation with extremely high platelet count |

Blood Smear

| | | | | | |
|------------------|--|--|------|---|--|
| Heinz body test | Heinz bodies are intraerythrocytic insoluble inclusions of hemoglobin. | Used to detect hemolytic disorders associated with Heinz body formation. | Zero | Increased in G6PD deficiency, Homozygous B-Thalassemia | |
| Sickle cell test | Abnormality of hemoglobin. RBC have a crescent shape. | Used to diagnose sickle cell trait and sickle cell disease | None | A positive test means a number of erythrocytes have assume the typical sickle cell shape. | A positive test must be confirmed by electrophoresis |

White Blood Cell (WBC) Count and Differential

| | | | | | |
|------------------------------|--|--|------------------------------|--|--|
| White blood cell (WBC) count | WBCs protect the body from threat of foreign agents such as bacteria. | Aids in determining type and severity of infection | 4500–10,500/ mm ³ | Increased = leukocytosis | WBC counts are lower in a.m. and higher in p.m. |
| Neutrophil | First WBC to arrive at area of inflammation; mature neutrophils = “segmented”; immature neutrophils = “bands.” | | Segs 40–60% Bands 0–3% | Decreased = leukopenia Increased in acute pyogenic infections | Percentages in the differential count total 100%. Thus, an increase in one type leads to a decrease in others. |
| Lymphocyte | Immune WBCs; integral part in the antibody response to antigens. | | 20–40% | Increased in viral infections (mono) | With low neutrophil count (neutropenia), client may require reverse isolation. |
| Monocyte | When move out of circulation and into tissue, mature into macrophages, which are phagocytic cells. | | 2–8% | Increased in chronic inflammatory disorders | |
| Eosinophil | Role in defense against parasitic infections, phagocytize cell debris in later stages of inflammation. | | 1–4% | Increased in parasitic infections | |

(continued on next page)

Table 16–2 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|-----------------------------------|--|---|-----------------------------------|--|---|
| Basophil | Release histamine, bradykinin, and serotonin when activated by injury or infection. | | 0.5–1% | May be increased in chronic conditions such as ulcerative colitis | |
| Coagulation Studies | | | | | |
| Prothrombin time (Protime, INR) | Useful for detecting bleeding disorders caused by problems in the extrinsic system (factors I, II, V, VII, and X). | Monitors anticoagulant therapy with warfarin | 8.8–11.6 sec | Increased in DIC, factor deficiency, liver disease, and warfarin use | Standardized through use of international normalized ratio (INR). Target INR for DVT and afib treatment: 2.0–3.0 Target INR for mechanical heart valve: 2.5–3.5 |
| Partial thromboplastin time (PTT) | Useful for detecting bleeding disorders caused by problems in the intrinsic system (factors I, II, V, VIII, IX, X, XI, and XII). | Monitors anticoagulant therapy with heparin | PTT: 60–90 sec APTT: 25–35 sec | Increased in DIC, factor deficiency, liver disease, and heparin use | Chemicals can be added to standardize results, a test known as APTT (activated PTT) |
| Bleeding time | Measures duration of bleeding after a standardized skin incision has been made. Detects disorders involving platelet function. | Screens for preoperative clients and those with personal or family history of bleeding tendencies | 1–9 min | Increased in DIC, factor deficiency, hypocalcemia, bone marrow disorder, liver and renal disease, and thrombocytopenia | Prolonged bleeding time with normal platelet count indicates a qualitative platelet disorder |
| Electrolytes | | | | | |
| Sodium | Major cation in extracellular fluid Role in acid-base balance and neuromuscular functioning Inverse relationship with potassium | Assesses fluid balance of the body | 135–145 mEq/l | Increased (hypernatremia) in: dehydration, diabetes insipidus, and impaired renal function Decreased (hyponatremia) in: diaphoresis, diarrhea, vomiting, GI suctioning, inadequate sodium intake, overhydration, and overdiuresis | Hypernatremia: dry mucous membranes, fever, thirst, and restlessness. Hyponatremia: lethargy, confusion, abdominal cramping, apprehension, oliguria, rapid weak pulse, headache, tremors, seizures, and coma |
| Potassium | Major cation in intracellular fluid. Responsible for acid-base balance, cellular osmotic pressure, electrical conduction in muscle cells (especially cardiac and skeletal). | Evaluates clients with cardiac and renal problems, confusion, GI distress | 3.5–5.0 mEq/l | Increased (hyperkalemia) in acidosis, acute renal failure, diabetes, and hypoaldosteronism Decreased (hypokalemia) in alkalosis, diarrhea, hyperaldosteronism, liver disease, malabsorption, and vomiting | Hyperkalemia: S&S include weakness, malaise, nausea, diarrhea, muscle irritability, oliguria, and bradycardia. Hypokalemia: confusion, anorexia, muscle weakness, paresthesias, hypotension, cardiac dysrhythmias, and decreased reflexes. |

(continued on next page)

Table 16–2 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---|---|--|------------------|---|--|
| Calcium | 50% of calcium in blood is in free state; 50% is bound to albumin. Role in muscle contraction, heart function, transmission of nerve impulses, and clotting of blood. Release of calcium from bones into bloodstream controlled by parathyroid gland. | Measures parathyroid gland function and calcium metabolism | 8.5–10.5 mg/dl | Increased (hypercalcemia) in hyperparathyroidism, hyperthyroidism, various cancers, and Paget's disease Decreased (hypocalcemia) in chronic renal disease, hypoparathyroidism, and malabsorption | Clients with hypercalcemia: deep bone pain, renal calculi, and muscle hypotonicity. With hypocalcemia: paresthesias, muscle twitching, cardiac dysrhythmias, convulsions |
| Magnesium | Primarily an ion of intracellular fluid. Essential for proper neuromuscular functioning, energy production, blood clotting. Majority found in bones combined with calcium and phosphorus. | Used in monitoring renal, GI, and cardiac conditions | 1.5–2.0 mEq/l | Levels controlled by absorption from the intestines and excretion or absorption by the kidneys. Many causes of abnormal magnesium levels involve GI and renal problems | Increased serum magnesium levels: lethargy, flushing, hypotension, bradycardia, and weak reflexes Decreased levels: muscle twitching, tremors, tetany, cardiac dysrhythmias, and hyperactive reflexes |
| Phosphorus/ phosphate | Most phosphorus is combined with calcium in the bones. About 15% exists in blood; main anion in the intracellular fluid. Role in glucose and lipid metabolism, energy storage, acid-base balance. Levels controlled by parathyroid gland. | Measures parathyroid gland function | 2.4–4.1 mg/dl | Increased phosphorus with decreased calcium: hypoparathyroidism, and renal disease Decreased phosphorus with increased calcium: hyperparathyroidism Decreased phosphorus and calcium: malabsorption, Vitamin D deficiency | Calcium and phosphorus in inverse relationship: excess in the serum of one results in kidneys excreting the other |
| Other | | | | | |
| Blood culture | Performed to detect infection due to bacteria or fungi in the blood (bacteremia). | Identifies cause of blood infections | Negative | The culture specifies the bacteria; the sensitivity identify antibiotics to which organism is susceptible or resistant | Specimen collection should occur prior to beginning antibiotic therapy |
| Therapeutic drug monitoring (digoxin, lithium, aminoglycosides) | Used to manage client drug therapy for drugs in which there is a narrow margin of safety between therapeutic drug effect and drug toxicity. | Monitors drug levels of medication | Varies with drug | Increased with toxic drug levels; decreased with Subtherapeutic drug levels | Drug levels are drawn at peak and trough times for aminoglycosides (antibiotics which are nephrotoxic and ototoxic) |

(continued on next page)

Table 16–2 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---------------|---|---|---------------|--|--|
| Wound culture | In suspected wound infection, the interior of the wound is swabbed. Open wounds are cultured using aerobic culture tube; anaerobic tubes used if fluid aspirated from closed wound. | Identifies bacteria responsible for wound infection | Negative | The culture specifies the bacteria; the sensitivity identify antibiotics to which organism is susceptible or resistant | Specimen collection should occur prior to beginning antibiotic therapy |

Indications: To determine changes in the acid–base status of the client due to problems involving the pulmonary, cardiovascular, renal, and gastrointestinal systems, or administration of certain medications

- Rotate the blood in the test tube to be sure it has mixed with the heparin
- Place the sample on ice and take it to be analyzed

Nursing Intervention Alert

- Allen test should be performed before test is done
- Direct pressure should be applied for 2–5 minutes to the puncture site
- Note if client is receiving oxygen when the test is being done

Urinalysis

Description/Definition: Urinalysis involves testing using two methods. A urine dipstick is used to test for numerous components, with a microscopic evaluation done to further investigate abnormalities.

Table 16–3 Respiratory System

| Component | Description/Definition | Normal Values | Interpretation |
|---|--|---------------|--|
| Partial pressure of oxygen (PaO ₂) | Indicates how well oxygen is able to move from the lungs into the blood. | 70–100 mm Hg | If <70 then hypoxemia |
| Partial pressure of carbon dioxide (PaCO ₂) | Indicates how well carbon dioxide is able to move from the blood into the lungs and then expired. | 35–45 mm Hg | Respiratory contribution to acid-base balance |
| pH | Is a measure of hydrogen ion (H ⁺) in blood which indicates the acid or base (alkaline) nature of blood. | 7.35–7.45 | pH of less than 7.35 is acidic, and a pH greater than 7.45 is called alkaline. |
| Bicarbonate (HCO ₃) | Is a chemical buffering substance that keeps the pH of blood within a normal range. | 22–26 mEq/l | Metabolic (nonrespiratory) contribution to acid-base balance |
| Oxygen saturation (O ₂ Sat) | Provides information about the amount of oxygen in the blood. | 95–100% | Measure of the amount of oxygen bound to hemoglobin |

Table 16–4 Gastrointestinal System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|-------------------------------|---|---|--|--|--|
| Total serum protein | The total amount of albumin and globulin in serum, produce antibodies, steroids, thyroid hormones, transport blood components, preserve chromosomes. | Monitors protein levels, evaluate problems related to protein deficit, differentiate between albumin and globulin | Adult: 6.0–8.0 g/dl Child: 4.3–7.6 g/dl | Elevated levels found in liver disease, renal disease, multiple myeloma, and dehydration due to hemoconcentration. Low levels found with malnutrition, low protein diet, acute cholecystitis, Hodgkin's disease, malabsorption syndrome, and severe hepatic disease. | When albumin is low, assess for edema in lower extremities. Hyperglycemia may cause levels to appear greater than actual level. Check for albumin or protein in urine. Protein levels affected by recent dialysis. Client should avoid high fat foods 24 hrs before test. Encourage protein intake (eggs, meat, cheese) if levels are low. |
| Serum protein electrophoresis | A process that separates different protein fractions into albumin, alpha-1, alpha-2, globulin, beta globulin and gamma globulin. Results are determined by use of an electrical field: proteins separate by electrical charge and molecular shape and size. | Evaluates and fractions serum proteins to monitor causes of diseases; differentiates between protein fractions | Total protein: 6.0–8.0 g/dl Albumin: 3.3–5.0 g/dl Alpha 1 Globulin: 0.1–0.4 g/dl Alpha 2 Globulin: 0.5–1.0 g/dl Beta Globulin: 0.7–1.2 g/dl Gamma Globulin: 0.8–1.6 g/dl | Albumin Increased with dehydration and exercise. Decreased with liver disease third space losses, inflammatory disease, pregnancy, malnutrition, and malabsorption. <i>Alpha-1 globulin</i> Increased with inflammatory disease, burns. Decreased in a client with a genetic disease or without this enzyme. <i>Alpha-2 globulin</i> Increased with inflammatory disease, nephrotic syndrome. Decreased with hyperthyroidism, hemolysis, and hepatic disease. <i>Beta globulin</i> Increased with iron deficiency anemia, biliary cirrhosis. Decreased with malnutrition, malabsorption, and hepatic disease. <i>Gamma globulin</i> Increased with acute and chronic infection, cirrhosis, and malignancy arthritis. Decreased with genetic immune disorders, lymphocytic leukemia, and lymphosarcoma. | Test may be performed on serum or plasma. To detect changes with this test about a 30% drop in albumin is required. When protein electrophoresis value is abnormal, an immunofixation electrophoresis, (IFE) is performed. |
| Serum albumin | Functions to maintain oncotic pressure in vascular system and in the transportation of | Identifies abnormal levels of albumin caused by disease processes (see interpretation) | Adult: 3.5–5 g/dl Age above 60 yr: 3.4–4.8 g/dl | Elevated levels found with dehydration, Hodgkin's Disease, stress, pneumonia, RA, neoplasms, | Check for albumin in urine. Low serum albumin may require a 24-hr urine collection to measure protein loss. |

(continued on next page)

Table 16–4 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|----------------|---|---|---------------|---|--|
| | bilirubin, one of the two main protein factors in blood, the smallest amount of protein molecules, makes up largest percentage of total protein value. | | | exercise, diarrhea, and vomiting. Low levels found in malnutrition, leukemia, malabsorption syndrome, chronic renal failure, severe burns, CHF, toxemia of pregnancy, and chronic liver disease. | When serum albumin is below normal, the total serum calcium is decreased. A lack of albumin in serum allows fluids to leak out of interstitial spaces and into peritoneal cavity (causing ascites). |
| Serum globulin | Refers to nonalbumin portion of serum protein, made up of a complex group of serum proteins, five times as large as albumin molecules, but not as effective as albumin in maintaining osmotic pressure, forms the main transport system for substances and constitutes the antibody and clotting systems. | Measures globulins produced by liver and lymphoid tissue, evaluates presence of abnormal levels | 2.3–3.5 g/dl | Elevated values with acute and chronic infection, malignancies, allergies, RA, iron deficiency anemia, biliary cirrhosis. Decreased levels found in hepatitis, asthma, and lupus erythematosus. | Electrophoresis divides globulins into alpha, beta, and gamma factors; medications that alter results: growth hormone, acetaminophen, estrogen, corticosteroids, niacin, and elevated serum lipid levels may cause abnormal results. |

Liver Function Tests

| | | | | | |
|--|--|--|---|---|--|
| Alanine aminotransferase (ALT) (formerly SGPT) | Enzyme found primarily in liver and in some body fluids, injury to liver causes release of this enzyme into the bloodstream, elevating ALT levels. | Diagnoses hepatocellular destruction; monitors liver problems related to hepatotoxic medications and response to treatment of liver disease and routine screening for hepatitis in donor blood samples; differentiates between hemolytic jaundice and jaundice | 4–36 IU/l | Elevated levels seen with hepatitis, cirrhosis, CHF, hepatic damage, hepatic cancer; and hepatotoxic drugs. Low levels seen with weight loss, hepatitis C, and exercise. | Medications that interfere with test should be held for 12 hr before and alcohol for 24 hr before test. With liver damage ALT elevates up to 50 times normal. ALT levels may be slightly elevated with myocardial infarction. |
| Alkaline phosphatase | Enzyme produced primarily in the liver and bone and in intestine, placenta, and kidneys; functions best at a pH of 9. | Diagnoses and monitors hepatic and bone diseases | Female: 30–100 IU/l Male: 45–115 IU/l Infant/ Child: 1–2 times of adult level | Elevated levels with bone or liver disease, obstructive jaundice, hyperparathyroidism, Paget's Disease, normal pregnancy, RA, MI, medications: antibiotics, Indocin, INH, allopurinol, and albumin made from placental tissue. Decreased levels with malnutrition, pernicious anemia, hypoparathyroidism, celiac disease, cystic fibrosis, scurvy, and placenta insufficiency. Medications: fluorides, phosphates, propranolol, and oxalates. | Alkaline phosphatase isoenzymes should be measured if alkaline phosphatase level is elevated. Levels increase during periods of bone growth. Benign hyperphosphatemia occurs mostly in young children and in a few adults, other enzyme tests may be ordered to verify client's diagnosis. |

(continued on next page)

Table 16–4 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|--|--|---|---|--|---|
| Aspartate Aminotransferase (AST) (formerly SGOT) | Increased AST levels occur when there is a serious damage to cells, related to disease or injury, AST is released into the blood stream; this enzyme is found primarily in heart, liver, and muscle tissue and in moderate amounts in pancreas and kidney. | Detects presence of AST, evaluates coronary artery disease or hepatocellular diseases, diagnoses an MI by comparing AST levels with CK and LDH | 8–38 IU/l Newborn: four times of normal adult | Elevated values with an acute MI, alcoholism, cirrhosis, diabetes mellitus, severe burns, musculoskeletal disease, acute pancreatitis, strenuous exercise, IM injections. Decreased levels with diabetic ketoacidosis, pregnancy, uremia, liver disease, and beriberi. | AST levels are often compared with ALT levels. Do not administer IM injection before taking this blood test. Assess for symptoms of an MI. Increased levels are seen with cardiac catheterization, angioplasty, or surgery. |
| Bilirubin, blood | Bilirubin is formed in the liver, spleen, and bone marrow, and as a result of hemoglobin breakdown (RBC destruction). Direct (conjugated) bilirubin is excreted by the GI tract, with minimal amounts entering bloodstream. Indirect (unconjugated) bilirubin is normally in the bloodstream. | Used to differentiate causes of jaundice | Direct: 0–0.4 mg/dl Indirect: 0.1–1.0 mg/dl Total: 0.3–1.0 mg/dl | Direct bilirubin rises when obstructive jaundice (as from gallstones) or hepatic jaundice occurs. Indirect bilirubin rises in cases of hemolytic jaundice (breakdown of hemoglobin) and in cases of hepatocellular dysfunction (as with hepatitis) | Testing with contrast medium within 24 hr will alter test results. Exposure of blood sample to sunlight or artificial light will decrease bilirubin content of sample. |
| Gamma glutamyl transpeptidase (GGTP) | A biliary excretion enzyme that assists with transfer of peptides and amino acids across cellular membranes, primarily found in the liver, biliary tract, kidney, prostate, and spleen and heart muscle. | Detects hepatobiliary disease, monitors alcohol abuse and drug toxicity | Female: 3–31 IU/l Male: 4–23 IU/l | Elevated values with liver disease, biliary obstruction, and damage to liver from alcohol, alcoholism, renal cancer, acute pancreatitis or cholecystitis, CHF, MI. Medications: phenobarbital, warfarin, aminoglycosides, phenytoin, 5FU, and alcohol; decreased levels are not clinically significant | During late pregnancy, values are low. Encourage client with an alcohol problem to join AA. Document any client medications that interfere with test results on laboratory form |
| Lactic dehydrogenase (LDH) | Intracellular enzyme released as a result of injury to body tissue, found in liver, heart, brain, skeletal muscle, kidneys, and RBCs. Made up of various formations of isoenzymes as: LDH 1: cardiac and RBC; LDH 2: cardiac and RBC; LDH 3: pulmonary, liver, and spleen; LDH 4: hepatic and skeletal; LDH 5: hepatic and skeletal. | Diagnoses myocardial or skeletal muscle damage, compares results with other cardiac enzyme tests, detects organ involvement with LDH isoenzymes | 100–190 IU/l <i>Isoenzymes</i> LDH 1: 25–36%, LDH 2: 35–46%, LDH 3: 13–26% LDH 4: 3–10%, LDH 5: 2–9% | Elevated levels with acute MI, leukemia, liver damage, shock/trauma, placental problems, pulmonary disease, skeletal muscle disease, stroke, and hepatitis. Medications: narcotics, anesthetics, aspirin, and alcohol; decreased results caused by ascorbic acid | Strenuous exercise may lead to increased LDH 1, 2 and 5 levels. IM injections can increase results. Cancer or megaloblastic anemia result in very high LDH levels |

(continued on next page)

Table 16–4 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|-------------------------------------|--|---|--|---|---|
| 5'-Nucleotidase | A specific liver isoenzyme, damage to hepatobiliary tissues leads to leakage of this isoenzyme into the blood resulting in elevated values. | Confirms diagnosis of hepatic/biliary obstructive disease, diagnoses a liver disorder by comparing test results with other liver enzyme tests, differentiates between a diagnosis of liver and bone cancer, 5'-Nucleotidase is rarely elevated in bone cancer | 0–1.6 u at 37 °C 0.3–3.2 Bodansky units Children's values are lower than adults | Elevated values with hepatitis, cirrhosis, cholestasis, bile duct obstruction, alcoholism, sickle cell anemia, and metastasis to liver. Medications: aspirin, narcotics, phenytoin, phenothiazine, and acetaminophen | Other liver enzyme results such as ALP, GGT, and alkaline phosphatase should be evaluated along with this test to evaluate and diagnose liver function/disorders. Encourage client to eat well-balanced meals, especially with cancer of the liver and cirrhosis. Inform client about possible tendency towards bleeding. |
| Other GI-related Tests | | | | | |
| Ammonia | Waste product that forms as a result of nitrogen breakdown during intestinal protein metabolism and from digestion of blood from the GI tract. Normally converted into urea by the liver and excreted by the kidneys. If disorder prevents this conversion, ammonia accumulates in blood, leading to hepatic encephalopathy. | Evaluates confusion and coma. Monitors effectiveness of treatment for liver disease | Adult: 15–45 mcg/dl Children: 40–80 mcg/dl Newborn: 90–150 mcg/dl | Increased with azotemia, cirrhosis, GI bleeding, hemolytic disease of the newborn, hepatic failure, and renal failure | Fasting for 8 hrs is required for this test (water is permitted). The client should avoid strenuous exercise and smoking just prior to the test. |
| Fecal occult blood testing (FOBT) | FOBT is used as a screening tool for colon cancer. It detects the presence of blood in the stool, but does not differentiate the location of the blood loss (upper GI vs. colon). Samples of stool are placed on specially treated cards. A developing solution is applied, with blue coloration indicating the presence of blood. | Detects blood loss into the stool | Negative | Positive test results may be due to colon polyp, diverticulitis, esophageal varices, gastritis, GI cancer, GI trauma/surgery, hemorrhoids, inflammatory bowel disease, and ulcer. | Red meats and foods with high peroxidase activity (beets, broccoli, cantaloupe, cauliflower, horseradish, and parsnips, turnips) cause <i>false-positive</i> results with guaiac-based FOBT ASA and NSAIDs should be avoided for 2 d before the test |
| Helicobacter pylori (H pylori) | Antibody test, determines presence of H Pylori with use of serological testing or urea breath test Transmission of H Pylori can occur with use of contaminated endoscopic equipment. | Detects presence of organism, H Pylori, causing recurrent gastrointestinal disorders | Not present | Positive result indicates presence of this gram-negative bacilli, causing gastritis, gastric ulcers, duodenal ulcers or inflammation, peptic ulcers, and gastric cancer | Most duodenal ulcers are caused by H Pylori. When detected and treated, ulcers usually heal. Breath test contraindicated in pregnant clients and children due to use of radioactive carbon |
| Hepatitis associated antigens (HAA) | Tests performed to evaluate inflammation of the liver due to Hepatitis viruses A, B, | Group of tests used to detect major types and current status of Hepatitis. Positive | Negative | <i>Hepatitis A antibody</i> IgM identifies the acute phase of infection, IgG identifies past infection or immunity. | Maintain standard precautions, client is considered infected until serology tests |

(continued on next page)

Table 16–4 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---------------|--|--|--|---|---|
| | C, and D. HEV, rarely seen in the United States, has no antigen or antibody tests available to identify virus at this time. | results indicate the specific type of Hepatitis that has infected the client | | <p><i>Hepatitis B surface antigen (HBsAB)</i> Identifies active hepatitis, acute or chronic</p> <p><i>Hepatitis B surface antibody (HBsAg)</i> Appears after disappearance of surface antigen, indicates end of acute infection phase.</p> <p><i>HBe antigen (HBe Ag)</i> Detects presence of antigen in blood and development of chronic HBV infection.</p> <p><i>HBe antibody (HBeAB)</i> Indicates resolution of acute infection.</p> <p><i>HB core antibody (HBcAb)</i> Indicates increased level during time between disappearance of HBsAg and appearance of HbsAb.</p> <p><i>Anti-HCV antibodies</i> Identified with the enzyme immunoassay (EIA) test, detects antibodies within 4 wk of infection;</p> <p><i>Hepatitis delta antibody (HDV)</i> Detects presence within a few days after infection</p> | indicate they are not, Hepatitis A, B, C (non-A, non-B), D, E, exist in acute, chronic, chronic active, and carrier phases. |
| Stool culture | Exposure to enteric pathogens may occur through foreign travel or contaminated food or water. GI symptoms can also occur if antibiotic therapy has suppressed normal intestinal flora, allowing remaining bacteria to become pathogenic. | Isolates and identifies organisms which might be causing GI symptoms | Normal flora present Negative for pathogens | Positive results occur with bacterial, parasitic, or protozoal enterocolitis | Follow-up stool analysis may be done if symptoms persist or to ensure pathogen is no longer present in stool |

Use: A screening test used in the diagnosis of urinary tract infections and in the diagnosis of diseases unrelated to the urinary system.

Normal values and interpretation:

- Appearance: clear to slightly hazy
 - Cloudy urine may be due to presence of WBCs, RBCs, bacteria
 - Smoky urine may be due to presence of blood

- Color: light yellow to amber
 - Many medications change the urine color
- Odor: aromatic
 - Sweet/fruity urine due to ketonuria
 - Fish/foul-smelling urine due to urinary tract infection
- Specific gravity (measure of urine concentration compared to water): 1.005–1.030
 - Indication of kidneys' ability to concentrate and excrete urine

Table 16–5 Neuromusculoskeletal System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|--------------------------------------|---|---|--|---|---|
| Erythrocyte sedimentation rate (ESR) | In the case of inflammation, necrosis, or physiologic stress (such as pregnancy), there is a change in blood proteins, which leads to a clumping of RBCs. The ESR measures the speed with which RBCs settle in a tube of blood. Clumped cells fall faster, resulting in a higher ESR (measured in mm/hr). | A nonspecific test for inflammatory and necrotic conditions | Male: <15 mm/hr Female: <20 mm/hr Elderly: slightly increased Child: 3–13 mm/hr Newborn: 0–2 mm/hr | Increased levels are seen in inflammatory bowel disease, infection, inflammation, malignancies, myocardial infarction, rheumatoid arthritis, temporal arteritis, tissue injury, and use of oral contraceptives. Aspirin and steroids decrease ESR levels. | Serial ESR measurements can be used to monitor effectiveness of steroids in treating conditions such as temporal arteritis. |

- Increased in renal disease, congestive heart failure, dehydration, diabetes mellitus, excessive fluid loss (diarrhea, vomiting), increased secretion of ADH, liver disease
- Decreased in ADH deficiency, use of diuretics, high fluid intake
- pH: 4.6–8.0 with a mean of 5.0–6.0
 - Provides information regarding acid-base status of the client
 - Increased (alkaline) with chronic renal failure, urinary tract infection
 - Decreased (acidic) with dehydration, diabetes mellitus, diarrhea
- Leukocyte esterase: Negative
 - Tests presence of enzyme released from WBCs when bacteria are present in the urine
 - False negative findings are extremely rare, but can occur when there is ascorbic acid or protein in the urine
 - False positive results may occur if the urine sample is contaminated with vaginal secretions.
 - Positive findings should be verified by a urine culture
- Nitrites: Negative
 - Nitrate, normally found in the urine, is converted to nitrite when gram-negative bacteria are present in the urine.
 - Some types of bacteria do not lead to a positive nitrite.
 - Most accurate if done on first morning specimen
- Protein (albumin): Negative
 - With normal renal function, there is no protein in the urine because the glomerular filtrate membrane of the kidney does not allow large protein molecules to pass through.
 - Protein may be positive in diabetes mellitus, exercise, glomerulonephritis, preeclampsia, pyelonephritis, lupus
- False-positive results may occur if the urine is highly alkaline due to standing too long before being tested, if urine is highly concentrated, and after receiving contrast dye.
- False-negative results may occur if the urine is very dilute.
- Glucose: Negative
 - If the serum glucose level is higher than the renal threshold for glucose, glucose will be excreted by the kidney
 - Glucose may be present in acromegaly, Cushing's syndrome, diabetes mellitus, gestational diabetes, infection, and proximal tubular dysfunction
 - Positive results should be followed by further testing to determine presence of diabetes mellitus.
- Ketones: Negative
 - With uncontrolled diabetes mellitus, the body, unable to use glucose as an energy source, breaks down fatty acids for energy. This results in ketone bodies being formed and excreted in the urine.
 - Positive results with alcoholism, anorexia, diabetes mellitus, diarrhea, fasting, high protein diet, hyperthyroidism, pregnancy, and vomiting.
- Urobilinogen: Negative or 0.1–1.0 Ehrlich units/dl
 - Bilirubin is converted to urobilinogen by intestinal bacteria. Normally a very small amount of urobilinogen is present in the urine. This increases in the case of hepatic dysfunction or a hemolytic process

Table 16–6 Endocrine System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---|--|---|---|--|--|
| Fasting plasma glucose (FPG) Also known as fasting blood sugar (FBS) | Glucose is a primary source of energy within cells. It is formed from the metabolism of ingested carbohydrates and from the conversion of glycogen to glucose in the liver. Normal blood glucose is dependent upon proper functioning of glucagon and insulin. | Detects problems with glucose metabolism. | <100 mg/dl | Increased with brain trauma, burns, Cushing's syndrome, diabetes mellitus, hyperthyroidism, liver disease, pancreatic dysfunction, pituitary tumors, and medications such as beta-blockers, corticosteroids, diuretics, and estrogens. Decreased with Addison's disease, excessive exercise, hypothyroidism, insulinoma, islet cell carcinoma of the pancreas, malabsorption, stress, and intake of insulin | FPG of 100–125 mg/dl is considered "Impaired fasting glucose". A provisional diagnosis of diabetes mellitus is made with FPG of ≥ 126 mg/dl, but the diagnosis must be confirmed. |
| Glucose tolerance test (GTT) | After intake of a meal, the blood sugar peaks in 1 hr and then returns to premeal levels within 2–3 hrs. The GTT is used to evaluate the rate at which glucose is removed from the bloodstream following administration of an oral glucose load. | Measures glucose levels after giving client an oral carbohydrate challenge, confirms diagnosis of diabetes mellitus when persons have a high or slightly elevated blood glucose level, used for those with a family history of, women who have babies weighing more than 10 lbs | Fasting: <110 mg/dl After 30 min: <200 mg/dl | Elevated levels seen with diabetes mellitus, gestational diabetes, acute pancreatitis, liver disease, infections, burns, Cushing's Syndrome, hyperthyroidism, stress, and chronic renal failure; medications as corticosteroids, estrogens, and diuretics, salicylates; low levels are seen with hyperinsulinism, hypoparathyroidism, malabsorption, protein malnutrition, alcoholism, and Addison's disease | Insulin production is decreased due to aging, causing higher glucose levels; client with an FBS greater than 150mg/dl may not need GTT to confirm diabetes; obesity can increase glucose levels. |
| Hemoglobin A1C | One type of hemoglobin, Hemoglobin A1C, absorbs glucose. This glucose remains in the A1C for the lifespan of the RBC (120 d). | Used to monitor long-term diabetic control (2–3 mo average) | Nondiabetic 2.2–5% Diabetic <7% | Increased in hyperglycemia, newly diagnosed diabetes mellitus, poor diabetic control, and after alcohol consumption. Decreased with chronic loss of blood, chronic renal failure, hemolytic anemia, pregnancy, and splenectomy. | The use of testing for Hgb A1C is not recommended for diagnosis of diabetes mellitus. |

(continued on next page)

Table 16–6 (continued from previous page)

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|-----------------------------------|--|---|--------------------|---|---|
| Thyroid stimulating hormone (TSH) | TSH stimulates the thyroid to release T3 and T4. When the levels of T3/T4 are elevated, the thyroid does not need to release more, so TSH levels decrease. | Used to diagnose and monitor client response to treatment for thyroid disease | 0.4–4.0 μ U/ml | Increased with Hashimoto's thyroiditis, Hyperpituitarism, pituitary adenoma, primary hypothyroidism, subtotal thyroidectomy, and medications such as amiodarone, lithium, and sulfa drugs. Decreased with hyperthyroidism, multinodular thyroid gland, and pituitary hypofunction. | Recent testing with radioactive isotope may affect test results. TSH levels are lowest around 10 a.m. and highest around 10 p.m. |

Table 16–7 Genitourinary System

| Test | Description/Definition | Use | Normal Values | Interpretation | Nursing Alerts |
|---------------------------------|--|---|---|---|---|
| Blood urea nitrogen (BUN) | Urea nitrogen is produced by the liver as a result of protein metabolism. It is normally excreted by the kidneys. In renal disease, this excretion decreases, resulting in higher levels in the blood. | Test of renal function, specifically of glomerular function | Adult: 7–20 mg/dl Elderly: slightly increased | Increased in congestive heart failure, diabetes mellitus, GI bleeding, high-protein diet, renal disease and use of medications such as ACE-inhibitors, aminoglycosides, diuretics, NSAIDs, and contrast dye. Decreased in celiac disease, inadequate protein intake, liver failure, and pregnancy. | Nephrotoxic drugs must be used cautiously if BUN is increased. BUN and creatinine are to be assessed before contrast dye is administered to clients aged above 60 yrs, or those with renal disease, diabetes mellitus, or lupus. |
| Creatinine | Creatinine is a waste product of creatine phosphate, found in skeletal muscle tissue. It is excreted entirely by the kidneys. Normally it remains at constant level, even with aging. | Test of renal function. | Female 0.6–1.2 mg/dl Male 0.8–1.4 mg/dl Children 0.2–1.0 mg/dl | Increased levels indicate a slowing of the glomerular filtration rate. Seen in CHF, dehydration, diabetes mellitus, renal disease, lupus, urinary obstruction. Decreased levels occur in pregnancy and with muscle atrophy | BUN and creatinine are to be assessed before contrast dye is administered to clients age 60+, or those with renal disease, diabetes mellitus, or lupus Creatinine must be monitored at least every 12 mo for clients taking metformin for diabetes mellitus. |
| Prostate-specific antigen (PSA) | PSA is a glycoprotein found only in the epithelium of the prostate. | Screens for prostate cancer. Used to monitor disease progression and response to treatment. | <4 ng/ml | Increased levels with benign prostatic hypertrophy, cirrhosis, prostate cancer, prostate inflammation/trauma/manipulation, prostatitis, urinary retention, urinary tract infection | Falsely elevated levels can occur after urinary catheterization, cystoscopy, transrectal ultrasound or prostate biopsy |

Table 16–8 Laboratory Values Essential to Basic Nursing Practice

| Test | Value | Test | Value |
|---|--|---|---|
| <i>Laboratory values about which the NCLEX-RN test plan states the test taker will “know”</i> | | <i>Laboratory values about which the NCLEX-RN test plan states the test taker will “recognize deviations from normal”</i> | |
| Arterial blood gases | | | |
| pH | 7.35–7.45 | Creatinine | High risk: >10 mg/dl Male: 0.8–1.4 mg/dl Female: 0.6–1.2 mg/dl |
| PaO ₂ | 70–100 mm Hg | Digoxin | 0.2–1.0 mg/dl Therapeutic range: 0.9–1.2 ng/ml |
| PaCO ₂ | 35–45 mm Hg | Erythrocyte sedimentation rate (ESR) | Male: <15 mm/hr Female: <20 mm/hr SI increased elderly Child: 3–13 mm/hr Neonate: 0–2 mm/hr |
| SaO ₂ | 95–100% | Lithium | <1.5 mEq/l (serum level to avoid serious dose related side effects) Therapeutic range: 0.5–1.2 mEq/l |
| HCO ₃ | 22–26 mEq/l | Magnesium | 1.5–2.0 mEq/l |
| Total cholesterol | 160–200 mg/dl | Partial thromboplastin time (PTT) | 60–90 sec |
| Glucose (FBS) | <100 mg/dl | Activated Partial thromboplastin time (APTT) | 25–35 sec |
| Hematocrit | Male: 42–52% Female: 37–48% | International normalized ratio (INR) | 0.7–1.8 (when used to monitor warfarin therapy, maintain between 2.0–3.0) |
| Hemoglobin | Male: 13–18 g/dl Female: 12–16 g/dl | Phosphorus/phosphate | 2.4–4.1 mg/dl |
| HbA1C | Nondiabetic: 2.2–5% Diabetic: <7% | Total protein | Adult: 6.0–8.0 g/dl Child: 4.3–7.6 g/dl |
| Platelets | 150,000–400,000/mm ³ | Prothrombin time (PT) | 8.8–11.6 sec |
| Serum potassium (K+) | 3.5–5.0 mEq/l | Urine albumin | Negative |
| Red blood cell count | Male: 4.7–6.1 × 10 ⁶ /mm ³ Female: 4.2–5.4 × 10 ⁶ /mm ³ | Urine pH | 4.6–8.0 |
| Serum sodium (Na+) | 135–145 mEq/l | Differential | Neutrophils: segs 40–60% Bands 0–3% Lymphocytes: 20–40% Monocyte: 2–8% Eosinophil: 1–4% Basophil: 0.5–1% |
| Urine specific gravity | 1.005–1.030 | | |
| White blood cell count | 4,500–10,500/mm ³ | | |
| <i>Laboratory values about which the NCLEX-RN test plan states the test taker will “recognize deviations from normal”</i> | | | |
| ALT | 4–36 IU/l | | |
| AST | 8–38 IU/l | | |
| Bilirubin | Direct: 0–0.4 mg/dl Indirect: 0.1–1.0 mg/dl Total: 0.3–1.0 mg/dl | | |
| Bleeding time | 1–9 min | | |
| Total calcium | 8.5–10.5 mg/dl | | |
| High density lipoprotein cholesterol (HDL-C) | Men: >40 mg/dl Women: >50 mg/dl | | |
| Low density lipoprotein (LDL) | Desirable: <130 mg/dl Borderline high risk: >140–159 | | |

—Positive/increased with acute hepatitis, cirrhosis, cholangitis, hemolytic anemia, severe ecchymosis.

—Decreased with biliary obstruction, inflammatory disease, renal insufficiency, severe diarrhea.

- Bilirubin: Negative (no more than 0.2 mg/dl)

—Bilirubin is normally converted to urobilinogen in the intestine. If jaundice occurs due to obstruction or liver disease, direct bilirubin is unable to reach the GI tract and instead enters the bloodstream and is then excreted in the urine.

—Positive/increased in cirrhosis of the liver, hepatitis, and obstructive jaundice.

- Microscopic examination of urine

—Bacteria: Negative

—Casts: None

—Crystals: New

—RBCs: 0–2/hpf

—WBCs: 4–5/hpf

Nursing Intervention Alert

Most accurate results occur with first morning voiding. Specimen should be “clean catch,” with the client carefully cleansing the area around the urethral meatus to avoid contamination of the specimen. The specimen should be taken to the laboratory as soon as possible for processing.

THERAPEUTIC PROCEDURES

INTRA-AORTIC BALLOON PUMP (IABP)

- A counter-pulsation mechanical aid to the circulatory function of the heart
- Improves coronary blood flow and systemic circulation
 - Increases perfusion of coronary arteries
 - Decreases cardiac workload
 - Decreases cardiac oxygen demand and consumption

Indications: To assess cardiogenic shock, unstable angina resistant to drug therapy, refractory ventricular dysrhythmias, ventricular septal rupture, and left ventricular failure after cardiac surgery

Preparation: Prepare the client and the family for the procedure. The client will be in a CCU or ICU setting with specially trained nurses or personnel to monitor the console and interpret the recordings. Obtain signed informed consent.

Procedure: An intra-aortic balloon and catheter is inserted percutaneously through the femoral artery and advanced to the descending aorta. This procedure is done in surgery, the cardiac catheterization laboratory or the critical care unit. The catheter is then connected to the console and pumping begins.

Nursing Process Elements

- Provide client education concerning IABP functioning and monitoring
- Make sure the catheter is secure and dry sterile occlusive dressing is in place
- Inspect site for signs of infection and complications
- Perform dressing change per protocol
- Change lines per protocol
- Assess vital signs, pulse oximetry, laboratory values, and hemodynamic parameters
- Assess peripheral perfusion by checking extremity for color, temperature, sensation, pulses, and movement
- Know procedures for immediate treatment if complications occur
- Maintain the head of the bed no higher than 45 degree elevation in order to prevent kinking of the catheter due to hip flexion
- Provide emotional support to client and family

Complications: Infection, embolism, thromboembolism, hemorrhage, dysrhythmias, peripheral ischemia, balloon perforation, inability to wean from IABP

Oxygen Therapy

- Provision of supplemental oxygen to restore the balance between oxygen taken in and carbon dioxide released

- Use results in reduced cardiac workload, decreased dyspnea, improved sleep, and exercise tolerance

Indications:

- Short-term use during recovery from acute lung disorder such as pneumonia, acute exacerbation of chronic obstructive pulmonary disease (COPD), or to decrease cardiac workload during congestive heart failure, angina, or acute myocardial infarction
- Long-term use for those with chronic lung diseases in which oxygen levels are consistently low, such as emphysema, occupational lung disease, lung cancer, cystic fibrosis, and nocturnal hypoxemia

Preparation:

- Need for oxygen therapy usually determined through oximetry or arterial blood gas analysis
- Prescription for oxygen therapy is needed, including oxygen flow rate in l/min, when to use the oxygen (such as while exercising or only while sleeping), how many hours to use the oxygen (some may need continuously), and the delivery system to be used.

Procedure:

- Oxygen can be supplied through three types of systems
 - Concentrators are devices that take oxygen from the room air and concentrate it for provision to the client. These devices are not available for portable use.
 - Compressed gas systems are available in metal cylinder tanks, which vary in size from large home-based tanks to small portable tanks.
 - Liquid gas systems include a large container of liquid oxygen and a portable unit, which can be refilled from the large container.
- Oxygen is delivered to the client from one of the above systems through the use of a nasal cannula, a mask, or a transtracheal catheter.
- During oxygen therapy, oximetry can be used to monitor oxygen saturation levels, with adjustments in oxygen flow settings made as needed.

You should never smoke while using oxygen. Warn visitors not to smoke near you when you are using oxygen. Put up no-smoking signs in your home where you most often use the oxygen. When you go to a restaurant with your portable oxygen source, ask to be seated in the nonsmoking section. Stay at least 5 feet away from gas stoves, candles, lighted fireplaces, or other heat sources. Do not use any flammable products like cleaning fluid, paint thinner, or aerosol sprays while using your oxygen.

If you use an oxygen cylinder, make sure it is secured to some fixed object or in a stand. If you use liquid oxygen, make sure the vessel is kept upright to keep the oxygen from pouring out; the liquid oxygen is so cold it can hurt your

skin. Keep a fire extinguisher close by, and let your fire department know that you have oxygen in your home. If you use an oxygen concentrator, notify your electric company so you will be given priority if there is a power failure. Also, avoid using extension cords if possible.

Complications:

- Although side effects are rare, oxygen overuse can result in oxygen toxicity and atelectasis. Respiratory depression can occur if too high of flow rate is used in a client with COPD.
- Administration of high oxygen levels to premature infants can cause retinopathy of prematurity or contribute to occurrence of patent ductus arteriosus. Avoid PaO₂ (partial pressure of oxygen) levels greater than 80 mm Hg.
- Problems related to equipment include perforation of the nasal septum from use of nasal cannulas without humidification, and bacterial infections from contamination of humidification systems.

Nursing Process Elements

- Clients should be monitored for S&S of inadequate oxygenation including, restlessness, confusion, anxiety, cyanosis, drowsiness, or dyspnea.
- Monitor oxygen saturation levels through use of oximetry while at rest and with activity.
- Ensure proper use and cleaning of equipment.
 - Gauze may be placed under tubing to prevent skin irritation.
- Provide client with information on home oxygen equipment suppliers.

Client teaching for self-care

- Do not change the flow rate of oxygen unless directed to do so by the physician.
- Avoid use of alcohol or other central nervous system depressants, which depress the respiratory rate.
- Have no open flames, combustible products, including petroleum jelly, oils, and aerosol sprays, or equipment which might produce a spark.
 - If client requires lubricant on lips or nostrils, use water-based lubricants.
- Have a smoke detector and fire extinguisher in the home.
- Clean the oxygen delivery equipment as instructed.
- Keep oxygen cylinder in safe location where it will not fall over or become heated (avoid placement near flames or in trunk of car).
- Contact medical supplier early for additional oxygen supplies.

CHEST TUBE

- A tube inserted through the chest wall to remove air or fluid from the pleural space

Indications: To treat pneumothorax or hemothorax, to drain blood from the mediastinum after open-heart surgery

Preparation: Perform a baseline cardiopulmonary assessment. Explain the procedure to the client. Place the client in high Fowler's or semi-Fowler position. Obtain signed informed consent. Administer sedation as ordered.

Procedure: The skin is cleansed and injected with a local anesthetic. A 1-inch skin incision is made and a hemostat is used to enter the pleural space. The tube is inserted and attached to a drainage device and to wall suction.

Clinical Alert

A postinsertion chest X-ray is done to ensure proper placement of the chest tube.

Nursing Process Elements

Routine Care

- Cardiopulmonary assessments are done at least every 4 hours.
- Monitor chest tube drainage every 2–4 hours.
- Dressing changes are done per hospital protocol
- Encourage client to cough and deep breathe, and to change positions every 2 hours.

Nursing Process Elements

Special Considerations

- Check chest drainage system for air leak.
 - Bubbling in the water seal chamber or air leak meter indicates the presence of an air leak.
 - If there is no leak, the water level in this chamber will oscillate with client respiration. This oscillation reflects normal pressure changes in the pleural cavity.
- Monitor chest tube drainage
 - Increased drainage suggests new or increased bleeding
 - Expect little drainage if the client has a pneumothorax (tube is draining air)
 - Check tube for blockage and kinks
- Maintain chest tube to water-seal drainage
 - Prevents air from entering the chest tube when client inhales.
 - Have the client take several deep breaths to fully inflate the lung and help push pleural air out through the tube.
 - Palpate the chest around the tube for subcutaneous emphysema and notify the MD if it increases.
 - Assess the function of the tube and describe and record amount of drainage.
- Care of the dislodged chest tube:
 - Cover the chest wall opening immediately with petroleum gauze.

- Apply pressure to prevent negative inspiratory pressure from sucking into the client's chest space.
- Call the physician and continue to keep the opening closed.
- Prepare/assist the physician to reinsert another chest tube
- If the drainage chamber is broken, change to a new chamber.

Complications: Inflammation, infection, subcutaneous emphysema

THORACENTESIS

- Insertion of needle through the chest wall in to the pleural space.

Indications: To obtain pleural fluid for analysis, to relieve lung compression

Preparation:

- Obtain signed informed consent
- No fasting is required
- Advise client not to move, cough, or deep breathe during the procedure
- A preprocedure chest X-ray is done

Procedure:

- The client leans forward with the arms resting on an overbed table
- The puncture site is cleansed and anesthetized
- A large needle is inserted and fluid withdrawn

Nursing Process Elements

- Assess vital signs, breath sounds
- Assist client to lie on unaffected side for 1 hour (to allow for lung expansion)
- Observe for S&S of pneumothorax, shock, leakage at puncture site
- Postprocedure chest X-ray may be done

TRACHEOSTOMY

- Incision into the trachea to form an opening called a stoma. The opening may be temporary or permanent.

Indications: Laryngectomy, severe infection, subglottic stenosis, congenital abnormalities of the airway, severe neck or mouth injuries, foreign body obstruction, tumors, need for prolonged respiratory support, chest wall injury, diaphragmatic dysfunction, neuromuscular disease, aspiration, cervical vertebral fractures, and coma

Preparation: Most tracheostomy procedures are done non-emergent, allowing time for client and family education regarding the procedure.

Procedure: Usually performed in the ICU or operating room. Client is monitored by EKG and pulse oximetry and receives IV sedation. A local anesthetic is given at the incisional area, located low in the neck below the larynx. A temporary tracheostomy tube is placed at the time of surgery. This is changed to a new tube 10–14 days post-op.

Complications: Respiratory distress, tube obstruction, bleeding, infection, tracheal stenosis, tracheoesophageal fistula, granuloma, and pressure necrosis

Nursing Process Elements

Special Considerations

- Monitor vital signs and respiratory status frequently
- Provide care for the tracheal site to prevent infection and skin breakdown (done daily or more frequently if on ventilator)
- Provide suction of the tracheal tube every 4–6 hours and as needed to remove mucus from the tube and trachea
- Change the tube every 1–4 weeks
 - Always have two people present for changing the tracheal tube
- Have emergency equipment available
- Ensure adequate environmental humidity (at least 50%)
- Prevent any substance or object from entering the tracheal tube
 - Avoid water, sand, dust, powder, talc, aerosol sprays, perfumes, ammonia, bleach, chalk dust, necklaces, fuzzy or fur clothing, and animal dander
 - Avoid smoke
- Avoid clothing that blocks the tracheal tube
- Ensure the client is up-to-date on all immunizations, including yearly flu shot

Client teaching for self-care

Before the client leaves the hospital, the client/family should demonstrate proficiency in care of the tracheal tube/site, including:

- Equipment functions
- Cleaning of equipment, especially inner cannula
- How to use a suction machine
- Observations to make/report (bleeding, infection, subcutaneous emphysema, tube obstruction, respiratory difficulty)
- Humidification of airway
- Dealing with tracheal ties
- Dealing with aspiration
- CPR

MECHANICAL VENTILATION

- Uses: To correct life-threatening alterations in blood gases; to reduce work of breathing allowing the respiratory

muscles to rest; and to maintain ventilation during bronchoactive therapy

Invasive Mechanical Ventilation

- Uses an invasive airway (endotracheal tube or tracheostomy if long term)

Common ventilator modes

Determine whether breathing is client-controlled or ventilator-controlled and in what fashion and to what extent.

- *Assist/Control mode*: In ventilator-controlled mode, when client starts to inhale, the ventilator delivers a breath; if the client does not start to inhale to trigger the ventilator, the ventilator delivers breaths in accord with a preset number per minute (20–24 is standard) and a preset tidal volume thus providing continuous mechanical ventilation.
- *Synchronized intermittent mandatory ventilation (SIMV) mode*: Ventilator delivers breaths intermittently in synchronization with client's spontaneous breaths so client can take more breaths than the number per minute set for the ventilator; number of ventilator breaths can be gradually decreased until client is breathing entirely on his/her own.
- *CPAP*: One constant level of pressure is delivered during inspiration and expiration; respiratory rate and other parameters of respiration are controlled by the client
- *BiPAP*: It allows different levels of pressure during inspiration and expiration

Common types of ventilators

- *Volume cycled*: Positive pressure is applied during inspiration to deliver a constant volume of air; amount of pressure varies according to how much is required to deliver the preset volume of air
- *Pressure cycled*: Preset amount of positive pressure is used on each inspiration and so the volume of air delivered varies with airway conditions.

Noninvasive Positive-Pressure Ventilation (NPPV)

- Uses a tight fitting face or nasal mask with a volume- or pressure-cycled ventilator or continuous positive airway pressure (CPAP) or bilevel positive airway pressure (BiPAP) device
- Client must be alert, cooperative, free of excessive secretions, and stable hemodynamically
- May be used for up to 7 days
- *Advantages*: Mask may be removed for short intervals allowing client to speak, drink, use nebulizer; fewer complications
- *Disadvantages*: Risk for aspiration and local skin breakdown; some clients are unable to tolerate the mask

Nursing Process Elements

- Verify ventilator settings according to agency policy which is usually hourly.

- Respond to ventilator alarms: check for problem in systematic fashion starting at the client and working outward toward the ventilator
- Disconnect client and ventilate with an Ambu bag if respiratory distress occurs and problem cannot be corrected immediately
- Use closed system suctioning: Use ventilator to hyperoxygenate and inflate lungs then insert suction catheter and apply suction for not more than 10 seconds as the catheter is withdrawn
- Use meticulous sterile technique: Pneumonia is a major risk associated with prolonged mechanical ventilation
- Prepare for weaning according to agency protocol

Weaning: Initiated when client meets physiologic criteria related to hematocrit, ABGs and respiratory function, electrolyte balance and nutritional status.

Common methods

- *T-piece weaning*: With client sitting up, the ventilator is disconnected and a T-piece is attached to the endotracheal cuff through which oxygenated, humidified air is given. Ventilator is reconnected when fatigue or respiratory distress occurs. Time off the ventilator with the T-piece is gradually increased.
- *SIMV weaning*: client remains connected to the ventilator but the number of ventilator delivered breaths is gradually decreased until the client is breathing on his/her own.
- *PSV weaning*: Client remains connected to the ventilator and the level of preset positive pressure during weaning is gradually decreased until client is breathing independently.

Nursing Process Elements

Weaning:

- Promote good nutritional status in preparation for weaning. —1500–2500 calories per day with 1–1.5 mg/kg or protein
- Avoid extra carbohydrates and calories because they can result in increased CO₂ production and, therefore, increased ventilatory demand.
- Explain the process noting several attempts may be required.
- Instruct in slow, deep breathing with a long exhalation phase.
- Obtain baseline vital signs, tidal volume, and vital capacity at start of weaning attempt.
- Coach in breathing.
- Assess for increased blood pressure, pulse or respiratory rate, dysrhythmias, diaphoresis, agitation or increasing somnolence which are signs of hypoxemia and hypercapnia.
- After weaning, monitor for increased work of breathing and respiratory distress.

Assessment Alert

Respiratory distress is indicated by

- respiratory rate less than 8 or over 30 per minute or increase of 10 breaths per minute over baseline.
- pulse rate increased or decreased by 10 or more beats/minute.
- blood pressure increased or decreased by 20 or more mm Hg
- PaO₂ decrease or PaCO₂ increase.
- pH < 7.35.

NEUROLOGICAL PROCEDURES

ECT Therapy

- Common mental illnesses include Alzheimer's disease, bipolar disorder, borderline personality disorder, depression, and schizophrenia. See Table 16-7 for the symptoms, treatment, and nursing interventions for these illnesses.
- An effective treatment for depression is electroconvulsive therapy (ECT). ECT is also used in the treatment of severe catatonia, mania, and schizophrenia.
 - ECT is used in clients who cannot tolerate side effects of antidepressants and in clients who are at risk for fluid and electrolyte imbalances secondary to the inability to eat or drink as a result of severe depression. ECT is also used in clients who experience major mood disorder; acute suicidal thoughts and behaviors; and melancholic, delusional, and psychotic depression.
 - Contraindications to ECT are increased intracranial pressure, recent myocardial infarction, aneurysms, acute respiratory infection, cardiac arrhythmias, throm-

bophlebitis, narrow-angle glaucoma, drug dependence, personality disorder, reactive depression, and paranoid schizophrenia.

- The nurse obtains an informed consent from the client after the client, family, and significant others have been thoroughly educated regarding the purpose of treatment, proposed number of treatments, and risk factors associated with the procedure. Baseline tests—CBC, SMA, urinalysis, ECG, and physical examination—are performed prior to the procedure.
- Clients scheduled for ECT fast overnight (NPO). Prior to the procedure, clients are asked to empty the bladder and remove jewelry, nail polish, eyeglasses, hearing aids, and dental work.
- Thirty minutes prior to the procedure, the nurse administers 0.5 mg of atropine by intramuscular injection to reduce secretions.
- The nurse ensures the procedure room is equipped with oxygen, suction equipment, and a cardiac arrest cart.
- Appropriate staff includes a psychiatrist, anesthetist, and nurse. The anesthetist administers a short-acting anesthetic and muscle relaxant to decrease client injury. The nurse administers a mouth guard and oxygen.
- The ECT electrodes are replaced after the client is anesthetized.
- A brief electrical stimulus is administered (total duration of less than 2 seconds). The client's body does not move, and the seizure is confirmed by EEG monitoring.
- After the client wakes, oxygen is discontinued, and the client is monitored for respiratory distress.
- The nurse monitors the client for 1–3 hours. The client is discharged when vital signs are stable and the client is alert, oriented, and ambulatory.
- Side effects associated with ECT are headache, memory loss, and fatigue. A mild analgesic and bedrest are usually offered after the procedure.
- The nurse continues to teach and support the client, family, and significant others.
- The nurse supports the client who experiences memory loss by providing orientation cues and an environment to express fears and anxiety.

GASTROINTESTINAL PROCEDURES

GI DECOMPRESSION AND DRAINAGE

- Insertion of a short nasogastric or long intestinal tube to remove fluids or gases by suction or gravity drainage

Indications: To protect suture lines after GI surgery; to remove GI contents when peristalsis and normal absorption is impaired

such as after anesthesia or with obstruction; to remove toxic substances such as in drug overdose or accidental poisoning

Preparation: Estimate length of tube to be inserted: distance from tip of nose to ear lobe to xiphoid process for stomach tube; add 5 cm for intestine. Note distance marking on tube. Check for patency of nares.

Procedure: Place client in Fowler's position. Lubricate tube according to package directions. Apply water-soluble lubricant or wet with water. Insert tube into nare. Aid passage of tube by asking client to lower head a bit, swallow, and if permitted sip water when tube reaches pharynx. Check placement when estimated length of tube is passed. Most accurate method is X-ray. Less reliable options for gastric placement are: using a 50-ml syringe to aspirate gastric juice; instilling 10–20 ml of air into the tube; auscultating just left of the xiphoid tip for a “swoosh” as it exits the tube into the stomach; and measuring pH of aspirate.

Nursing Intervention Alert

Placing end of tube in water to check for bubbling is not acceptable practice for checking tube placement.

Anchor gastric tubes and mark tube at level of exit with indelible pen to allow checking for tube movement. Do not anchor intestinal tubes at time of insertion as they must progress to desired location with peristalsis. Position client on right side until intestinal tube passes pyloric sphincter.

Clinical Alert

Signs that a GI tube is entering the trachea and must be withdrawn and reinserted are coughing, choking, and inability to talk or hum in an otherwise unimpaired client.

Nursing Process Elements

- Maintain suction at no greater than 25 mm Hg.
- Assess function q4 hour: Assessment should include: check drainage, note color, note amount, check consistency; note there is no c/o fullness or nausea; note there is no abdominal distention; check patency by irrigating with N/S as ordered.
- Check for passage of flatus or stool and report if it occurs; it indicates peristalsis so tube may no longer be needed.
- Assess for fluid, electrolyte or acid-base imbalance: monitor skin turgor, body weight, and serum electrolytes.
- Do not give ice chips, sips of water, etc. without orders because these are a source of hypotonic fluid, which can contribute to F&E imbalance.
- Record I&O; include irrigating solution instilled and returned.
- If tube is protecting a suture line, use strict sterile technique to irrigate.

- Assess for sore nares or throat from pressure of tube.
- Good mouth care because most intubated clients mouth breathe.
- Cleanse nares area and apply water-soluble lubricant.
- Prevent pull on tube and keep firmly anchored to prevent dislodgment.

Clinical Alert

A clogged tube can lead to gastric distention and shock.

Nursing Intervention Alert

When peristalsis fully returns, a tube used for decompression and drainage is ready to be removed as indicated by presence of bowel sounds, absence of abdominal distention, tolerance of ice chips and/or clamping of the tube, decreased volume of drainage, and passage of flatus or feces.

Removal: Place client in semi-Fowler's position. Flush tube with 10 ml of N/S to cleanse and move away from mucosa to prevent damage; clamp; tell client to take deep breath; remove during exhalation; give mouth care. Gagging, sneezing, or nasal discomfort may occur. After removal of the tube, monitor for nausea, vomiting, and abdominal distention.

OSTOMY (GI)

- Surgical opening through the abdominal wall into the intestine. May enter ileum (ileostomy) or colon (colostomy). May be temporary (and be reversed) or permanent.

Indications: To aid in treatment of cancer, diverticulitis, Hirschsprung's disease, trauma, and perforated bowel

Preparation: Involve ostomy specialist prior to surgery to assist with client teaching and determination of stoma placement during surgery. Obtain signed informed consent. NPO at least 8 hours prior to surgery. Bowel prep as ordered. Preoperative sedation.

Nursing Process Elements

Special Considerations

- Monitor vital signs frequently postoperatively
- Keep skin around stoma clean and dry; monitor for leakage
- Assess pouching system for proper fit
- Empty and clean ostomy bag as needed

- Monitor amount of drainage from ostomy
- If ileostomy, bowel movements move through body more quickly than usual. Medications may need to be changed from “sustained release” formulation to more frequent dosing.

Client teaching for self-care

- Reinforce to the client that having an ostomy does not affect work, sexual function, or other activities
- Client should avoid very heavy lifting
- Application and cleaning of ostomy bag
- Irrigation of colostomy (if applicable)
- What to report (abdominal pain, vomiting, weakness, bleeding, and lack of ostomy output)
- Ostomy support group
- When traveling, carry supplies on person, not in luggage that might be lost
- With ileostomy, stools are liquid; client needs to maintain fluid intake to avoid dehydration (6–8 glasses per day)

DIALYSIS

- Life saving method of removing toxic substances from the blood when the kidneys are unable to do so.

Hemodialysis

- Removal of waste products and excess fluid from the blood by passing it through a machine outside of the body (dialyzer) with a semipermeable membrane and then returning the filtered blood, without the waste products and fluid, to the client through one of several types of access devices.
- Uses a combination of osmosis, diffusion, and filtration to remove by-products of protein metabolism, creatinine, and excess water thereby restoring acid-base and electrolyte balance and preventing complications associated with uremia.
- Performed three times per week for 3–4 hours per session, often in outpatient settings

Indications: To treat uremia or quickly remove drugs or poisons in acute situations

Preparation: Temporary or permanent access is established.

- Temporary access involves placing Y-shaped catheters in large veins (subclavian, internal jugular, or femoral) with one port for carrying blood to the dialyzer and the other port for returning filtered blood to circulation.
- Permanent access involves surgically connecting an artery and vein (arteriovenous fistula or AVF) or surgically placing a tube to join an artery and vein (arteriovenous graft or AVG) in an arm or leg.

AVF is typically allowed to mature for 3 months before being used; AVG may be used once the swelling subsides, usually 10–14 days. A temporary catheter is used in the interim.

Dry weight/target weight (the amount a client would weigh after urinating if renal function was not impaired) is established to determine the amount of fluid to be removed with each dialysis session.

Nursing Process Elements

Special Considerations

- Explain the purpose of hemodialysis and describe what to expect before, during, and after the procedure
- Monitor laboratory values including BUN/Creatinine, H&H, and Potassium
- Monitor weight, vital signs, and intake and output
- Assess circulation at the access site by auscultating for the presence of bruits and palpating for thrills; lack of these may indicate a blood clot requiring immediate surgical attention
- Make sure the extremity used for vascular access is not used for intravenous therapy, blood pressure monitoring, or venipuncture
- Follow institution-specific protocols for care of temporary dialysis catheters
- Monitor for possible dialysis-related complications including bleeding, hypotension, nausea, vomiting, leg cramps, light-headedness, back pain, headache, chest pain, pruritus, infection, thrombosis, stricture, or aneurysm
- Only during emergency situations, should dialysis access devices be used for purposes other than dialysis
- Refer client and family for appropriate counseling and support

Clinical Alert

Life-threatening complications rarely occur, but include air embolism, acute hemolysis, and anaphylaxis

Client teaching for self-care

- Keep incision clean and dry
- Report pain, swelling, redness, or drainage in the accessed arm
- Use a stethoscope to auscultate for bruits
- Refuse treatment or procedures on the accessed arm, including blood pressure monitoring or needle punctures
- Avoid constriction of the accessed arm, such as wearing tight clothing, lying on it, or lifting heavy objects
- Avoid showering, bathing, or swimming for several hours after dialysis
- Take medications as prescribed; adhere to dietary restrictions and treatment plan

Peritoneal Dialysis (PD)

- Removes waste products and fluids without removing the blood from the body by using the peritoneal lining of the abdomen as a semipermeable dialyzing membrane
- A two-way catheter is placed in the abdomen and allows access for fluid exchanges
- May be continuous ambulatory peritoneal dialysis (CAPD) or continuous cyclical peritoneal dialysis (CCPD)
 - CAPD: Performed four times daily and involves filling the peritoneum with dialysate through tubing connected to the two-way catheter; dialysate remains for 3–6 hours; during this “dwell” time, fluid and waste products cross the peritoneal membrane through osmosis and diffusion; the dialysate containing the waste products is then exchanged for fresh fluid.
 - CCPD: Performed once daily over 8–12 hours, commonly while the client sleeps, and involves connecting a machine to the two-way catheter to move fluid in and out of the peritoneum.

Indications: PD offers some advantages over hemodialysis, including not having to travel to a dialysis center several times per week for therapy; fewer dietary and fluid restrictions, due to treatments being done daily; performed by client in own home environment

Preparation: Two-way catheter is surgically placed in the abdomen (Tenckhoff (most common), Toronto-Western Hospital (TWH), or Swan-neck).

Nursing Process Elements

Special Considerations

- Explain the purpose of PD and describe what to expect before, during, and after procedure
- Use sterile technique to change the catheter dressing daily
- Use sterile technique to open catheter for use
- Monitor for complications including peritonitis and catheter site infection

Clinical Alert

Dialysate must be present in the abdomen at all times with peritoneal dialysis to ensue adequate cleansing of the blood.

Client teaching for self-care

- Follow plan for frequency, duration, and timing of treatments
- Participate in a training program before performing independently

- Wear medical identification bracelet with contact information
- Report fever, persistent abdominal pain and cramping, slow or cloudy dialysis drainage, and swelling and tenderness around the catheter
- Follow up with doctor and dialysis team to evaluate success of treatment and detect any problems

PESSARY

- A device placed in the vagina to help support pelvic structures; used when surgery is contraindicated (can be temporary or permanent form of treatment)

Nursing Process Elements

- Explain to client the indications and use of the pessary
- Instruct client on how to remove, clean, and reinsert pessary
- Reinforce with client that pessary must be inspected and changed regularly to prevent ulceration, fistula formation, stool impaction, and infection
- Vaginal estrogen cream may help improve a woman's tolerance of the pessary
- Encourage lifestyle modifications including maintaining a healthy weight, practicing Kegel exercises to strengthen pelvic floor muscles, controlling coughing, and avoiding heavy lifting or straining
- Occasionally, a pessary may interfere with intercourse

PELVIC EXERCISES (KEGELS)

- Pelvic exercises used to strengthen and maintain the tone of the pubococcygeal muscle which supports the pelvic organs; involves the conscious contracting and relaxing of the pelvic muscles; also use is encouraged to reduce or prevent stress incontinence and uterine prolapse; enhance sensation during sexual intercourse, and hasten postpartum healing

Nursing Process Elements

- Explain the significance of performing Kegel exercises to client
- Instruct client to properly do exercises using the perivaginal muscles and anal sphincter while avoiding contracting the abdominal, buttock, or inner thigh muscles
- Measures that help reduce the symptoms of pelvic relaxation should be encouraged such as lying down with the legs elevated several times a day; encourage client to eat a healthy, well-balanced diet to avoid constipation and straining upon defecation

CATHETER DRAINAGE

- Removal of urine through a catheter inserted into the bladder.

Indications: To drain bladder; to relieve retention associated with neurogenic bladder, to temporarily manage incontinence

Preparation: Strict asepsis observed during catheter insertion.

Procedures:

- **Indwelling urethral:** Female client—The client is positioned supine with knees bent, hips flexed, and feet resting on bed about 2 feet apart. Labia minora separated, urethra meatus prepped with cotton pads saturated three times with iodine or hibiclens using downward strokes from anterior to posterior and discarding cotton pad after single use. Well-lubricated catheter, preconnected to a closed drainage system is inserted into urethral meatus using strict aseptic technique and advanced until urine flow is seen then advanced 2 inches further. Balloon inflated and catheter slightly withdrawn. Male client—Same procedure except positioned supine, meatus cleaned with circular motion, catheter advanced almost to its bifurcation before balloon inflated.
- **Suprapubic:** With the client in supine position, skin is prepped and local anesthetic is injected. Physician introduces catheter into bladder percutaneously via a guide wire through a small stab wound and catheter is advanced until flange is against the skin and secured with sutures.
- **Clean intermittent self catheterization (CISC):** Intermittent, self-placement of a catheter to drain the bladder. Client is taught to assemble equipment (catheter, lubricant, and drainage receptacle), wash hands with soap and water, lubricate catheter, clean around meatus, insert catheter and gently advance (upward insertion in females; penis held perpendicular to body in males), drain urine into receptacle, then withdraw catheter. Procedure is considered “clean” not sterile.

Complications: Urinary tract or kidney infections, septicemia, urethral injury, skin breakdown, bladder stones, and hematuria. After many years of catheter use, bladder cancer may also develop.

Clinical Alert

Catheterization intervals should be frequent enough to prevent the bladder from becoming over-distended with > 500 ml urine.

Nursing Process Elements

- Maintain unobstructed, downhill flow of urine.
- Empty bag at regular intervals, making sure the drainage valve is not contaminated.
- Wash hands before and after handling the catheter and drainage system and also between clients.
- Provide daily and as needed catheter care with mild soap and water; avoid pulling on catheter during cleaning; avoid using powders and sprays.

- Secure indwelling urethral catheter to thigh using tape, strap, or adhesive anchor; allow some slack for movement.
- Maintain asepsis during daily suprapubic catheter dressing changes.
- Assess color, consistency, and amount of drainage; record accurate I&O
- Monitor for fever, dysuria, pain, redness, swelling, or drainage around insertion.
- If a “trial of voiding” is requested, the suprapubic catheter is clamped for 4 hours, client voids, catheter unclamped and drained to measure residual volume.
- Follow institutional policy on obtaining urine specimens from catheters; label specimen as “catheterized specimen.”
- Teach proper procedure for intermittent self-catheterization.

Client teaching for self-care

- Drink 8–12 glasses of fluid daily; increase intake if urine becomes dark and concentrated.
- Keep drainage bag at a lower level than the bladder.
- Wipe all connecting junctions with alcohol before changing from leg-bag drainage to overnight drainage bag.
- Discard disposable CISC catheters immediately after use. Wash reusable catheters with mild soap and water and store in a clean, closed container. Soak catheter in half strength vinegar solution overnight once a week.
- Report foul smelling or bloody urine, pain, fever, or diminished output.

ASSISTIVE DEVICES (WHEELCHAIRS, CANE, CRUTCHES, PROSTHESES)

- Devices used to aid a client in performing activities of daily living, including mobility

Wheelchairs

Uses: self-mobility, transportation

Nursing Process Elements

- Assess functionality of wheelchair
- Maintain cleanliness of multiuse wheelchairs
- Assure breaks are locked prior to transferring client to or from wheelchair

Client teaching for self-care

- Transfer from bed or chair to wheelchair
- Propelling nonmotorized wheelchairs
- Use of controls on motorized wheelchairs

Canes

- Several types are available: Straight-legged cane, quad cane (has four legs)

Uses: provides support while walking

Nursing Process Elements

- Assess ability to walk with cane; may encourage use of two canes

Client teaching for self-care

- Elbow should be flexed slightly when using cane
- Use cane on the unaffected side.

Crutches

Uses: Self-mobility, transportation

Nursing Process Elements

Teach client regarding correct use of crutches

- Weight should be placed on hand grips, not on axillary area
- Crutches always move with the affected leg
 - When going up stairs, the unaffected leg goes first, followed by affected leg and crutches
 - When going down stairs, the affected leg and crutches go first, followed by the unaffected leg

Prosthesis

- An artificial limb or part that replaces an injured, missing or malformed, or diseased body part, such as an arm, hand, or leg.

Uses: Joint replacement, limb replacement, breast augmentation, hearing (cochlear implant)

Nursing Process Elements

- Assess psychosocial response to prosthesis
- Assist the client through the grieving process
- Assess ability to attach prosthesis
- Encourage client involvement in the rehabilitative process
- Maintain cleanliness of prosthesis
- Assess skin integrity beneath applied prostheses
- Provide appropriate skin care as needed

Client teaching for self-care

- Teach the use of walker or crutches
- Teach how to propel nonmotorized wheelchairs
- Involve family in educational process

Nursing Intervention Alert

In the case of a total hip replacement, to prevent the prosthesis from dislocating after surgery, the hip is maintained in abduction through use of an abduction pillow.

CASTS

- A mold over a portion of the body using plaster or synthetic material

Uses: Maintain proper alignment and immobilization of a body part during healing.

Preparation: Cleanse skin; inspect skin for potential areas of infection or breakdown; bony prominences are padded with sheet wadding or felt

Nursing Process Elements

Special Considerations

- Monitor neurovascular status of the affected extremity
- Facilitate drying of plaster cast
- Petal rough edges

Client teaching for self-care

- Keep cast dry. When taking a shower cover it with a plastic bag and secure the bag to your skin with waterproof tape. If the cast gets wet, dry it thoroughly, including the cast padding inside the cast, with a blow dryer on low temperature to avoid burning yourself.
- Do not insert anything inside of the cast, such as additional padding or any device to scratch.
- Frequently move fingers or toes to prevent swelling and stiff joints.
- Elevate extremity to relieve swelling and reduce pain.
- Place padding under your cast to prevent scratching or damaging your furniture if you are resting the cast on a piece of furniture.
- Contact your physician if the edges of the cast become ragged, so that the physician can trim the cast.
- Contact your physician if the following occur: Persistent pain, cast feels too tight or loose, the cast becomes broken or cracked, if you feel painful rubbing under the cast, there is discoloration of the fingers or toes, or an unusual odor or drainage.

BUCK'S EXTENSION TRACTION

Simple skin traction using counter traction

Uses: Provides straight pull on the extremity for immobilization or to relieve muscle spasms

Preparation: Shave hair off extremity if an adhesive is being applied and apply tincture of benzoin to protect skin

Clinical Alert

Contraindicated for clients with stasis dermatitis, arteriosclerosis, allergy to adhesive tape, severe varicosities of varicose veins, diabetic gangrene, or marked overriding bone fragments.

Postapplication Course:

- Maintain 8–10 pounds of traction
- Maintain foot of bed elevated to provide counter traction

Nursing Process Elements

Special Considerations

- Monitor neurovascular status of the affected extremity
- Maintain body in alignment
- Apply and maintain TED hose to nonaffected extremity
- Assess bony prominences for alteration in skin integrity, such as pressure ulcer
- Assess muscle strength, range of motion, and ability to perform ADLs

Client teaching for self-care

- Demonstrate how to move in bed without altering the traction

RUSSELL TRACTION

- Skin traction that provides a double pull by using a knee sling

Uses: To treat intertrochanteric fracture of femur prior to or without surgical repair

Nursing Process Elements

Special Considerations

- Maintain foot of bed slightly elevated
- Monitor neurovascular status of the affected extremity
- Maintain body in alignment
- Apply and maintain TED hose to nonaffected extremity
- Assess bony prominences for alteration in skin integrity, such as pressure ulcer

Client teaching for self-care

- Demonstrate how to move in bed without altering the traction

CERVICAL TRACTION

- Skin traction to the head

Uses: Used to treat muscle spasm, strain, or spasm by holding head in extension

Preparation: Applied with head halter, elastic bandages, or adhesive

Nursing Process Elements

Special Considerations

- Apply powder to ears to prevent friction rub
- Maintain head of bed elevated 30–40 degrees
- Maintain weights to pulley over the head of the bed
- Maintain body in alignment; when in side position, place a full length bath blanket roll behind client and pillow between the knees
- Apply and maintain TED hose
- Assess bony prominences for alteration in skin integrity, such as pressure ulcer
- Turn client by log rolling
- Align the client's head with the pull of the traction to maintain counter traction

Client teaching for self-care

- Demonstrate how to move in bed without altering the traction

PELVIC TRACTION

- Skin traction to the pelvis

Uses: Reduce muscle spasms and relieve low back, hip, or leg pain

Preparation: Apply the traction snugly over the pelvis and iliac crest and attach to weights

Nursing Process Elements

Special Considerations

- Assess for pressure and skin irritation under device
- Maintain weights hanging freely
- Maintain proper bed position for counter traction
- Maintain ropes in proper position
- Maintain body in alignment
- Apply and maintain TED hose

Client teaching for self-care

- Demonstrate how to move in bed without altering the traction

MONITORING CONSCIOUS SEDATION

CONSCIOUS SEDATION

- Minimally depressed level of consciousness in which the client retains the ability to maintain an airway and respond appropriately to verbal commands and physical stimuli but emotionally and physically accepts a painful procedure
- Associated with a low level of risk to client
- Typically achieved with sedative-hypnotics and/or opioids

Indications: To relax and/or relieve pain during procedures of short duration such as biopsy, radiologic imaging, endoscopic procedure, radiation therapy, bone marrow aspiration, painful dressing changes, wound packing, bedside wire or drain removals, or wherever client anxiety is likely to hinder necessary care. It is also commonly used as an adjunct to local or regional anesthesia for larger procedures such as dental surgeries, appliance removals, wound suturing, and other short but highly stimulating procedures.

Preparation:

- Assess client for any history of adverse reactions to the proposed medications or severe cardiopulmonary disease.
- Obtain informed consent for procedure and sedation.
- Verify plan for discharge, including a driver.
- Establish a working intravenous line.
- Connect monitors: Pulse oximeter, blood pressure monitor, three-lead ECG.
- Ensure availability of functioning wall or tank oxygen and delivery system.
- Ensure immediate access to emergency resuscitation equipment and medications.
- Ensure availability of medications to be used and reversal agents if any. Conscious sedation is usually accomplished through use of a short-acting benzodiazepine such as midazolam and a narcotic such as fentanyl (reversal agent for fentanyl is naloxone).

- Reassure the client that the medication (midazolam) has an amnesiac effect so there will be little or no memory of the procedure.
- Obtain baseline vital signs and oxygen saturation.

Procedure:

- The client is kept in the direct vision of a trained and licensed health care professional who is not involved in performing or assisting with the procedure.
- Medications are administered intravenously.
- Vital signs and oxygen saturation are measured every 5 minutes during the procedure.
- Sedation level is monitored throughout by conversation or ability to follow commands if client is unable to speak during the procedure.

Clinical Alert

The oxygen saturation is the most sensitive parameter affected during the increased levels of conscious sedation.

- Common side effects of the sedation are: dizziness, nausea, amnesia, sleepiness, cardiovascular depression, respiratory depression, and pain or itching on injection.

Postsedation Care:

- Continue to monitor the client for at least 30 minutes, more if the amount of sedation was large or the procedure lengthy or complicated.
- Discharge when vital signs remain stable and client appears to have resumed preprocedure status.
- Provide all necessary instructions for self-care and follow up medical care.

WORKSHEET

TRUE & FALSE QUESTIONS

1. Glucophage should not be discontinued prior to a radiographic examination using contrast medium.
2. Start time for a 24-hour urine collection begins when the first urine sample is voided and saved.

T F

T F

(continued)

- | | | |
|---|------------------|------------------|
| 3. Only a sample of a 24-hour urine collection needs to be sent to the laboratory as long the total volume voided is accurately documented. | <u> </u> T | <u> </u> F |
| 4. Serum BUN levels are decreased with kidney disease and acute renal failure. | <u> </u> T | <u> </u> F |

FILL IN THE BLANKS

Fill in the blank space with the correct word or phrase to complete each statement.

1. What serum creatinine level indicates the need for renal dosing of medications excreted by the kidneys?
_____.
2. What should a client be instructed to avoid for 24 hours prior to a creatinine clearance test?
_____.
3. What is the single most important indicator of fluid status? _____.
4. What test needs to be done before arterial blood gases are drawn? _____.
5. What is the most sensitive parameter affected during increased levels of conscious sedation? _____.
6. When performing an electrocardiogram, where is the grounding electrode placed? _____.
7. If bronchospasm occurs during an exercise stress test using adenosine, what medication is used to reverse it?
_____.
8. What is the range of normal oxygen saturation? _____.
9. What is the range normal specific gravity of urine? _____.
10. The normal volume of air inspired/expired during normal respiration is known as what? _____.
11. A chest X-ray would be contraindicated in what type of client? _____.
12. A postprocedure chest X-ray is done after a thoracentesis to check for what complication? _____.
13. For an upper GI series, the client drinks what substance? _____.
14. If the barium used in a lower GI series is not expelled within 2–3 days, what complication might occur?
_____.
15. Why is a fat free meal taken the night before an oral cholecystogram? _____.
16. Why is a T-tube cholangiogram done? _____.
17. An EGD visualizes what parts of the GI tract? _____.
18. A client scheduled for a colonoscopy is to drink Colyte as the bowel prep. How is Colyte taken? _____.
19. What types of blood tests are especially important to obtain prior to a liver biopsy? _____.
20. After a liver biopsy, the client is placed in what position? _____.

21. What can a client do to relieve discomfort after a cystoscopy? _____.
22. What substance is applied to the cervix during a colposcopy to highlight abnormal areas? _____.
23. A pregnant woman should be instructed to do what before a nonstress test to enhance fetal activity? _____.
24. What test should not be performed if the client has pelvic inflammatory disease? _____.
25. If a woman undergoing an amniocentesis has Rh negative blood and her fetus is Rh positive, what medication should the woman receive? _____.
26. What cholesterol is known as the “good” cholesterol? _____.
27. A test useful in diagnosing congestive heart failure is what? _____.
28. A protein found only in cardiac muscle with rises within 3–6 hours of cardiac damage is what? _____.
29. A test used to assess for skeletal muscle damage is what? _____.
30. Normal values of hemoglobin for a female are what? _____.
31. Spontaneous bleeding occurs with platelet counts below what level? _____.
32. Total red blood cell count is increased in what condition? _____.
33. What type of white blood cell is involved in antibody responses to antigens? _____.
34. What is the range of normal WBC count? _____.
35. What test is used to monitor anticoagulant therapy with heparin? _____.
36. What is the major cation in intracellular fluid responsible for electrical conduction in cardiac muscle cells? _____.
37. The levels of what substances are controlled by the parathyroid gland? _____.
38. Open wounds are cultured with what type of culture tube? _____.
39. What is the normal range for arterial blood gas pH? _____.
40. A test used to differentiate causes of jaundice is what? _____.
41. What medications should be avoided for 2 days before fecal occult blood testing is done? _____.
42. What is the nonspecific test for inflammatory conditions? _____.
43. What is the counter-pulsation mechanical device used to aid the circulatory function of the heart? _____.
44. What is used to determine the amount of fluid to be removed with each dialysis session? _____.
45. What can a client do to decrease risk of infection which a urinary catheter is in place? _____.
46. On which side of the body is a cane used? _____.

APPLICATION QUESTIONS

1. Which of the following is a good indicator of the glomerular filtration rate (GFR)?
 - a. BUN
 - b. Bence-Jones
 - c. Creatinine
 - d. Urine cytology
2. Which of the following is a measurement of the kidney's ability to concentrate urine?
 - a. Urine osmolality
 - b. Creatinine clearance
 - c. Specific gravity
 - d. Urine cytology
3. Which of the following examinations requires a serum sample and 24-hour urine sample?
 - a. Urine cytology
 - b. Creatinine clearance
 - c. Bicarbonate
 - d. BUN
4. A 69-year-old client with diabetes mellitus type 2 is to undergo a CT scan using contrast media. Which laboratory test(s) should be performed prior to the CT scan?
 - a. Liver function tests
 - b. Electrolytes
 - c. BUN and creatinine
 - d. Fasting blood sugar
5. Which test can a pregnant woman undergo without concern for causing harm to the fetus?
 - a. CT scan of the brain
 - b. Chest X-ray
 - c. CT scan of the abdomen
 - d. Ultrasound of the gallbladder
6. Immediate postprocedure care of the client who has undergone a bronchoscopy includes all of the following except:
 - a. monitoring vital signs
 - b. ensuring siderails are up
 - c. pushing fluids
 - d. assessing breath sounds
7. You are monitoring a client who is receiving conscious sedation while undergoing a colonoscopy. Medications used are midazolam and fentanyl. You notice that the client is experiencing respiratory depression. You should:
 - a. increase the intravenous infusion rate.
 - b. administer naloxone.
 - c. administer CPR.
 - d. recheck the vital signs in 15 minutes.
8. A PPD test is administered to a healthy 23-year-old nurse who is starting employment at a local hospital. Which of the following measurements would be considered a "positive" reading for this individual?
 - a. 10 mm of erythema
 - b. 5 mm of induration
 - c. 10 mm of induration
 - d. 15 mm of induration
9. Which of the following procedures would be contraindicated in a client with a bleeding disorder?
 - a. Intravenous pyelogram
 - b. Liver biopsy
 - c. Renal scan
 - d. CT scan of the brain
10. A client with diabetes mellitus self monitors blood sugar at home. His primary care provider wants to assess the client's average blood sugar over a 3 month period. The best test for this would be:
 - a. fasting plasma glucose
 - b. urine dipstick for glucose
 - c. glucose tolerance test
 - d. hemoglobin A1C
11. A pregnant client is undergoing a nonstress test. Which of the following would be considered a "non-reactive" test?
 - a. There is fetal movement only after she rubs her abdomen.
 - b. There is no fetal movement in 20 minutes.
 - c. There is fetal movement at 30 minutes only after a loud noise is placed near the abdomen.
 - d. There is no fetal movement in 40 minutes.
12. A client has a severe bacterial infection. Which of the following would be expected on the client's complete blood count (CBC) with differential?
 - a. WBC 8,500, lymphocytes 45%
 - b. WBC 15,000, segmented neutrophils 50%
 - c. WBC 25,000, band neutrophils 20%
 - d. WBC 20,000, segmented neutrophils 58%
13. A client with atrial fibrillation is receiving warfarin (Coumadin) 5 mg each day. His INR today is

- 2.4. What is the expected change in medication dosage?
- His INR is too low. His warfarin dose needs to be increased.
 - His INR is too high. His warfarin dose needs to be decreased.
 - His INR is too high. His warfarin dose needs to be increased.
 - His INR is within desired range. No change in warfarin dose is needed.
14. A client is experiencing cardiac dysrhythmias, confusion, and weakness. An abnormal level of which of the following would most likely be the cause?
- Phosphorus
 - Calcium
 - Potassium
 - Sodium
15. For which of the following medications should a client undergo therapeutic drug monitoring?
- Penicillin (antibiotic)
 - Propranolol (beta-blocker)
 - Furosemide (diuretic)
 - Digoxin (cardiac glycoside)
16. A client has acute hepatitis. Which of the following would most likely be elevated?
- Serum protein electrophoresis
 - Alanine aminotransferase (ALT)
 - Ammonia
 - Troponin
17. You note that your client with chronic renal failure has a urine specific gravity (SG) of 1.035. You explain to the client that:
- this specific gravity is normal.
 - this specific gravity indicates very concentrated urine and you recommend increased fluid intake.
 - this specific gravity is high and indicates the presence of a urinary tract infection.
 - this specific gravity indicates dilute urine due to the kidneys' lack of ability to concentrate urine.
18. Which of the following findings from a urinalysis would most likely indicate renal dysfunction?
- Positive leukocyte esterase
 - Positive urobilinogen
 - Positive protein
 - Positive nitrites
19. Which of the following is a normal finding for the client with a chest tube?
- New pockets of air are palpated under the skin
 - Bubbling is present in the water seal chamber
 - Drainage from the chest tube increases each day
 - The water level in the water seal chamber oscillates with the client's respirations
20. Which of the following is the most accurate method of determining proper placement of a nasogastric tube?
- Using a 50-ml syringe to aspirate gastric contents
 - Instilling air into the tube and auscultating for a swooshing sound
 - Obtaining a chest X-ray
 - Placing the end of the tube in water to check for bubbling
21. A client is to undergo three tests: upper GI series, lower GI series (barium enema), and renal ultrasound. In what order should these tests be performed?
- Lower GI series, then upper GI series, then renal ultrasound
 - Upper GI series, then renal ultrasound, then lower GI series
 - Renal ultrasound, then lower GI series, then upper GI series
 - It does not matter in what order these tests are performed
22. Colonoscopy is contraindicated for clients with which of the following disorders?
- Polyps
 - Hemorrhoids
 - Diarrhea
 - Acute diverticulitis
23. Your client is a 32-year-old healthy female whose maternal grandmother had breast cancer at age 45. Your client is asking your guidance as to when she should have a mammogram. According to the American Cancer Society, she should begin screening at age:
- 32
 - 35
 - 40
 - 50
24. Your client is to undergo an amniocentesis. Which of the following should be included in your care of this client?
- The client should have a full bladder for the procedure.

(continued)

- b. The client should be reassured that the procedure is risk-free.
- c. The client should be instructed to report abdominal pain, cramping, chills, fever, vaginal bleeding, fetal hyperactivity, or lethargy.
- d. Explanation that the procedure involves obtaining a sample of amniotic fluid through the cervical os.
25. A client is diagnosed with a wound infection which is quite painful. Which of the following is true?
- a. An antibiotic should be started immediately. The client can return for a wound culture when the wound is less painful.
- b. Antibiotic therapy will be withheld until the culture and sensitivity report is available.
- c. A wound culture is obtained first, after which a broad spectrum antibiotic is started.
- d. The culture report will identify the correct antibiotic to use to treat the infection.

ANSWERS & RATIONALES

TRUE & FALSE ANSWERS

1. Glucophage should not be discontinued prior to a radiographic examination using contrast medium. *False*
Failure to discontinue Glucophage on the day of test and for 48 hours following may result in lactic acidosis.
2. Start time for a 24-hour urine collection begins when the first urine sample is voided and saved. *False*
The timing begins with the first voiding, but the first sample of urine is discarded.
3. Only a sample of a 24-hour urine collection needs to be sent to the laboratory as long the total volume voided is accurately documented. *False*
Failure to collect and send to the laboratory ALL urine voided in the 24 hour period invalidates the test.
4. Serum BUN levels are decreased with kidney disease and acute renal failure. *False*
BUN measures urea and nitrogen levels in a blood sample and are elevated when kidney function is impaired and alters the excretion of these metabolic end products.

ANSWERS FOR FILL IN THE BLANKS

1. What serum creatinine level indicates the need for renal dosing of medications excreted by the kidneys? Answer: Level > 2.
2. What should a client be instructed to avoid for 24 hours prior to a creatinine clearance test? Answer: Consumption of meat, stress, and strenuous exercise.
3. What is the single most important indicator of fluid status? Answer: Daily weight.
4. What test needs to be done before arterial blood gases are drawn? Answer: Allen test.
5. What is the most sensitive parameter affected during increased levels of conscious sedation? Answer: Oxygen saturation.
6. When performing an electrocardiogram, where is the grounding electrode placed? Answer: On the right leg.

7. If bronchospasm occurs during an exercise stress test using adenosine, what medication is used to reverse it? Answer: aminophylline.
8. What is the range of normal oxygen saturation? Answer: 95–100%.
9. What is the range of normal specific gravity of urine? Answer: 1.005–1.030.
10. The normal volume of air inspired/expired during normal respiration is known as what? Answer: Tidal volume.
11. A chest X-ray would be contraindicated in what type of client? Answer: A pregnant client.
12. A postprocedure chest X-ray is done after a thoracentesis to check for what complication? Answer: Pneumothorax.
13. For an upper GI series, the client drinks what substance? Answer: Barium sulfate.
14. If the barium used in a lower GI series is not expelled within 2–3 days, what complication might occur? Answer: Intestinal obstruction.
15. Why is a fat free meal taken the night before an oral cholecystogram? Answer: It prevents contraction of the gallbladder and allows dye to accumulate in the gallbladder.
16. Why is a T-tube cholangiogram done? Answer: To check for patency of the common bile duct prior to removal of the T-tube after a cholecystectomy.
17. An EGD visualizes what parts of the GI tract? Answer: Esophagus, stomach, and upper duodenum (EGD stands for esophagogastroduodenoscopy).
18. A client scheduled for a colonoscopy is to drink Colyte as the bowel prep. How is Colyte taken? Answer: An 8-oz glass every 10 minutes until 1 gallon has been taken.
19. What types of blood tests are especially important to obtain prior to a liver biopsy? Answer: Coagulation studies (PT, bleeding time).
20. After a liver biopsy, the client is placed in what position? Answer: On the right side to keep pressure on area of needle insertion.
21. What can a client do to relieve discomfort after a cystoscopy? Answer: Warm sitz bath, mild analgesics.
22. What substance is applied to the cervix during a colposcopy to highlight abnormal areas? Answer: 3% acetic acid.
23. A pregnant woman should be instructed to do what before a nonstress test to enhance fetal activity? Answer: Eat a meal to ensure a high maternal serum glucose level.
24. What test should not be performed if the client has pelvic inflammatory disease? Answer: Hysterosalpingography.
25. If a woman undergoing an amniocentesis has Rh negative blood and her fetus is Rh positive, what medication should the woman receive? Answer: RhoGAM.
26. What cholesterol is known as the “good” cholesterol? Answer: High density lipoprotein cholesterol (HDL).
27. A test useful in diagnosing congestive heart failure is what? Answer: Brain Natriuretic Peptide (BNP).
28. A protein found only in cardiac muscle with rises within 3–6 hours of cardiac damage is what? Answer: Troponin.

(continued)

29. A test used to assess for skeletal muscle damage is what? Answer: Creatine kinase (CK).
30. Normal values of hemoglobin for a female are what? Answer: 12–16 g/dl.
31. Spontaneous bleeding occurs with platelet counts below what level? Answer: 20,000/mm³.
32. Total red blood cell count is increased in what condition? Answer: Polycythemia.
33. What type of white blood cell is involved in antibody responses to antigens? Answer: Lymphocyte.
34. What is the range of normal WBC count? Answer: 4,500–10,500/mm³.
35. What test is used to monitor anticoagulant therapy with heparin? Answer: PTT (partial thromboplastin time).
36. What is the major cation in intracellular fluid responsible for electrical conduction in cardiac muscle cells? Answer: Potassium.
37. The levels of what substances are controlled by the parathyroid gland? Answer: Calcium and phosphorus.
38. Open wounds are cultured with what type of culture tube? Answer: Aerobic.
39. What is the normal range for arterial blood gas pH? Answer: 7.35–7.45.
40. A test used to differentiate causes of jaundice is what? Answer: Bilirubin.
41. What medications should be avoided for 2 days before fecal occult blood testing is done? Answer: Aspirin and NSAIDs.
42. What is the nonspecific test for inflammatory conditions? Answer: Erythrocyte sedimentation rate.
43. What is the counter-pulsation mechanical device used to aid the circulatory function of the heart? Answer: Intra-aortic balloon pump.
44. What is used to determine the amount of fluid to be removed with each dialysis session? Answer: Dry weight/target weight.
45. What can a client do to decrease risk of infection which a urinary catheter is in place? Answer: Drink 8–12 glasses of fluid daily, keep drainage bag at a level lower than the bladder.
46. On which side of the body is a cane used? Answer: On the unaffected side.

APPLICATION ANSWERS

1. Which of the following is a good indicator of the glomerular filtration rate (GFR)?
- BUN
 - Bence-Jones
 - Creatinine
 - Urine cytology

Rationale

Correct answer: c.

Creatinine is formed and excreted at a constant rate and is the ideal substance for measuring renal clearance. Incorrect answers: BUN reflects the balance between production and excretion of urea; Bence-Jones proteins are positive for multiple myeloma; urine cytology detects urinary inflammatory diseases.

2. Which of the following is a measurement of the kidney's ability to concentrate urine?

- a. Urine osmolality
- b. Creatinine clearance
- c. Specific gravity
- d. Urine cytology

Rationale

Correct answer: c.

Incorrect answers: a, b, and d—urine osmolality identifies the osmotic concentration; creatinine clearance determines the glomerular filtration rate; urine cytology detects urinary inflammatory diseases.

3. Which of the following examinations requires a serum sample and 24-hour urine sample?
- a. Urine cytology
 - b. Creatinine clearance
 - c. Bicarbonate
 - d. BUN

Rationale

Correct answer: b.

Midway through the 24-hour urine collection, a serum creatinine level is collected to help calculate the rate at which kidneys are clearing creatinine from the blood.

Incorrect answers: a, c, and d—urine cytology requires a urine sample only; bicarbonate levels can be done on either serum or urine samples; BUN requires a serum sample.

4. A 69-year-old client with diabetes mellitus type 2 is to undergo a CT scan using contrast media. What laboratory test(s) should be performed prior to the CT scan?
- a. Liver function tests
 - b. Electrolytes
 - c. BUN and creatinine
 - d. Fasting blood sugar

Rationale

Correct answer: c.

Clients undergoing CT scans using contrast media need adequate renal function to process the media. Elderly clients and clients with diabetes mellitus are at risk due to decreased renal function.

Incorrect answers: a, b, and d—Abnormal liver function, electrolyte, or blood sugar tests do not typically prevent a client from having a CT scan.

5. Which test can a pregnant woman undergo without concern for causing harm to the fetus?
- a. CT scan of the brain
 - b. Chest X-ray
 - c. CT scan of the abdomen
 - d. Ultrasound of the gallbladder

Rationale

Correct answer: d.

An ultrasound of the gallbladder involves only sound waves, not radiation.

Incorrect answers: a, b, and c—CT scans and X-rays involve exposure of the fetus to radiation.

6. Immediate postprocedure care of the client who has undergone a bronchoscopy includes all of the following except:
- a. monitoring vital signs
 - b. ensuring siderails are up
 - c. pushing fluids
 - d. assessing breath sounds

Rationale

Correct answer: c.

The client is not to have fluids until the nurse is certain the gag reflex is intact.

Incorrect answers: a, b, and d—After a bronchoscopy the nurse is to periodically monitor the vital signs and breath sounds to assess for development of complications such as pneumothorax. Due to receipt of sedation during the procedure, the client is to remain in bed with the siderails up until fully conscious.

7. You are monitoring a client who is receiving conscious sedation while undergoing a colonoscopy. Medications used are midazolam and fentanyl. You notice that the client is experiencing respiratory depression. You should:
- a. increase the intravenous infusion rate.
 - b. administer naloxone.
 - c. administer CPR.
 - d. recheck the vital signs in 15 minutes.

Rationale

Correct answer: b.

The client is most likely experiencing respiratory depression from the narcotic fentanyl. The antidote for fentanyl overdose is naloxone.

Incorrect answers: a, c, and d—Increasing the IV rate will not affect the respiratory depression. CPR is not needed since the client is still breathing. Vital signs are to be monitored every 5 minutes during conscious sedation.

8. A PPD test is administered to a healthy 23-year-old nurse who is starting employment at a local hospital. Which of the following measurements would be considered a “positive” reading for this individual?
- a. 10 mm of erythema
 - b. 5 mm of induration
 - c. 10 mm of induration
 - d. 15 mm of induration

(continued)

Rationale

Correct answer: c.

For health care workers, 10 mm and above of induration is considered positive.

Incorrect answers: a—Erythema is not considered as positive; b—5 mm of induration is positive if the person is immunocompromised; d—15 mm of induration is positive for persons with no known risk factors.

9. Which of the following procedures would be contraindicated in a client with a bleeding disorder?
- Intravenous pyelogram
 - Liver biopsy
 - Renal scan
 - CT scan of the brain

Rationale

Correct answer: b.

Liver biopsy is contraindicated in clients with bleeding disorders due to the risk of bleeding from the biopsy site. Incorrect answers: a, c, and d—A client with a bleeding disorder can safely undergo an intravenous pyelogram, renal scan, or CT scan of the brain since, other than a venipuncture for administration of contrast dye or radioisotope, they are noninvasive.

10. A client with diabetes mellitus self monitors blood sugar at home. Now the primary care provider wants to assess the client's average blood sugar over a 3 month period. The best test for this would be:
- fasting plasma glucose
 - urine dipstick for glucose
 - glucose tolerance test
 - hemoglobin A1C

Rationale

Correct answer: d.

Hemoglobin A1C absorbs glucose and holds it for the lifespan of the red blood cell (up to 120 days).

Incorrect answers: a, b, and c—The fasting plasma glucose, urine dipstick for glucose, and glucose tolerance test provide information on glucose levels at one point in time.

11. A pregnant client is undergoing a nonstress test. Which of the following would be considered a “non-reactive” test?
- There is fetal movement only after she rubs her abdomen.
 - There is no fetal movement in 20 minutes.
 - There is fetal movement at 30 minutes only after a loud noise is placed near the abdomen.
 - There is no fetal movement in 40 minutes.

Rationale

Correct answer: d.

The NST is considered nonreactive if there is no fetal movement in 40 minutes. A contraction stress test is then scheduled.

Incorrect answers: a, b, c—Any fetal movement in less than 40 minutes is considered normal, even if external stimulation, such as rubbing the abdomen or a loud noise, is needed to stimulate the fetus.

12. A client has a severe bacterial infection. Which of the following would be expected on the client's complete blood count (CBC) with differential?
- WBC 8,500, lymphocytes 45%
 - WBC 15,000, segmented neutrophils 50%
 - WBC 25,000, band neutrophils 20%
 - WBC 20,000, segmented neutrophils 58%

Rationale

Correct answer: c.

With a severe bacterial infection, the total white blood cell count would be above normal. Band neutrophils would be elevated because the body is trying to quickly fight the infection; so quickly, that the neutrophils are being released into the circulation before they are mature cells.

Incorrect answer: a—WBC count is normal with elevated lymphocytes, indicating viral infection; b—WBC count is above normal but segs are normal, thus indicating the infection is not severe; d—although the WBC count is elevated, the segs are still within normal limits, again indicating the infection is not severe.

13. A client with atrial fibrillation is receiving warfarin (Coumadin) 5 mg each day. His INR today is 2.4. What is the expected change in medication dosage?
- His INR is too low. His warfarin dose needs to be increased.
 - His INR is too high. His warfarin dose needs to be decreased.
 - His INR is too high. His warfarin dose needs to be increased.
 - His INR is within desired range. No change in warfarin dose is needed.

Rationale

Correct answer: d.

Target INR for clients with afib is 2.0–3.0. This client's INR is within this range.

Incorrect answers: a, b, and c—the client's INR is not too low or high.

14. A client is experiencing cardiac dysrhythmias, confusion, and weakness. An abnormal level of which of the following would most likely be the cause?
- Phosphorus
 - Calcium

- c. Potassium
- d. Sodium

Rationale

Correct answer: c.

Low potassium levels (hypokalemia) cause confusion, anorexia, muscle weakness, paresthesias, hypotension, cardiac dysrhythmias, and decreased reflexes.

Incorrect answers: a, b, and d—Abnormal levels of phosphorus, calcium, and sodium do not result in the triad of dysrhythmias, confusion, and weakness.

15. For which of the following medications should a client undergo therapeutic drug monitoring?
- a. Penicillin (antibiotic)
 - b. Propranolol (beta-blocker)
 - c. Furosemide (diuretic)
 - d. Digoxin (cardiac glycoside)

Rationale

Correct answer: d.

There is a narrow margin of safety between therapeutic drug effect and drug toxicity with digoxin.

Incorrect answers: a, b, and c—there is a wide margin of safety with penicillin, propranolol, and furosemide, so therapeutic drug monitoring is not needed.

16. A client has acute hepatitis. Which of the following would most likely be elevated?
- a. Serum protein electrophoresis
 - b. Alanine aminotransferase (ALT)
 - c. Ammonia
 - d. Troponin

Rationale

Correct answer: b.

ALT, an enzyme found primarily in the liver, is elevated in clients with hepatitis.

Incorrect answers: a—serum protein electrophoresis is decreased in hepatitis; c—ammonia is not elevated until there is liver damage from long-term liver problems; d—troponin is a protein used in the diagnosis of cardiac damage.

17. You note that your client with chronic renal failure has a urine specific gravity (SG) of 1.035. You explain to the client that:
- a. this specific gravity is normal.
 - b. this specific gravity indicates very concentrated urine and you recommend increased fluid intake.
 - c. this specific gravity is high and indicates the presence of a urinary tract infection.
 - d. this specific gravity indicates dilute urine due to the kidneys' lack of ability to concentrate urine.

Rationale

Correct answer: d.

Clients with renal disease lose the ability to concentrate urine.

Incorrect answers: a—normal specific gravity is 1.005–1.030, this client's SG is above normal; b—an increased SG indicates dilute, not concentrated urine; c—urinary tract infection does not typically cause this increase in SG.

18. Which of the following findings from a urinalysis would most likely indicate renal dysfunction?
- a. Positive leukocyte esterase
 - b. Positive urobilinogen
 - c. Positive protein
 - d. Positive nitrites

Rationale

Correct answer: c.

With renal dysfunction, the glomerular filtrate membrane “leaks”, allowing large protein molecules to pass through into the urine.

Incorrect answers: a, b, and d—positive leukocyte esterase and nitrites are indicative of urinary tract infection. Positive urobilinogen occurs with liver dysfunction.

19. Which of the following is a normal finding for the client with a chest tube?
- a. New pockets of air are palpated under the skin
 - b. Bubbling is present in the water seal chamber
 - c. Drainage from the chest tube increases each day
 - d. The water level in the water seal chamber oscillates with the client's respirations

Rationale

Correct answer: d.

If there is no air leak, the water level in the water seal chamber will oscillate with the client's respirations.

Incorrect answers: a—pockets of air represent subcutaneous emphysema, the physician should be notified if it increases; b—bubbling in the water seal chamber indicates the presence of an air leak; c—increased drainage suggests new or increased bleeding and needs to be reported.

20. Which of the following is the most accurate method of determining proper placement of a nasogastric tube?
- a. Using a 50-ml syringe to aspirate gastric contents
 - b. Instilling air into the tube and auscultating for a swooshing sound
 - c. Obtaining a chest X-ray
 - d. Placing the end of the tube in water to check for bubbling

Rationale

Correct answer: c.

A chest X-ray is the most accurate method.

Incorrect answers: a, and b—both of these methods are less reliable options; d—this option is not acceptable practice.

(continued)

21. A client is to undergo three tests: upper GI series, lower GI series (barium enema), and renal ultrasound. In what order should these tests be performed?
- Lower GI series, then upper GI series, then renal ultrasound
 - Upper GI series, then renal ultrasound, then lower GI series
 - Renal ultrasound, then lower GI series, then upper GI series
 - It does not matter in what order these tests are performed

Rationale

Correct answer: c.

The renal ultrasound is done before any studies involving barium. Then the lower GI series is done so that barium from the upper GI series does not obscure the lower GI images.

Incorrect answers: a, b, and d—lower GI series is done before the upper GI series; renal ultrasound cannot be done within 2 days of barium studies, so it is best to complete this first.

22. Colonoscopy is contraindicated for clients with which of the following disorders?
- Polyps
 - Hemorrhoids
 - Diarrhea
 - Acute diverticulitis

Rationale

Correct answer: d.

Performing a colonoscopy in the presence of acute diverticulitis increases the risk of perforation of the colon wall during the procedure.

Incorrect answers: a, b, and c—none of these problems would prevent the client from having a colonoscopy.

23. Your client is a 32-year-old healthy female whose maternal grandmother had breast cancer at age 45. Your client is asking your guidance as to when she should have a mammogram. According to the American Cancer Society, she should begin screening at age:
- 32
 - 35
 - 40
 - 50

Rationale

Correct answer: b.

Screening for women who are high-risk is to begin 10 years before the age of the diagnosis of breast cancer in a family member.

Incorrect answers: a, b, and c—32 is her current age; age 40 is initial screening for those women with no personal or family history of breast cancer; age 50 is too late for initial screening to begin.

24. Your client is to undergo an amniocentesis. Which of the following should be included in your care of this client?
- The client should have a full bladder for the procedure.
 - The client should be reassured that the procedure is risk-free.
 - The client should be instructed to report abdominal pain, cramping, chills, fever, vaginal bleeding, fetal hyperactivity, or lethargy.
 - Explanation that the procedure involves obtaining a sample of amniotic fluid through the cervical os.

Rationale

Correct answer: c.

These signs are all indicators of possible complications and need to be reported immediately.

Incorrect answers: a—the client should empty her bladder prior to the procedure to avoid accidental puncture during the amniocentesis; b—there are numerous possible complications of the procedure, including hemorrhage, infection, premature labor, and spontaneous abortion; d—the procedure involves transabdominal needle aspiration of amniotic fluid.

25. A client is diagnosed with a wound infection which is quite painful. Which of the following is true?
- An antibiotic should be started immediately. The client can return for a wound culture when the wound is less painful.
 - Antibiotic therapy will be withheld until the culture and sensitivity report is available.
 - A wound culture is obtained first, after which a broad spectrum antibiotic is started.
 - The culture report will identify the correct antibiotic to use to treat the infection.

Rationale

Correct answer: c.

Specimen collection should occur prior to beginning antibiotic therapy.

Incorrect answers: a—treatment with antibiotics before obtaining the culture may produce false-negative results; b—the client is started on a broad spectrum antibiotic while awaiting the culture and sensitivity report. If the bacteria are found to be resistant to the prescribed antibiotic, the medication will be changed; d—the sensitivity report identifies the antibiotics to which the bacteria are susceptible.

Test Plan Category:

Physiological Integrity

Sub-category: Reduction of Risk Potential—Part 2

Topics: Vital Signs

System Specific Assessments

Potential for Alteration in Body Systems

▸ System Specific Assessments

527

▸ Vital Signs (VS)

517

VITAL SIGNS (VS)

- Traditional four VS are temperature, pulse, respirations, and BP.
- Pain is now considered the fifth vital sign.
- Change in VS can indicate a problem before other more obvious and specific S&S occur.
- Baseline VS are taken on admission; in addition, VS should always be taken before and after any invasive procedure, when new S&S occur; before and after any interventions that could affect them such as getting a client out of bed postoperatively; or before and/or after administering a medication with desired effects or side effects affecting cardiovascular or respiratory function.

Practice Alert

VS can be delegated provided the clients have been assessed by the nurse as stable; therefore, the VS for those clients are routine.

TEMPERATURE

- Temperature is the balance between heat produced and heat lost.
- Heat is produced by
 - metabolism: the higher the basal metabolic rate, the higher the heat produced;
 - muscular activity including shivering and raising of goose bumps (piloerection);
 - increased cellular metabolism through increased thyroxine, action of epinephrine, norepinephrine sympathetic stimulation, and fever.
- Heat is lost by
 - radiation: transfer of heat from one surface to another without actual contact;
 - conduction: loss of heat from a warm molecule to a colder one, e.g., cooling by taking a cold shower;
 - convection: loss of heat by movement of air currents around the body, e.g., cooling by use of a fan;

—vaporization: continuous evaporation of moisture (insensible water loss) from skin, mucous membranes of mouth, and respiratory tract.

Temperature Control

- Core temperature, i.e., temperature deep in the tissues is relatively stable.
- Surface temperature, i.e., temperature of skin, subcutaneous tissue, and fat varies with environment.
- Core temperature is controlled by a center in the hypothalamus, which initiates heat loss mechanisms when the body temperature is too high and heat generating/conserving measures when it is too cold.
 - Heat loss measures are peripheral vasodilation and sweating.
 - Heat generating/conserving measures, e.g., shivering and piloerection, vasoconstriction, release of epinephrine to increase cellular metabolism.
- Factors influencing body temperature are
 - age: young and old do not regulate temperature as effectively as other age groups and are more vulnerable to negative effects from high or low environmental temperature;
 - time of day: temperature has a diurnal rhythm being highest between 8 p.m. and midnight and lowest between 4 and 6 a.m., with the variation being as high as 1.8°F;
 - exercise: hard work or strenuous exercise can raise temperature;
 - stress: raises temperature through release of epinephrine and norepinephrine and their effects on cellular metabolism;
 - hormones: progesterone raises temperature at the time of ovulation;
 - environmental temperature: extremes can raise or lower temperature once compensatory capacity has been exceeded.

Body Temperature Measurement

- Oral
 - If the client has been eating, drinking, or smoking, wait for 20 minutes before taking an oral temperature.
 - Instruct client to keep the lips shut; not to talk and not to bite down.
 - Contraindicated for confused or disoriented clients or anyone who cannot follow directions; those who cannot breathe through their noses because of packing or other problems; those with oral surgery/disease or those receiving oxygen.
- Rectal
 - Generally avoided in infants because of the risk of rectal perforation.
 - Children should be positioned prone across one's lap or on the side with knees flexed when a rectal temperature is taken.

—Contraindicated for clients with rectal surgery, diarrhea, severe hemorrhoids, other rectal disease, and for those who are immunosuppressed or have a clotting disorder.

- Ear (tympanic)
 - For infants, position supine with head stabilized and pull the pinna straight back and slightly down; insert probe tip far enough to seal canal.
 - For children over age 3, pull pinna straight back and upward.
 - Do not use in the presence of active ear infection or tympanic membrane drainage tubes.
- Axillary
 - Preferred site in newborns because it eliminates risk of rectal perforation.

Assessment Alert

Temperature sensitive strips/chemical dots—if one of these is used to measure temperature and it indicates a fever, measurement should be repeated with a thermometer to obtain a more accurate reading.

Altered Body Temperature

Hyperthermia (pyrexia or fever: elevated body temperature)

- Cause: hypothalamic thermostat is set higher than normal temperature by tissue destruction, dehydration, or pyrogenic substances.

S&S:

- Fever onset
 - S&S reflect body's attempt to generate heat and prevent heat loss in order to raise temperature.
 - Cool, pale skin resulting from vasoconstriction and the absence of sweating; shivering and appearance of goose flesh, increased pulse and respiratory rates, complaints of feeling cold.
- Fever course
 - When higher temperature is reached, heat generating mechanisms cease.
 - Client is glassy-eyed, sensitive to light, thirsty, somewhat dehydrated, and may be drowsy, restless, delirious, or may seize; skin is warm; pulse and respirations are increased; and malaise, muscle aches, weakness, and fever blisters (herpetic lesions) may develop.
- Fever break
 - Signs reflect body's attempt to lose heat.
 - Skin is flushed and warm due to vasodilation and sweating.

Nursing Process Elements

- Aid heat production and loss by adding clothing/blankets or removing them. Further heat loss by tepid sponge baths and reducing activity
- Provide 2500–3000 ml of fluid per day to prevent dehydration
- Provide nutrition to meet increased metabolic need
- Monitor VS and for signs of dehydration and infection
- Maintain comfort through mouth care, provision of clean dry linens

Assessment Alert

Fever is not always a good indication of the seriousness of a problem especially in older people who often have only a low-grade fever with pneumonia or a UTI.

Hypothermia

Low body temperature

- Cause: excessive heat loss as from a cold environment or immersion in cold water, insufficient heat production, or impaired hypothalamic control

S&S: Low body temperature, pulse and respiratory rates and BP; shivering and feelings of cold; pale, cool, waxy skin; low urinary output; lack of coordination, disorientation; drowsiness progressing to coma.

Nursing Process Elements

- Provide dry clothing, warm environment, blankets, or warming pads
- Keep limbs close to the body and cover head with a cap or turban
- Give warm oral or IV fluids

PULSE

- Palpable waves of blood flow are pumped by the heart into the arterial system
- Reflects stroke volume or amount of blood pumped into the arteries with each contraction of the ventricle
- Felt wherever an artery lies close to the surface of the body and can be compressed against firm, dense tissue or bone
- Assessing the pulse provides information about the function of the heart and the blood flow to an area of the body

- Rate, rhythm, and quality of the pulse are assessed when taking the pulse

Assessment Alert

When the purpose of taking a pulse is to assess blood flow to a part, the same pulse on each side of the body must be compared.

Common sites for obtaining the pulse are

- temporal artery,
- carotid artery: indicates blood flow to the brain; used during CPR,

Assessment Alert

Never palpate both carotid arteries at the same time.

- brachial artery: used during cardiac arrest in infants,
- radial artery,
- femoral artery,
- popliteal artery,
- posterior tibial artery,
- dorsalis pedis artery, and
- apex of the heart (apical pulse).
 - Auscultated with a stethoscope placed over point of maximal impulse (PMI)
 - Located at about the left, fifth intercostal space at the midclavicular line and slightly more left in children
 - Uses
 - Routine pulses in children up to age 3
 - Adults with cardiac, pulmonary, or renal disease or taking medications with a cardiac effect
 - Lub-dub equals one heartbeat
 - Lub is the first heart sound (S1) heard when the atrioventricular valves close at the end of ventricular filling.
 - Dub is the second heart sound (S2) heard when the semilunar valves close after ventricular emptying.

Pulse Rate

- Number of bpm
- Normal pulse rate varies with age
 - Infants: 120–160 bpm
 - Toddlers: 90–140 bpm

- Preschoolers: 80–110 bpm
- School-agers: 75–100 bpm
- Adolescents: 60–90 bpm
- Adults: 60–100 bpm
- Tachycardia: pulse rate higher than the top of the range for the client's age.
- Bradycardia: pulse rate lower than the bottom of the range for the client's age. Athletic persons may have normal bradycardia.
- Factors affecting pulse rate are
 - exercise: pulse rate increases with activity;
 - temperature: pulse rate increases with fever;
 - emotion/stress: sympathetic stimulation increases rate and force of cardiac contraction;
 - medications: depending on the medication, either raises or lowers pulse rate;
 - trauma/hemorrhage: hypovolemia causes an increase in pulse rate as a compensatory mechanism to maintain BP in the face of low volume;
 - postural changes: with pooling of blood in the extremities, pulse increases to maintain BP despite the decreased venous return;
 - pulmonary conditions: if oxygenation is impaired, pulse rate increases in an attempt to supply adequate amounts of oxygen to the tissues.
- Always count an irregular pulse for a full minute.
- After activity, allow client to rest for 10–15 minutes before taking pulse to allow it to return to its resting rate.
- Most accurate rate is the apical.
- Pulse deficit: radial pulse rate is lower than the apical rate.
 - Occurs when some ventricular contractions are so weak that the resultant pulse wave does not reach the periphery or that pathology in or around the artery is preventing the passage of blood.
 - To measure a pulse deficit, two nurses are needed: one who counts the apical pulse and one who counts the radial pulse. They use one watch/clock and start and stop at a predetermined time.

Assessment Alert

A peripheral pulse rate can never be higher than the apical rate because the heart generates the pulse wave.

Rhythm

Rhythm is the pattern of pulse waves or heartbeats.

- Regular rhythm: pulse waves or beats occur at evenly spaced intervals.
- Regularly irregular: pattern is irregular but consistent, e.g., skips every fifth beat.
- Irregular irregularity: no discernible pattern exists.

Assessment Alert

When an irregular pulse is detected, an apical pulse which is always counted for a full minute, should be obtained.

Quality

- Strength of the pulse wave
 - A full or strong pulse that is easily palpated is normal.
 - A bounding pulse is stronger than normal.
 - A weak or thready pulse is easily obliterated by pressure of the examiner's fingers.
- Quality depends on
 - stroke volume, which is the amount of blood ejected from the left ventricle with each contraction; normal for an adult is about 70 ml;
 - elasticity of the arteries;
 - adequacy of local blood flow.

Equality

- Equality is the comparison of corresponding pulses on the right and left sides of the body.
- Normally, pulse characteristics in an artery on right side of body should be equal to pulse characteristics in same artery on the left side.

DOPPLER DEVICE

- Doppler device detects movement of red blood cells through an artery; therefore, it eliminates environmental noise interference and produces audible sound.
- It is used to determine adequacy of blood flow when peripheral pulses cannot be palpated due to obesity, presence of occlusive vascular disease, cardiopulmonary collapse with vasoconstriction, postoperatively when peripheral blood flow may be compromised.

RESPIRATION

- Respiration is a process by which oxygen and carbon dioxide are transferred between the atmosphere and the blood and the blood and the cells.

- External respiration refers to the movement of oxygen and carbon dioxide between the alveoli of the lungs and the pulmonary blood.
- Internal respiration refers to the movement of oxygen and carbon dioxide between the circulating blood and the cells throughout the body.
- Ventilation is movement of air in and out of the lungs, i.e., inhalation and exhalation (breathing).

BREATHING

- Breathing is an automatic and involuntary process requiring functioning lungs, chest wall, respiratory muscles, respiratory center in the medulla oblongata, and functioning nerve tracts connecting brain to muscles.
- One breath is composed of one inspiration and one expiration.
- Inspiration is active; expiration is passive.
- Stimulus to breathe in healthy persons is an increase in CO₂ pressure in the arterial blood; the resultant increase in rate and depth of breathing removes the excess CO₂.
- Chemoreceptors located in the aorta and carotid arteries are sensitive to CO₂, pH, and low levels of O₂. If O₂ decreases, stimulus is sent to respiratory center.
- Cerebral cortex also exerts voluntary control over breathing allowing one to “hold the breath.” The CO₂ stimulus to the respiratory center is stronger than the control.
- Basic types of breathing
 - Costal (thoracic) breathing
 - uses external intercostal muscles and other accessory muscles such as the sternocleidomastoids;
 - chest moves up and out.
 - Diaphragmatic (abdominal) breathing
 - uses the diaphragm;
 - abdomen moves in and out.
 - Young children are diaphragmatic breathers.
- Factors that influence breathing are
 - age: normal range of respiratory rates varies with age;
 - medications: narcotics and sedatives can decrease rate and depth;
 - stress/anxiety: increases rate and depth through action of fight or flight hormones;
 - exercise: increases rate and depth to meet cells’ increased demand for oxygen and removal of carbon dioxide;
 - altitude: increases rate to compensate for decreased atmospheric oxygen;
 - gender;
 - body position: can inhibit or facilitate chest expansion;
 - environmental temperature: high temperature increases the respiratory rate and low temperature decreases the respiratory rate;

- fever: increases respiratory rate as a result of increased metabolism;
- presence of pain;
- smoking;
- neurological injury: increased ICP associated with decreased respiratory rate;
- hemoglobin abnormalities.
- Respiratory characteristics to be assessed are rate and rhythm.

Rate

- Number of breaths per minute
- Resting normal respiratory rate ranges for different age groups are
 - newborn: 30–60 rpm
 - infant: 30–50 rpm
 - toddler: 25–32 rpm
 - child: 20–30 rpm
 - adolescent: 16–19 rpm
 - adult: 12–20 rpm
- Eupnea—normal rate and depth
- Tachypnea—abnormally fast respiratory rate
- Bradypnea—abnormally slow respiratory rate
- Apnea—absence of respiration, described in terms of length of time between respirations, e.g., apnea × 15 seconds; continuous apnea is respiratory arrest

Rhythm

- Rhythm is a pattern of inspiration and expiration.
- Normally, pattern is regular with expiration twice as long as inspiration.

Depth

- Depth is described as shallow, deep, or normal.
- Normal tidal volume (amount of air taken in and let out during a normal respiration) in an adult is 500 ml or 6–8 l/min.
- Hyperventilation is very deep, rapid respiration.
- Hypoventilation is shallow respiration.

Quality

- Normal is quiet and effortless or easy.
- Abnormal is labored and/or noisy.
 - Dyspnea: labored breathing
 - Orthopnea: needs to be in an upright sitting or standing position to breathe
 - Wheeze: continuous, high-pitched musical sound resulting from air passing through obstructed airways; may be expiratory and/or inspiratory

- Gurgles: bubbling sounds heard as air passes through wet secretions
- Stridor: harsh shrill sound heard on inspiration when larynx is obstructed
- Stertor: snoring sound heard as air passes through a partially obstructed upper airway

BLOOD PRESSURE

- Blood pressure is the force of blood against the arterial walls.
- Determinants of BP are cardiac output, peripheral vascular resistance (size of the arterioles and capillaries and arterial elasticity), blood volume, and blood viscosity.
- Pressure when ventricle is contracting is the systolic; pressure when heart is at rest is the diastolic.
- Pulse pressure is the difference between diastolic and systolic pressure.
- Factors influencing BP are
 - age: increases from birth to puberty; declines somewhat and then tends to increase again with age-related loss of elasticity of arterial walls;
 - time of day: lowest in early morning and peaks late afternoon or evening;
 - stress/emotion;
 - gender and race: females tend to have lower BP than men at least until menopause when it tends to rise; black males are more likely to have hypertension than any other group;
 - medications;
 - family history;
 - environment;
 - extremity on which measured: same extremity should be used to obtain consistent and comparable measurements;
 - vasodilation/vasoconstriction;
 - head injury;
 - changes in blood volume, exercise, or body position.

Measuring Blood Pressure

- Use correct-size cuff.
 - The short side of the cuff bladder should be 40% the diameter of the extremity where it will be placed; the long side should be 60% of the diameter of the extremity where it will be placed.
 - Too narrow a cuff gives a false high reading; too wide a cuff gives a false low reading.
- Support the limb at heart level and allow the client to rest before taking.
 - If the limb is unsupported or above the level of the heart or the client has insufficient rest prior to measure-

ment, the BP will be falsely high. If the limb is below heart level, the pressure is falsely low.

- Wrap cuff smoothly and tightly.
 - If it is uneven or too loose, BP will be falsely high.
- Deflate cuff at a rate of 2–3 mm Hg/sec.
 - If the cuff is deflated too slowly, the diastolic pressure may be falsely high.
 - If the cuff is deflated too quickly, the systolic reading may be falsely low and the diastolic falsely high.
- Wait for 1–2 minutes before repeating the procedure.
 - If redone immediately systolic reading can be falsely high and diastolic falsely low.

Measuring BP when client has just eaten, is in pain, or is smoking can result in falsely high readings.

Assessment Alert

Do not take BP in an arm with an IV, cast, or dialysis shunt; that has recently been used to draw blood samples; is on the side with a mastectomy or the side affected by a stroke.

Orthostatic Hypotension

- Orthostatic hypotension is the drop in BP that occurs when the client assumes a sitting or standing position.
- Assess for orthostatic hypotension by
 - taking pulse and BP after client has been in a supine position for 2–3 minutes;
 - assist client to sit or stand for at least 1 minute and then repeat measures using same locations.
- Increase of 40 bpm in pulse rate or a drop of 30 mmHg or more in BP indicates orthostatic abnormality.

PAIN

- Pain is what the client says it is: it is subjective and only the client knows what he or she feels.
- Reaction to pain is in part a learned experience and as such is influenced by the individual's life and background.
- Clients do not/cannot always describe pain accurately; therefore, careful assessment is necessary.
- Clients do not always use the term pain; soreness, pressure, heaviness, and other words may be used.
- Clients have a right to pain relief.
- Pain is a complex experience and multiple approaches may be needed for pain relief to be effective.

Types of Pain

- Cutaneous
 - Cutaneous pain originates in skin and subcutaneous tissue.
 - It is short, sharp, sometimes burning, and well-localized pain.
- Deep somatic
 - Deep somatic pain originates in ligaments, tendons, bones, blood vessels, and nerves.
 - It is diffuse, longer lasting, feeling of burning, aching, or pressure.
- Visceral
 - Visceral pain originates in cranial, thoracic, or abdominal cavities.
 - It is often diffuse and difficult to localize, may be crampy, sharp or like deep somatic a feeling of burning, aching, or pressure.
 - It results from stretching of tissues, ischemia, or muscle spasm.
- Radiating pain: felt at site of problem but also in surrounding areas.
- Referred pain: pain felt in an area distant from the source of the problem.
- Intractable pain: pain that is very difficult to relieve.
- Neuropathic pain: results from damage to the nervous system.
 - It is sharp, spasmodic pain along the path of a nerve.
 - It is severe, burning pain from damage to a peripheral nerve in the extremities.
 - Phantom pain: perception of pain in an amputated or paralyzed part of the body.

Acute Versus Chronic Pain

- Acute pain
 - Duration of the pain is limited to the time it takes for healing to occur.
 - Pain is not referred to as acute because of its intensity or abruptness of onset.
 - Acute pain usually has not as a known cause such as trauma (accidental or therapeutic), infection, or inflammation.
 - Sympathetic nervous system responses predominate: elevated VS, sweating, pupil dilation; client reports pain; manifests signs of pain such as restlessness, anxiety, crying, guarding, or holding affected area.
- Chronic pain
 - Its duration is of 3 months or longer.
 - It accompanies progressive diseases such as cancer and sickle cell disease, may be due to a neuropathic pain syndrome such as postherpetic neuralgia or the cause may be unknown.

—Parasympathetic nervous system predominates: normal VS, warm, dry skin, normal or constricted pupils; appears depressed or withdrawn, does not report pain unless asked, pain behaviors absent.

Factors Influencing Response to and Tolerance of Pain

- Culture: attitudes of stoicism
- Age
- Environment
- Support systems
- Past experience with pain
- Meaning of pain: something to be endured for a good outcome such as cure or delivery of a baby or something indicating loss of function or injury
- Psychological factors such as anxiety, stress, depression, and boredom decrease pain tolerance; faith and belief increase it
- Fatigue decreases tolerance to pain

Pain Management

- Analgesics
 - Opioids
 - Alter perception of pain by action in the CNS.
 - Classified as strong, e.g., morphine and weak, e.g., codeine based on the strength of effect.
 - Relieve moderate to severe pain but must be taken regularly to maintain relief.
 - Tolerance, the need for larger doses to obtain the same analgesic effect, develops in some clients but doses can be increased to maintain analgesia, because no dosage ceiling exists.
 - Constipation is most common side effect.
 - Naloxone (Narcan) is the antidote for respiratory depression induced by opioids.
 - Non-opioids
 - Block pain impulses at the periphery and if an NSAID decrease pain from inflammation due to an anti-inflammatory effect.
 - Effective for mild to moderate pain.
 - Most common: acetaminophen and NSAIDs.
 - NSAIDs in combination with opioids reduce the dose of opioids needed and provide better pain relief than either type of drug alone.
 - Adjuvant analgesic drugs
 - Diazepam (Valium), chlorpromazine (Thorazine), hydroxyzine (Vistaril), and amitriptyline (Elavil).
 - Drugs not developed as analgesics but found to support pain relief.

- Nonpharmacological treatments for pain relief
 - Electrical stimulation
 - By externally (Transcutaneous Electrical Nerve Stimulation [TENS] unit) or internally placed electrodes (spinal cord stimulators)
 - Works by using the electrical stimulus to block or change the pain stimulus
 - Acupuncture
 - Behavior modification
 - Biofeedback
 - Hypnosis

Practice Alert

Drugs, dosages, and time intervals for administration of analgesics need to be tailored to the needs of the individual client and very often a combination of drugs is needed for effective pain control.

Equianalgesic Dosing

- Equianalgesic dosing applies when clients are being switched from one opioid analgesic to another.
- Reasons for such a switch include occurrence of adverse effects or need for change of route of administration.
- Equianalgesic dosing refers to giving a dose of the new opioid that is equivalent to the previous opioid in its ability to provide pain relief.

Nursing Process Elements

- Treat clients in accord with Joint Commission directives regarding pain
 - Tell client as part of the initial discussion of care that pain relief is an important part of care and that caretakers will act quickly to provide relief measures when pain is reported
 - Assess pain each time VS or other assessments are made
 - Use client's report of presence, quality, and intensity of pain as the primary guide to the need for pain relief
 - Develop a goal and plan of care related to pain relief in collaboration with the client and other members of the health care team

Assessment Alert

When assessing VS, always compare findings to baseline data.

- Obtain a pain history
 - Location: have client point to area of pain or mark on diagram of body
 - Quality: what does it feel like?
 - Severity: use a pain intensity scale
 - Most scales ask client to rate pain intensity on a scale of 0–5 or 0–10 where 0 is no pain and the highest number is the most severe pain imaginable
 - Scales also may have word modifiers such as moderate or very severe pain
 - Scales that show faces with differing expressions along with the numbers may be used with children and adults who cannot communicate verbally due to developmental stage, cognitive impairment, or language barrier

Assessment Alert

A pain rating of three or higher requires intervention.

- Onset of pain: abrupt or gradual
- Pattern of pain: constant or intermittent; if intermittent, what is the duration, duration of time between periods of pain
- Associated symptoms might include nausea and vomiting, abdominal distention, diarrhea, dizziness, visual changes, and weakness
- Precipitating or Aggravating factors might include eating, exercising, exposure to heat or cold, positioning, or emotionally stressful experience
- Relieving factors: restriction of movement, rubbing, positioning, decreased light, hot liquids, rest, meditation, prayer, herbs, medications
- Treatments tried that were ineffective
- When pain is chronic, also determine
 - effect of pain on daily life;
 - prior pain experiences;
 - meaning of pain to the client;
 - coping strategies used to deal with the pain;
 - emotional reaction to the pain.
- Suggest use of a daily pain diary for persons with chronic pain if needed to help identify and clarify the above information
- Assess for physical manifestations of pain
 - Facial grimacing
 - Moaning, groaning, crying, or screaming
 - Guarding/limiting movement of painful area
 - Rhythmic body movements

- Restless, purposeless movements
- Early in pain experience signs of sympathetic nervous stimulation: elevated pulse, and respiratory rates, elevated BP, pallor, diaphoresis, and dilation
- Assess and manage common side effects of opioids: constipation, sedation, respiratory depression, nausea, postural hypotension, and pruritus
 - Monitor bowel movements
 - Ensure adequate fluid intake
 - Encourage increase in dietary fiber
 - Administer stool softeners and stimulants as prescribed

Nursing Intervention Alert

Stool softeners alone will not prevent constipation; they must be used in conjunction with a stimulant laxative.

- Monitor sedation level especially during the first 12–24 hours of opioid therapy. Note if client is sleeping but arousable, awake, and alert; somewhat drowsy but easily aroused; frequently drowsy, drifting off to sleep during conversations but arousable; somnolent with minimal or no response to physical stimulation. If sedative effects last beyond 2–3 days required to build up tolerance, dosage and/or drug regimen needs revision
- Monitor respiratory status especially during the first 12–24 hours that opioids are taken; make certain naloxone (Narcan) is available
- Administer antiemetic for nausea on a scheduled basis; if nausea persists beyond the 2–3 days needed to develop tolerance, change the opioid
- Encourage self-care activities, deep breathing, and use of incentive spirometer to decrease depressant effect on respirations
- Encourage client to change position slowly and provide assistance when moving from a lying or sitting to standing position because of the risk of dizziness and falling due to orthostatic hypotension
- Administer antihistamines as prescribed for pruritus; support effectiveness with cool compresses, lotion, and diversional activities
- Reassure client that pruritus should disappear as tolerance is developed
- Assess for adverse effects of NSAIDs
 - Monitor for signs of GI or other bleeding
 - Monitor serum levels of NSAIDs and for signs of hepatic or renal toxicity in older adults with renal impairment

- Assess for signs of hepatotoxicity in clients taking acetaminophen and be certain that the maximum daily dose is not exceeded
- Promote effectiveness of analgesics or other pain-relief modalities through use of guided imagery; relaxation exercises; distraction or in some cases provision of a quiet, darkened environment; application of heat or cold, rubbing/massage

Client teaching for self-care

- Prevent constipation if taking opioids; adequate fluid and fiber intake; taking a mild laxative regularly in the evening; using a rectal suppository in the morning if needed in addition
- Take NSAIDs with food and full glass of fluid
- Report any signs of bleeding
- Do not mix alcohol with NSAIDs; and do not mix different NSAIDs
- Proper use of TENS
 - Do not place electrodes over hair, broken skin areas, the carotid sinus (may induce bradycardia), throat (may induce laryngeal or pharyngeal spasms), or pregnant uterus
 - Use prep pad to wipe the skin before applying the conductor pad
 - Remove and wash both electrodes and underlying skin every day
 - Expect to feel numbness or tingling during use; if not, check battery
- Proper application of heat and cold
 - Apply over painful area when possible; otherwise apply on the opposite side of the body over an acupuncture point located between the pain and the CNS
 - Use a towel or other cover to protect skin from direct contact with source of heat or cold
 - Apply ice for a maximum of 10 minutes at a time and heat for 20–30 minutes and never so cold or hot that it hurts
 - Use heat or cold when pain starts; don't wait for it to worsen

Think Smart/Test Smart

If the limb needs to be supported at heart level for an accurate BP measurement then if a BP must be taken in the lower extremity the client must be positioned in a prone or supine position.

Common system specific assessment measures used in nursing practice are presented in Table 17-1.

Table 17–1 System Specific Assessments

| System/Function to be Assessed | How to Assess | When to Assess |
|---|---|---|
| Bowel function/ peristalsis | Auscultate for bowel sounds. Check for passage of flatus. Determine if defecation has occurred. Check for abdominal distention or crampy pain. Assess frequency and consistency of bowel movements. | Post general or spinal anesthesia After barium studies; during opioid therapy |
| Bladder/urethral function | Monitor time and amount of voiding. | After cystoscopy or other urethral/bladder instrumentation or surgery; post prostatectomy; after vaginal childbirth During opioid therapy With BPH or prostate cancer |
| Kidney function | Monitor I&O. | After general or spinal anesthesia; when disease exists that is associated with decreased renal blood flow |
| Respiratory status | Check breath sounds. Assess rate and depth of respirations. | Before and after coughing, deep breathing, use of incentive spirometer or other respiratory therapy During opioid therapy or magnesium sulfate therapy |
| Cardiac status | Assess apical pulse. | If radial pulse is irregular; prior to administering medications such as digoxin that act on the heart |
| Arterial blood flow to an extremity | Assess pedal pulses for blood flow to feet; popliteal for blood flow to lower leg; femoral for blood flow to thigh; brachial for blood flow to forearm and radial and ulnar for blood flow to the respective sides of the hand. | After vascular surgery involving the extremity; in clients presenting with a cold or cyanotic extremity or with intermittent claudication; after insertion of a dialysis shunt. |
| Neurovascular status of an extremity | Assess most distal pulse; check for normal color, warm temperature, normal capillary refill, and ability to move part and perceive touch. | After application of a cast or other potentially constricting device or garment. |
| Venous and lymphatic flow in an extremity | Assess for peripheral edema. | With kidney disease; after dissection or removal of area lymph nodes as with mastectomy. |
| Neurological function | Assess orientation to time, place, and person. Assess PERRLA. Assess lifts and grips. | Following head trauma or intracranial surgery; after CVA; in the presence of degenerative neurological disease, meningitis, encephalitis, space occupying intracranial lesions, post seizure. |
| Swallowing | Assess swallow reflex. | Before initiating oral feeding in clients with CVAs, Parkinson's disease. |
| Gagging | Assess gag reflex. | Post general anesthesia |

(continued on next page)

Table 17–1 (continued from previous page)

| System/Function to be Assessed | How to Assess | When to Assess |
|--------------------------------|--|---|
| Wound healing | Assess for approximation, redness, warmth, swelling, drainage in wounds healing by primary intention. Assess for granulation tissue in wounds healing by second intention Assess for adherence to wound bed, color, signs of epithelialization, vascularization and new granulation in grafts. | |
| Reproductive system | Obtain a pregnancy test. Assess height and contraction of the fundus. | Clients who present with undiagnosed abdominal pain; prior to administration of category X drugs; prior to an abortion. Postpartum |

SYSTEM SPECIFIC ASSESSMENTS

CONFUSION/DELIRIUM/AGITATION

- **Confusion**—Impairment of memory, cognitive function, perception, emotional function; disorientation; reduced level of consciousness
- **Delirium**—acute onset (hours or days) with fluctuation over the course of the day of impaired cognition, perception, speech and memory; sleep disturbance; exaggerated emotions with displays of aggression, paranoia, or terror. May be hyperactive or hypoactive delirium.
- **Agitation**—result of confusion or delirium; may manifest as abusive behaviors (physical or verbal), hiding or hoarding behaviors, or repetitive actions such as pacing, dressing, and undressing, etc.

Etiology: Medications such as opioids, phenothiazines, benzodiazepines, anticholinergics, beta-blockers, diuretics, dopaminergics, steroids, atropine, phenytoin, H₂ antagonists, toxic level of digoxin; unrelieved pain; full bladder or bowel; infection such as UTI, respiratory, septicemia; brain pathology; cardiac or respiratory failure; nicotine, alcohol, or drug withdrawal; metabolic problem such as increased BUN; fever; sleep deprivation; or extreme anxiety.

Rx: Determined by etiology, e.g., treat infection, discontinue medication, hydrate.

Nursing Process Elements

Assessment: Use standardized tool to confirm and identify degree of confusion or delirium; assess for etiology, e.g., pal-

pate for full bladder, check for history of drug use, check medications.

Assessment Alert

If the client is confused or delirious, always assess for client safety.

Intervention:

- Provide consistent, repeated reorientation to client as tolerated and needed for care
- Institute safety measures
- Support family and explain expected response to intervention

PRURITUS (ITCH)

Etiology: Dry or wet, macerated skin; contact dermatitis; drugs such as morphine, phenothiazines, or antibiotics; fungal infections or infestations with lice, scabies, fleas, bed bugs; renal failure; jaundice; infiltration of tumors into subcutaneous tissues.

Complications: break in skin integrity with or without infection.

Rx: See below for nonpharmacologic measures and Table 17–2 “Pharmacologic Interventions for the Management of

Table 17–2 Pharmacologic Interventions for the Management of Pruritus

| Medication | Use |
|---|---|
| Antihistamines Topical corticosteroids | Acute, localized itch only; not for chronic or generalized itch |
| Ondansetron | Opioid, uremia, or jaundice associated itch |
| Antifungal creams | Itch associated with <i>Candida</i> infection |
| Systemic corticosteroids | Itch associated with inflammatory and neoplastic conditions |
| Bile acid sequestrants | End-stage liver disease itch |
| Anesthetics | Intractable itch |

Pruritus” for pharmacologic measures. TENS may also be used for localized pruritus.

Nursing Process Elements

Assessment: Onset, duration, severity, location, condition of skin including integrity, rash, or other lesion; aggravating or relieving factors; review of history for precipitating or associated factors.

Client teaching for self-care

- Avoid measures that cause excessive drying of the skin such as frequent baths and use of hot water, deodorant soaps, alcohol, and other irritants. Use tepid water, neutral pH cleansers, and apply skin moisturizer/lubricant
- Wear loose, light clothing and keep environment cool to prevent sweating and increased moisture on the skin
- Take cool starch baths or use cool compresses to decrease itch
- Avoid alcohol, caffeine, and theophylline all of which can increase itch

Practice Alert

Do not apply cool compresses to extremities if peripheral vascular compromise is present.

ANOREXIA

Etiology: Nausea & vomiting; constipation; pain; oral problems such as dry mouth or mucositis; dental problems such as pain or ill-fitting dentures; change in taste or smell of foods; impaired gastric emptying; depression; confusion; dementia; anxiety; fatigue; medications such as opioids and

antibiotics; radiation; chemotherapy; symptom of disease such as mononucleosis.

Rx: Treat problems contributing to the anorexia. See Table 7-3 for pharmacologic interventions for the management of anorexia.

Nursing Process Elements

Assessment: History of anorexia; condition of mouth and teeth; signs of bowel function including bowel sounds; food likes and dislikes.

Assess for symptoms of problems that can cause anorexia.

Interventions:

- Provide food that the client likes and at time of request.
- Provide frequent meals with small portions attractively served.
- Avoid very hot or very cold food and those with strong odors.
- Give nutritional supplements as tolerated.
- Refer to dietician.

Client teaching for self-care

- Eat small, frequent meals
- Avoid very hot or very cold food and those with strong odors

CONSTIPATION

- Constipation is characterized by abnormally infrequent defecation and/or passage of abnormally hard stool.
- Colon absorbs water from GI contents; therefore, the longer stool stays in rectum, the drier it becomes and the harder to pass.

Table 17–3 Pharmacologic Interventions for the Management of Anorexia

| Medication | Use |
|---------------------------------------|--|
| Gastrokinetic agents | Control nausea and early satiety |
| Corticosteroids | Short term improvement of appetite |
| Progesterone analogs | Improve appetite; decrease n&v; reduce taste and odor changes; promote weight gain |
| Cannabinoids | Stimulate appetite |
| Alcohol (beer or sherry before meals) | Improve appetite and morale |
| Vitamins | Reported to improve appetite |

Adapted with permission from Waller, A. Caroline NL: *Handbook of Palliative Care in Cancer*, 2nd ed. Elsevier, 2000, p. 87.

- The gastrocolic reflex in which food entering stomach initiates the urge to defecate. If urge is suppressed feces will remain in the bowel and become increasingly dry as more water is absorbed. The urge may not recur for 24 hours as it is strongest after breakfast.
- Occasional constipation is basically a universal experience; more common experience in the elderly.

Etiology: Factors that cause decreased bowel motility or retention of stool include endocrine and neurological diseases such as diabetes mellitus, hypothyroidism, Parkinson's disease, multiple sclerosis, side effect of drugs including opioids, anticholinergics, anticonvulsants, and calcium channel blockers. Lifestyle factors such as physical inactivity, stress, dietary changes, inadequate dietary bulk or fluids, and ignoring urge to defecate.

Complications: Hemorrhoids from repeated straining, impaction, primary symptoms of which are pain and bleeding on defecation. External hemorrhoids appear as lumps of pink or red tissue around the anus and often itch.

Rx: Diet and fluid, fiber supplements, increased activity, regular fluid modifications, stool softeners, and laxatives.

Nursing Process Elements

Assessment Alert

Abnormal refers to variance from what is normal for the individual. Normal patterns of defecation vary widely from person to person ranging from three times per day to once every three or more days.

Client teaching for self-care

- High-fiber diet
- 2000 ml of fluid daily
- Regular exercise
- Planned daily time for defecation
- Bulk forming rather than harsh laxatives for occasional constipation

Nursing Intervention Alert

Institution of measures to prevent constipation in clients at risk is more effective and easier than treating constipation that has developed. Clients at great risk are those on opiates for pain, confused, immobilized clients.

HICCOUGHS (SINGULTUS)

- Hiccoughs are characterized by involuntary contraction of the diaphragm followed by rapid closure of the glottis.

Etiology: Gastric distention related to impaired motility or excessive gas, esophagitis, gastritis, peptic ulcer disease, gastric or pancreatic cancer, gall bladder disease, bowel obstruction; irritation of the vagus or phrenic nerve as seen for example with an enlarged spleen or a grossly distended urinary bladder; mediastinal, cervical or lung tumors; thoracic surgery or trauma, uremia, hypocalcemia, hyponatremia; renal or hepatic problems; respiratory problems such as COPD, TB, pneumonia; pulmonary edema; malaria, herpes zoster, influenza, sepsis; CNS tumors, stroke, MS, hydrocephalus, ventriculoperitoneal shunts, AV malformations, head trauma; general anesthesia; IV corticosteroids, barbiturates, benzodiazepines, diazepam; stress, grief reaction, personality disorders, and anorexia.

Rx: Treat underlying cause.

Nursing Process Elements

Assessment:

- Severity of the problem (frequency, duration, degree of discomfort)
- S&S of any causative problems
- History of causative factors such as medications, relationship to sleep (gone at night suggests psych)
- Relief measures

Interventions:

- Promote symptomatic relief by instructing client to
 - hold breath or hyperventilate;
 - rebreathe into a paper bag;
 - coughing;
 - gargle with water;
 - bite a lemon;
 - swallow crushed ice or a teaspoon of table sugar.
- Recommend hypnosis or acupuncture because these can also be effective.

BLADDER SPASMS

- Intermittent, painful contractions of the detrusor muscle accompanied by pain and a sense of urgency.

Etiology: Indwelling catheter, UTI, pressure of tumor, radiation, or chemotherapy cystitis, urethral obstruction by clots or tumor, stroke, spinal cord lesions, MS.

Rx: Antispasmodic medications (oxybutynin, NSAIDs, B&O suppositories).

Nursing Process Elements

Assessment: Appropriate catheter size, placement and function, signs of UTI or other disease problem, hematuria, adequacy of fluid intake, fecal impaction.

Interventions:

- Assist to void every 4 hours, sitting or standing
- Teach relaxation techniques

INCREASED INTRACRANIAL PRESSURE (IICP)

- Normally, intracranial pressure (ICP) varies continually within a range of 80–180 mm of H₂O or 0–15 mm Hg.
- ICP is temporarily increased by actions such as bending, coughing, sneezing, and straining at stool, which increase intrathoracic or intra-abdominal pressure.
- ICP is lower when sitting or standing.

Etiology: Obstruction of CSF flow, tumors, intracranial hemorrhage, inflammation with edema as in meningitis, encephalitis, or abscess.

Rx:

- Treat underlying problem
- Osmotic diuretics such as mannitol given IV to draw fluid from brain tissue into vascular system; have short-term effect but useful during surgery or as an emergency measure
- Steroids such as dexamethasone (Decadron) to decrease inflammation and edema
- Analgesics for headache
- Anticonvulsants to prevent seizures

Nursing Process Elements

Assessment: Signs of increasing ICP: new headache, vomiting, slow irregular respirations, which may ultimately become Cheyne–Stokes respirations, altered mental status, decreased motor function, increased restlessness, agitation, blurred vision, and widening pulse pressure.

Assessment Alert

Change in level of consciousness (early changes include restlessness, irritability, drowsiness, confusion, apathy, difficulty or hesitation in following simple directions or in verbalizing) is the most sensitive sign of increasing ICP.

Fixed, dilated pupils are a late sign of increased ICP because these result from compression of the oculomotor nerve due to herniation of the cerebral brain tissue through the uncus onto the brain stem.

Interventions:

- Maintain semi-Fowler's position to promote venous return and decrease cerebral blood volume.
- Provide darkened, quiet environment.
- If diuretic is given, monitor urinary output to evaluate its effectiveness.
- If glucocorticoids are given, monitor for GI bleeding, infection, and hyperglycemia.

Nursing Intervention Alert

Opioids can contribute to ICP because of their vasodilation and respiratory depression effects. Tramadol is contraindicated with ICP because it can lower seizure threshold.

OTALGIA

Ear pain

Etiology:

- Infection
- Trauma
- Pressure change in the Eustachian tubes
- Temporomandibular joint disease
- Pressure from a tumor in the head or neck

Rx: Treat underlying problem.

Nursing Process Elements

Assessment: One or both ears affected; constant or intermittent type of pain; feeling of fullness, pressure, throbbing, or pounding.

OTORRHEA

Drainage from the ear

Etiology:

- Trauma such as skull fracture can cause hemorrhage with bloody drainage leakage of CSF that presents as clear, watery drainage or a combination of the two.

- Infection of the external or middle ear can cause thick, yellow, foul smelling, purulent sometimes bloody drainage.
- Tumors can cause bloody or serosanguineous drainage.

Rx: Treat underlying problem.

TINNITUS

Ringling or buzzing in one or both ears

Etiology:

- Most commonly associated with aspirin toxicity
- Accompanies some sensorineural hearing loss
- Chronic ear infection
- Labyrinthitis
- Systemic diseases such as arteriosclerosis, hypertension, anemia, and hypothyroidism
- Temporomandibular joint disease

Rx:

- Treat underlying problem when possible
- Masking
 - Use a hearing aid-like device, which produces low level white noise that blocks perception of tinnitus.
 - Residual inhibition: masking of tinnitus occurs for a short time after masking device is removed.
- Alternative treatments (none are proven effective)
 - Magnesium, zinc, Ginkgo biloba, or vitamin B supplements, acupuncture, magnets, hyperbaric oxygen, hypnosis, craniosacral therapy
- Hearing aid
 - Hearing aid is most likely to help if hearing loss is in the same frequency range as the tinnitus because hearing aids allow ambient sound to be heard that covers up the ringing.
- Biofeedback to control stress
- Cognitive therapy
 - Cognitive therapy is designed to change perception of tinnitus and the emotional reaction to it by promoting identification of negative behaviors and thoughts and then altering them.
- Drug therapy
 - Antianxiety drugs like Xanax, antidepressants like nortriptyline, antihistamines, and anticonvulsants
- Tinnitus retraining therapy (TRT)
 - TRT combines low-level, steady background sounds produced by an in-the-ear generator for a minimum of 8 hr/d with one-on-one client/clinician directive counseling

—In 1–2 years, clients habituate to the tinnitus and no longer need the sound generator to make them unaware of the tinnitus.

Nursing Process Elements

Assessment: Ask about use of products containing aspirin; how often and how much. Explore carefully because many OTC products contain aspirin although aspirin is not in their name and often clients are unaware of its presence.

Interventions:

- Provide information about available treatment approaches
- Provide referrals as needed

BLURRED VISION

Etiology: Most often results from refractive error. Other intraocular causes are cataracts, glaucoma, and inflammation. Systemic causes include diabetes mellitus, hypertension, and kidney disease. Can be related to use of tobacco, phenothiazines, sulfonamides, and beta-blockers.

Rx: Treat underlying cause.

Nursing Process Elements

Assessment: Date of last eye examination, history of eye disease or of systemic diseases known to cause blurred vision, S&S of eye or systemic diseases; use of tobacco, phenothiazines, sulfonamides, and beta-blockers.

Interventions:

- Caution to take regarding risk for injury while vision is blurred

DIPLOPIA

Double vision: may be horizontal (two images side by side) or vertical (one image above the other)

Etiology: Weakness or paralysis of an extraocular muscle associated with problems such as TIA, myasthenia gravis, trauma, or use of alcohol or drugs such as imipramine, diazepam (Valium), and nitrofurantoin (Macrochantin).

Rx: Treat underlying cause.

Nursing Process Elements

- Insitute/teach safety measures

FLOATERS

Tiny, moving dots or squiggles in the visual field

Etiology: Most common in near-sighted persons and in the older population especially when tired or worried. Many floaters occasionally result from a retinal detachment but most often floaters do not indicate a problem.

Rx: No treatment unless related to retinal detachment.

PHOTOPHOBIA

Photophobia is sensitivity to ultraviolet light.

Etiology:

- Occupation/lifestyle exposure to bright, intense sunlight, snow dazzle, constant darkness, or fine, close work
- Use of contact lenses
- Eye disease: keratitis, corneal abrasion, iritis, and foreign bodies
- Systemic disease: migraine headache, meningitis, Rocky Mountain spotted fever
- Drugs: Cholinergic-blocking agents, antimalarial drugs, MAO inhibitors, vidarabine and idoxuridine, and rabies vaccines.

Nursing Process Elements

- Instruct in use of dark glasses

EDEMA

- Excess fluid in intercellular tissues (Also see ascites and superior vena cava syndrome)

Peripheral (Extremities) Edema

Etiology: Obstruction of venous return, e.g., CHF, DVT, constricting bandages, clothing, etc; renal failure.

Rx: Treat underlying problem; diuretics if lung crackles also present, good skin care.

Nursing Process Elements

Assessment: Pitting, nonpitting, severity (amount), increasing or decreasing, duration, new, recurrent, temperature, and perfusion of skin in involved area, presence or absence of fluid leaking through skin, S&S of underlying problem

Interventions:

- Promote venous return by

- use of compression stockings;
- active or passive exercise;
- elevation of extremities above heart level.

- Prevent skin breakdown

SUPERIOR VENA CAVA SYNDROME (SVCS)

- Upper body edema
- Oncologic emergency

Etiology: Obstruction of the superior vena cava caused by lung cancer or other primary or metastatic tumor in the mediastinal or paratracheal lymph nodes.

S&S: Dyspnea, facial and neck swelling, chest pain, cough, dysphagia, and ruddy facial coloration.

Rx: Palliative radiation with or without steroids. Diuretics have no effect.

Nursing Process Elements

Assessment: Presence and severity of S&S: papilledema, facial edema, distended neck veins, arms, dyspnea, headache, chest pain, dry cough, visual or mental status changes, dizziness, vertigo.

ASCITES

- Ascites is the accumulation of excess fluid in the peritoneal cavity.

Etiology: Obstruction of portal vessels with resultant fluid leak into peritoneal cavity as in cirrhosis, CHF, hepatic, gastric, ovarian, endometrial, breast, colon, or pancreatic cancer or lymphoma; decreased plasma albumin in nephritic syndrome and malnutrition, lymphatic obstruction, pancreatitis, TB, and bowel perforation.

Rx: Symptomatic: spironolactone, paracentesis, analgesics for pain, fluid restriction to 500–1000 mg/d and sodium 200–1000 mg/d, paracentesis, administration of albumin to replace that lost from blood into body fluid. Diuretics are generally ineffective.

Nursing Process Elements

Assessment: S&S of underlying problems, weight gain, tachycardia, dyspnea, orthopnea, unable to bend or sit straight, abdominal pressure, abdominal girth measure (in cms at standard location), tenderness, distention, fluid wave, abdominal striae, distended abdominal veins, anorexia, and early satiety.

Interventions:

- Monitor I&O.
- Restrict fluids and sodium as ordered

DIARRHEA

Diarrhea is the passage of abnormally liquid feces and/or abnormal frequency of defecation.

Etiology:

- Increased water in intestinal contents
 - Impaired absorption occurs due to disorders of the intestinal wall cells.
 - Increased secretion of water into intestine occurs as a reaction to presence of bacteria, toxins, and hormones.
 - Presence of solutes such as bran, which pulls water into intestine by osmosis.
- Increased intestinal motility from inflammation, abnormal bowel contents, or intrinsic irritability, which results in inadequate absorption time
 - Enteritis
 - Ulcerative colitis and Crohn's disease
 - Irritable bowel syndrome

Accompanying S&S: Abdominal cramping, urgency, tenesmus, perianal discomfort, presence of mucus, blood, or fat in unformed stool.

Complications: Dehydration and electrolyte imbalance, metabolic acidosis, malnutrition, skin breakdown in anal area.

Rx: Treatment of underlying cause; fluid and electrolyte replacement.

**Clinical Alert**

Potassium is not added to IV fluids until renal function is confirmed.

**Nursing Process Elements**

- Monitor I&O
- Obtain daily weight
- Monitor stool; measure liquid stool and count as output
- Administer IV fluids as ordered
- Limit oral intake because of its stimulating effect on peristalsis: NPO then small amounts of clear liquids and thin-cooked cereal; add low residue, bland foods as tolerated

- Avoid cold liquids, caffeine, spicy foods, and concentrated sweets
- Protect skin in rectal area by regular cleansing and use of protective salves; Sitz baths for irritation

DYSPHAGIA

Difficulty swallowing

Etiology: Motility disorders of the esophagus such as achalasia, laryngeal cancer, chemotherapy, radiation therapy, neuromuscular disorders, occasionally occurs with mitral stenosis.

Rx: Treat underlying problems.

**Nursing Process Elements****Client teaching for self-care**

- Sit up straight; keep head upright but tilted slightly forward
- Eat slowly; do not rush
- Take small bites of food and small sips of liquid
- Eat a soft or blenderized diet
- Avoid sticky foods
- Avoid spicy, highly seasoned and very hot or cold foods
- May need thickened liquids

DYSPNEA

Dyspnea is characterized by labored or difficult breathing. Its symptoms include distressful feeling of breathlessness or suffocation.

Etiology: COPD, CHF, pulmonary embolism, pleural effusion, anemia, pneumothorax, lung tumor, ascites, and CNS disease.

S&S: Rapid, audible, labored breathing, use of accessory muscles of respiration, gasping, cyanosis, dilated nostrils, tachycardia, and anxious facies.

Rx: Oxygen, palliative thoracentesis.

**Clinical Alert**

For terminal client—cannula not mask, value of O₂ based on relief of dyspnea not pulse oximetry, opioids for bronchodilation, high dose steroids for obstructive or inflammatory problems, bronchodilators, anticholinergics, and anxiety control.

Nursing Process Elements

Assessment: Onset, respiratory rate and depth, use of accessory muscles, lung sounds, constant or intermittent, triggers, and alleviating measures.

Interventions:

- High Fowler's position

Nursing Intervention Alert

COPD client is relieved leaning forward with upper arms supported on a table.

- Encourage pursed-lip breathing in COPD clients
- Maintain a cool environment with fan blowing on client
- Use of guided imagery or relaxation techniques

COUGH

Etiology: Infection, inflammation, left HF, pleural effusion, bronchospasm, bronchogenic cancer, ACE inhibitors, environmental respiratory pollutants including smoking, allergies, and GERD.

Rx: Nonproductive cough: non-opioid or opioid antitussives; productive cough: may use humidifier or expectorants to facilitate raising sputum; treat underlying disorder.

Nursing Process Elements

Assessment: Productive, nonproductive, paroxysmal (periodic, spasmodic); sputum amount color, consistency; fever; effect on quality of life; fatigue, lethargy, and weakness.

Interventions:

- Productive cough: encourage expectoration and proper disposal of tissues; increased fluid intake to liquefy mucus; good mouth care; for pain or muscle ache on coughing demonstrate splinting

FATIGUE

Etiology: COPD, CHF, hypothyroidism, uremia, hypercalcemia, advanced malignancy, sepsis, anemia, chronic pain, dyspnea, nausea, vomiting, etc, radiation therapy, chemotherapy, medications such as beta-blockers, antihistamines,

benzodiazepines, phenothiazines, zidovudine, and nutritional deficiencies.

Rx: Treat underlying cause. If medication-induced, taper, change, or alter administration schedule.

Nursing Process Elements

Assessment: Degree of fatigue, constant or intermittent; effect on quality of life, and functional status; S&S of underlying problems; type and dose of medications used; presence of uncontrolled debilitating symptoms, e.g., dyspnea, pain, vomiting, sleep and rest patterns, stress, and anxiety level.

Interventions:

- Balance activity and rest throughout the day
- Use equipment designed to decrease exertion—use of bedside commode or electric bed
- Set realistic goals for ADLs
- Set priorities for activities
- Caution against prolonged bed rest or inactivity

HYPOXIA/HYPOXEMIA

- Hypoxia is a lack of sufficient oxygen in the tissues of the body.
- Hypoxemia is the decreased oxygen in the blood as indicated by a decreased PaO₂.

Etiology: Ventilation/perfusion mismatch, high altitude, anemia or abnormal hemoglobin, and circulatory dysfunction.

S&S: The symptoms of hypoxia include restlessness, tachycardia, tachypnea, irritability, apprehension, clumsiness, poor judgment, headache, and ultimately decreased level of consciousness. Chronic hypoxia causes fatigue, apathy, drowsiness, and muscle twitches.

Rx: Treatment of underlying disorder; oxygen.

Nursing Process Elements

Assessment Alert

Monitor respirations of clients with chronic hypoxemia closely if oxygen is administered because with chronic hypoxemia the stimulus to breathe becomes a decrease in oxygen as opposed to the increase in CO₂, which is the normal stimulus. Because of this administration of high levels of oxygen can result in the client ceasing to breathe.

HYPERCAPNIA

Hypercapnia is an excess of CO₂ in the arterial blood.

Etiology: Respiratory depression, pneumonia, pulmonary edema, and COPD.

S&S: Tachycardia, hypertension, dizziness, headache, mental clouding, and acidosis.

HYPOCAPNIA

Hypocapnia is the presence of too little CO₂ in the arterial blood.

Etiology: Hyperventilation secondary to anxiety, fever, anemia, salicylate poisoning, and incorrect mechanical ventilation.

S&S: Light-headedness, fatigue, tingling, muscle twitching, inability to concentrate, irritability and change in level of consciousness.

INTERMITTENT CLAUDICATION

- Intermittent Claudication is severe aching or cramping pain in the lower extremities precipitated by walking or muscular contraction and relieved by rest.
- It is usually bilateral.

Etiology: Arterial insufficiency is usually due to a block in the femoral arteries.

Dx: After pain has disappeared with rest, it can be re-elicited by walking the same distance again.

Rx: Femoral–popliteal bypass.

NAUSEA

- Nausea is accompanied by autonomic nervous system changes: increased salivation, diaphoresis, dizziness, faintness, pallor, and tachycardia.
- Nausea usually precedes vomiting.

Etiology: Pregnancy, GI dysfunction, cholecystitis, radiation illness, spinal anesthesia, motion sickness, food poisoning, chemotherapy, drugs such as opioid analgesics.

Rx: Treatment of underlying cause; antiemetic drugs: anticholinergics, antihistamines, serotonin blockers.

Nursing Process Elements

Assessment:

- Frequency, duration, association with emesis, presence of pain, and appetite.

- Precipitating factors.

Interventions:

- Keep environment quiet and free of stimuli likely to induce nausea
- Encourage deep breathing when feeling nauseated
- Provide oral hygiene and comfort measures
- Give small amounts of clear liquids such as ginger ale as tolerated and gradually progress to small, frequent meals of bland, nonirritating foods

VOMITING

- Vomiting occurs when the vomiting center in the brain is stimulated.
- The vomiting center can be stimulated in the following three ways:
 - by pressure when ICP is increased;
 - by autonomic nervous system stimulation that occurs as the result of factors such as gastric distention, irritation or toxins; pain, injury to abdominal viscera, and even emotion;
 - by stimulation from the chemoreceptor trigger zone, an area which is stimulated by emetic drugs such as morphine and ergot as well as metabolic products resulting from radiation, uremia, and infection, and which in turn causes vomiting by impulses sent to the vomiting center.

Clinical Alert

Projectile vomiting is associated with increased ICP and pyloric obstruction.

Rx:

- Treatment of both underlying cause and precipitating factors, e.g., N/G tube for gastric distention; suction to remove irritating gastric contents.
- Antiemetic drugs decrease sensitivity of the CRTZ.

Complications:

- Fluid and electrolyte imbalance: dehydration, metabolic alkalosis, and hypokalemia.
- Aspiration causing asphyxia, atelectasis, pneumonitis.

Nursing Process Elements

Assessment:

- Characteristics of emesis: color, consistency, odor, amount and frequency (coffee ground, bile colored, undigested food, or hematemesis).

- Precipitating factors/causes as: GI disorders, intestinal obstruction, food poisoning, medication side effects, pregnancy, motion sickness, neurological disorders as migraines.

Interventions:

- Keep environment quiet and free of stimuli likely to induce vomiting.
- Encourage deep breathing when feeling nauseated.
- Position client on the side or in a sitting position to decrease risk of aspiration.
- Remove false teeth.
- Give mouth care after every episode of emesis.
- Maintain record of I&O; measure and include all emesis.
- When oral intake is resumed, give small amounts of clear fluids such as ginger ale as tolerated and gradually progress to small, frequent meals of bland, nonirritating foods.
- Drink fluids an hour before or after meals to avoid over distending the stomach and causing vomiting.
- Offer mouth care and comfort measures.
- Maintain fluid and electrolyte balance.
- Administer medications as antiemetics, anticholinergics, antihistamines, and serotonin blockers.

ALTERED LEVEL OF CONSCIOUSNESS

- Content of consciousness: ability to think, communicate and feel; functions of cerebral cortex
- Arousal: state of wakefulness; function of the reticular activating system and brain stem
- Full consciousness: awake, alert, oriented to time, place, and person; appropriate in communication
- Unconsciousness: unable to interact with environment; unable to open eyes, obey commands; speak

Terms used to describe levels of consciousness between these extremes include confusion, delirium, stupor, and semicomatose.

Nursing Process Elements

Assessment:

- Assess status using Glasgow Coma Scale that scores the client on eye opening, motor and verbal response. Each of the three parameters is scored for a maximum possible score of 15 and a minimum possible score of 3. The fully conscious client scores the maximum 15; the totally unconscious client scores the minimum 3.

| Parameter | Response | Score |
|----------------------|--------------------------------------|-------|
| Opens eyes | Spontaneously | 4 |
| | On verbal command | 3 |
| | In response to pain | 2 |
| | Do not open | 1 |
| Best motor response | Obeys verbal command | 6 |
| | Localizes pain | 5 |
| | Normal flexion withdrawal | 4 |
| | Abnormal flexion | 3 |
| | Extension | 2 |
| | Does not respond | 1 |
| Best verbal response | Oriented and carries on conversation | 5 |
| | Confused and converses | 4 |
| | Uses inappropriate words | 3 |
| | Makes incomprehensible sounds | 2 |
| | Does not respond | 1 |

- Check PERRLA and the corneal reflex.
- Assess patency of airway and rate, rhythm, and depth of respirations.
- Auscultate for adventitious breath sounds.
- Check circulatory status by taking pulse and BP and checking color, temperature, and capillary refill in extremities.
- Monitor rectal temperature for elevation which may be the first sign of a drug reaction or a urinary tract, respiratory tract, wound, or other infection.
- Monitor skin for signs of breakdown.

Interventions:

- Maintain a patent airway.
 - Turn client at least every 2 hours to prevent pooling of secretions in the lungs.
 - Do not position supine because of the risk of tongue falling back and obstructing the airway.
 - Have suction equipment quickly available and use to remove pooled secretions from the oro or nasopharynx.
 - If suctioning a tracheostomy, preoxygenate and suction no longer than 15 seconds to avoid hypercapnia and increase in ICP.
- Maintain skin integrity.
 - Turn a minimum of every 2 hours to relieve pressure on skin; utilize other pressure-relieving devices as needed.
- Keep skin clean, dry, and free from friction and irritating substances such as urine and feces.
- Position to minimize pressure on bony prominences and to maintain good alignment.
- Maintain NPO status because of absence of swallowing and gag reflexes.
- If the blink reflex is absent, apply an eye patch being careful not to let it touch the cornea, or tape the eyes

shut. Apply saline drops or artificial tears four times per day.

- Record I&O; notify physician if urinary output drops below 30 ml/hr.
- Monitor for signs of UTI if an indwelling catheter is in place: odor, cloudy appearance, and hematuria.
- Record occurrence of bowel movements and their characteristics.
- Palpate abdomen to detect distention.
- Auscultate bowel sounds to confirm peristalsis.
- Perform passive range of motion to maintain joint mobility.
- Use a foot board or high-top sneakers to prevent foot drop.
- Support limbs at heart level to prevent dependent edema.

SPINAL CORD COMPRESSION

Signs: Sudden loss of sensation, motor function of lower extremities with or without loss of bladder or bowel control

- Warning signs of impending compression: escalating back pain with or without bladder changes and before lower extremity weakness, worse when lying down, improved with standing.

Rx: Steroids and if ambulatory palliative radiation.

Nursing Process Elements

Assessment Alert

Early recognition and treatment is critical because the amount of impairment at time of treatment is generally permanent.

GASTROINTESTINAL BLEEDING

Occult Blood

Presence of unseen blood in the stool.

Etiology: Bleeding associated with GI disease such as colon cancer or peptic ulcer disease or from medications as aspirin, iron–potassium preparations, thiazide diuretics.

Dx: Occult blood test (Guaiac test)

Rx:

- Treatment of condition causing blood in stool
- Elimination of medications causing occult blood

Melena

Black, tarry stool with a distinctive foul odor as a result of the presence of digested blood

Etiology: Bleeding from esophagus, stomach, or small intestine.

Rx: Control of bleeding and treatment of underlying cause.

Think Smart/Test Smart

Do not assume that black, sticky stool indicates the presence of digested blood. Other factors such as oral iron and ingestion of black licorice can produce similar effects.

HEMATEMESIS

Vomiting of blood: may be frank blood or, if bleeding is slow or has stopped and gastric juices have acted on the blood, have the appearance of coffee grounds.

Etiology: Gastric or duodenal ulcers, esophageal varices, and esophagitis.

Rx: Management of underlying problem; transfusions; IV fluids; proton pump inhibitors or H-2 receptor antagonist.

Nursing Process Elements

Assessment:

- Consistency and character of emesis: fluid, mixed with food, light red, coffee ground if bleeding slowed or stopped
- Amount
- Frequency
- Clotting
- S&S of underlying problem

Intervention:

- Position client to prevent aspiration
- Monitor I&O

FLATUS

Flatus is the gas passed through the rectum.

Nursing Process Elements

Assessments:

- Auscultate for presence and frequency of bowel sounds
- Abdominal distention

- Type of diet, foods eaten as beans, cabbage, lentils, carbonated beverages; assess if client eats large amounts of fruits, sugars, and proteins (increase flatus)
- Pain

Interventions:

- Enemas to relieve gas.
- Encourage ambulation to increase peristalsis
- Turning in bed, when on bedrest

**Client teaching for self-care**

- Avoid gas-forming foods
- Use of antiflatulent medications and simethicone

JAUNDICE

Jaundice is characterized by the yellow discoloration of the skin, sclerae, and mucous membranes as a result of excessive amounts of bilirubin in the blood.

Etiology:

- Hemolytic jaundice: result of destruction of red blood cells with release of bilirubin which is occurring more rapidly than the liver can remove the bilirubin from the blood; occurs in pernicious anemia, sickle cell anemia, and transfusion reactions.
- Hepatocellular jaundice: result of liver cells being unable to metabolize bilirubin due to infection such as hepatitis, drug or chemical injury as with cirrhosis, or necrosis as in liver cancer.
- Obstructive jaundice: results from obstruction of bile flow in the ductules of the liver or in the common bile duct; can be due to inflammation or tumor.

**Clinical Alert**

Physiological jaundice is jaundice that occurs in the newborn as a result of the normal breakdown of red blood cells, which occurs with entry into extrauterine life exceeding the ability of the immature liver to metabolize the hemoglobin. This is a transient phenomenon but a potentially dangerous one because bilirubin can cross the blood–brain barrier of the newborn and result in kernicterus.

Associated S&S: Light-colored stool because bile is not emptied into intestine in normal amounts.

- Deep orange, tea-like urine that foams when shaken because bile is excreted through the kidney.

- Pruritus because irritating bile salts are deposited in the skin.

Rx: Treatment of underlying cause.

**Nursing Process Elements****Assessment Alert**

In light-skinned individuals, jaundice is generally first apparent in the sclerae; in dark-skinned individuals, jaundice is best identified in the hard palate because the sclerae often have a normal yellow tinge.

- Initiate measures to relieve pruritus (see section on pruritus).
- Maintain skin integrity.

AMENORRHEA

Amenorrhea is characterized by the absence of menstruation.

- Physiologic amenorrhea: normal absence of menses before puberty, during pregnancy, and after menopause.
- Primary amenorrhea: menses never began.
- Secondary amenorrhea: occurs after menses has been established.

Etiology:

- Hypothalamic, pituitary, ovarian, adrenal, pancreatic or thyroid disorders; congenital defects of uterus, vagina or hymen; cirrhosis, nephritis and other chronic illness; anorexia nervosa or bulimia.
- Temporary secondary amenorrhea: stress, strenuous exercise, low body weight, severe illness, use of phenothiazides and oral contraceptives.

ABNORMAL UTERINE BLEEDING

Patterns of abnormal bleeding are

- infrequent or scant bleeding;
- frequent but regular bleeding;
- excessive bleeding at regular intervals (menorrhagia);
- normal amount of bleeding occurring irregularly (metrorrhagia);
- excessive bleeding occurring at irregular but frequent intervals (menometrorrhagia).

Etiology: Endocrine or organic

- Menorrhagia: at puberty, usually the result of low estrogen levels; later associated with ovarian tumors, uterine fibroids, polyps, endometritis, and PID.
- **OB** Metrorrhagia: occurs with ectopic pregnancy, threatened abortion, and hydatidiform mole disease.
- Bleeding outside menstrual cycle in a perimenopausal woman or bleeding after menopause is often the first indication of endometrial or cervical cancer.
- Medications causing abnormal bleeding include androgens, estrogens or corticosteroids; thiazide diuretics; digoxin; anticholinergics, and phenothiazines.

LEUKORRHEA

Leukorrhea is a vaginal discharge other than blood.

Etiology:

- Over secretion of Bartholin's glands or the cervical glands whose normal function is to moisturize and lubricate the mucous membrane of the vagina and external genitalia.
- Vaginal or cervical infection in which case the discharge is purulent or mucopurulent and may be foul smelling.
- Infected or necrotic uterine polyps or tumors.

WORKSHEET

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Normal pulse pressure in adult is about _____ mm Hg.
2. Pulse pressure > _____ mm Hg or < _____ is abnormal.
3. Adult systolic pressure as measured in the popliteal artery is _____ to _____ mm Hg higher than in the brachial artery because of the larger cuff bladder.
4. Fluid intake for clients with a fever should be between _____ and _____ ml/d unless contraindicated by a coexisting condition.
5. The diurnal variation in temperature can be as high as _____ °F
6. The normal pulse rate for a toddler is between _____ and _____ bpm.
7. After activity, allow client to rest for _____ minutes before taking pulse to allow it to return to its resting rate.
8. The apical pulse in an adult is found at the level of the _____ intercostal space.
9. The normal respiratory rate of a newborn is between _____ and _____ rpm.
10. The stimulus to breathe in the healthy client is the pressure of _____ in the arterial blood.
11. Normal tidal volume (amount of air taken in and let out during a normal respiration) in an adult is _____ ml or _____ l/min.
12. The short side of the cuff bladder should be _____ the diameter of the extremity where it will be placed; the long side should be _____ of the diameter of the extremity where it will be placed.
13. When measuring BP, the cuff should be deflated at a rate of 2–3 mm Hg/sec.
14. A _____ occurs when some ventricular contractions are so weak that the resultant pulse wave does not reach the periphery or when pathology in or around the artery is preventing the passage of blood.

(continued)

15. When assessing for orthostatic hypotension, take pulse and BP after client has been in a supine position for _____ to _____ minutes.
16. A rating of pain of _____ or more on a 0–10 pain scale requires intervention.
17. For clients taking opioids, sedation level must be monitored especially during the first _____ to _____ hours of opioid therapy.
18. The drug used to counteract opioid-induced respiratory depression is _____.
19. Nausea associated with the start of opioid therapy should disappear in _____ to _____ days.
20. Fluid restriction to _____ to _____ ml/d is typically part of the protocol for managing ascites.

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|-------|-------|
| 1. A UTI in an elderly person may be the cause of confusion. | _____ | _____ |
| | T | F |
| 2. Phenothiazines, opioids, and antibiotics can cause generalized pruritus. | _____ | _____ |
| | T | F |
| 3. If a BP cuff is inflated, deflated, and immediately reinflated, the resulting BP reading is likely to be incorrect with the systolic reading falsely low and diastolic falsely high. | _____ | _____ |
| | T | F |
| 4. Hypovolemia causes an increase in pulse rate as a compensatory mechanism to maintain BP in the face of low volume. | _____ | _____ |
| | T | F |
| 5. Under age three, the carotid artery is used routinely to obtain the pulse rate. | _____ | _____ |
| | T | F |
| 6. Phantom pain refers to perceived pain in an amputated or paralyzed part of the body. | _____ | _____ |
| | T | F |
| 7. Measuring BP when the client has just eaten, is in pain, or is smoking can result in falsely high readings. | _____ | _____ |
| | T | F |
| 8. NSAIDs in combination with opioids, reduce the dose of opioids needed and provide better pain relief than either type of drug alone. | _____ | _____ |
| | T | F |
| 9. Females tend to have lower BP than men at least until menopause when it tends to rise. | _____ | _____ |
| | T | F |
| 10. The client's report of presence, quality, and intensity of pain should be used as the primary guide to the need for pain relief. | _____ | _____ |
| | T | F |
| 11. If a TENS unit is functioning correctly, the client feels nothing during use. | _____ | _____ |
| | T | F |
| 12. Vomiting of black, coffee ground like material occurs when bleeding has occurred into the stomach and the blood has begun to be digested before being vomited. | _____ | _____ |
| | T | F |
| 13. Streaks of red blood on the stool indicates bleeding somewhere between the ileum and the rectum. | _____ | _____ |
| | T | F |

| | | |
|---|------------------|------------------|
| 14. For the terminally ill client, administration of oxygen is guided by pulse oximetry readings. | <u> </u> T | <u> </u> F |
| 15. Joint deformity is a symptom of rheumatoid arthritis. | <u> </u> T | <u> </u> F |
| 16. Leukorrhea is a pathological event indicative of inflammation or infection of the vagina. | <u> </u> T | <u> </u> F |
| 17. Gastrokinetic agents are given to anorexic clients to control nausea and early satiety. | <u> </u> T | <u> </u> F |
| 18. Agitation may manifest as verbally or physically abusive behaviors. | <u> </u> T | <u> </u> F |
| 19. Setting priorities for activities is an important aspect of managing fatigue. | <u> </u> T | <u> </u> F |
| 20. Menstrual bleeding that occurs with abnormal frequency; is excessive in amount; or lasts an abnormal amount of time is referred to as dysfunctional bleeding. | <u> </u> T | <u> </u> F |
| 21. Hepatotoxicity is a major risk associated with overdose of acetaminophen. | <u> </u> T | <u> </u> F |
| 22. The management of ascites includes daily administration of diuretics. | <u> </u> T | <u> </u> F |
| 23. Stridor is a snoring sound heard as air passes through a partially obstructed upper airway. | <u> </u> T | <u> </u> F |
| 24. Vomiting from increased ICP differs from most other types of vomiting in that it is sudden, forceful, and spews away from the body. | <u> </u> T | <u> </u> F |

APPLICATION QUESTIONS

- The nurse should plan to obtain an apical pulse on which client?
 - The client with a tachy dysrhythmia.
 - The client who is less than 12 hours postoperative.
 - The client with orthostatic hypotension.
 - The client who is unconscious.
- When assessing the progression of ascites, which parameter would the nurse assess?
 - Serum albumin
 - Intake and output
 - Lung sounds
 - Abdominal girth
- Which assessment finding would indicate to the nurse that an antitussive medication administered to a client with bronchogenic cancer is having the desired effect?
 - Dyspnea is relieved.
 - Coughing is decreased.
 - Expectoration is increased.
 - Wheezes and gurgles have diminished.

(continued)

4. When caring for a client with pruritus related to jaundice, which intervention is appropriate for the nurse to recommend?
 - a. Apply skin moisturizer
 - b. Dab alcohol onto the itchy areas
 - c. Take frequent, warm baths
 - d. Drink tea
5. A client complains of constipation. In assessing this complaint, which is the most important question for the nurse to ask?
 - a. What is the consistency of the stool?
 - b. How often do you normally move your bowels?
 - c. When did you move your bowels last?
 - d. Do you strain when you move your bowels?
6. What direction should the nurse give to a male client with bladder spasms related to pressure from a tumor?
 - a. Always sit to void.
 - b. Empty the bladder at least every 4 hours.
 - c. Limit fluid intake to 1500 ml/d.
 - d. Use the Crede technique to ensure that the bladder is empty.
7. When assessing a client admitted with a traumatic head injury, how should the nurse interpret a gradually increasing systolic BP accompanied by a gradually decreasing diastolic pressure?
 - a. Precursor of seizure activity
 - b. Expected response as cranial blood flow stabilizes
 - c. Indicative of developing hypovolemic shock
 - d. Suggestive of increasing ICP
8. When evaluating the effect of a progesterone analog given to a client with metastatic cancer, which data would the nurse collect? Mark all that apply.
 - a. Weight
 - b. Presence or absence of mouth sores
 - c. Food intake
 - d. Occurrence of N&V
 - e. Ability to swallow
 - f. Presence of abnormal taste
9. Which type of medication would the nurse expect to administer for control of pruritus associated with neoplastic infiltration of subcutaneous tissues?
 - a. Ondansetron
 - b. Antifungal cream
 - c. Systemic corticosteroid
 - d. Bile acid sequester
10. Which assessment finding should the nurse interpret as indicative of impending spinal cord compression in a client with metastatic prostate cancer?
 - a. Increasing back pain, which is worse when standing than when lying down
 - b. Lower extremity weakness and/or paresthesias
 - c. Urgency accompanied by bladder spasms
 - d. Lower extremity muscle cramping
11. The nurse is giving instructions regarding taking morning temperatures to an unlicensed assistant. Which clients would not be on the list of those to have an oral temperature taken? Mark all that apply.
 - a. An alert 80-year old with a cardiac dysrhythmia
 - b. A 64-year old with delirium tremens
 - c. A 21-year old with nasal packing
 - d. A 55-year old with a tracheostomy
 - e. A 10-year old with a seizure disorder
12. When taking a tympanic temperature on a 2-year old, how does the nurse position the ear for insertion of the probe?
 - a. Pull the ear lobe straight down
 - b. Pull pinna straight back and upward
 - c. Pull pinna straight back and slightly down
 - d. Pull the pinna forward
13. Which instructions would the nurse give to a mother regarding the care of her 9-year-old child with a fever?
 - a. Encourage fluids to between 2500 and 3000 ml/d
 - b. Keep child warmly covered
 - c. Limit food intake to small amounts of light — CHO foods like toast
 - d. Call physician if child exhibits sensitivity to light
14. Which action would be contraindicated as part of the immediate care for a client with hypothermia?
 - a. Remove wet clothing
 - b. Cover the head snugly and warmly
 - c. Place in a tepid bath
 - d. Give warm fluids
15. To ease dyspnea in a terminally ill client, which intervention is most appropriate?
 - a. Administer oxygen by mask rather than cannula
 - b. Coach in slow, deep rhythmic breathing
 - c. Have a fan blowing across the client
 - d. Maintain a warm, humidified environment

16. When giving medication instructions to a client who is to take Tylenol for pain following an out-client surgical procedure, the nurse stresses the importance of not taking more than ___ mg in a 24-hour period because of the danger of liver damage.
Answer is _____ mg.
17. Following a knee replacement, a client receives OxyContin for pain control in accord with an established protocol. The side effects of N&V develop and on the fourth postoperative day, still persist. Which is an appropriate nursing intervention?
- Withhold the medication and see if the N&V are relieved.
 - Move the client to a private room because an intestinal virus is likely the cause of the symptoms.
 - Request a change in medication order to another opioid.
 - Notify the physician that the client apparently is allergic to the OxyContin.
18. Which statement made by the caretaker of a client with severe fatigue indicates the need for further teaching regarding client care?
- "I will get a bedside commode so she doesn't have to walk to the bathroom since she has to go so frequently."
 - "I will have her rest quietly before meals so she can have more energy to eat."
 - "I will investigate getting an electric bed so she can change position easily."
 - "I will try to anticipate her needs so she has to move as little as possible."
19. Which nursing intervention is appropriate for a client with increased ICP?
- Position supine with head elevated no more than 30 degrees
 - Keep room darkened
 - Avoid rectal treatments
 - Keep radio or TV on to provide meaningful sound
20. Which is the priority goal of nursing care for a client with ankles that swell by the end of the day and return to normal overnight?
- Increase venous return
 - Promote urinary output
 - Protect against infection
 - Maintain skin integrity
21. When delegating BP measurement to an unlicensed assistant, the nurse cautions that correct technique must be used to avoid obtaining falsely low pressures. Which errors in technique should be identified as the potential causes of falsely low pressures? Mark all that apply.
- ___ Taking the BP on an extremity positioned below heart level
 - ___ Using a cuff that is too wide
 - ___ Deflating the cuff too rapidly
 - ___ Applying the cuff unevenly to the arm
22. A decrease in pulse rate of _____ bpm or more between the pulse taken after the client has been supine for 3 minutes and the pulse taken after the client arises and stands for a minute is indicative of orthostatic hypotension.
Answer is _____ .
23. Why is monitoring respiratory status a nursing priority when a client with COPD is receiving oxygen?
- Hyperventilation leading to respiratory alkalosis and loss of consciousness is a risk.
 - Sudden increase in arterial oxygen can precipitate diaphragmatic spasm.
 - Decreased arterial oxygen is the stimulus for breathing in a client with COPD.
 - Oxygen administration can trigger reflex bronchospasm.
24. To prevent an increase in ICP, tracheostomy suctioning should be limited to no more than ___ seconds following each preoxygenation.
25. When assessing a client with a head injury, which finding should the nurse interpret as an early sign of increasing ICP?
- Widening pulse pressure
 - Fixed dilated pupils
 - Confusion
 - Cheyne–Stokes respirations

ANSWERS & RATIONALES

ANSWERS FOR FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Normal pulse pressure in adult is about 40 mm Hg.
2. Pulse pressure $>$ 50 mm Hg or $<$ 30 is abnormal.
3. Adult systolic pressure as measured in the popliteal artery is 20 to 30 mm Hg higher than in the brachial artery because of the larger cuff bladder.
4. Fluid intake for clients with a fever should be between 2500 and 3000 ml/d unless contraindicated by a coexisting condition.
5. The diurnal variation in temperature can be as high as 1.8 °F.
6. The normal pulse rate for a toddler is between 90 and 140 bpm.
7. After activity, allow client to rest for 10–15 minutes before taking pulse to allow it to return to its resting rate.
8. The apical pulse in an adult is found at the level of the fifth intercostal space.
9. The normal respiratory rate of a newborn is between 30 and 60 rpm.
10. The stimulus to breathe in the healthy client is the pressure of CO₂ in the arterial blood.
11. Normal tidal volume (amount of air taken in and let out during a normal respiration) in an adult is 500 ml or 6–8 l/min.
12. The short side of the cuff bladder should be 40% the diameter of the extremity where it will be placed; the long side should be 60% of the diameter of the extremity where it will be placed.
13. When measuring BP, the cuff should be deflated at a rate of 2–3 mm Hg/sec.
14. A pulse deficit occurs when some ventricular contractions are so weak that the resultant pulse wave does not reach the periphery or when pathology in or around the artery is preventing the passage of blood.
15. When assessing for orthostatic hypotension take pulse and BP after client has been in a supine position for 2 to 3 minutes.
16. A rating of pain of 3 or more on a 0–10 pain scale requires intervention.
17. For clients taking opioids, sedation level must be monitored especially during the first 12 to 24 hr of opioid therapy.
18. The drug used to counteract opioid induced respiratory depression is naloxen (Narcan).
19. Nausea associated with the start of opioid therapy should disappear in 1 to 2 days.
20. Fluid restriction to 500 to 1000 ml/d is typically part of the protocol for managing ascites.

TRUE OR FALSE ANSWERS

Mark each of the following statements True or False. Correct all false statements in the space provided.

1. A UTI in an elderly person may be the cause of confusion. *True*
2. Phenothiazines, opioids, and antibiotics can cause generalized pruritus. *True*
3. If a BP cuff is inflated, deflated, and immediately reinflated, the resulting BP reading is likely to be incorrect with the systolic reading falsely low and diastolic falsely high. *False*
If a BP cuff is inflated, deflated, and immediately reinflated, the resulting BP reading is likely to be incorrect with the systolic reading falsely high and diastolic falsely low.
4. Hypovolemia causes an increase in pulse rate as a compensatory mechanism to maintain BP in the face of low volume. *True*
5. Under age three, the carotid artery is used routinely to obtain the pulse rate. *False*
6. Phantom pain refers to perceived pain in an amputated or paralyzed part of the body. *True*
7. Measuring BP when the client has just eaten, is in pain, or is smoking can result in falsely high readings. *True*
8. NSAIDs in combination with opioids, reduce the dose of opioids needed and provide better pain relief than either type of drug alone. *True*
9. Females tend to have lower BP than men at least until menopause when it tends to rise. *True*
10. The client's report of presence, quality, and intensity of pain should be used as the primary guide to the need for pain relief. *True*
11. If a TENS unit is functioning correctly, the client feels nothing during use. *False*
If a TENS unit is functioning correctly, the client should feel numbness or tingling during use.
12. Vomiting of black, coffee ground like material occurs when bleeding has occurred into the stomach and the blood has begun to be digested before being vomited. *True*
13. Streaks of red blood on the stool is indicates bleeding somewhere between the ileum and the rectum. *False*
Stool with streaks of red blood on it occurs with colon or rectal bleeding; bleeding in the ileum causes red blood mixed in with the stool.
14. For the terminally ill client, administration of oxygen is guided by pulse oximetry readings. *False*
For the terminally ill client, use of oxygen is guided by the relief of dyspnea, not by pulse oximetry readings.
15. Joint deformity is a symptom of rheumatoid arthritis. *True*
16. Leukorrhea is a pathological event indicative of inflammation or infection of the vagina. *False*
Leukorrhea may be the result of a normal increase in vaginal secretions in response to the increased estrogen levels of pregnancy.
17. Gastrokinetic agents are given to anorexic clients to control nausea and early satiety. *True*
18. Agitation may manifest as verbally or physically abusive behaviors. *True*

(continued)

19. Setting priorities for activities is an important aspect of managing fatigue. *True*
20. Menstrual bleeding that occurs with abnormal frequency; is excessive in amount; or lasts an abnormal amount of time is referred to as dysfunctional bleeding. *True*
21. Hepatotoxicity is a major risk associated with overdose of acetaminophen. *True*
22. The management of ascites includes daily administration of diuretics. *False*
Diuretics are generally ineffective in the treatment of ascites.
23. Stridor is a snoring sound heard as air passes through a partially obstructed upper airway. *False*
Stertor is a snoring sound heard as air passes through a partially obstructed upper airway.
24. Vomiting from increased ICP differs from most other types of vomiting in that it is sudden, forceful, and spews away from the body. *True*
25. Chronic hypoxia causes fatigue, apathy, drowsiness, and muscle twitches. *True*
26. Metabolic alkalosis is a complication of diarrhea. *False*
Metabolic acidosis is a complication of diarrhea.
27. Breath sounds should be auscultated before and after use of an incentive spirometer. *True*
28. Floaters indicate free blood in the aqueous humor and require immediate evaluation. *False*
Floaters can occur with a retinal detachment but the vast majority of the time they are clinically insignificant and do not require treatment.
29. Melena is indicative of colon bleeding. *False*
Melena is indicative of bleeding higher up in the GI tract; bleeding in the colon presents as red blood as it is unaffected by the digestive enzymes.
30. Diuretics are effective in relieving edema associated with superior vena cava syndrome. *False*
Diuretics are not effective in relieving edema associated with superior vena cava syndrome because the cause of the edema is obstruction of the lymphatic drainage by tumor and diuretics work on the kidney to increase fluid output.

APPLICATION ANSWERS

1. The nurse should plan to obtain an apical pulse on which client?
- The client with a tachy dysrhythmia.
 - The client who is less than 12 hours postoperative.
 - The client with orthostatic hypotension.
 - The client who is unconscious.

Rationale

Correct answer: a.

An apical pulse should be obtained on any client with an irregular heartbeat because the strength of myocardial contractions may vary and not all may be of sufficient strength to generate a pulse wave that can be felt in a

peripheral artery. Being newly postoperative, unconscious or having orthostatic hypertension does not necessitate taking an apical pulse.

2. When assessing the progression of ascites, which parameter would the nurse assess?
- Serum albumin
 - Intake and output
 - Lung sounds
 - Abdominal girth

Rationale

Correct answer: d.

Ascites is the accumulation of excess fluid in the peritoneal cavity. This fluid distends the abdomen and so abdominal girth increases as more fluid collects. Decreased plasma albumin that occurs with nephritic syndrome and malnutrition is a cause of ascites. Restricted fluid and sodium intake may be prescribed in the management of ascites but I&O measurement is not a measure of progression of ascites. Lung sounds are unrelated to ascites although ascites may cause dyspnea.

3. Which assessment finding would indicate to the nurse that an antitussive medication administered to a client with bronchogenic cancer is having the desired effect?
- Dyspnea is relieved.
 - Coughing is decreased.
 - Expectoration is increased.
 - Wheezes and gurgles have diminished.

Rationale

Correct answer: b.

An antitussive stops coughing. Antitussives are used for nonproductive coughs and to prevent exhaustion from coughing. Antitussives are not typically used for productive coughs because the secretions need to be raised. Secretions that are not raised will be pulled by gravity deep into the lung where the warm, dark, moist environment is supportive of bacterial growth. Antitussives do not relieve dyspnea. Antitussives do not increase expectoration rather they decrease it because they suppress coughing. Wheezes and gurgles are caused by narrowed airways and presence of secretions. Since antitussives do not act on either of these problems, their decrease is not reflective of the desired effect of an antitussive.

4. When caring for a client with pruritus related to jaundice, which intervention is appropriate for the nurse to recommend?
- Apply skin moisturizer
 - Dab alcohol onto the itchy areas
 - Take frequent, warm baths
 - Drink tea

Rationale

Correct answer: a.

Application of moisturizers to prevent drying helps limit pruritus. Alcohol is drying so it aggravates the itch. Cool baths can soothe itch; warm baths increase it. Drinking tea is contraindicated because it contains caffeine and theophylline, which increase itch.

5. A client complains of constipation. In assessing this complaint, which is the most important question for the nurse to ask?
- What is the consistency of the stool?
 - How often do you normally move your bowels?

- When did you move your bowels last?
- Do you strain when you move your bowels?

Rationale

Correct answer: a.

Abnormally hard stool is always an indication of constipation so determining the consistency of the stool is the most important question to determine the validity of the client's complaint. Frequency of defecation varies significantly among different people so what constitutes an abnormally infrequent defecation for a person can only be determined by asking about what is normal and when he or she defecated last. Thus, these are pertinent assessment questions but they do not define constipation as well as the question about consistency. Straining generally accompanies constipation but does not define it.

6. What direction should the nurse give to a male client with bladder spasms related to pressure from a tumor?
- Always sit to void
 - Empty the bladder at least every 4 hours
 - Limit fluid intake to 1500 ml/d
 - Use the Crede technique to ensure that the bladder is empty

Rationale

Correct answer: b.

Clients with bladder spasms should empty the bladder at least every 4 hours and can either sit or stand to void. Fluid intake should not be limited and the Crede techniques should not be used.

7. When assessing a client admitted with a traumatic head injury, how should the nurse interpret a gradually increasing systolic BP accompanied by a gradually decreasing diastolic pressure?
- Precursor of seizure activity
 - Expected response as cranial blood flow stabilizes
 - Indicative of developing hypovolemic shock
 - Suggestive of increasing ICP

Rationale

Correct answer: d.

Widening pulse pressure (systolic minus diastolic pressure) is a sign of increased ICP. Other signs of increased ICP are new headache, vomiting, change in respirations, altered mental status, decreased motor function, increased restlessness, agitation, and blurred vision. Tramadol is contraindicated in the presence of ICP because it can lower the seizure threshold but widening of the pulse pressure is not indicative of the onset of seizure activity.

8. When evaluating the effect of a progesterone analog given to a client with metastatic cancer, which data would the nurse collect? Mark all that apply.
- ___ Weight
 - ___ Presence or absence of mouth sores

(continued)

- c. ___ Food intake
- d. ___ Occurrence of N&V
- e. ___ Ability to swallow
- f. ___ Presence of abnormal taste

Rationale

Correct answers: a, c, d, and f.

Progesterone analogs are used to improve appetite; decrease N&V; reduce taste and odor changes; and promote weight gain. They are not used for problems related to mouth sores or ability to swallow; therefore, these factors are unrelated to their effectiveness.

9. Which type of medication would the nurse expect to administer for control of pruritus associated with neoplastic infiltration of subcutaneous tissues?
- a. Ondansetron
 - b. Antifungal cream
 - c. Systemic corticosteroid
 - d. Bile acid sequester

Rationale

Correct answer: c.

Systemic corticosteroids are used for pruritus associated with inflammatory or neoplastic conditions. Ondansetron is used for pruritus related to opioid use, uremia, or jaundice. Antifungal cream is used for Candida-associated itch. Bile acid sequestrants are used for itch related to end-stage liver disease.

10. Which assessment finding should the nurse interpret as indicative of impending spinal cord compression in a client with metastatic prostate cancer?
- a. Increasing back pain, which is worse when standing than when lying down
 - b. Lower extremity weakness and/or paresthesias
 - c. Urgency accompanied by bladder spasms
 - d. Lower extremity muscle cramping

Rationale

Correct answer: a.

Escalating back pain with or without bladder symptoms, worse on lying down and improved on standing is the warning sign of impending spinal cord compression. Sudden loss of sensation and motor function in the lower extremities occurs with compression. Loss of bowel or bladder control may or may not occur.

11. The nurse is giving instructions regarding taking morning temperatures to an unlicensed assistant. Which clients would not be on the list of those to have an oral temperature taken?

Mark all that apply.

- a. ___ An alert 80-year old with a cardiac dysrhythmia
- b. ___ A 64-year old with delirium tremens

- c. ___ A 21-year old with nasal packing
- d. ___ A 55-year old with a tracheostomy
- e. ___ A 10-year old with a seizure disorder

Rationale

Correct answers: b, c, and e.

Oral temperatures are contraindicated for clients who are unable to close their mouths tightly or follow directions to keep their mouth shut and not bite down; for clients unable to breathe through their noses; and for clients with surgery or mouth disease that could be painful, disrupted, or otherwise worsened by the insertion of the thermometer. Therefore, clients with delirium tremens, nasal packing, or seizures are among those for whom oral temperatures are contraindicated.

12. When taking a tympanic temperature on a 2-year old, how does the nurse position the ear for insertion of the probe?
- a. Pull the ear lobe straight down
 - b. Pull pinna straight back and upward
 - c. Pull pinna straight back and slightly down
 - d. Pull the pinna forward

Rationale

Correct answer: c.

The pinna is pulled straight back and slightly downward prior to inserting the tympanic probe when taking temperatures on children under the age of three. Over the age of three, the pinna is pulled straight back or upward. The ear lobe is never pulled straight down nor is the pinna pulled forward for a tympanic temperature.

13. Which instructions would the nurse give to a mother regarding the care of her 9-year-old child with a fever?
- a. Encourage fluids to between 2500 and 3000 ml/d
 - b. Keep child warmly covered
 - c. Limit food intake to small amounts of light -CHO foods like toast
 - d. Call physician if child exhibits sensitivity to light

Rationale

Correct answer: a.

Fluids in the amounts of 2500–3000 ml/d are needed to prevent dehydration. The child should be kept warmly covered to aid heat production during the period when temperature is rising but child should be uncovered to aid heat loss when temperature is falling. Foods should be given according to child's appetite and tolerance. Fever increases metabolic need for food stuffs and so efforts should be made to encourage intake not discourage it. Sensitivity to light is an expected symptom during the course of a fever and the client often appears glassy-eyed. This does not warrant notifying the physician.

14. Which action would be contraindicated as part of the immediate care for a client with hypothermia?
- ___ Remove wet clothing
 - ___ Cover the head snugly and warmly
 - ___ Place in a tepid bath
 - ___ Give warm fluids

Rationale

Correct answer: c.

The client would not be placed in a tepid bath rather dry clothing, a warm environment and blankets or warming pads are provided. Wet clothing is removed, the head is covered with a cap or turban and warm oral or IV fluids are given. In addition, the limbs are kept close to the body to conserve heat.

15. To ease dyspnea in a terminally ill client, which intervention is most appropriate?
- Administer oxygen by mask rather than cannula
 - Coach in slow, deep rhythmic breathing
 - Have a fan blowing across the client
 - Maintain a warm, humidified environment

Rationale

Correct answer: c.

Air blowing across the client is successful in relieving dyspnea in the terminally ill client. Oxygen should be administered via cannula rather than mask because the mask can create a feeling of suffocation. Coaching in slow, deep breathing is not identified as an effective intervention and the environment should be cool not warm.

16. When giving medication instructions to a client who is to take Tylenol for pain following an out-client surgical procedure, the nurse stresses the importance of not taking more than ___ mg in a 24-hour period because of the danger of liver damage.

Rationale

Correct answer: 4 grams/4000 mg.

17. Following a knee replacement, a client receives OxyContin for pain control in accord with an established protocol. The side effects of N&V develop and on the fourth postoperative day, still persist. Which is an appropriate nursing intervention?
- Withhold the medication and see if the N&V are relieved.
 - Move the client to a private room because an intestinal virus is likely the cause of the symptoms.
 - Request a change in medication order to another opioid.
 - Notify the physician that the client apparently is allergic to the OxyContin.

Rationale

Correct answer: c.

N&V is a common response to opioids in the client who has not taken them before and developed tolerance. However, tolerance should develop and N&V disappear by day three. If this does not occur, a different opioid should be ordered for pain. Pain medication would not be withheld in order to determine the effect on the N&V because severe pain follows a knee replacement and pain interferes with healing. Further, clients have a right to pain relief. Although an intestinal virus can cause N&V, it is not the most likely cause since opioids also cause N&V and the client is receiving them. Therefore, it is not appropriate to move the client to a private room because of the likelihood of an intestinal virus. Allergic reactions involve rash, itch, hives, difficulty breathing, and out-right anaphylactic shock. N&V are not signs of an allergic reaction.

18. Which statement made by the caretaker of a client with severe fatigue indicates the need for further teaching regarding client care?
- “I will get a bedside commode so she doesn’t have to walk to the bathroom since she has to go so frequently.”
 - “I will have her rest quietly before meals so she can have more energy to eat.”
 - “I will investigate getting an electric bed so she can change position easily.”
 - “I will try to anticipate her needs so she has to move as little as possible.”

Rationale

Correct answer: d.

Prolonged inactivity and bedrest places the client at risk for all the hazards of immobility. When a client has severe fatigue, it is beneficial to use equipment which requires the least exertion such as a bedside commode and an electric bed. It is also important to space activities such as eating and bathing with periods of rest. However, caution must be taken not to limit activity to the point where the negative effects of immobility occur.

19. Which nursing intervention is appropriate for a client with increased ICP?
- Position supine with head elevated no more than 30 degrees
 - Keep room darkened
 - Avoid rectal treatments
 - Keep radio or TV on to provide meaningful sound

Rationale

Correct answer: b.

Unnecessary stimuli should be avoided so the room should be kept dark and quiet. The client should be maintained in semi-Fowler’s position. Rectal treatments are not contraindicated by ICP.

(continued)

20. Which is the priority goal of nursing care for a client with ankles that swell by the end of the day and return to normal overnight?
- Increase venous return
 - Promote urinary output
 - Protect against infection
 - Maintain skin integrity

Rationale

Correct answer: a.

The cause of peripheral edema that occurs during the day when sitting and standing and resolves overnight when lying down is impaired venous return. When sitting and standing, venous return must occur against the force of gravity; when lying down, the legs are on the same level as the heart so the force of gravity is not a significant factor. Because impaired venous return is the causative factor, the goal of nursing interventions is to improve it. Interventions to meet this goal include encouraging use of compression stockings, active or passive exercise of the lower extremities, elevating the legs at specified intervals throughout the day and whenever sitting down, and avoiding constricting clothing or bandages. Skin that is edematous is at risk for breakdown so maintenance of skin integrity is a nursing goal; however, it is not the primary goal because if the venous return problem is corrected the risk for skin breakdown of edematous tissue will also be resolved. Promoting urinary output does not impact edema from impaired venous return. Protection against infection is not a primary goal.

21. When delegating BP measurement to an unlicensed assistant, the nurse cautions that correct technique must be used to avoid obtaining falsely low pressures. Which errors in technique should be identified as the potential causes of falsely low pressures? Mark all that apply.
- ___ Taking the BP on an extremity positioned below heart level
 - ___ Using a cuff that is too wide
 - ___ Deflating the cuff too rapidly
 - ___ Applying the cuff unevenly to the arm

Rationale

Correct answers: a, b, and c.

Taking the BP on an extremity positioned below heart level; using a cuff that is too wide; and deflating the cuff too rapidly all can cause falsely low BP. Applying the cuff unevenly to the arm can cause a falsely high BP.

22. A decrease in pulse rate of ___ bpm or more between the pulse taken after the client has been supine for 3 minutes and the pulse taken after the client arises and stands for a minute is indicative of orthostatic hypotension.

Rationale

Correct answer: 40 bpm.

23. Why is monitoring respiratory status a nursing priority when a client with COPD is receiving oxygen?
- Hyperventilation leading to respiratory alkalosis and loss of consciousness is a risk.
 - Sudden increase in arterial oxygen can precipitate diaphragmatic spasm.
 - Decreased arterial oxygen is the stimulus for breathing in a client with COPD.
 - Oxygen administration can trigger reflex bronchospasm.

Rationale

Correct answer: c.

Decreased oxygen in the blood is the stimulus for breathing in a client with COPD. Therefore, if oxygen is administered there is the risk that respiratory arrest will occur because high oxygen saturation levels in the blood eliminate the stimulus for breathing. This is a particular risk with the administration of 100% oxygen. The normal stimulus to breathe is an increase in CO₂ in the blood but the client with COPD has become insensitive to CO₂ because of long-term elevated levels associated with the COPD. Oxygen administration does not cause hyperventilation; nor does it precipitate diaphragmatic spasm or bronchospasm.

24. To prevent an increase in ICP, tracheostomy suctioning should be limited to no more than ___ seconds following each preoxygenation.

Rationale

Correct answer: 15.

Fifteen seconds is the length of time that can elapse without oxygen before pulse rate and BP increase in response to a decrease in oxygen in the brain. Increased pulse and BP increases cerebral blood flow, which in turn occupies more space in the bony cranium and thereby causes an increase in ICP.

25. When assessing a client with a head injury, which finding should the nurse interpret as an early sign of increasing ICP?
- Widening pulse pressure
 - Fixed dilated pupils
 - Confusion
 - Cheyne–Stokes respirations

Rationale

Correct answer: c.

Change in level of consciousness, the early signs of which include restlessness, irritability, drowsiness, confusion, apathy, difficulty or hesitation in following simple directions or in verbalizing, is the most sensitive indicator of increasing ICP. Widening pulse pressure and Cheyne–Stokes respirations are considered late signs and fixed dilated pupils are late signs and indicate that pressure has increased to the degree that a portion of cerebral cortex has slipped under the tentorium through the uncus and is compressing the area of the brainstem where the oculomotor nerve exits.

Test Plan Category:

Physiological Integrity

Sub-category: Reduction of Risk Potential—Part 3

Topic: Potential for Complications from Surgical Procedures and Health Alterations

| | | | |
|-------------------------------------|-----|------------------------------|-----|
| ▸ Bariatric Surgery | 580 | ▸ Neurological Surgery | 570 |
| ▸ Cardiovascular Surgery | 558 | ▸ Perioperative Care | 551 |
| ▸ Dermatologic Surgery | 590 | ▸ Plastic Surgery | 598 |
| ▸ Endocrine Surgery | 582 | ▸ Reproductive Tract Surgery | 591 |
| ▸ Gastrointestinal (GI) Surgery | 575 | ▸ Respiratory Surgery | 565 |
| ▸ Hepatic and Biliary Tract Surgery | 581 | ▸ Surgery of the Eye and Ear | 571 |
| ▸ Musculoskeletal Surgery | 573 | ▸ Transplant Surgery | 595 |
| | | ▸ Urinary Surgery | 585 |

PERIOPERATIVE CARE

PREOPERATIVE CARE

Nursing responsibilities preoperatively:

- Physical assessment:
 - Cardiovascular system
 - Compare BP bilaterally.
 - Assess for hypoxia by checking for clubbing and capillary refill.

Assessment Alert

Notify physician if there is a difference of more than 15 mm Hg in either the systolic or diastolic pressure between the right and left extremity.

—Respiratory system

- Assess lung sounds.
- Assess respiratory rate and pattern.
- Assess symmetry of chest expansion and use of accessory muscles.
- Review medical history for disease processes that place client at increased risk for pulmonary aspiration.
 - Gastric esophageal reflux disease
 - Hiatal hernia
 - Gastric motility disorders
 - Pregnancy
 - Bowel obstruction
 - Diabetes
 - Obesity
- Identify risk factors related to higher incidence of postoperative pulmonary complications.
 - Smoking
 - Chronic obstructive pulmonary disease
 - Respiratory infection
 - Skeletal deformities

—GI system

- Inspect contour and symmetry of abdomen.
- Auscultate bowel sounds.
- Palpate abdomen for tenderness or distension.

—GU system

- Inspect and palpate the suprapubic area for distension.
- Obtain sample for urinalysis, if ordered.

—Neurological system

- Assess orientation to person, place, and time.
- Assess pupils for uniformity in size and shape and reaction to light.
- Assess speech pattern.

—Psychological system

- Assess client's understanding of the surgical procedure and postoperative care.
- Encourage client to talk about anxiety related to surgery.

Clinical Alert

Risk factors for surgical complications need to be identified preoperatively to allow the nurse to provide appropriate preoperative teaching and postoperative management. Risk factors include:

- Hypovolemia
- Dehydration, electrolyte imbalance
- Nutritional deficits (serum albumin <3.5 mg/dl)

- Extremes of age and weight
- Infection, sepsis
- Toxic conditions
- Immunological abnormalities
- Pulmonary disease (obstructive disease, restrictive disorder, respiratory infection)
- Renal or urinary tract disease (decreased renal function, urinary tract infection, obstruction)
- Pregnancy
- Cardiovascular disease (coronary artery disease, previous myocardial infarction, cardiac failure, dysrhythmias, hypertension, prosthetic heart valve, thromboembolism, hemorrhagic disorders, cerebrovascular disease)
- Endocrine dysfunction (diabetes mellitus, adrenal disorders, thyroid malfunction)
- Hepatic disease (cirrhosis, hepatitis)
- Preexisting mental or physical disability

- Review medication list for prescribed and over-the-counter drugs

—Instruct client on the possible interaction of prescribed medications with anesthetic agents

- Corticosteroids: may potentiate cardiovascular collapse if stopped suddenly.
- Diuretics: may cause excessive respiratory depression during surgery from an associated electrolyte imbalance.
- Phenothiazines: may increase hypotensive action of anesthetics.
- Tranquilizers: may cause anxiety, tension, and seizures with sudden withdrawal of medication.
- Insulin: may interact with anesthetics.
- Antibiotics: may cause interruption in nerve transmission when combined with curariform muscle relaxants resulting in apnea from respiratory paralysis.
- Anticoagulants: can increase possibility of bleeding intraoperatively and postoperatively.
 - Instruct client that use of aspirin will increase likelihood of bleeding intraoperatively and postoperatively.
- Antiseizure medication: will need to have IV dose during surgery to prevent seizure activity.
- Monoamine oxidase (MAO) inhibitors: may increase hypotensive action of anesthetics.

—Instruct client on the possible interaction of over-the-counter medications with anesthetic agents

- *Echinacea angustifolia*: There is a risk of hepatotoxicity; may decrease effectiveness of corticosteroids.
 - *Tanacetum parthenium* (Feverfew) may inhibit platelet aggregation and increase bleeding time.
 - *Allium sativum* (Garlic) inhibits platelet aggregation, potentiates warfarin, increases INR and PT, and decreases blood glucose levels.
 - *Zingiber officinale* (Ginger) has an anticoagulant action, large doses will cause bleeding and dysrhythmias.
 - *Panax ginseng* (Ginseng root) causes tachycardia and hypertension; inhibits platelet aggregation; decreases effectiveness of warfarin; decreases INR and PT; lowers blood glucose; potentiates effects of digoxin.
 - *Ginkgo Bilboa* inhibits platelet-activating factor; prolongs bleeding time; increases effects of anticoagulants.
 - *Piper methysticum* (Kava-kava) potentiates central nervous system depressants, anesthetics, and alcohol; increases hypertension and edema; neutralizes antibiotics; potentiates corticosteroids.
 - *Hypericum perforatum* (St. John's wort) prolongs sedative effects of anesthesia and opioids; possible interactions with warfarin, steroids, benzodiazepines, and calcium channel blockers, and protease inhibitors.
 - *Valeriana officinalis* (Valerian) causes hepatotoxicity with other herbs; prolongs sedative effects of anesthesia; potentiate actions of barbiturates and alcohol.
- Inform anesthesiologist of client's use of herbal medications that may interact with anesthetic agents
- Describe the equipment that will be used to provide anesthesia and monitor client during surgery.
 - Review postanesthesia care unit (PACU).
 - Describe to client the typical equipment used (oxygen via nasal canula, sequential compression device, pain control) and sensations that might be experienced as anesthesia is wearing off, such as feeling chilled.
 - Instruct on leg exercises.
 - Straight leg raises: leg is lifted off bed straight, repeat five times at least four times per day on each leg.
 - Do not have client perform this exercise if having abdominal surgery or has existing back problems.
 - Quad sets: tighten thigh muscles and hold for 5 seconds, repeat five times each hour.
 - Ankle pumps: point toes up and down (moving ankle) and then circle ankles, repeat 10 times each hour.
 - Gluteal tightening: tighten buttock muscles and hold for 5 seconds then relax, repeat five times each hour.

Clinical Note

Client may initially have sequential compression devices on both legs to stimulate the movement of blood through the lower extremities.

Client teaching for self-care

- Assess learning needs.
- Provide explanations for diagnostic tests that may be required prior to the surgical procedure.
- Discuss anesthesia that might be used for the particular procedure.
 - Contact anesthesia department for specific questions that client may have.
- Discuss nutritional requirements prior to surgical procedure.
 - Importance of nutrition prior to surgical procedure
 - Importance of not eating or drinking starting at 8 hours prior to the scheduled surgery
- Review operating procedure.
 - Explain to client and family that there will be a short period of time in which client will be in the holding area.
 - Describe the surgical garb that the nurses and doctors will be wearing in the operating room.
 - Describe the operating room setting, including cool temperature of the rooms.
 - Instruct on respiratory hygiene exercises.
 - Deep breathe and coughing (three deep breaths and forceful cough)
 - Splinting incisional area to decrease pain when coughing
 - Incentive spirometry
 - Blow bottle
- Perform preoperative preparation appropriate for surgical procedure.
 - Cleanse skin using an antiseptic solution the evening or morning before surgery.
 - Shaving of the surgical site will typically be done in the operating room.
 - Bowel prep will depend on the surgical procedure and can include antibiotics to decrease intestinal flora, enemas, and/or laxatives.
 - Preoperative medications are administered 45 minutes to 1 hour prior to induction of anesthesia
 - Decrease anxiety: diazepam (Valium), hydroxyzine hydrochloride (Vistaril, Atarax)
 - Permit a smoother induction of the anesthetic agent: pentobarbital sodium

- Decrease the amount of anesthetic required (meperidine hydrochloride, morphine sulfate, fentanyl citrate (Sublimaze, Duragesic))
- Provide amnesia for the events preceding the surgical procedure: midazolam hydrochloride (Versed)
- Decrease pharyngeal, respiratory, and gastric secretions: atropine sulfate, glycopyrrolate (Robinul), scopolamine hydrobromide (Hyoscine), ranitidine, metoclopramide
- Provide sedation and impairs memory of perioperative events: lorazepam (Ativan)
- Review preoperative checklist
 - Surgical consent is signed and understood by client
 - Identification of client using two sources of information
 - Verification of reports on chart
 - X-rays: chest
 - 12-lead electrocardiogram
 - Pulmonary function test, if ordered
 - Laboratory reports
 - CBC with differential
 - Basic metabolic panel: BUN, creatinine, glucose, potassium, sodium, chloride, and CO₂
 - Liver enzymes
 - Coagulation studies: prothrombin time (PT), partial prothroboplastic time (PTT), international normalized ratio (INR)
 - Beta-human chorionic gonadotropin
 - Urinalysis
 - Completion of nursing physical assessment
 - VS.

PEDS**Pediatric considerations:**

- Use of play, books, films, tours, rehearsals, and other age appropriate orientation activities familiarize the child with the perioperative procedures and help to decrease the stress of the surgical experience.
- Having the parent with the child during induction or leaving a favorite possession with the child and reuniting parent and child as soon as possible after surgery decreases stress.

**Clinical Alert**

Infants should not be without fluids for an extended time prior to surgery because of the risk of dehydration and glycogen depletion.

- Children should be encouraged to drink fluids prior to being NPO to ensure hydration and decrease later thirst.
- Preoperative medications should be given orally (e.g., oral transmucosal fentanyl or fentanyl Oralet) or by existing IV (e.g., Versed) to avoid unnecessary stress.

**Clinical Alert**

GERI

Physiological changes related to aging place older clients at greater perioperative complications.

- Cardiovascular: hypotension, dysrhythmia, congestive heart failure, thrombi, hypervolemia, and delayed stress response
- Gastrointestinal: aspiration, paralytic ileus, constipation, and altered drug metabolism
- Immunologic: reduced ability to protect against microorganisms
- Integumentary: pressure ulcer, impaired healing, delayed recovery from anesthetics due to storage in adipose tissue, and hypothermia
- Metabolic: decreased inflammatory response, altered fluid dynamics, increased cardiac workload, delayed shivering, and delayed recovery from anesthetics
- Musculoskeletal: deep vein thrombosis, positioning difficulty, pathological fracture, and falls
- Neurologic: delirium, falls, and increased anxiety
- Renal: prolonged response to anesthesia, overhydration, delirium, and urinary retention
- Respiratory: difficult intubation, aspiration, decreased gas exchange, ineffective cough, and difficulty maintaining airway

POSTOPERATIVE CARE

Nursing responsibilities postoperatively:

- PACU
 - Maintain airway.
 - Provide oxygen therapy until client is breathing on his/her own.
 - Shivering increases oxygenation needs.
 - Use oxygen cautiously with clients with a history of COPD.
 - Encourage client to deep breathe.
 - Elevate head of bed unless contraindicated.

**Clinical Alert**

Common causes of airway obstruction include: tongue blocking the airway, hypoxemia (PO₂ < 60 mmHg, atelectasis, pulmonary edema), bronchospasm, hypoventilation (decreased respiratory rate, hypoxemia, increased PaCO₂).

—Assess client every 10–15 minutes dependent on client condition and wakefulness for VS, oxygen saturation level, lung sounds, level of consciousness, neurological status, capillary refill, and color of skin and mucous membranes.

—Maintain cardiovascular stability.

- Monitor for S&S of hypotension and shock.
 - Pallor
 - Cool, moist skin
 - Rapid breathing
 - Cyanosis (lips, gums, tongue)
 - Rapid, weak, thready pulse
 - Decreasing pulse pressure
 - Decreasing BP
 - Concentrated urine
- Monitor for hemorrhage.
 - Pulse rate increased
 - Restless, apprehensive, thirsty
 - Skin is cold, moist, and pale
 - Low hemoglobin level
 - Decreased cardiac output
- Monitor for hypertension and dysrhythmia.

—Monitor intake (IV fluids) and output (all drains, including urinary output).

Assessment Alert

Encourage client without a Foley catheter to use bedpan or urinal to empty bladder, thereby preventing the possible development of a urinary tract infection secondary to urinary stasis.

—Assess all tubes and drains for insertion site, drainage, and security to body.

—Assess surgical dressing.

—Provide warm blanket(s) to decrease hypothermia.

—Administer medications per physician's order (i.e., narcotic, antiemetic, antihypertensive agent).

—Assess for potential reaction to the administration of anticholinesterase (neostigmine, pyridostigmine) to reverse nondepolarizing anesthetic agents.

—Administer naloxone (Narcan) to reverse opioids.

—Provide pain management.

—Provide antiemetics as needed to relieve N&V.

- Phenothiazines: promethazine, prochlorperazine
- Butyrophenones: haloperidol, droperidol
- Antihistamines: hydroxyzine, diphenhydramine

- Anticholinergics: transdermal scopolamine, atropine
- Benzamides: metoclopramide, domperidone
- Serotonin antagonists: ondansetron, dolasetron, granisetron
- Corticosteroids: dexamethasone, betamethasone

—Determine client's readiness for discharge from PACU.

- Stable VS
- Oriented to person, place, time
- Pulmonary function not impaired
- Pulse oximetry is 92% or greater
- Urine output greater than 30 ml/hr
- N&V is absent or under control
- Minimal pain

Assessment Alert

There is the potential for the client to experience respiratory depression.

- Nursing Unit

Assessment Alert

The client returning to the surgical unit will need to be assessed frequently. The frequency of assessing VS or other body systems can be as often as every 15 minutes until the client is stable. Most often once the client has been discharged from PACU VS and body systems are assessed every 4 hours, which is the minimum frequency of assessment to assure client safety.

—Respiratory system

- Assess lung sounds.
- Assess respiratory rate and pattern.
- Assess symmetry of chest expansion and use of accessory muscles.
- Encourage respiratory hygiene activities.
- Assess for hypoxia (oxygen saturation level, capillary refill).

—Cardiovascular

- Assess heart rate.
- Assess BP; notify physician if the systolic is greater than 15% of the client's baseline value.

Clinical Alert

An irregular heart rate can be an effect of anesthesia or a preexisting arrhythmia, such as atrial fibrillation.

—GU

- Monitor urinary output (normal output should be 0.5–1 ml/kg/hr)
- Assess for difficulty voiding if the client does not have a Foley catheter

Assessment Alert

Causes of postoperative urinary retention include: medication, such as atropine and opioids, administered to manage pain which can decrease parasympathetic stimulation; epidural anesthesia, recumbent position, abdominal surgery (pelvic, perineal, and bowel), prolonged immobility, and sympathetic nerve stimulation due to pain, anxiety, or fear.

—GI

- Assess bowel sounds (peristalsis should be present within 6 hours postoperatively with normal bowel sounds present within 24–48 hours).
- Assess for distension and rigidity.
- Assess for Cullen's sign (bluish tinge around the umbilicus that is an indicator of intra-abdominal or peritoneal bleeding).
- Encourage ambulation to promote peristalsis.
- Administer stool softener if prescribed.

—Neurological

- Assess orientation to person, place, and time.
- Assess pupils for uniformity in size and shape and reaction to light.
- Assess speech pattern.

—Surgical site

- Monitor postoperative dressing, including type of dressing and any drainage if present.
- Change per physician's order.
- Monitor and maintain patency of drains.
- Assess surgical incision and periwound skin.
- Remove sutures and/or staples per physician's order, typical 7–10 days postoperatively.

—Ostomy care

- Describe and monitor output of a bowel diversion (ileostomy, ascending colostomy, transverse colostomy, descending colostomy, or sigmoid colostomy) and/or urinary diversion (ileal conduit).
- Consult the ostomy nurse (WOCN).
- Monitor stoma for circulatory problems, such as gray color or darkening of mucosa.

—Assess for potential infection.

- Monitor temperature and other vital signs.

Clinical Alert

Typical changes in VS with infection include an elevated temperature, tachycardia, and either an elevation of BP or hypotension. The client may also experience a decrease in urinary output.

- Monitor urinary output.
- Monitor wound and drain sites.
- Monitor laboratory values (i.e., WBC).
- Assess for changes in mentation.

—Monitor and record I&O.

- Monitor IV fluids.
- Record output from all tubes and drains (i.e., nasogastric tube, HemoVac, or Jackson Pratt drain [JP drain]).
- Monitor nutritional intake.

—Encourage mobility and ambulation, if appropriate.

—Provide comfort.

- Offer ice chips if client has bowel sounds.
- Reposition.
- Offer distraction activities, such as television, radio.
- Offer a back rub, if appropriate based on surgical site.

—Pain management

- Encourage client to splint surgical site when coughing.
- Encourage use of PCA pump.
- Offer and provide nonanalgesic pain measures.
 - Imagery
 - Relaxation
 - Heat/cold, if prescribed by physician
 - Distraction, such as TV, radio
 - Back rub
 - Noncontact therapeutic touch

—Monitor nutrition.

Nursing Intervention Alert

Surgery increases the basal metabolic rate requiring more calories than is usually consumed by the client.

- Administer supplemental protein if client is protein deficient (serum albumin level < 3.5 g/dl) or immunocompromised.
- Consult nutritionist if client is only receiving IV fluids for 3 or more days.
- Encourage client to consume meals provided to get adequate calories needed to spare protein and replace lost body mass from the catabolic phase that follows stress.
- Determine special nutritional needs to promote wound healing:
 - Vitamin C (needed for capillary and antibody formation)
 - Vitamin K (needed for blood clotting)
 - Vitamin A (needed for tissue synthesis, reverses the suppression of immune response created by the stress of surgery)
 - Iron (replaces iron lost from blood loss associated with surgery)
 - Zinc (needed for protein synthesis and wound healing)

Clinical Alert

Protein stores will deplete within 3–5 days without adequate calorie and protein intake. Some clients may require total parenteral nutrition (TPN).

- Perform nursing interventions to prevent postoperative complications.
 - Turn and position every 2 hours, unless contraindicated by physician's orders, to promote circulation and decrease alteration in skin integrity.
 - Encourage deep breathing and coughing.
 - Encourage calf muscle exercises, if client does not have sequential compression devices or TED stockings in place.
 - Promote ambulation.
 - Perform either active or passive range of motion.
 - Monitor for hypovolemia.

Assessment Alert

The most common postoperative complications include pressure ulcer, paralytic ileus, pulmonary emboli, fat emboli, hypostatic pneumonia, hematoma, deep vein thrombosis, infection, and wound dehiscence and evisceration.

- Managing postoperative complications

Assessment Alert

Common risk factors for DVT include: orthopedic surgery (hip, knee, and lower extremities), transurethral prostatectomy, general surgery and gynecological/obstetric client over 40 years old, and neurosurgical clients.

- Wound dehiscence and evisceration
 - Use moist wound healing products (i.e., hydrogel, alginate) to manage dehisced surgical incision.
 - Apply abdominal binder to prevent evisceration.

Nursing Intervention Alert

Immediate action is to be taken when bowel eviscerates through a dehisced surgical wound.

- Position client in low-Fowler's.
- Instruct client to lie quietly.
- Cover exposed intestine with a moist sterile saline dressing.
- Notify surgeon.

- Paralytic ileus
 - Insertion of nasogastric tube to decompress intestine
- Urinary retention
 - Insert straight catheter to empty bladder.
 - Encourage fluid intake, if not NPO.
- Pulmonary emboli
- Fat emboli

PEDS

Pediatric considerations:

Assessment Alert

Monitor for malignant hyperthermia, a genetic myopathy characterized by hypermetabolism, and muscle destruction, which may occur during or after surgery. Symptoms include: tachycardia, tachypnea, rising BP, mottled skin, muscle rigidity, and ultimately high fever.

During the preoperative assessment, questions should be asked to determine if any family members had problems with anesthesia suggestive of this disorder.

- Use age-appropriate techniques (drawing, story telling, play) to discover child's ideas and reactions to the surgery and support or correct perceptions to alleviate sources of continuing stress.

CARDIOVASCULAR SURGERY

VALVULOPLASTY

- Valvuloplasty involves repair or reconstruction of a stenosed or regurgitant cardiac valve.
- Type of valvuloplasty depends on the cause and type of valve dysfunction.
 - Commissurotomy is performed to separate the thickened, adherent leaves of a stenosed valve. The site where leaflets meet is called a commissure.
 - Closed commissurotomies do not require cardiopulmonary bypass and the valve is not directly visualized.
 - Percutaneous balloon valvuloplasty is a nonsurgical invasive technique in which a balloon is positioned across the stenosed valve and inflated.
 - A midsternal incision is made and a dilator is used to break open the commissure.
 - Open commissurotomy is a direct visualization of the valve and requires cardiopulmonary bypass.
 - Annuloplasty involves repair of a narrowed or enlarged valve annulus, the supporting ring of the valve.
 - Chordoplasty involves repair of the chordae tendineae and most generally involves the mitral valve. The chordae tendineae can be shortened, reattached to the leaflet, or lengthened.
 - Leaflet repair is for leaflets that have been damaged as a result of stretching, shortening, or tearing.

- Mechanical valves are considered to be more durable and longer lasting. Often used for younger clients. Thromboemboli are a significant complication and thus, clients require lifetime anticoagulation with warfarin (Coumadin).
- Tissue or biologic valves are not as durable as mechanical valves and require replacement more frequently but are less likely to cause thromboemboli and the client does not require long-term anticoagulation therapy.
 - Three types: Xenograft (also known as heterograft) valves are from animals generally pigs or cows. Homografts (also known as allografts) are from human cadavers. And autografts are excised from the client's own pulmonic valve.

Nursing Process Elements

- Assess VS and hemodynamic parameters.
- Assess for clinical manifestations of decreased cardiac output.
- Monitor I&O and note any weight gain greater than 3–5 lb/24 hrs.
- Administer medications as ordered.
- Assess and treat pain.
- Assess laboratory values—CBC, APPT, PT, and ABGs.
- Provide emotional support.
- Provide wound care if open procedure was used.
- Implement bleeding precautions if client is on anticoagulant therapy.
- Provide client education following surgical interventions.
- Alternate periods of rest and activity.

Valve Replacement

- Complete replacement of the valve.
 - Two types

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of CHF including weight gain, increased pulse rate, and difficulty breathing.
- Know S&S of strep throat and seek treatment immediately.
- Adhere to routine for prophylactic antibiotic treatment prior to dental work and invasive procedures, if required.
- If on anticoagulant therapy
 - Use bleeding precautions including using a soft-bristled tooth brush and electric razor.
 - Report signs of bleeding immediately: joint pain, black or tarry stools, blood in urine, and bleeding gums.
 - Adhere to laboratory schedule for hematocrit (Hct) and hemoglobin (Hgb), Prothrombin time, and bleeding times.
 - Know dose and side effects of warfarin (Coumadin).
 - Know to avoid medications such as aspirin or foods such as dark green, leafy vegetables that may increase bleeding times or that interfere with vitamin K production.
- If an open procedure was used
 - Know wound care.
 - Know S&S of infection including redness, warmth, edema, exudate at incisional site.
 - Know follow-up routine care schedule.
- If a valve replacement was done
 - Know how long the usual life of the replacement valve should be.
 - Report immediately S&S of valve failure: decreased BP, increased pulse rate, dyspnea, and weight gain.

Assessment Alert

Clinical manifestations of infective endocarditis include: murmur, cough, fever, chills, petechiae, splinter hemorrhages, and Osler's nodes.

Dynamic Cardiomyoplasty

- The client's own latissimus dorsi muscle is used as a graft, wrapped around the heart, and then is stimulated in synchrony with cardiac systole
- It is a muscle-powered cardiac assist procedure
- Dynamic cardiomyoplasty decreases myocardial wall stress and myocardial oxygen demand
- It requires insertion of an epicardial pacing wire and implanted pace maker
- Two incisions are needed: a thoracotomy to dissect the latissimus muscle and a mediastinal incision in order to wrap the muscle around the heart.

Clinical Alert

Hypertrophic cardiomyopathy is considered a contraindication.

Use: Generally used for Class III NYHA heart failure clients who are deteriorating despite maximal medical therapy.

Preparation: Usual preoperative care for cardiac surgery including physical, emotional, and psychosocial assessment; preoperative teaching of client and family concerning postoperative care; and close monitoring of the client's condition.

Postoperative course: similar to client's undergoing open heart surgery. Pacing is not started for 2–3 weeks following surgery and takes up to 3 months for full function to be achieved.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Measure and record I&O hourly.
- Assess pain level.
- Administer medications as ordered.
- Provide emotional support to client and family.
- Evaluate respiratory status.
- Assess incisions for presence of infection and drainage.
- Assess for S&S of complications.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of CHF including weight gain, increased pulse rate, and difficulty breathing.
- Know follow-up routine and when cardiac conditioning will be maximized.
- Understand cardiac pacing and how to check heart rate and pacing effectiveness.
- Understand that procedure is palliative.
- Follow low-fat cardiac diet
- Adhere to medical regime.

MYOTOMY/MYECTOMY

- The dissection or cutting of a muscle (myotomy)
- The excision of all or part of the muscle (myectomy)

Use: Hypertrophic Cardiomyopathy, used with severe symptomatic clients to remove a portion of the thickened muscle of the upper portion of the cardiac ventricular septum to relieve outflow obstruction.

Preparation: Usual preoperative care for client undergoing open heart surgery including physical, emotional, and psychosocial assessment; preoperative teaching of client and family concerning postoperative care including respiratory support, sensory stimuli, monitoring equipment; and close monitoring of the client's condition.

Postoperative course: As for clients undergoing open heart surgery, client will be in an intensive care unit for 1–3 days and will be discharged home after a total hospital stay of 7–10 days.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Measure and record I&O hourly including chest tube drainage.
- Monitor laboratory values especially Hct & Hgb, ABGs, CBC, and APPT.
- Keep temporary pacemaker at bedside.
- Assess for S&S of cardiac tamponade: increased heart rate, decreased BP, increased CVP, decreased UOP, and distant heart sounds.
- Monitor core body temperature and keep temperature above 96.8°F (36°C)
- Assess pain level.
- Administer medications as ordered.
- Note ETT placement and ventilator settings.
- Provide emotional support to client and family.
- Evaluate respiratory status.
- Assess incisions for presence of infection and drainage.
- Assess for S&S of complications.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of CHF including weight gain, increased pulse rate, and difficulty breathing.
- Know follow-up routine.
- Know wound care.
- Understand that procedure is palliative.
- Follow low-fat cardiac diet.
- Adhere to medical regime.

PERICARDECTOMY

- Pericardectomy-operation to remove the pericardium

Use: In cases of pericardial disease, it may be necessary to remove or partially remove the pericardial sac to remove

scarred and inflexible areas of the pericardium or to prevent recurrent pericarditis. Requires a sternotomy and thoracotomy.

Clinical Alert

Even though the pericardium helps to support and protect the heart, its removal does not cause any harm. The heart can function without it.

Preparation: Usual preoperative care for client undergoing open heart surgery including physical, emotional, and psychosocial assessment; client education concerning the anatomy and physiology of the heart and the surgical procedure, pain management and emotional support, sensory stimuli, and monitoring equipment; and the need for close monitoring of the client's condition.

Postoperative course: As for clients undergoing open heart surgery. Client will be in an intensive care unit for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Measure and record I&O hourly including chest tube drainage.
- Monitor laboratory values especially Hct & Hgb, ABGs, CBC, and APPT.
- Keep temporary pacemaker at bedside.
- Assess for S&S of cardiac tamponade: increased heart rate, decreased BP, increased CVP, decreased UOP and distant heart sounds.
- Monitor core body temperature and keep temperature above 96.8°F (36°C).
- Assess pain level.
- Administer medications as ordered.
- Note Endotracheal tube placement and ventilator settings.
- Provide emotional support to client and family.
- Evaluate respiratory status.
- Assess incisions for presence of infection and drainage.
- Assess for S&S of complications.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.

- Report S&S of CHF including weight gain, increased pulse rate, and difficulty breathing.
- Know follow-up routine.
- Know wound care.
- Understand that procedure is palliative.
- Follow low-fat cardiac diet.
- Adhere to medical regime.

PERICARDIOSTOMY

- Surgical construction of an opening into the pericardium

Use: For pericardiocentesis (procedure to remove fluid from the pericardial sac) and pericardial decompression (cardiac tamponade)

Clinical Alert

Cardiac tamponade is a life-threatening event and requires emergency treatment.

Preparation: Gather supplies: pericardiocentesis tray, ECG machine and patches, emergency cart and defibrillator; provide client support; be sure permit is signed.

Postprocedure: Monitor client; send samples to laboratory; record amount of fluid removed; if chest tube was inserted during procedure, assure the patency of the tube and system.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Assess for S&S of cardiac tamponade: increased heart rate, decreased BP, increased CVP, decreased UOP, and distant heart sounds.
- Assess pain level.
- Administer medications as ordered.
- Provide emotional support to client and family.
- Evaluate respiratory status.
- Assess incisions for presence of infection and drainage.
- Assess for S&S of complications.

Client teaching for self-care

- Resume usual activities gradually.
- Report S&S of complications or recurring symptoms.

- Know follow-up routine.
- Know wound care.
- Adhere to medical regime.

MINIMALLY INVASIVE DIRECT CORONARY ARTERY BYPASS GRAFT (MICAB)

- MICAB is an alternative to traditional CABG.
- A small anterior thoracotomy incision is used.
- It does not require cardiopulmonary bypass.
- A chest wall artery is grafted to the affected heart area while the heart continues to beat

Uses: For low risk clients who have a single anterior lesion and for high risk clients who are not candidates for conventional bypass surgery.

Preparation: Usual preoperative care for client undergoing heart surgery including physical, emotional and psychosocial assessment; preoperative teaching of client and family concerning postoperative care and close monitoring of the client's condition.

Postoperative course: Client will be admitted to PACU for recovery from anesthesia and then to a telemetry unit for 1–3 days.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Assess pain level.
- Administer medications as ordered.
- Evaluate respiratory status (especially if the lung was collapsed for the surgery in which case may have a chest tube in place).
- Assess incisions for presence of infection and drainage.
- Assess for S&S of complications.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of angina.
- Know follow-up routine.
- Know wound care.
- Understand that procedure is palliative.
- Follow low-fat cardiac diet.
- Adhere to medical regime.

CORONARY ARTERY BYPASS GRAFT (CABG) AND OFF PUMP CORONARY ARTERY BYPASS (OPCAB)

- A blood vessel from another part of the body is used to bypass the obstructed coronary artery. Attachment is made from the aorta or if using the internal mammary artery, the proximal end remains attached to the subclavian artery, and the other end of the vessel is attached to the distal portion of the obstructed coronary artery thus, providing revascularization of the heart.
- CABG is performed on a stopped heart and requires the use of extracorporeal circulation by the cardiopulmonary bypass pump.
- OPCAB is similar to conventional CABG but cardiopulmonary bypass pump is not used; a median sternotomy approach is used.

Uses: For clients with severe CAD, clients with blockages greater than 70% of two or three coronary arteries, left main coronary artery lesions greater than 60%, unstable angina, angina which cannot be controlled by medical therapy or when complications have developed from percutaneous coronary intervention (PCI).

Clinical Alert

When using cardiopulmonary bypass pump, the client receives Heparin to prevent thrombus formation and hypothermia is maintained to decrease the body's metabolic needs.

Preparation: Usual preoperative care for client undergoing open heart surgery including physical, emotional, and psychosocial assessment; provide emotional support; client education concerning the anatomy and physiology of the heart and the surgical procedure, postoperative procedures and equipment including hemodynamic monitoring equipment, ventilator, endotracheal tube, pacing wires, chest tubes, and nasogastric tube, ICU policies and visiting hours, possible complications and treatments, pain management, and sensory stimuli and sensory overload.

Postoperative course: As for clients undergoing open heart surgery, client will be in an intensive care unit for 1–2 days and will be discharged home after a total hospital stay of 5–7 days.

Nursing Process Elements

- Monitor hemodynamic measures.
- Assess cardiac monitoring.
- Assess peripheral pulses.
- Assess bowel sounds and measure abdominal girth every 8 hours.
- Measure and record I&O hourly including chest tube and NG drainage.
- Monitor laboratory values especially Hct and Hgb, ABGs, CBC, APPT, and electrolytes.
- Keep temporary pacemaker at bedside.
- Monitor core body temperature and keep temperature above 96.8°F (36°C).
- Assess pain level.
- Administer medications as ordered.
- Note ETT placement and ventilator settings.
- Provide emotional support to client and family.
- Evaluate respiratory status.
- Assess incisions for presence of infection and drainage.
- Turn and have client deep breathe.
- Assess for S&S of complications including thrombophlebitis, pulmonary embolism, CHF, and cardiac tamponade.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of CHF including weight gain, increased pulse rate, and difficulty breathing.
- Know follow-up routine.
- Know wound care.
- Understand that procedure is palliative: risk factor modification.
- Follow low-fat cardiac diet.
- Adhere to medical regime.
- Can resume sexual intercourse in 3–4 weeks.
- Avoid heavy lifting and excessive arm movements for 6–8 weeks.
- No driving for 6–8 weeks.

PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY (PTCA)

- Alternative to CABG for some clients.
- Insertion of a balloon-tipped catheter to dilate a stenotic artery and revascularize the myocardium.
- Performed in the cardiac catheterization laboratory.

Uses: For clients who have CAD in one or more vessels, have recurrent chest pain unresponsive to medical interventions, poor surgical candidates.

Preparation: Similar to client undergoing cardiac catheterization. Preoperative teaching concerning the procedure

and recovery; NPO for several hours prior to procedure; client will be awake during the procedure and may be asked to take deep breaths, cough, describe pain, etc; anti-coagulants, antiplatelets, and/or vasodilators may be given preprocedure.

Assessment Alert

Ask client if he/she is allergic to dye or shellfish because contrast may be given during the procedure.

Nursing Intervention Alert

Warn clients that they may feel warm, flushed, or get a metallic taste when contrast is injected and they may feel intense chest pain when balloon is inflated.

Postoperative course: Sheath will be removed in 2–4 hours and client will be discharged 6–8 hours later.

Nursing Process Elements

- Observe catheter insertion site for bleeding, hematoma, and pseudoaneurysm.
- Check peripheral pulses for color, pulses, sensation according to hospital protocol.

Nursing Intervention Alert

Remember “P’s of circulatory checks”: pain, paresthesia, paralysis, pulse, pallor, poikilothermia (cold)

- Continuously monitor cardiac rhythm.
- Obtain 12-lead ECG if signs of cardiac ischemia or client complains of chest pain.
- If leg used, maintain client, according to hospital protocol, on complete bed rest with head elevated no higher than 30 degrees and cannulated extremity straight.
- Monitor I&O.

Clinical Alert

Contrast dyes cause osmotic diuresis and can cause renal damage.

- Monitor laboratory values especially electrolytes, BUN, CBC, creatinine, PTT, and cardiac enzymes.
- Observe for signs of decreased cardiac output.
- Assess client for pain and anxiety.
- Medicate as prescribed.
- Have emergency drugs on hand.
- Observe client for S&S of vasovagal reaction when sheath is removed-hypotension, light-headedness, and bradycardia.

Client teaching for self-care

- Schedule rest periods to prevent fatigue.
- Resume usual activities gradually.
- Report S&S of angina, CHF, and vessel reocclusion.
- Know follow-up routine.
- Know puncture site care.
- Understand that procedure is palliative: risk factor modification
- Follow low-fat cardiac diet.
- Adhere to medical regime.

EMBOLECTOMY

- A surgical incision into an artery for the removal of an embolus or thrombi.
- An embolectomy catheter may be inserted to extract the embolus.

Uses: For acute artery occlusion due to thrombi or embolus which may include an accumulation of air, fat, bacteria, amniotic fluid, or other material. Arterial emboli are often associated with MI, atrial fibrillation, left-sided heart failure, pericarditis, or endocarditis.

S&S:

- Pain in affected area
- Paralysis
- Pulselessness
- Pallor
- Paresthesia
- Numbness
- Poikilothermia (cool)

Preparation: Usual preoperative teaching and preparation. Since this is often emergency surgery, the client and family

may be quite anxious. Nursing measures should focus on gaining the client's trust and decreasing the client's and family's anxiety. The client is usually on bed rest with the affected extremity kept level of slightly dependent.

Postoperative course: Generally discharged within 1–2 days.

Nursing Process Elements

- Observe incisional site for bleeding, hematoma, and infection
- Check extremities for color, pulses, and sensation according to hospital protocol.
- Maintain fluid volume.
- Monitor laboratory values especially APTT if client is on heparin.
- Assess client for pain and anxiety.
- Medicate as prescribed.
- Discourage activities that decrease circulation to extremities such as knee gatch, crossed legs, and pillow under the knees.
- Keep client warm to increase circulation.

Client teaching for self-care

- Resume usual activities gradually.
- Report S&S of reocclusion or infection.
- Know follow-up routine.
- Know incisional site care.
- Understand risk factor modification.
- Adhere to medical regime.

ENDARTERECTOMY

- Surgical incision is made in an artery and atheromatous material is removed.

Uses: To remove plaque accumulation from an artery.

Preparation: Usual preoperative teaching and care.

Postoperative course: Generally discharged within 1–2 days.

Nursing Process Elements

- Observe incisional site for bleeding, hematoma, and infection.
- Check peripheral pulses for color, pulses, and sensation according to hospital protocol.
- Maintain fluid volume.
- Monitor laboratory values especially APTT if client is on heparin.
- Assess client for pain and anxiety.
- Medicate as prescribed.

- Discourage activities that decrease circulation to extremities such as knee gatch in use, crossed legs, pillow under the knees, and neck not in alignment.
- Keep client warm to increase circulation.

Client teaching for self-care

- Resume usual activities gradually.
- Report S&S of reocclusion or infection.
- Know follow-up routine.
- Know incisional site care.
- Understand risk factor modification.
- Adhere to medical regime.

VASCULAR GRAFTS

- Grafts may be used to reroute the blood flow around an occluded area.
- Grafts may be autologous (using client's own vein) or synthetic.

Uses: Revascularization of occluded vessels

Preparation: Usual preoperative teaching and care

Postoperative course: Generally discharged within 2–3 days.

Nursing Process Elements

- Assessment of graft patency.
- Observe incisional site for bleeding, hematoma, and infection.
- Check extremities for color, pulses, and sensation according to hospital protocol.
- Maintain fluid volume.
- Assess ankle-brachial index (ABI) every 8 hours for first 24 hours then everyday.
- Monitor laboratory values especially APTT if client is on heparin and BUN and creatinine if graft was above renal arteries.
- Assess client for pain and anxiety.
- Medicate as prescribed.
- Discourage activities that decrease circulation to extremities such as knee gatch in use, crossed legs, pillow under the knees, neck not in alignment, and hip flexion.
- Keep client warm to increase circulation.
- Prevent skin breakdown, sheepskin, foot cradle, frequent repositioning.

Client teaching for self-care

- Resume usual activities gradually.
- Report S&S of reocclusion or infection.

- Know follow-up routine.
- Know incisional site care.
- Understand risk factor modification and life style changes.
- Adhere to medical regime.

SPLENECTOMY

- Splenectomy is the removal of the spleen.
- It may be done through an upper left quadrant abdominal incision or by laparoscopy.

Use: Control hemorrhage or remove a spleen ruptured by traumatic injury; treatment of idiopathic thrombocytopenia purpura, hemolytic anemia, thrombosis of splenic vessels, portal hypertension, hereditary spherocytosis (splenectomy is only treatment since the fragile blood cells are injured passing through the spleen), or significant splenomegaly associated with leukemia or lymphoma.

Preparation: If performed as an elective procedure,

- client is vaccinated against pneumococcal pneumonia and meningitis about a month before surgery;
- any infection is treated; and
- attempts are made to return blood parameters to normal.

Postoperative course:

- If performed as an emergency procedure, vaccines are given postoperatively.
- **PEDS** Children receive long-term antibiotic therapy as prophylaxis against sepsis.
- Healing complete in 4–6 weeks.

Complications:

- Postsplenectomy syndrome characterized by elevated platelet count with risk of thrombosis, erythrocyte destruction, and increased susceptibility to infection
- Pancreatitis

Assessment Alert

PEDS

Children have the greatest risk of post-splenectomy sepsis. Older adults also have increased risk of both infection and thrombosis.

Nursing Process Elements

- Assess for pain in the left shoulder, which can be an indication of hemorrhage due to stimulation of the phrenic nerve as a result of pressure from the accumulation of blood in the operative area, which is just beneath the diaphragm.

Client teaching for self-care

- See health care provider if any signs or type of infection occur; this includes otherwise benign infections such as sinusitis, sore throat, or ear ache.
- Avoid travel to areas with endemic infections such as malaria.
- Get booster of pneumococcal vaccine in 5–10 years.

RESPIRATORY SURGERY

TONSILLECTOMY

Tonsillectomy is the removal of the palatine tonsils; bleeding areas are cauterized and sutured; it can be combined with an adenoidectomy—removal of the adenoids; most common surgery for children

Assessment Alert

Contraindicated with bleeding disorders, presence of acute infections at time of surgery, systemic diseases that are not under control as diabetes, cardiac or renal disease.

Use: Tonsillectomy treats recurrent tonsillitis, peritonsillar abscess, hypertrophy of tonsils causing swallowing difficulty, difficult breathing; adenoidectomy relieves persistent otitis media, breathing and swallowing difficulty, sleep apnea, and speech distortion.

Preparation: NPO, IV, check temperature; child needs to be without a fever and without a sore throat; no respiratory infection for about 2 weeks before surgery; no aspirin or ibuprofen for 2 weeks before surgery; assess for loose teeth; ask if child has been given herbal medication.

Assessment Alert

Check for bleeding tendencies in child and family.

Postoperative course:

- Monitor VS frequently, also for airway obstruction, and respiratory distress.
- Check for signs of hemorrhage: increased pulse, low BP, restlessness, and frequent swallowing.
- Begin diet with ice chips and, flavored ice pops but nothing brown or red which may cause emesis to look like old or new blood.
- Low-grade fever and earache are common postoperative symptoms.

**Nursing Process Elements**

- Assess for complications as hemorrhage, injury to upper airway, and aspiration pneumonia.
- Place on side or abdomen until completely awake.
- Administer acetaminophen and apply ice collar to neck for pain relief.
- Encourage fluids.
- Discourage coughing and clearing throat.
- Encourage to chew gum, to relieve muscle spasms around the throat.

**Client teaching for self-care**

- Encourage rest and quiet activities.
- Include soft foods, cool liquids and nothing irritating in diet.
- Teach to take analgesics and antibiotics as ordered; do not take aspirin
- Report any signs of bleeding.
- Report an elevated temperature more than 102°F or 38.8°C to the surgeon

LARYNGECTOMY

Removal of all or part of the larynx.

- Partial laryngectomy involves removal of a section of the larynx, a vocal cord and tumor; airway remains intact; there is no difficulty in swallowing but the voice quality is changed.
- Hemilaryngectomy is the removal of one half the larynx and a portion of the vocal chord along with the tumor; airway and swallowing remain intact but the voice may be hoarse with limited projection.
- Supraglottic laryngectomy involves removal of the hyoid bone, glottis, and false vocal cords.
- Total laryngectomy involves the removal of the larynx, epiglottis, thyroid cartilage, three tracheal rings, hyoid bone, and vocal chords; speech is lost, and a permanent tracheostomy is created, which may be in place permanently or removed leaving a natural stoma.

Use: Treatment of cancer of the larynx

**Assessment Alert**

An advantage of the supraglottic is that the vocal chords are intact and the voice is preserved, although the voice quality may change.

Preparation: Encourage discussion with the client and significant others about their fears and anxiety related to surgery. Review procedures to expect after surgery such as IV fluids, suctioning, humidification, NG tubes feedings, and a laryngectomy tube. Additional treatment may include chemotherapy and radiation. Reinforce teaching about loss of normal speech and breathing through a hole in the neck. Plan for immediate postoperative communication using a pad and pencil or pictures. Arrange a meeting with a speech pathologist about changes in means of communication with use of esophageal speech, external voice boxes, or an artificial larynx.

**Assessment Alert**

If metastasis to cervical lymph nodes is detected, a radical neck dissection may be performed.

Postoperative course:

- Monitor for respiratory complications, check rate, effort, and ABG values.
- Elevate head of bed 30–40 degrees, this promotes ventilation and decreases edema.
- Support client's feelings and encourage discussion about loss of voice and altered body image.
- Need to assess wound for bleeding, edema, infection, and poor wound healing.
- Cleanse incision with one-half strength hydrogen peroxide.
- Promote adequate pain relief.
- Maintain sterile technique during tracheostomy care and suctioning; suction as needed.
- Introduce speech rehabilitation.

**Nursing Process Elements**

- Refer to a laryngectomy support group; arrange a visit by a postlaryngectomy client.
- Teach need to report symptoms that require special medical attention.
- Encourage to follow speech therapist's recommendations.
- Give information about devices used to produce speech, this information may be obtained from the American

Cancer Society or the International Association of Laryngectomies.

- Maintain adequate intake as IV fluids; provide nutrition by NG feeding; and initiate oral intake of soft foods.

Client teaching for self-care

- Self care of tracheostomy or stoma; offer guidance and opportunities to practice.
- Protect site with a shield during a shower.
- Use a special device for swimming to prevent drowning.
- Use a humidifier to add humidity to the air to maintain moist mucous membranes and secretions.
- Purchase an ID alert bracelet, chain, or card.

PNEUMONECTOMY

- Pneumonectomy involves removal of an entire lung usually through a posterolateral incision.
- It is done only when disease involves entire lung.

Use: Treatment of lung cancer, lung abscess, bronchiectasis, extensive unilateral tuberculosis

Preparation:

- Chest X-rays, lung scan, and EKG to determine cardiorespiratory status and ability to tolerate the surgery
- Pulmonary function tests to determine if lung tissue that will remain after surgery is adequate to support client and ADLs.
- ABGs to provide another measure of pulmonary reserve and a baseline for postoperative assessment
- Exercise tolerance test
- Clients who smoke are encouraged to stop or cut down to improve oxygen saturation and reduce secretions
- Any existing infection treated with antibiotics
- Postural drainage to remove secretions if needed

Postoperative course:

- No chest tube inserted for pneumonectomy: diaphragm is paralyzed in an elevated position and remaining space is left to fill with serosanguineous fluid, which ultimately solidifies.
- Severe shoulder and chest pain causes guarding, which predisposes to hypoventilation and atelectasis is expected and must be treated.
- Pain control may be aided by long-acting local anesthetic nerve block at end of surgery.
- Breathing exercises and passive shoulder range of motion begun immediately after recovery from anesthesia.
- Oxygen for 24 hours.
- Temperature is maintained between 98°F and 102°F because hypothermia or hyperthermia causes change in metabolism and respiratory demand.

Think Smart/Test Smart

Every implication of every fact cannot be identified in a text. Therefore, it is important as you review to think about not just what the fact is but what does it mean for the nurse in practice. It is also important to think about how questions can be asked about the practice implications of the fact. For example, if temperature needs to be maintained within certain range then temperature must be monitored at regular intervals to determine if it is within the desired range. If it is outside the range, then an action must be taken to return it to within the acceptable range. If a corrective action is an independent nursing intervention such as applying blankets for hypothermia or if it is a dependent action such as giving an antipyretic for hyperthermia but an order is already written for it, then the nurse implements the action and evaluates its effectiveness. If there is no order for a dependent intervention or if an independent intervention is not effective, the nurse must notify the physician. Thus, questions that could be asked based on the knowledge that temperature affects demand on the respiratory system and, therefore, needs to be maintained between 98°F and 102°F include how often temperature needs to be monitored following a pneumonectomy; for what reasons is it important to monitor temperature; what is the appropriate action for the nurse to take if the client's temperature is either lower or higher than the specified range; and which situation/finding requires that the physician be notified.

- Dangled evening of surgery; ambulated next day.
- Oral fluids begun when alert and bowel sounds are present.

Nursing Intervention Alert

Rate of IV infusion may be as low as 10 ml/hr because of risk of pulmonary edema as a result of a decrease in the pulmonary vascular bed.

- Scant serous/serosanguineous drainage is normal.
- Weakness and easy fatigue expected for 3–4 weeks.
- Altered sensation, numbness, or tenderness may persist for months in area around incision.

Complications:

- Atelectasis most often due to retained bronchial secretions
- Pneumonia
- Hemorrhage
- Cardiac dysrhythmia
- Pulmonary edema due to overinfusion of fluids and loss of pulmonary vascular bed
- Empyema:
 - pus in the pleural cavity
 - S&S: pleuritic pain, fever, dullness to percussion over affected area
 - Rx: chest drainage and antibiotics
- Bronchopleural fistula
 - Abnormal opening between a bronchus and a pleural space
 - S&S: hemoptysis, fever, subcutaneous emphysema, and severe air leak
 - Occurs in first postoperative week
 - Rx: surgery to reclose bronchial stump
- Persistent air leak
 - Openings in lung tissue fail to close within 72 hours after surgery
 - S&S: bubbling in water seal compartment of chest drainage system
 - Rx: injection of a sclerosing agent into pleural cavity or surgery
- Subcutaneous emphysema
 - Presence of air under the skin as a result of escape from the respiratory tract from a persistent air leak or a blocked chest tube
 - S&S: Puffiness and crepitation (crackling sound) on palpation
- Respiratory failure
- Hypotension
- Mediastinal shift
 - Movement of the mediastinum including the heart, trachea, esophagus and great vessels to one side of the thorax

**Nursing Process Elements**

- Assess respiratory status. Monitor for slow, rapid, shallow, or irregular respirations; use of accessory muscles; dusky-ness or cyanosis; restlessness, irritability, confusion, somnolence, decreased or absent breath sounds over remaining lung tissue, and changes in ABGs.
- Assess cardiovascular status.

**Assessment Alert**

After pneumonectomy, clients are at particular risk for:

- dysrhythmias especially atrial fibrillation and atrial flutter
- pulmonary edema—severe dyspnea, tachycardia, dull percussion note over unoperated areas, adventitious breath sounds, persistent cough with frothy, blood tinged sputum, cyanosis, and apprehension.
- mediastinal shift—severe dyspnea, restlessness, agitation, rapid or irregular pulse, cyanosis, displacement of the trachea from the midline, and change in location of point of maximum impulse (PMI).

—Monitor fluid and electrolyte status: CVP below the normal range of 5–12 cm of water is indicative of hypovolemia and above the normal range of hypervolemia.

- Position client on back or with unoperated side up to aid maximal expansion of remaining lung.
- Turn every 2 hours to reduce pooling of secretions in a dependent area of the remaining lung.
- Encourage client to splint incision and to cough and deep breathe every 1–2 hours to prevent atelectasis: Use palm of hands or a pillow or folded sheet or towel as a splint; sit client upright or on side with hip and knees flexed; direct client to take 2–3 short breaths and then a deep one; contract the abdominal muscles; and cough forcefully with the mouth open.
- Assess breath sounds before and after coughing and deep breathing.
- Encourage huffing if client is unable to cough: take a deep breath and exhale forcefully in a rapid huff.

**Nursing Intervention Alert**

Postural drainage, percussion, and vibration may be ordered to aid removal of copious secretions. Never percuss or vibrate over operative site.

- Space nursing care activities to allow rest periods.
- Support affected arm on pillows or with a sling to decrease pull on transected muscles.
- Put affected shoulder through passive range of motion at least two times every 4 hours for the first 24 hours postoperatively; then guide in active ROM 10–20 times every 2 hours.

Assessment Alert

Report immediately if sputum is excessive or contains bright red blood.

Client teaching for self-care

- Continue breathing exercises at home as directed, usually about 3 weeks.
- Continue arm and shoulder exercises (10–20 of each) five times per day.
- Use a mirror to check if posture is erect: if the affected side is being favored, practise standing straight with shoulders even in front of the mirror.
- Apply hot soaks or a heating pad for chest or shoulder soreness, which is expected for several weeks.
- Avoid lifting more than 20 lb for 3 months when muscles of chest will be completely healed.
- Stop any activity that causes dyspnea, chest pain, or excessive fatigue.
- Avoid exposure to respiratory irritants and to persons with respiratory infections.
- Obtain influenza and pneumonia vaccine.
- Report signs of respiratory infection (fever, cough, and increased sputum), shortness of breath, decreased mobility, or increased discomfort in chest or shoulder.

LOBECTOMY

- Removal of a lobe of the lung
- May be done by open thoracotomy or by thoroscopic surgery.
- Chest tubes used to drain air and fluid from chest cavity and allow reexpansion of remaining lobes. When two chest tubes are placed, the upper tube drains air and the lower one drains fluid.

Use: Manage disease such as lung cancer or bronchiectasis limited to a single lobe of the lung.

Preparation and postoperative course:

- Similar to pneumonectomy if an open thoracotomy is done.
- After thoroscopic lobectomy:
 - Pain is slight and managed with an analgesic such as acetaminophen.
 - Clients ambulate on the day of surgery and resume normal activity thereafter.
 - Shower as soon as chest tube(s) is/are removed.

Nursing Process Elements

- Monitor chest drainage every 15 minutes and then at progressively longer intervals.
- Maintain drainage system below level of client's chest; keep free of leaks, dependent loops, and external pressure.
- Place rolled towel under chest tube when client is lying on affected side to keep body weight from compressing it.

Assessment Alert

Report persistent chest drainage of more than 200 ml/hr.

Care is otherwise similar to that of postpneumonectomy.

Client teaching for self-care

- After open lobectomy, teaching is the same as after pneumonectomy. See above.
- After thoroscopic lobectomy:
 - Continue to cough and deep breathe while awake.
 - Exercise arm on affected side by lifting arm up over the head and doing arm circles.
 - Wash incisions daily; shower at will.
 - Avoid heavy lifting for a month.
 - Report any shortness of breath, temperature over 101°F, incisional swelling, redness, or drainage.

NEUROLOGICAL SURGERY

INTRACRANIAL SURGERY

- Supratentorial: surgery performed on the cerebral hemispheres
- Infratentorial: surgery performed on the brain stem or cerebellar region below the cortex

STEREOTACTIC SURGERY

- Refers to targeting the operative area of the brain by using three-dimensional coordinates determined by CT or MRI.
- Preciseness of approach limits damage to healthy brain tissue
- Used for biopsy, removal of an area of tissue by dissection, or destruction of tissue by radiosurgery.
- It is done under local or general anesthesia.
- Craniotomy is done to allow entry of instruments: probe, biopsy needles etc.

CRANIOTOMY

- Location depends on area of brain that needs to be reached: frontal, parietal, occipital, temporal, or a combination.
- Burr holes are drilled; bone between holes is sawed to create a flap that is removed and then wired or sutured back in place when the surgical procedure is completed.
- Drains may be placed to remove blood and fluid.

Uses: Access the brain and meninges for removal of tumors, management of bleeding or vascular defects, treatment of infection/ abscesses, repair damage from trauma

Preparation:

- Routine preoperative preparation
- Include in teaching:
 - Head will be shaved when under anesthesia; hair will grow back at about $\frac{3}{4}$ in./mo; wigs, hats, and turbans can be used.
 - Client will be on positioning restriction postoperatively (see under “Nursing Process Elements”)

Postoperative course:

- ICU until stable: Usually 24–48 hours because this is the time frame in which maximal swelling of the operative area occurs
- Dressing in place 3–5 days (when no dressing, OR cap is used to cover area)
- Protocols for incision care vary: Scalp may be washed with antiseptic soap once dressing is removed; incision may be

cleansed with antiseptic and an antibiotic ointment applied; or no special treatment is ordered unless signs of infection develop.

- By time of discharge, client can usually shampoo with a mild soap and blow dry on a warm to cool setting
- Without complications and depending on reason for and type of surgery, discharge may be in as few as 2–3 days
- Rehabilitation may be needed for residual deficits: Help with mobility and ADLs, communication, and job retraining

Nursing Process Elements

- Obtain a baseline preoperative neurological assessment.
- Postoperative assessment: As for ICP (See Chapter 16).
- Primary goal: Prevent increased ICP.
- Maintain prescribed position:
 - Flat or 10–15 degree head elevation and no neck flexion for posterior fossa incisions.
 - 30–45 degree head elevation for anterior or middle fossa incisions.
 - Do not position on operative side if craniectomy (removal of bone flap) was done.
 - Assess dressing for drainage; when dressing removed assess incision: A boggy feeling to the tissue around the incision indicates fluid accumulation.

GAMMA KNIFE SURGERY

- Gamma knife surgery is a type of stereotactic radiosurgery.
- Stereotactic radiosurgery uses ionizing radiation targeted by means of a guiding device through the closed skull to destroy an intracranial lesion.
- Gamma knife usually uses cobalt 60 radiation in either a single high dose or fractionated over several treatments.
- CT or MRI scans done to target area; cerebral angiograms also done if blood vessels are involved such as in repair of an arteriovenous malformation.
- Three dimensional frame attached to client's head using four burr holes and metal pins.
- Procedure done under general anesthesia on children. Teens and others are lightly sedated.
- Helmet with over 200 separate ports for radiation beams is placed over head frame: individual beams are too weak to damage tissue but they converge at the site of the lesion and destroy it.
- Each treatment takes 2–15 minutes.
- Most effective for lesions of 3 cm or less.

Nursing Process Elements

Client teaching for self-care

- Head does not need to be shaved.
- No unusual sounds or sensations are experienced during treatments.
- Staff can see and talk to client and client can talk to staff.
- Helmet is removed when treatment is completed.
- Pin site care: Remove four dressings morning after frame is removed; wash daily with mild soap and water; apply

bacitracin ointment if ordered; observe for signs of infection.

- Shampoo day after surgery.
- Have someone stay with you for 24 hours after discharge.
- Do not drive or ingest alcohol for 24 hours after discharge because of the sedation.
- Avoid heavy lifting (>5 lbs) for 24 hours after discharge, then resume normal activity.
- Contact surgeon if seizures, numbness, tingling, paresis, paralysis, loss of coordination, prolonged N&V, change in speech, hearing, taste, smell or vision, temperature over 100.5 for 24 hours, or signs of pin infection occur.

SURGERY OF THE EYE AND EAR

OPHTHALMIC SURGERY

General care considerations:

- Approach from unaffected side decreases risk of startle.
- Provide constant description and reinforcement.
- Test corneal reflexes and PERRLA.

Clinical Alert

Mydriatic and cycloplegic drugs are contraindicated in narrow angle glaucoma.

- Pledgets soaked in a mixture of mydriatic/cycloplegic eye drops (may also add antibiotic and local anesthetic) which stay in the eye 15–20 minutes may be used in place of traditional eye drop preoperative routine which takes an hour
- Dressing depends on procedure: sterile eye pad secured with nonallergic tape; eye shield if protection from external pressure is needed, gauze roller bandage over sterile eye pad if compression needed. May just use collagen corneal shield rather than traditional ointment and dressing.

CATARACT REMOVAL

Use: Restore vision impaired by a clouded or opaque lens (cataract) at the point at which the impairment interferes with daily activities—no longer wait until the cataract is “ripe”

Preparation: Face scrub and instillation of cycloplegic dilating drop in the operative eye

Procedure:

- Extracapsular cataract extraction, most common, usually with phacoemulsification (ultrasonic vibration to break up the lens for removal)
- Local anesthesia
- Intraocular lens implant (IOL) placed behind iris: Restores vision to near 20/20; no loss of depth vision
- Often no dressing needed if a collagen corneal shield is used

Nursing Intervention Alert

Most clients need glasses for reading after cataract removal because the implanted lens cannot accommodate but an accurate prescription cannot be made until vision stabilizes 8–12 weeks after surgery. Bifocal and multifocal lens implants are available which can eliminate the need for glasses.

Complications: Infection, bleeding, and elevated IOP

Nursing Process Elements

Client teaching for self-care

- Plan for transportation to/from ambulatory surgical site.
- Plan for help at home during first few postoperative days.

- Postoperatively, report promptly drainage, excessive tearing, redness, swelling, decline in visual acuity, or acute, unrelieved eye pain, or severe headache.
- Keep dressing on eye as directed, usually 1–2 days, and wear eye shield at night for 2–3 weeks to avoid accidental trauma to the eye.
- Avoid use of OTC drugs unless first approved by MD.
- Avoid activities that increase IOP.
- Do not do strenuous exercise.
- Sleep on unaffected side.
- Wear dark glasses for photophobia.
- Do not rub or squeeze eyes shut.

Assessment Alert

Severe, acute unrelieved pain after cataract surgery is typically indicative of increased IOP, which requires immediate intervention to prevent loss of vision.

- Avoid touching eye or getting soap, water, hairspray or other foreign matter in it.
- Resume normal activities as feels comfortable but exercise in moderation and avoid heavy lifting. Resume sexual activity and driving when approved by MD.
- Wash hands before instilling eye medications; wait 2–5 minutes between different medications; use eye ointments last.
- Wear sunglasses to protect against dazzle from bright light or color.
- Note: No limitation on bending is required unless an unusually large incision was necessary.

Glaucoma Surgery

- Goal: Create path for outflow of aqueous humor from the anterior chamber of the eye thereby lowering IOP
- Common Types:
 - Argon laser trabeculoplasty (ALT): Uses laser beam to create a surface burn on the trabecular meshwork thereby increasing its tension and allowing increased outflow of aqueous humor.
 - Trabeculectomy: Typically used when ALT is not successful. Fistula is created at limbus under a thin flap of sclera through which aqueous humor can flow into the subconjunctival spaces.
 - Complications of trabeculectomy: fibrosis at site of flap with increase in IOP
 - Postoperative care: sitting position to have any hyphema in dependent location; use of cycloplegics

and combination steroids and antibiotics; monitoring of IOP and condition of bleb

Retinal Reattachment Surgery

Use: Treat retinal detachment

Preparation: If large detachment or macula is threatened, client is encouraged not to make any abrupt, jerky movement that might further the detachment; otherwise normal activities are permitted.

Postoperative course:

- Eye is patched in immediate postoperative period.
- Position face down using pillows and head supports to maintain intraocular gas bubble in place against the repair.
- Avoid coughing, sneezing, and vomiting because of risk of raising IOP. Medicate PRN to prevent.
- Moderate eye pain is expected, treat with analgesics.
- Give cycloplegic ophthalmic drops to rest iris.
- Administer alpha agonist to prevent increase IOP.
- Provide corticosteroid and antibiotic combination eye drop to prevent infection and decrease inflammation.

Nursing Process Elements

Client teaching for self-care

- Use cold compresses to reduce edema.
- Use dim lights and dark glasses to prevent discomfort from light sensitivity.
- Wear eye shield for sleep for 2 weeks.
- Report acute eye pain, increased discharge, or symptoms of retinal detachment.
- Positioning restrictions: lying prone; sitting with face down supported on a table; walking with head down but not bent at waist may be in place from 4 to 30 days if applicable
- Activity restrictions will vary with location and severity of detachment and the corrective procedure used.

EAR SURGERY

Common types of procedures:

- Tympanoplasty: repair or replacement of some or all of the conductive mechanism of the middle ear; various types of prostheses used which may consist of bone, cartilage, or other material.
- Myringoplasty: simple repair of the tympanic membrane; graft used in repair held in place with Gelfoam or similar substance.
- Myringotomy: incision into the tympanic membrane to remove fluid and relieve pressure when antibiotics and

decongestants have not been successful and there is acute infection with bulging of the membrane. Drainage tubes may be inserted which eject themselves with time.

- Mastoidectomy: removal of the mastoid bone to treat infection, remove cholesteatoma or treat other inner ear problems.

Nursing Process Elements

Client teaching for self-care

- Avoid rapid head movements, bending over for 3 weeks.
- Blow nose or cough gently.

- Avoid drinking with a straw. Open mouth if sneezing is unavoidable.
- Avoid vomiting.
- Do not drive for 7 days.
- Avoid swimming or diving for 4 weeks; longer for certain procedures such as insertion of myringotomy tubes.
- Avoid air travel for 1–4 weeks varies with procedure.
- Contact surgeon in event of URI, foul smelling drainage from ear, increased pain in operated ear, fever, bleeding or clear otorrhea or rhinorrhea, and vertigo.

MUSCULOSKELETAL SURGERY

AMPUTATION

Removal of a body part, such as hand or leg, by trauma or surgery

Uses: To control pain or a disease process that is affecting the limb, such as cancer, ischemia, or gangrene

Preparation: Food and fluid restrictions, possible antibiotics

Postoperative course:

- Phantom limb pain that may be represented as an itch, ache or the feeling that the limb is moving.
- Most clients are fitted with a prosthesis.

Nursing Process Elements

- Elevate stump on pillow for first 24–28 hours to decrease swelling. Keep joint, such as the knee, straight.
- Wrap stump in 2 in., 3 in., or 4 in. ace wraps to keep surgical dressing in place and reduce swelling. The ace wrap should be removed every 4–6 hours or sooner if the bandage becomes loose. Assess the stump for drainage and note the color, temperature, and most proximal pulse before rewrapping the stump.
- Prevent development of flexion contractures of lower extremity by not placing a pillow under hip or knee of residual limb.
- Support client through grieving process for lost limb.

Nursing Intervention Alert

Keep a tourniquet at the bedside and apply immediately if hemorrhage occurs and contact physician.

Client teaching for self-care

- Inspect stump incision daily for redness, swelling, warmth, pain to touch, drainage or an opening in the incision.
- Clean stump daily with mild soap and water, rinse and pat dry. Apply lotion to stump if skin gets too dry.
 - Gentle massage to the stump (residual limb) decreases sensitivity and increases tolerance to pressure in preparation for use of a prosthetic device.
 - Provide information on phantom limb pain and management of pain.

External Fixation

Also known as external fixators

Uses: Manage open fractures with soft tissue damage.

Preparation: Food and fluid restriction

Postoperative course: Remains in place for approximately 6 weeks, though can remain in place for longer periods of time dependent on the type and severity of fracture.

Nursing Process Elements

- Provide pain management.
- Assess for neurovascular impairment every 2–4 hours.
- Assess pin sites for redness, drainage, tenderness, pain, and loosening of pin.
- Perform pin care tid using NS on cotton tip applicator.
- Skin assessment with appropriate skin care.

Assessment Alert

Completion of skin risk assessment tool, such as Braden or Norton Scale for clients that are on prolonged bed rest.

Client teaching for self-care

- Take diet adequate in protein, minerals, and vitamins, particularly calcium, zinc, phosphorous, and vitamins C and D.
- Avoid smoking.
- Limit alcohol consumption.
- Maintain optimum body weight or lose weight as is appropriate.
- Maintain mobility as is permitted, including range of motion exercises.
- Learn skin and/or pin care.
- Understand medication use.
- Know about signs of complications, such as infection and neurovascular compromise.
- Use assistive devices, if appropriate.
- Safety measures including fall prevention, if appropriate

Internal Fixation

Uses: Stabilization of fractures using pins, nails, rods, or screw plates.

Preparation: Food and fluid restriction

Postoperative course: Weight bearing limitations

Nursing Process Elements

- Provide pain management.
- Assess for neurovascular impairment.
- Skin assessment with appropriate skin care.

Client teaching for self-care

- Diet adequate in protein, minerals, and vitamins, particularly calcium, zinc, phosphorous, and vitamins C and D.
- Avoid smoking.
- Limit alcohol consumption.
- Maintain optimum body weight or lose weight as is appropriate.
- Maintain mobility as is permitted, including range of motion exercises.

- Learn skin and/or wound care
- Learn medication use
- Report signs of complications, such as infection and neurovascular compromise.
- Use of assistive devices, if appropriate.
- Observe safety measures including fall prevention, if appropriate.

TOTAL JOINT REPLACEMENT (HIP, KNEE)

Uses: Replacement of a joint with a synthetic prosthesis to restore mobility, stability, and relieve pain.

Preparation: NPO after midnight or as ordered by physician, education of client and family regarding expected postoperative regime (possible bed rest for up to 48 hours, range of motion exercises, physical therapy).

Postoperative course: Hip precautions if appropriate.

Nursing Process Elements

- Continuous passive motion (CPM) device for knee replacement
- Turn and reposition every 2 hours while on bed rest
- Hip precautions for hip surgery
- Maintain affected joint in proper body alignment
- Administer analgesics
- Monitor for complications, such as hypovolemic shock, fat emboli (S&S include apprehension, diaphoresis, fever, dyspnea, pulmonary effusion, tachycardia, seizure, decreased level of consciousness, petechia on chest and shoulders), infection, dislocation of hip replacement (S&S will include sudden severe pain, shortening or internal/external rotation of surgical leg)
- Assist client in performing range of motion exercises as appropriate

Client teaching for self-care

- Report S&S of infection
- Report to health care provider a sudden increase in pain (possible dislocation of prosthetic device)
- Continue exercise regime to promote function of joint replacement
- Follow limitations described by physician based on surgical procedure
 - Total hip precautions: do not cross legs or adduct operative leg beyond midline of body, avoid flexing hips more than 90 degrees when rising from bed or chair,

avoid turning affected leg inward, use high-seated chairs and raised toilet seat, do not flex hip to put on clothing
 —Total knee replacement: avoid bending or lifting, excessive stair climbing, sitting for prolonged periods, overuse of replaced joint

DISKECTOMY/LAMINECTOMY

Uses: Relieve pressure on the spinal cord or nerve roots due to a herniated disc (herniated nucleus pulposus)

Preparation: NPO after midnight or when indicated by physician, baseline assessment of motor function and sensation, demonstrate logrolling

Postoperative course: Cervical discectomy: a cervical collar is worn for approximately 6 weeks. Laminectomy: gradually increase activity over a 6-week period and avoid heavy work for 2–3 months; may need to wear a back brace or corset if pain continues.

Nursing Process Elements

- Bed rest as ordered by the physician
- Maintain head of bed flat for first 24 hours with client in supine position
- Maintain body alignment when in side-lying position with knees flexed to chest and pillow between knees
- Assess neurovascular status
- Logrolling to maintain body alignment
- Administration of analgesics

Client teaching for self-care

- S&S of surgical site infection
- Gradual resumption of activities as directed by physician

- Maintain and use proper body mechanics
- Sleep on firm surface

SPINAL FUSION

Uses: Grafting of bone chips between vertebral spaces to stabilize the spine.

Preparation: NPO after midnight or when indicated by physician, baseline assessment of motor function and sensation.

Postoperative course: Activity restrictions including prolonged sitting, lifting heavy objects, bending over, and climbing long flights of stairs.

Nursing Process Elements

- Bed rest as ordered by the physician
- Maintain head of bed flat for first 24 hours with client in supine position
- Maintain body alignment when in side-lying position with knees flexed to chest and pillow between knees
- Assess neurovascular status
- Logrolling to maintain body alignment
- Administration of analgesics

Client teaching for self-care

- S&S of surgical site infection
- Gradual resumption of activities as directed by physician
- Maintain and use proper body mechanics
- Sleep on firm surface

GASTROINTESTINAL (GI) SURGERY

General considerations:

- Clients having GI surgery are at particular risk for
 - Infection
 - abdominal wall—very susceptible to infection
 - GI tract not sterile

- risk greater with intestinal as opposed to gastric surgery
- Wound dehiscence
 - Predisposing factors: stress from breathing, coughing, moving, defecating; nutritional deficits, and postoperative abdominal distention

- Prevention: careful nutritional and F&E assessment and replacement preoperatively; protein and vitamin C for wound healing, NG tube for decompression postoperative.

—Ileus
 —Atelectasis
 —Urinary retention

Nursing Process Elements

- Monitor for signs of peritoneal irritation caused by leaking of the suture line
- Assess for return of peristalsis: check for bowel sounds, passage of flatus, and feces
- Check for presence of bowel sounds and a soft, nondistended abdomen, which indicate that oral intake can be resumed.
- Teach client to splint abdomen with pillows when coughing,
- When surgery will involve an upper abdominal incision, preoperative respiratory assessment and instruction on coughing and deep-breathing techniques is critical because the location of the incision near the diaphragm tends to limit respiratory excursion. Postoperatively, respiratory status should be checked initially every hour, then at least q 4 hour. Look for shallow or guarded breathing, weak cough, decreased or adventitious breath sounds.
- Injury to the suture line can occur if GI suction is not functioning correctly. Nausea and abdominal distention are signs of malfunction. Measure girth to check for developing distention.
- Fever occurring 4–7 days postoperative suggests a leak at the anastomosis or a wound abscess

GASTRECTOMY

- Total or subtotal: excision of all or part of the stomach
 - Total: esophagus sutured to duodenum or jejunum
 - Subtotal: Billroth I/II
 - Billroth I: pyloric portion of stomach is removed; remaining stomach sutured to duodenum (gastro-duodenostomy)
 - Billroth II: pyloric portion of the stomach is removed; end of duodenum is sutured closed, and a gastrojejunostomy is done.

Uses: Removal of tumors or chronic ulcers; stop bleeding from a perforated ulcer.

Preparation:

- Fluid diet ×24 hours then NPO after MN before surgery.
- Parenteral nutrition for protein replacement PRN
- Vitamin K and C supplementation PRN

Postoperative course: NPO on IV therapy until BS return and NG tube removed, then clear fluids progressed to six small, bland meals with 120 ml fluid between.

Nursing Process Elements

- Assess preoperative nutritional status: dietary history, weight loss or gain, signs of dehydration, serum electrolyte, and albumin levels
- Assess amount and character of NG tube drainage: expect it to be bloody for 24 hours, then changing to brown-tinged, and then to yellow or clear. Fecal odor indicates regurgitation of large intestine contents into operative area

Assessment Alert

NG drainage decreases as peristalsis returns and is less after total than after partial gastrectomy.

Nursing Intervention Alert

Measure abdominal girth to check for development of abdominal distention; notify surgeon if it occurs.

- Assess for bowel sounds, flatus, and defecation
- Assess tolerance of fluids and foods when oral intake resumed
- Assess for signs of dumping syndrome: N&V and diarrhea
- Do not give fluids with meals to prevent early satiety

Client teaching for self-care

- Decrease S&S of dumping syndrome by
 - eating six small meals per day of dry foods;
 - not drinking fluids with meals;
 - avoiding concentrated carbohydrates;
 - lying down for 30–60 minutes after eating;
 - avoiding very hot or very cold foods; and
 - taking prescribed anticholinergic drugs 30 minutes before meals as prescribed.
- Control postprandial hypoglycemia by
 - eating frequent meals low in sugar and
 - ingesting sugar or hard candy when symptoms occur.
- Report persistent fatigue which could indicate iron or B12 deficiency

FUNDOPLICATION

- Fundoplication is an antireflux procedure in which the gastric fundus is wrapped around the LES to stabilize it. It may be done laparoscopically or via open chest or abdomen.

Nursing Process Elements

Prevention of respiratory complications is primary concern.

INTESTINAL RESECTION

Intestinal resection is excision of part of the small or large bowel; with anastomosis, intestine is rejoined and function is normal; without anastomosis, an ostomy is created.

Uses: Removal of neoplasms, areas of obstruction, inflammatory bowel disease, ischemic or traumatic injury or perforated diverticulum.

Preparation:

- Extensive bowel cleansing: Low residue diet followed by liquid diet for 24 hours before surgery so stool does not collect; liquid preparations and/or series of enemas to empty bowel; nonabsorbable antiinfective such as neomycin, kanamycin sulfate, or succinylsulfathiazole to disinfect the bowel.
- Fluid electrolytes, vitamins C and K for wound healing and clotting, and PRN for protein as needed to make up preoperative deficiencies/losses.
- Insertion of NG or intestinal tube to remove secretions and prevent vomiting until peristalsis returns.
- Insertion of an indwelling urinary catheter because urinary retention is common after intestinal surgery, especially if on the colon or rectum.

Postoperative course: IV fluids, PRN, tube for low intermittent suction until bowel sounds return and suture lines begin to heal; when tube removed, clear fluids progressing to regular diet as tolerated.

Nursing Process Elements

- Assess NG or intestinal tube for patency and amount and color of drainage q 4 hours (drainage may be bloody for 24 hours, then turns brown tinged, to yellow or clear and should decrease in 24–48 hours), S&S of fluid imbalance, serum electrolyte values, and I&O
- Measure abdominal girth to check for developing distention
- Semi-Fowler's position to relieve stress on the suture line
- Ambulate and use of rectal tube to promote peristalsis and relieve gas pains

Clinical Alert

Jejunum resection results in malabsorption of fluids, electrolytes, fat, and fat-soluble vitamins (A, D, E, K).

Ileal resection results in malabsorption of fat and vitamin B12.

Resections involving the ileocecal valve frequently result in diarrhea.

Weight loss expected after almost all bowel resections; regained over a period of months.

ILEOSTOMY

- Surgically created opening between the ileum and the abdominal wall.
- Ileum is brought to the surface of the abdomen and formed into a stoma through which fecal material exits the body.
- Abdominal perineal resection: Ileostomy is created and remaining colon, rectum and anus are removed and the anal canal is closed.
- Continent or Kock ileostomy: A reservoir with a nipple to prevent leakage, is constructed from the ileum to hold fecal material until it is drained by the insertion of a catheter through the nipple.

Use: To treat recurrent or advanced inflammatory bowel disease (considered a cure for ulcerative colitis; sometimes used to treat Crohn's disease) and cancer of the colon.

Preparation:

- Emotional support including arranging for a visit with an ostomate if desired
- Referral to an enterostomal specialist for stoma site selection
- Bowel preparation that includes a variety of cathartics, enemas, and intestinal antibiotics; a low-fiber diet several days prior to surgery; a clear fluid diet the day before surgery

Postoperative course:

IV fluids; NPO with NG tube to low suction; frequent stoma care; monitoring of fluid and electrolytes; assessment of bowel sounds; pain management; wound care; progressive diet; and activity.

Nursing Process Elements

- Assess stoma: should be pink or red, moist and protrude 2 cm from the abdominal wall

Assessment Alert

A dusky, dark brown, black, or white stoma indicates a lack of circulation.

- Expect stoma drainage to be serosanguineous and contain mucus at first with fecal drainage beginning between days 2 and 4
- Take regular measurements of stoma size and cut the opening of the appliance so that it is no more than one-eighth of an inch bigger than the stoma; size changes as edema subsides starting between days 5 and 7 and reaching final size by week 8
- Empty the pouch when it is one-third full to prevent excessive pulling on the skin
- Record I&O, including output from the stoma
- Assess for fluid and electrolyte imbalances: large amounts of water, sodium, and potassium can be lost in the initial postoperative period in the fecal discharge
- Protect peristomal skin from contact with fecal drainage
- Cleanse skin with warm water and skin cleanser and pat dry
- Apply skin sealants under pouch adhesives and skin barrier paste around the stoma base
- If an abdominoperineal resection, provide care for perineal wound that may be either packed or sutured: may take Sitz baths after packing is removed

Nursing Intervention Alert

No rectal procedures, including, temperatures are possible with an abdominal perineal resection because the anal canal is closed.

Client teaching for self-care

- How to assess stoma and peristomal skin; empty, change, and apply ostomy appliances
- Encourage adequate fluid and salt intake, especially if perspiring
- Consume foods high in potassium (bananas, melons, oranges, avocados, yogurt, and potatoes) because of potassium loss through ileostomy drainage
- Recognize signs of fluid and electrolyte imbalances:
 - Decreased urine output
 - Excessive thirst
 - Weakness, dizziness, and light-headedness

—Muscle and abdominal cramps

—N&V

- Avoid gas-producing foods, as well as foods that may cause blockage such as popcorn, raw fruits, and vegetables with or without skins, nuts, or seeds
- Chew all foods thoroughly
- Avoid eating large meals close to bedtime because food passes through an ileostomy in 4–6 hours
- Recognize signs of obstruction: decreased fecal drainage or crampy abdominal pain
- Use warm shower/tub bath, peristomal massage, knee–chest position, pouch change to treat obstruction; seek medical attention if unrelieved.
- Assist client to achieve a positive self-concept:
 - Encourage verbalizations about stoma
 - Facilitate contact with the local chapter of the United Ostomy Association if not done preoperatively
 - Assure clients they can resume all regular activities

COLOSTOMY

- Surgically created opening between the colon and the wall of the abdomen named for the part of the colon from which they are formed: ascending colostomy, transverse colostomy, descending colostomy or sigmoid colostomy.
- Colon is brought to the surface of the abdomen and formed into a stoma through which fecal material exits the body.
- Consistency of fecal matter varies with location of colostomy: the closer the colostomy to the rectum, the more of the water-absorbing function of the colon is conserved so the less liquid is the fecal matter. With a descending colon colostomy, a bag is sometimes not needed because predictable elimination through the colostomy can be obtained with diet regulation and/or irrigation.
- May be temporary or permanent; if temporary, once the inflammation or trauma to the bowel has been resolved, the ends of the colon are reanastomosed and placed back into the abdominal cavity.
- May be single barreled (one stoma formed from end of bowel proximal to the incision: [fecal matter] exits the GI tract through this stoma because the proximal bowel is the section that remains continuous with the upper GI tract through which food enters) or double barreled (two stomas, one being the end of the proximal section of bowel and one being the end of the distal section of the bowel, which connects to the rectum).
- Due to placement of the colostomy in the large bowel, clients usually do not have the fluid and electrolyte problems associated with ileostomies.

Use: To treat cancer of the colon/rectum; bowel obstruction; bowel inflammation; and intestinal trauma.

Preparation and postoperative course: See “Ileostomy.”

Nursing Process Elements

- Stoma and skin care as for ileostomy
- If the colostomy is double barreled, expect the proximal stoma to drain feces and the distal stoma to drain mucus
- Other activities as for ileostomy

Client teaching for self-care

- How to assess stoma and peristomal skin and empty, change, and apply ostomy appliances
- Dietary guidelines
- Dietary adjustments vary from individual to individual and in fact, no alteration may be needed
- To limit gas, avoid gas-forming foods: beans, cabbage, eggs, peas, carbonated drinks, broccoli, cauliflower, dairy products; also avoid gas-producing behaviors: gum chewing, skipping meals, and smoking.
- To improve consistency of stool, avoid foods that loosen stool: fried foods, spicy foods, chocolate, raw fruits, and vegetables.
- To limit odor, avoid foods that increase fecal odor: garlic, onions, eggs, cabbage, asparagus, fish, etc.
- Irrigate the colostomy to achieve regularity if so directed: instillation of water into the colostomy stimulates peristalsis and results in the movement of fecal material.

APPENDECTOMY

Appendectomy is the removal of appendix under either local or general anesthesia; it may be done laparoscopically if uncomplicated.

Use: Usual treatment of appendicitis.

Preparation: Usual preoperative care, prophylactic IV antibiotics, NG tube inserted if ileus suspected

Postoperative course: Fluids when alert progressing to regular diet as tolerated; activity as tolerated as soon as alert; discharge may be same day or in 1–3 days.

Nursing Process Elements

- Place client in Fowler's position when recovered from anesthesia.
- Recognize that client/family may be anxious and need information because of limited preoperative teaching due to emergency nature of the surgery.
- Assess for return of bowel sounds and tolerance of p.o. intake when resumed.
- Assess for S&S of complications.

Client teaching for self-care

- Wash incision with soap and warm water daily; Steri-Strips if present will fall off by themselves.
- Avoid clothing such as bikini underwear that puts pressure on incision.
- Inspect incision daily and report increased redness, swelling, or drainage.
- Resume normal activities gradually over 2–3 weeks and avoid strenuous exercise and heavy lifting.
- Eat small, frequent high-calorie meals and increase as tolerated.
- Report chills, fever, or increased pain.

HERNIORRHAPHY

- Herniorrhaphy is permanent surgical reduction of a hernia sometimes with mesh reinforcement; it may be done laparoscopically; intestinal resection is necessary if herniated intestine is necrotic.
- It is as an emergency procedure in cases of incarceration and strangulation.

Use: Repair hernia to relieve or prevent strangulation.

Complications: Infection, hemorrhage, compromise of the vas deferens.

Nursing Process Elements

- Assess for respiratory infection, chronic cough, or allergies since postoperative coughing and sneezing can disrupt the repair. Surgery may be delayed or antihistamines ordered.
- Urination may be difficult after surgery especially during the first 8 hours after an inguinal repair—measure I&O; observe and palpate suprapubic area for bladder distention; report distention.
- Assess for pain and scrotal swelling that usually last 24–48 hours.
- Discourage coughing but encourage turning and deep breathing.
- Elevate scrotum and apply ice packs when in bed; scrotal support when OOB.
- Instruct to splint incision with hands or pillow if must cough or sneeze; also sneeze with mouth open. Avoid straining at stool to avoid pull on suture line.

Client teaching for self-care

- Report difficulty urinating.

- Resume nonstrenuous activities gradually over 5–7 days.
- Avoid heavy lifting or sexual activity for 6–8 weeks or as specified by surgeon.
- Avoid straining at stool: eat a high-residue diet; drink at least 2000 cc/d of fluid; take stool softeners as ordered.
- Wear scrotal support if ordered.

BARIATRIC SURGERY

Bariatric surgery is a surgical procedure designed to aid weight loss. It can be done through an open abdominal incision or laparoscopically. Lifestyle changes are necessary in addition to the surgery for weight loss goals to be reached.

Use: To assist with weight loss in clients who have Body Mass Index (BMI) of 40 or greater or BMI of 35 and a serious medical condition related to obesity.

Other desirable characteristics of candidates for bariatric surgery are

- history of obesity for at least 5 years with serious, but unsuccessful attempts to lose weight using other approaches;
- no history of alcohol abuse, depression, or other major emotional disorder; and
- age between 18 and 65 years.

RESTRICTIVE OPERATIONS

- Restrictive operations lead to decrease in the size of the stomach resulting in a sense of fullness after eating less food to limit the amount of food and number of calories consumed.
 - Stomach stapling (vertical banded gastroplasty)
 - Surgical staples and a plastic band are used to make a small pouch at the top of the stomach, which holds only half to one cup of food before an uncomfortable feeling of fullness occurs
 - Gastric banding: Small band around the upper stomach creates a pouch like that in stapling but the band can be inflated or deflated to change the size of the opening between the pouch and the stomach depending on the need of the client

Postoperative course: Studies estimate that about 80% of clients lose some weight and about 30% drop to normal weight; a significant number regain the lost weight in 3–5 years.

Complications: Infection in the incision or peritonitis from a leak of gastric contents into the abdominal cavity; pulmonary embolism; development of gallstones or anemia or osteoporosis from malnutrition. Second surgery may be needed if stomal stenosis causing N&V or esophageal reflux occurs or if staples loosen, or bands slip.

Client teaching for self-care

- Resume normal activities within 3–5 weeks.
- Chew food well and stop eating when you feel full which will be after eating only a cup or less of food.
- N&V or other discomfort will develop if too much food is eaten or it is not chewed well.
- Repeated overeating can stretch the pouch, eliminating any benefit from the surgery.
- Nutritional problems can develop and you may need to take vitamins or other supplements.
- Liquids and foods that contain little or no fiber can pass through the pouch more quickly than meats, fruits, and vegetables so drinking high-calorie liquid such as soda or milk shakes or eating a diet high in highly refined foods can limit weight loss or cause weight to be regained.

GASTRIC BYPASS PROCEDURES

- Gastric bypass procedures involve construction of a gastric pouch to restrict food intake along with a bypass of the lower stomach and upper small intestine so fewer nutrients and, therefore, fewer calories are absorbed.
- This creates a state of malabsorption.

ROUX-EN-Y GASTRIC BYPASS (RGB)

After the stomach is stapled or banded to form a gastric pouch, a Y-shaped section of the small intestine is attached to the pouch to allow food to bypass the duodenum as well as the first portion of the jejunum.

BILIOPANCREATIC DIVERSION

After the stomach is stapled or banded to form a gastric pouch, remainder of the stomach is removed and the pouch is connected directly to the ileum, completely bypassing both the duodenum and jejunum.

Complications:

- Bypass surgery has the same complications as the restrictive procedures but the risk of nutritional deficiency (B12 and iron in particular) is increased, with the greatest risk associated with biliopancreatic bypass.
- May cause “dumping syndrome,” with its symptoms of nausea, weakness, sweating, faintness, and, occasionally, diarrhea after eating and the inability to tolerate high-carbohydrate foods.

**Nursing Process Elements****Client teaching for self-care**

See Restrictive procedures above. Also refer to section on GI surgery.

HEPATIC AND BILIARY TRACT SURGERY

CHOLECYSTECTOMY

Cholecystectomy is the removal of gall bladder; most done laparoscopically, open done if acute inflammation or adhesions are present; T tube is placed into common bile duct if duct is explored.

Use: Treat cholelithiasis and cholecystitis

Preparation: Food and fluid restriction, cleansing enemas, NG tube and urinary catheter before laparoscopic procedures to decompress stomach and bladder and decrease the risk of accidental perforation.

Assessment Alert

Check PT of clients with obstructive jaundice. vitamin K may be needed before surgery.

Postoperative course: Laparoscopic: minimal pain

Open:

- Serosanguinous drainage with small amount of bile expected from Penrose drain in first 24 hours; drain removed in 48 hours
- T-tube drainage of 500 ml in first 24 hours, decreasing to about 200 ml/24 hours for next 3–4 days; initially bloody then green–brown
- Diet progressed as tolerated, dietary fat may be limited temporarily
- Excess bile drainage may be returned to client via NG tube to prevent electrolyte imbalance or synthetic bile salts given

**Nursing Process Elements**

Laparoscopic cholecystectomy:

- Assess for pain referred to the right shoulder secondary to pressure on the phrenic nerve from carbon dioxide insufflated into the abdomen during the procedure.
- Position in left Sims' for comfort.
- Encourage ambulation to promote CO₂ absorption.

**Client teaching for self-care**

- Take oral analgesics as prescribed for pain.
- Resume usual activities gradually over 3 days; avoid heavy lifting for 10.
- Report increased redness, swelling, or the appearance of bile-colored drainage at the puncture sites.

**Nursing Process Elements**

Open cholecystectomy:

- Medicate for pain; Demerol is generally drug of choice; opiates can increase biliary duct spasm.
- Assess respiratory status.
- Coach in deep breathing; because of pain secondary to location of incision near the diaphragm, breathing tends to be shallow.
- Position in semi-Fowler's or on side; turn frequently.
- Splint incision when moving, coughing, or deep breathing.
- Monitor I&O; include T tube drainage in output measurement every shift.
- Monitor for displacement of T tube: bile drainage at tube exit site may indicate displacement.
- Check T-tube patency and amount and character of drainage.
- Maintain closed gravity T-tube drainage system.
- Keep drainage bag below level of T tube.
- Keep tubing free of pressure, tension, and kinks.
- Monitor skin around drain(s) and cleanse often since bile extremely irritating.
- Monitor stool and urine color. Expect light stools while bile is exiting T tube; color darkens as T-tube drainage decreases.
- Assess for signs of peritonitis.

Assessment Alert

A sudden increase in T-tube drainage after it has diminished can indicate an obstruction below the T tube. Report immediately.

Nursing Intervention Alert

Never irrigate, aspirate, or clamp a T tube; back pressure may disrupt suture line. Exception: T tube may be ordered to be clamped 1 hour ac and pc to check client's tolerance to elimination of external drainage. Immediately unclamp tube and notify surgeon if distress occurs.

Client teaching for self-care

- If discharged with a T tube, instruct in care of tube as stated above with the following additional directions:

- Avoid tight-fitting clothing, which can irritate wound and put pressure on tube.
- Wear clothing that can be washed in a solution of detergent, bleach and baking soda if bile staining occurs.
- Drain the bile bag at the same time each day and record amount of drainage.
- Take showers, not baths, to minimize bacterial contamination of the wound.
- Resume normal activities gradually; avoid heavy lifting for at least 6 weeks.
- Report signs of complications: fever, pain, foul drainage, N&V, jaundice, dark urine, and pale stools.

ENDOCRINE SURGERY

HYPOPHYSECTOMY

- Hypophysectomy involves removal of the pituitary gland.
- It is used for treatment of pituitary adenoma.
- It may be total or subtotal.
 - Total hypophysectomy
 - Used if adenoma has spread outside sella turcica.
 - Performed through a transfrontal craniotomy.
 - Results in panhypopituitarism requiring lifelong hormone replacement due to the absence of ACTH, thyrotropin, and the gonadotropins.
 - Subtotal hypophysectomy
 - Uses transsphenoidal microsurgery with entry of instruments through an incision in the mouth at the junction of the gum and the upper lip or may be through the nose.
 - Dura mater may be patched with fascia or muscle from leg to prevent leakage of CSF.
 - Nose is packed to absorb drainage and a gauze dressing or sling is placed under the nose.

Complications: Transient diabetes insipidus from damage to the posterior pituitary is most common; also can be ICP, cerebrospinal fluid leak, visual impairment, and other hormonal dysfunction.

Preparation: Antibiotic therapy as prophylaxis against meningitis

Postoperative course:

- Pain similar to a headache occurs and is controlled with low dose narcotics.
- Nasal packing removed in 24 hours.

- Dura mater should seal in 72 hours.
- Prophylactic antibiotic therapy is given.

Nursing Process Elements

- Assess neurological status to detect early signs of increased pressure from cerebral edema: monitor for restlessness, lethargy, confusion, bradycardia, widening pulse pressure, dilated pupils, double or blurred vision, and weakening of lifts and grips.
- Elevate head of bed 30 degrees to reduce cerebral edema.
- Assess for signs of CSF leak: frequent swallowing, complaints of a postnasal drip, or rapid saturation of gauze under nose.
- Test any nasal drainage for glucose: presence of glucose is indicative of CSF because nasal secretions do not contain glucose.
- Coach the client in taking five deep breaths every half hour postoperatively to support ventilation but caution not to cough.
- Medicate promptly for nausea because if vomiting occurs, ICP is raised.
- Measure I&O to detect onset of diabetes insipidus.

Assessment Alert

If output is more than 100 ml/hr, notify the physician.

- Change pad under nostrils as soon as soiled to eliminate medium for bacterial growth.
- Provide frequent oral hygiene using mouthwash or a foam toothette (no bristles because of risk of mechanical trauma to incision line) to keep the incision line clean.
- Assess changes in S&S related to endocrine function.
- Assess for signs of meningitis such as nuchal rigidity and severe headache.

Client teaching for self-care

Avoid all activities that increase ICP such as bending, sneezing, coughing, or vigorous hair brushing because increased ICP can cause leaking of CSF.

THYROIDECTOMY

- Removal of the thyroid gland; may be total or subtotal
 - Total thyroidectomy requires lifelong thyroid hormone replacement therapy
 - Subtotal thyroidectomy: enough gland is left to produce needed thyroid hormone without replacement therapy; in cases of thyroid cancer, lifelong thyroid hormone replacement may be used to suppress thyroid function and decrease risk of recurrence

Use: Treat thyroid cancer, or relieve dyspnea or dysphagia resulting from pressure on the esophagus or trachea from an enlarged thyroid gland.

Preparation: Restore a euthyroid state to the extent possible.

- Antithyroid medications to reduce hormone levels
- Iodine preparations to decrease size and vascularity of the gland thereby reducing the risk of hemorrhage associated with surgery

Postoperative course:

- Temporary hoarseness may occur due to placement of the endotracheal tube or edema; permanent hoarseness can result from injury to the laryngeal nerve
- Humidification provided to facilitate respiration
- Risk of hemorrhage greatest in first 12–24 hours postoperatively
- Tetany may occur 1–7 days after surgery if parathyroid glands were removed inadvertently or injured

Complications: Recurrent laryngeal nerve injury, hemorrhage, transient hypocalcemia, and respiratory obstruction.

Nursing Process Elements

- Monitor for respiratory distress that can occur if edema or bleeding compresses the trachea and blocks airflow; if laryngeal spasm occurs due to hypocalcemic tetany

secondary to injury or removal of the parathyroid glands; or vocal cord spasm secondary to laryngeal nerve damage.

Assessment Alert

Onset of tetany from injury to the parathyroid glands is typically in 24–48 hours.

- Assess for hoarseness, which may simply indicate temporary irritation from intubation or may be the first sign of recurrent laryngeal nerve damage, which can lead to spasm of the vocal cords and respiratory distress.

Nursing Intervention Alert

Keep a tracheostomy set, oxygen and suction equipment immediately available to the bedside.

- Monitor pulse and BP for signs of hypovolemic shock.
- Assess for bleeding: check dressing and under the client's neck and shoulders because blood may pool there as a result of gravity.
- Check tightness of dressing: dressing may become too tight as a result of bleeding in the operative area.

Nursing Intervention Alert

If hemorrhage causes compression of the trachea and respiratory distress, loosen the dressing immediately. If distress is not relieved, notify surgeon immediately as sutures or clips may need to be removed.

- Ask the client to speak out loud and note changes in quality or tone from preoperative assessment.
- Monitor for hypocalcemia and onset of tetany: check serum calcium levels and assess for numbness and tingling in the extremities, muscle twitching, positive Chvostek's and Trousseau's signs.

Nursing Intervention Alert

Make certain IV calcium gluconate or calcium chloride is immediately available to the bedside.

- Position in semi-Fowler's with head and neck supported with pillows to reduce strain on suture line.

Client teaching for self-care

- Preoperative teaching: How to decrease strain on the suture line when moving, sitting up in bed, or coughing by placing both hands behind the neck.
- Reassure client that scar will heal to a thin line, which can be covered with a collar, scarf, or piece of jewelry.
- If hypocalcemia has occurred, reinforce need to take oral calcium supplements until parathyroid function has returned.

PARATHYROIDECTOMY

- Parathyroidectomy is the removal of one or more abnormally enlarged parathyroid glands through a 5–6-cm transverse incision in the neck under general anesthesia.
- When multiple glands are removed, some of the excised parathyroid tissue excised is autotransplanted in the client's forearm.

Use: Treatment of primary hyperparathyroidism.

Preparation: Parathyroid hormone levels are determined.

Postoperative course:

- Parathyroid hormone levels are drawn in the operating room to confirm the abnormal glands have been removed
- Presence of an incisional drain is common
- Serum ionized calcium levels decrease to near normal levels 24–48 hours postoperatively
- Transient tetany may occur due to sudden drop in calcium concentration and the rapid absorption of serum calcium by the demineralized bone
- 1–2 days' hospitalization
- If all the glands are removed, high-calcium diet and calcium and vitamin D supplements are prescribed for several months until bone recalcification stabilizes
- Renal damage that occurred prior to surgery may be irreversible
- Bony deformities are permanent
- Complications: airway obstruction, paralysis of vocal cords, temporary or permanent hoarseness due to injury or inflammation of the vocal nerve, or hypocalcemia

Nursing Process Elements

- Monitor serum calcium levels: should drop to near normal in 24–48 hours.
- Assess for symptoms of tetany: tingling and spasms of the extremities. Positive Chvostek's and Trousseau's signs.

- Keep tracheostomy set immediately available at bedside.
- If parathyroid tissue autotransplanted, be certain to check condition of both the cervical incision and the site of transplant.

Client teaching for self-care

- Increase fluid intake before being NPO to decrease risk of renal calculi.
- Dressing changes and care of the incision.
- Inspect the incision daily.
- Report occurrence of any of the following symptoms:
 - Tingling and spasms of the extremities
 - Fever
 - Warmth, redness, or swelling around the incision
 - Drainage
- Resume normal activities after 1–2 weeks of rest

ADRENALECTOMY

- Surgical removal of one or both adrenal glands.
- Performed under general anesthesia using an open incision or laparoscopic approach.

Use: Cancer of the adrenal; benign tumors such as aldosterone-secreting adenoma and pheochromocytoma or idiopathic hyperplasia, which excrete hormones causing severe Cushing's syndrome. Also an option for pituitary-dependent Cushing's syndrome (Cushing's disease) when transsphenoidal hypophysectomy is contraindicated.

Postoperative course:

- Continuous hemodynamic monitoring (CVP, BP, P, and sometimes pulmonary capillary wedge pressure) to guide maintenance of fluid and electrolyte balance
- Fluids usually include saline–dextrose solutions
- IV cortisol replacement for 24–48 hours
- On postoperative day 2, mineralocorticoid replacement is begun
- Lifelong glucocorticoid and mineralocorticoid replacement is required after bilateral adrenalectomy
- After unilateral adrenalectomy, temporary physiologic cortisol replacement may be needed because of suppression of the normal ACTH-adrenal axis. Cortisol doses are gradually tapered off but replacement may be needed for 6 months to 2 years
- 4–5-days' hospitalization with an open adrenalectomy and 2–3 days with a laparoscopic adrenalectomy
- Generally, no restrictions after a laparoscopic adrenalectomy

Complications: Adrenal crisis, hypo or hypertension, high or low blood glucose, fluid and electrolyte imbalance.

Nursing Process Elements

- Maintain invasive hemodynamic monitoring.
- Monitor serum electrolytes daily.
- Monitor blood glucose every 4 hours.
- Keep hourly I&O record.
- Weigh client daily.
- Assess for signs that glucocorticoid dosage need to be increased: marked weakness, anorexia, N&V
- Maintain strict aseptic technique during wound care and avoid exposure to sources of contagion because infection is a significant risk due to excess cortisol.
- Alternate care activities with rest periods because the client may have significant activity intolerance.
- Protect from effects of orthostatic hypotension: change position slowly, assist with ambulation, and apply elastic stockings.
- Assist with ambulation until BP stabilizes.

Client teaching for self-care

- Protocol for prescribed hormone replacement therapy.
- Keep bandages clean and dry.
- After laparoscopic adrenalectomy, return to normal activities such as showering, driving, walking up stairs, light lifting, and work as soon as you feel comfortable.
- Avoid heavy lifting or straining for 6–8 weeks after open surgery.
- Do not drive if taking narcotic medications for pain.
- Notify the surgeon if any of the following symptoms occur.
- Fever.
- Worsening pain.
- Redness, swelling, or warmth to the touch around the incision.
- Drainage from the incision.
- Follow dietary guidelines that often include restriction of calories, sodium, lipids, and cholesterol.
- Keep follow-up appointment 2 weeks after the procedure.

URINARY SURGERY

NEPHRECTOMY

Nephrectomy is the removal of kidney either laparoscopically through three small incisions in the abdomen and flank, or open (radical) through a larger transabdominal, flank, or extraperitoneal incision. Radical nephrectomy, performed to prevent metastasis, includes removal of the kidney, adrenal gland, proximal ureter, renal artery and vein, and surrounding fascia.

Use: Remove cancerous or diseased kidney; remove healthy kidney for donation.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, cleansing enema, surgical skin prep.

Postoperative course:

- Serosanguineous drainage expected; JP drain removed when decreased to less than 30 ml/d
- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels
- Incisional pain managed with opioid analgesics
- Diet progressed as tolerated
- Sutures/staples removed when healing by primary intention occurs (~7–10 days)
- Deep breathing, coughing, and incentive spirometry exercises reduce risk for postoperative pneumonia

Nursing Process Elements

- Assess BP, fluid and electrolyte balances carefully as these functions are controlled in part by the kidney.
- Medicate for pain.
- Assess cardiovascular and respiratory status.
- Coach in deep breathing exercises.
- Assess incision for evidence of wound healing.
- Monitor for S&S of infection.
- Keep JP drain compressed and empty when half full.
- Monitor urinary catheter drainage and perform routine catheter care.
- Teach about home care; refer for support as appropriate.

Clinical Alert

If both kidneys removed or remaining kidney functioning is impaired, renal replacement will be necessary with dialysis or kidney transplantation.

**Client teaching for self-care**

- Take oral analgesics as prescribed for pain.
- Splint incision when moving, coughing, or deep breathing.
- Resume usual activity gradually; avoid strenuous activity for 6 weeks.
- Report incisional redness, swelling, or drainage, unrelied pain, or temperature $\geq 101^{\circ}\text{F}$.
- Keep appointments for postoperative follow-up.

CYSTECTOMY

Cystectomy is the removal of all (radical) or part (segmental) of the bladder. Transurethral resection may be used for a partial cystectomy. Radical cystectomy requires a large abdominal incision and involves removing the entire bladder, nearby lymph nodes, part of the urethra, and establishing a urinary diversion. In males, radical cystectomy may also include removal of the prostate and seminal vesicles; in females, it may include removal of the anterior vaginal wall, uterus, cervix, fallopian tubes, and ovaries.

Use: Treat cancer that has invaded the bladder wall.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, cleansing enema, surgical skin prep, autologous blood donation.

Postoperative course:

- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels
- Transfusion may be required for significant perioperative blood loss
- Incisional pain managed with opioid analgesics
- Diet progressed as tolerated
- Activity increased gradually
- Serosanguineous drainage expected; JP drain removed when decreased to less than 30 ml/d
- Urine pink initially, but changes to clear by the third postoperative day
- Beefy red and edematous stoma expected; mucous discharge may be present
- Intermittent catheterization required for continent urostomy
- Sutures/staples removed when healing by primary intention occurs (~7–10 days)
- Surgical treatment often complemented with radiation and chemotherapy

**Clinical Alert**

In the immediate postoperative period following a partial cystectomy, bladder capacity is usually

less than 60 ml. Over several months time, elastic tissue of the bladder regenerates and capacity increases up to 400 ml.

**Nursing Process Elements**

- Encourage deep breathing exercises and promote early ambulation.
- Monitor patency and output of urinary catheters and surgical drains.
- Monitor for bright red blood on dressings or in urine.
- Administer analgesics to control pain.
- Provide opportunity to grieve and begin to cope with changes in body image and function.
- Assess for potential postoperative complications including infection, fistula formation, bowel obstruction, rectal injury, or sexual dysfunction.
- Arrange home care supplies.
- Refer to enterostomal therapy nurse and ostomy support group if urinary diversion created.

**Client teaching for self-care**

- Take oral analgesics as prescribed for pain.
- Splint incision when moving, coughing, or deep breathing.
- Resume usual activity gradually; avoid strenuous activity for 6 weeks.
- Report incisional redness, swelling, or drainage, unrelied pain, temperature $\geq 101^{\circ}\text{F}$, bloody urine, or decreased output.
- Assess stoma and surrounding skin daily.
- Follow instructions for ostomy management.
- Keep appointments for postoperative follow-up.

ILEAL CONDUIT

Ileal conduit is the most common urinary diversion procedure whereby the ureters are excised from the bladder and transplanted into a segment of resected ileum brought through the abdominal wall to the skin surface creating a stoma and allowing the ileal segment to function as a passageway for urine. The intestinal segment of the resection is then anastomosed and GI function returns to normal after healing.

Use: Divert urine postradical cystectomy or irreparable trauma to the bladder.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, bowel prep and intestinal antibiotics, surgical skin prep.

Postoperative course:

- Visualization of stoma, stents, and sutures created by transparent pouch
- Beefy red and edematous stoma expected; mucous discharge may also be present
- Urine pink initially, but changes to clear by the third postoperative day
- Pouch changed within 24–48 hours after surgery to allow greater visualization and assessment of stoma and peristomal skin
- Pouch positioned to drain to the side of the bed and valve opened for continuous drainage
- Pain managed with opioid analgesics
- Diet progressed as tolerated
- Activity increased gradually
- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels

**Nursing Process Elements**

- Encourage deep breathing exercises and promote early ambulation.
- Monitor patency and output of urinary catheters and surgical drains.
- Monitor for bright red blood on dressings or in urine.
- Restrict food and oral fluids if bowel sounds absent.
- Administer analgesics to control pain.
- Assess for potential complications including breakdown or leakage of the anastomosis, paralytic ileus, mucocutaneous separation, stomal necrosis, retraction, hernia, UTI, and peristomal skin irritation.
- Assist client to master self-care before discharge.
- Refer to enterostomal therapy nurse and ostomy support group.

**Client teaching for self-care**

- Increase oral fluid intake to 3 l/d.
- Keep urine acidic with cranberry juice and vitamin C.
- Uncover stoma during showering or bathing and pat gently, but do not scrub as tiny capillaries in the highly vascular stoma may cause it to bleed easily.
- Report any noticeable changes in color, texture, contour, or general appearance of stoma and surrounding skin.
- Wash and air-dry peristomal skin daily. Use prescribed cleaners and ointments as directed
- Use mirror to help center faceplate on the stoma.
- Empty bag every 2 hours; leg bags can be used for extra capacity.

- Report flank/back pain, fever, unusually strong smelling urine, dark urine, or reduction in output
- Keep a spare ostomy appliance available at all times in a clean drawer or box.
- Keep appointments for follow-up.

NEPHROSTOMY

Surgically created passageway maintained by a tube, stent, or catheter that perforates the skin, passes through the renal parenchyma, and terminates in the renal pelvis or calyx. The procedure is performed under fluoroscopy, ultrasonographic or CT scan guidance, or open surgery.

Use: Provides urinary drainage when ureter obstructed (renal stones, ureteral tumors, postoperative and radiation strictures, anatomical anomalies), and provides access to upper urinary tract for certain diagnostic or therapeutic procedures such as stone removal, radiography, or chemotherapy.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, surgical skin prep. Often performed as outpatient procedure.

**Clinical Alert**

Tight control of blood pressure is an essential preparation as uncontrolled hypertension increases the risk for developing perirenal hematoma or hemorrhage.

Postoperative course:

- Postobstructive diuresis can occur
- Urine pink initially, but changes to clear by the second postoperative day
- Asepsis maintained when changing nephrostomy dressing
- Pain managed with opioid analgesics

**Nursing Process Elements**

- Maintain hydration and voiding schedule.
- Maintain patency and dependent position of nephrostomy tube.
- Monitor patency and output of urinary catheters and perform routine catheter care.
- Strain urine for calculi and send specimen for analysis.
- Administer antibiotics and analgesics as prescribed.
- Assist client to master self-care before discharge.
- Monitor for complications including acute bleeding, pneumothorax, infection, impaired urinary elimination, or return of calculi.

**Client teaching for self-care**

- Increase oral fluid intake (up to 3 l/d).
- Take medication as directed.
- Strain urine as directed.
- Avoid bathing, swimming, strenuous activity, and sports until nephrostomy tube is removed.
- Keep dressing clean and dry; protect when showering.
- Change dressing daily as directed.
- Rinse external drainage bag and clean once a week with soap and warm water.
- Report redness, tenderness, or drainage at nephrostomy site, fever, urinary frequency or urgency, incontinence, painful or bloody urination, or recurrence of costovertebral pain.
- Keep appointments for follow-up.

URETEROSIGMOIDOSTOMY

In ureterosigmoidostomy, ureters are detached from the bladder and implanted into the sigmoid colon to drain urine, eliminating the need for an outside stoma.

Use: Uncommonly used urinary diversion procedure except in parts of the world where adhesive devices are unavailable or not practical because of tropical heat.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, bowel prep, and surgical skin prep.

Postoperative course:

- Pain managed with opioid analgesics
- Diet progressed as tolerated
- Activity increased gradually
- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels.

**Clinical Alert**

Neoplasia occurs at the anastomosis of the ureters and colon in 24% of clients with any urinary diversion that mixes urine and stool at 20 years of follow-up. An annual flexible sigmoidoscopy is recommended starting 10 years after surgery.

**Nursing Process Elements**

- Assess surgical incision for signs of healing or evidence of infection.

- Administer analgesics for pain as needed.
- Evaluate fluid and electrolyte status frequently.
- Report abnormal blood chemistry results.
- Monitor for potential complications including kidney infections from reflux of feces and biochemical blood changes.

**Client teaching for self-care**

- Take oral analgesics as prescribed for pain.
- Splint incision when moving, coughing, or deep breathing.
- Resume usual activity gradually; avoid strenuous activity for 6 weeks.
- Report incisional redness, swelling, or drainage, unrelied pain, temperature $\geq 101^{\circ}\text{F}$, costovertebral pain, significant changes in color, consistency, or amount of output.
- Keep appointments for postoperative follow-up.

CUTANEOUS URETEROSTOMY

In cutaneous ureterostomy, one (single ureterostomy) or both (bilateral ureterostomy) ureters are detached from the bladder and brought to the surface of the abdomen with the formation of a stoma to allow passage of urine. A double-barrel ureterostomy brings both ureters to the same side of the abdominal surface and a transuretero ureterostomy (TUU) brings both ureters through the same stoma.

Use: Urinary diversion postcystectomy or irreparable bladder damage.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, bowel prep, and surgical skin prep.

Postoperative course:

- Visualization of stoma and sutures created by transparent pouch
- Beefy red and edematous stoma expected; mucous discharge may also be present
- Urine pink initially, but changes to clear by the third postoperative day
- Pouch changed within 24–48 hours after surgery to allow greater visualization and assessment of stoma and peristomal skin
- Pouch positioned to drain to the side of the bed and valve opened for continuous drainage
- Pain managed with opioid analgesics
- Diet progressed as tolerated
- Activity increased gradually

- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels

Nursing Process Elements

- Assess surgical incision for signs of healing or evidence of infection.
- Assess color and appearance of the stoma and surrounding skin.
- Assess client and family's response to stoma and readiness to learn about stoma care
- Monitor fluid and electrolyte status.
- Monitor for potential complications including infection and anastomotic leaking.
- Assist client to master self-care before discharge.
- Refer to enterostomal therapy nurse and ostomy support group.

Client teaching for self-care

- Increase oral fluid intake to 3 l/d
- Keep urine acidic with cranberry juice and vitamin C.
- Uncover stoma during showering or bathing and pat gently, but do not scrub as tiny capillaries in the highly vascular stoma may cause it to bleed easily.
- Report any noticeable changes in color, texture, contour, or general appearance of stoma and surrounding skin.
- Wash and air-dry peristomal skin daily. Use prescribed cleaners and ointments as directed
- Use mirror to help center faceplate on the stoma.
- Use bag fitted with antireflux valve to prevent urine back-flow.
- Empty bag every 2 hours; leg bags can be used for extra capacity.
- Report flank/back pain, fever, unusually strong smelling urine, dark urine, or reduction in output.
- Keep a spare ostomy appliance available at all times in a clean drawer or box.
- Keep appointments for follow-up.

PROSTATECTOMY

Prostatectomy is the removal of all or part of the prostate gland through a transurethral resection (TURP) or lower abdominal incision (open surgery).

Use: Treatment of Benign Prostatic Hypertrophy (BPH) or prostate cancer.

Preparation: Informed consent, preoperative laboratory and diagnostic screening, food and fluid restriction, cessation of medications that impair clotting, surgical skin prep, preoperative teaching about procedure's effects on urinary elimination, sexual functioning and fertility, and the expected postoperative course.

Postoperative course:

- A 3-way urinary catheter (urethral or suprapubic) and bladder irrigation with sterile normal saline keeps urine pink-tinged
- Urine becomes clear by third postoperative day
- Catheter may be left in place for several weeks following open surgery
- Bladder spasms treated with antispasmodics
- Pain managed with opioid analgesics
- Diet progressed as tolerated
- Activity increased gradually
- Fluid and electrolytes balanced through IV therapy, and monitoring of I&O, daily weight, hematocrit, hemoglobin, and electrolyte levels
- Constipation prevented with stool softener, mild laxatives, and adequate hydration

Nursing Process Elements

- Monitor flow of irrigation solution.
- Monitor fluid and electrolyte status closely.
- Encourage hydration and voiding schedules.
- Monitor for potential complications including blood clots that interfere with urinary drainage, infection, infertility, impotence, and incontinence.
- Provide opportunity to express anxiety and begin to cope with changes in body image and function.
- Assess for S&S of embarrassment with female care provider; if necessary and possible, assign client to male nurse.
- Assist client to master self-care before discharge.
- Refer to support group.

Client teaching for self-care

- Take medication as prescribed.
- Increase oral fluid intake (up to 3 l/d).
- Void at regular intervals.
- Empty and measure urinary catheter every 8 hours.
- Keep drainage bag in dependent position to prevent reflux.
- Wash around catheter insertion site daily with mild soap and water.
- Avoid heavy lifting, climbing, driving, and sexual activity for 3 weeks.
- Avoid alcoholic beverages.

- Avoid antihistamines that increase risk for urinary retention.
- Report fever $\geq 101^{\circ}\text{F}$, symptoms of cloudy, foul-smelling, bloody, painful urination, or changes in urine stream.
- Anticipate ejaculate fluid to be projected into the bladder instead of through the penis.
- Keep appointments for follow-up care.

DERMATOLOGIC SURGERY

BIOPSIES

- Shave biopsy: Scalpel is used to shave lesion to depth of mid-dermis.
- Excision biopsy: Entire lesion is removed.
- Curettage: Lesion is scraped off the surface of skin.
In addition to biopsy, it is used to remove superficial skin lesions such as keratoses and nevi.
Heal by second intention.
- Punch biopsy: Punch devices removes a circle of tissue containing the lesion down to the level of the subcutaneous tissues
 - Removes deep lesions up to 10 mm in diameter
 - Allows for histological study
 - Requires sutures or healing by secondary intention

Cryosurgery: destruction of tissue takes place by topical application of a freezing substance such as liquid nitrogen.

- Used to remove a variety of benign and malignant lesions
- Depth of tissue destruction depends on degree of freeze
- Tingling pain occurs when freezing substance applied
- Tissue necrosis occurs in first 24 hours after surgery and a bulla forms; serous exudate during first week is followed by crust, which drops off in 3–4 weeks.
- Topical antibiotic applied to prevent infection
- No inflammation or bleeding usually occurs but hypopigmentation may result

Electrosurgery: destruction of tissue occurs with a high-frequency alternating current.

- Electrodesiccation
 - Superficial skin destruction
 - Used to remove surface lesions such as warts and angiomas
- Electrocoagulation
 - Deep skin destruction
 - Used to remove lesions such as superficial skin cancers other than melanoma and telangiectases
- Delayed bleeding may occur but is easily controlled with direct pressure

- Wound left exposed for air-drying or covered with dressing to protect from trauma

LASER SURGERY

Laser surgery is used to treat many skin lesions including port wine stains and telangiectases.

CHEMICAL DESTRUCTION OR PEELING

- Topical application of a chemical that destroys or peels lesions
- Crust forms overtreated area, sloughs in about a week
- Used to remove benign and premalignant lesions; cosmetic chemical peel done to smooth, firm, and remove wrinkles from skin

Nursing Process Elements

Client teaching for self-care

Skin surgery

- Need for aseptic technique including good hand washing when caring for wound.
- How and when to change dressings if used.
- Keep wound dry; do not remove any crust.
- Protect site from trauma and irritation.
- Cleanse gently as directed with pH neutral mild soap-like agent.
- Apply alcohol to promote drying if directed.
- Whether covering with makeup is permissible.
- Report signs of bleeding or infection (redness, edema, or pain).
- Avoid aspirin and other drugs affecting clotting for 7 days before and after surgery.

REPRODUCTIVE TRACT SURGERY

MASTECTOMY

- Mastectomy is the removal of breast.
- Total (simple) mastectomy: All breast tissue is removed but all or most axillary of the lymph nodes and chest muscles remain intact.
- Modified radical mastectomy: Entire breast, some or most lymph nodes, and sometimes the pectoralis minor chest muscles are removed. Major chest muscles are left intact.
- Radical (Halsted's) mastectomy: Rarely performed removal of the entire breast, skin, major and minor pectoral muscles, axillary lymph nodes, and sometimes internal mammary or supraclavicular lymph nodes.
- Mastectomy may be done with or without breast reconstruction.

Use: Treatment of breast cancer; occasionally prophylaxis for breast cancer in genetically positive women.

Preparation: Psychological: allow time for client to verbalize fears and anxieties; assess support systems and involve significant others as determined by client.

Postoperative course:

- IV fluids, strict I&Os, Foley catheter, elastic compression stockings while on bed rest, drain(s), incentive spirometer, diet progression as tolerated

Nursing Process Elements

- Keep arm on affected side moderately elevated to relieve discomfort, prevent tension on surgical site, and prevent venous congestion.
- Prepare client to look at the incision at the first dressing change by describing the incision.
- Empty drain regularly; recording amount each shift; noting the color and consistency.
- Start limited postoperative arm exercises within 24 hours after surgery.
- Encourage use of the affected arm for activities that do not require that the arm be abducted or raised above shoulder height until the drains are removed.

Nursing Intervention Alert

Place a sign on the woman's bed warning that no BP readings, injections, IV lines, or blood sampling should be performed on the arm on the operative side.

Client teaching for self-care

- Begin teaching wound care to client with first dressing change; have client demonstrate care of the drain and wound prior to discharge.
- Explain it is normal to have decreased sensation in the surgical area or to have phantom breast pain.
- Wear loose-fitting clothing.
- Gently massage healed incision with emollients.
- Hold affected arm appropriately—no dangling or swinging; place arm above heart level when sitting/lying down.
- Maintain well-balanced, nutritious meals and adequate fluid intake to promote healing.
- Gradually resume normal activities; schedule alternating rest and activity periods during day, especially when sitting/standing is prolonged.
- Continue exercise program for at least 1 year.
- Protect affected hand and arm from injury and infection: wear long sleeves and gloves when gardening, be cautious sewing and doing dishes, use potholders when handling hot items, avoid lifting or moving heavy objects, and do not carry purse or wear jewelry/wristwatch on affected side.
- Never allow BP to be taken, blood withdrawn, immunizations or medications injected, or IV fluids administered on the affected side.
- Seek medical evaluation for S&S of breast or arm infection: redness, warmth, edema, purulent wound drainage, fever/chills.
- Use positions for sex that avoid pressure on the chest wall; explore alternative forms of sexual expression such as cuddling, touching, and massage.
- Perform regular self-breast exam on unaffected breast; follow recommended schedule for mammography.
- Keep regular medical follow-up appointments.

LUMPECTOMY

- Lumpectomy is the removal of a cancerous mass from the breast along with some normal tissue for clean margins.
- An initial excisional biopsy may be the lumpectomy.
- Reexcision may be needed of the margins that are not clean in the original biopsy.

Use: Treatment of breast cancer.

Nursing Process Elements

- Assess for pain and medicate with mild analgesic as prescribed.
- Assess dressing for bleeding or drainage.
- Prepare client for wound by describing it to her before she views it.

Client teaching for self-care

- Wound care.
- Take oral analgesics as prescribed for pain.
- S&S of infection, hematoma formation, and over the long term, recurrence of breast cancer in the incision.
- Resume usual activities gradually over 3 days; avoid heavy lifting for 10 days.
- Keep follow-up appointment with health care provider for assessment of wound healing and review of pathology reports; discuss further treatment options as necessary.

VULVECTOMY

- Vulvectomy is the removal of abnormal tissue of the vulva, through procedures such as the skinning technique, local wide excision, or a simple or radical vulvectomy.
- *Simple vulvectomy*: removal of the labia majora, labia minora, and sometimes the glans.
- *Radical vulvectomy*: excision of tissue from the anus to a few centimeters below the symphysis pubis (skin, labia majora, labia minora, and clitoris); bilateral dissection of groin lymph.
- Nodes, superficial groin and deep inguinal, femoral, iliac, hypogastric, obturator, may also be done.

Use: Treatment of vulvar carcinoma.

Preparation: Psychosocial support; extensive counseling on what the procedure will entail and what to expect postoperatively; sexual counseling; NPO after midnight the night before procedure; shave of the perineal, pubic, and inguinal areas; vulva cleansing with hexachlorophene or povidone-iodine shower or scrub; enema to evacuate intestinal tract before surgery; Foley catheter insertion on the morning of the procedure

Postoperative course: IV fluids, drains with suction (Hemovac), compression stockings, Foley catheter, low-dose anticoagulant therapy, diet progression as tolerated, and analgesics.

Nursing Process Elements

- Assess for pain and medicate as prescribed.
- Monitor VS.

- Record I&O.
- Maintain low-Fowler's position to promote comfort and reduce tension on sutures.
- Change dressing frequently to keep wound clean and dry.
- Monitor drains and/or tubes for amount and color of drainage.
- Keep compression stockings on while on bed rest.
- Encourage early ambulation.
- Prevent straining with defecation by providing a low-residue diet initially with stool softeners.
- Maintain patency of urinary catheter and administer frequent peri-care.
- Give frequent Sitz baths, including after bowel movements.
- Encourage client to ventilate feelings about sexual mutilation.
- Help client explore alternate methods of sexual intimacy and encourage her to discuss feelings with her partner.
- Encourage sexual counseling.

Client teaching for self-care

- Teach client to do frequent dressing changes.
- Perform frequent peri-care, including Sitz baths, including after bowel movements.
- Maintain patency of Foley catheter that usually remains in place for 7–14 days or until healing is adequate.
- Avoid sitting with the legs dependent, standing, and crossing the legs.
- Keep follow-up visits for additional therapy if needed.
- Seek care/early evaluation of any suspicious lesions, bleeding, or discharge.
- Obtain regular health checkups and screening for cancer and other age-related illness.

HYSTERECTOMY

- Hysterectomy is the removal of the uterus.
- It can be done abdominally or vaginally depending on the underlying disease process.

Use: Treatment of uterine cancer and nonmalignant conditions such as endometriosis, fibroid tumors, pelvic relaxation with uterine prolapse; to control life-threatening bleeding/hemorrhage and in the event of intractable pelvic infection or irreparable rupture of the uterus.

Abdominal hysterectomy types: Subtotal (partial): body of the uterus is removed, cervical stump remains.

Total: removal of the uterus and cervix.

Total with bilateral salpingo-oophorectomy: Removal of the uterus, cervix, fallopian tubes, and ovaries is the treatment

of choice for invasive cancer, fibroid tumors that are rapidly growing or produce severe abnormal bleeding, and endometriosis invading other pelvic organs.

Total pelvic exenteration (TPE): Total hysterectomy with dissection of pelvic lymph nodes and bilateral salpingo-oophorectomy, total cystectomy, and abdominoperineal resection of the rectum. Colostomy and/or urinary conduit may or may not be performed.

Vaginal hysterectomy types:

Vaginal hysterectomy or laparoscopically assisted vaginal hysterectomy (LAVH): Performed for certain conditions, such as uterine prolapse, cystocele/rectocele, carcinoma in situ, and when high-risk obesity exists.

Preparation: Lower half of the abdomen and the pubic and perineal regions are cleansed with soap and water and may be shaved; intestinal tract emptied and Foley catheter inserted to prevent contamination and injury to the bladder and intestinal tract; enema and antiseptic douche may be prescribed the evening before surgery.

Postoperative course:

- IV fluids, fluid and food restriction for 1 or 2 days, until bowel sounds and peristalsis returns; may have a NG tube
- Foley catheter
- Elastic compression stockings when on bed rest
- Rectal tube for abdominal distension
- Wound care
- Strict I&O

Nursing Process Elements

- Administer analgesics as prescribed.
- Allow client to verbalize her concerns about the effects of surgery: change in body image and reproductive ability; and feelings of loss.
- Monitor abdominal dressings for drainage (abdominal hysterectomy).
- Monitor VS.
- Assess bleeding and extent of saturation of perineal pads.
- Assess for signs of deep vein thrombosis or phlebitis: leg pain, warmth, redness, positive Homan's sign.
- Monitor for signs of pulmonary embolism: chest pain, dyspnea, and tachycardia.
- Encourage and assist client in changing positions often when in bed with pressure under knees avoided; discourage crossing of legs and ankles, encourage to exercise legs and ankles.
- Encourage early ambulation.
- Monitor CBCs for blood count and WBCs.
- Monitor abdominal girth for distension.

Client teaching for self-care

- Take oral analgesics for pain as prescribed.
- Check surgical incision daily for redness or discharge.
- Report elevated temperature to health care provider.
- Although periods are now over, monitor for bleeding; some light bleeding/discharge is normal postsurgery for a few days; if persistent, notify health care provider immediately.
- Report vaginal discharge and/or foul odor to health care provider.
- Consume diet and fluid intake adequate for healing, bowel and bladder function.
- Resume activities gradually.
- Take stool softeners as prescribed and empty bladder frequently.
- Avoid prolonged sitting with pressure behind knees, crossing legs/ankles, and inactivity.
- Expect postoperative fatigue, which should gradually decrease.
- Seek out counseling and/or support groups for self and family.
- Keep follow-up appointment with health care provider.

OVARIECTOMY (OOPHORECTOMY)

Ovariectomy is the removal of one or both ovaries.

Use: To remove tumors of the ovaries.

Preparation: Surgical staging of the tumor is essential in guiding treatment. Preoperative workup includes a barium enema or colonoscopy, upper GI series, chest X-rays, and IV urography. CT scans and immunoscintigraphy, the use of radioactive antibodies, may be used preoperatively to rule out intra-abdominal metastasis.

Postoperative course: IV fluid, I&Os, Foley catheter, wound care, compression stockings, drainage tubes; diet progressed as bowel sounds/peristalsis returns.

Nursing Process Elements

- Monitor VS.
- Assess for pain and medicate as prescribed.
- Monitor CBC blood counts and WBCs.
- Assess dressing for bleeding/drainage.
- Maintain strict I&O.
- Assess for signs of deep vein thrombosis or phlebitis.
- Encourage frequent position changes.
- Encourage early ambulation.
- Manage any drainage tubes.
- Assess for S&S of pleural effusion: shortness of breath, hypoxia, cough, and pleuritic chest pain.

Assessment Alert

Clients with advanced ovarian cancer may develop ascites and pleural effusion.

- Provide small, frequent meals.
- Decrease fluid intake.
- Administer diuretic agents as prescribed.
- Provide frequent rest periods.
- Monitor for side effects of chemotherapy and treat as appropriate.

Client teaching for self-care

- Take oral analgesics for pain as ordered.
- Check surgical incision daily for redness or discharge.
- Report elevated temperature to health care provider.
- Report vaginal discharge and/or foul odor to health care provider.
- Maintain diet and fluid intake adequate for healing, and bowel and bladder function.
- Resume activities gradually.
- Maintain bowel and bladder function (stool softener as prescribed and emptying bladder frequently).
- Avoid prolonged sitting with pressure behind knees, crossing legs/ankles, and inactivity.
- Expect postoperative fatigue, which should gradually decrease.
- Seek out counseling and/or support groups for self and family.
- Keep follow-up appointment with health care provider.

SALPINGECTOMY

Salpingectomy is the removal of one or both of the fallopian tubes.

Use: Management of tubal pregnancies, infected tube, or as part of the surgical treatment of tubal cancer. Commonly done in conjunction as part of a “complete” hysterectomy, or salpingo-oophorectomy where the uterus and both ovaries and fallopian tubes are removed at the same time.

Preparation: NPO night before procedure if not an emergency situation; Foley catheter; premedication for anxiety.

Postoperative course: IV fluid, I&O, Foley catheter, wound care; diet progressed as bowel sounds/peristalsis return.

Nursing Process Elements

Similar to hysterectomy and oophorectomy.

VASECTOMY

Vasectomy is the ligation and transection of the vas deferens, with or without removal of a segment of the vas deferens.

Use: Male sterilization

Nursing Process Elements

Client teaching for self-care

- Apply ice packs, intermittently for several hours, to the scrotum to decrease edema and pain.
- Wear cotton jockey-type brief for added comfort and support.
- Reassure client that procedure has no effect on sexual potency, erection, ejaculation, or production of male hormones.
- Use another form of contraception until infertility is confirmed by examination of the ejaculate; some physicians examine ejaculate 1 month after surgery and again in a month; other physicians consider clients to be sterile after 36 ejaculations.

PENECTOMY

Penectomy is the removal of part or all of the penis with or without removal of groin tissue and lymph nodes.

Use: Treatment of penile cancer.

Nursing Process Elements

- Refer to cancer support groups.
- Refer to therapists who work with couples experiencing changes in their sex lives to teach new ways of arousing and satisfying each other.

PENILE IMPLANT

Penile implant is the insertion of a penile prosthesis used in clients with erectile dysfunction secondary to organic causes.

Nursing Process Elements

Refer client and partner for counseling because this is usually needed to help in adapting to the prosthesis.

TRANSPLANT SURGERY

Use: Tissue and organ transplants are typically done when an organ is no longer able to function despite medical intervention, as a result of traumatic injury such as burns, or disease has rendered it nonfunctional.

Types of grafts:

- Autograft—transplantation of tissue from one area of the body to another
- Heterograft—transplantation of tissue from two different species. Most commonly done in skin grafts with pig skin and is usually temporary
- Allograft—transplantation of tissue between the same species using either live or cadaver donors

Common transplants:

- Cornea
- Bone
- Bone Marrow
- Kidney
- Liver
- Heart
- Lung
- Pancreas
- Skin

Once the client has been deemed an eligible recipient, the client's name is entered into the United Network for Organ Sharing (UNOS) computer database. This organization is responsible for ensuring available organs are distributed in an equitable and nondiscriminatory manner.

Legal requirements of donation and transplantation

- Uniform Anatomical Gift Act (UAGA)—authorizes donation of all or part of the human body. This act provides
 - guidelines for who can donate, how donation can occur, and who can receive donation
 - for the organ donor card
 - liability protection for health care providers
- Required-Request Legislation—defines hospital responsibilities in identifying potential donors and requires information about the opportunity to donate be provided to families
- National Organ Transplant Act—established the National Organ Procurement and Transplantation Network, which creates national registries to track potential recipients and posttransplantation organ recipients. Also establishes national system to match organs with potential recipients. Prohibits the selling of organs and tissues

- Uniform Determination of Death Act—guideline for states to develop a legal definition of death

Types of donors:

- Live donor:
 - Usually related to the client
 - Primarily used in kidney transplants
 - Used with segmental organ donation such as one lobe of lung or liver, usually a parent provides to a recipient child
- Cadaver donor:
 - Organs removed after death, most commonly brain death
 - Family required to give written consent prior to organ removal

Pretransplant considerations:

- General criteria for determining transplant need:
 - End-stage organ failure
 - Short life expectancy
 - Severe functional disability
 - No other serious health problems
 - Psychological readiness
 - Financial status
- Clinical status
 - Immunologic
 - Histocompatibility is the ability of the transplanted tissue or organs to live without attack by the immune system. The closer the histocompatibility antigens match between donor and recipient, the less likely the immune system is to recognize transplanted tissue as nonself
 - Donor–Recipient compatibility testing
 - Tissue typing—determines the degree to which the donor and recipient tissue match
 - Cross-matching—tests the recipient for antidonor antibodies that may have developed from a prior organ transplant, blood transfusions, or pregnancy. Antidonor antibodies can cause rapid rejection including death
 - ABO Typing—blood group typing
 - General laboratory studies
 - CBC with differential
 - Blood chemistries
 - Coagulation studies
 - Urinalysis
 - Viral titers

- Infection testing—blood cultures, urine cultures, etc
- Cardiac studies
 - ECG
 - Echocardiogram
- Radiographic
 - Chest X-ray
- Psychological status evaluation
- Financial status

Posttransplantation complications:

While each type of organ transplant has unique posttransplant complications, there are three major types of complications associated with transplantation in general.

- Technical complications are associated with the surgical procedure.
 - Vascular thrombosis: blood clot in the vasculature of the transplanted organ or tissue, usually the major artery.
 - Bleeding: usually occurs postoperatively and is managed similarly to other postsurgery clients, except with liver transplant clients.
 - Anastomosis leakage: occurs at area where transplanted organ/tissue is joined to the client, usually occurs 1–3 weeks after transplant. Most often will require surgical intervention to repair.
- Graft rejection is an immune response by the body against the new tissue.
 - Acute rejection: cell-mediated response; sudden onset, days or months following transplant.
 - Hyperacute rejection: humoral, hypersensitivity response, occurs within minutes to hours of transplant, rare due to better donor–recipient screening
 - Chronic rejection: humoral, can begin any time after transplant and take years to make the transplant nonfunctional
- Immunosuppressant-related problems are caused from the drugs given to prevent rejection.
 - Infection: major problem following, transplant in clients, whose immune systems are suppressed, who are unable to mount the same type of response as an immunocompetent client.

Assessment Alert

Monitor for fever posttransplant as it is the primary symptom of infection.

- Types of infection—bacterial, viral, fungal, and parasitic
- Lungs and urinary tract are most common sites of infection
- Organ dysfunction: frequently caused by nephrotoxicity and hepatotoxicity, which can occur with any organ

transplant but is very serious if it involves transplanted kidney or liver

- Malignancy: common problem with long-term immunosuppressant therapy
- Steroid-induced problems: due to long-term steroid therapy and would include such things as hyperglycemia and weight gain

KIDNEY TRANSPLANT

- Kidney transplant is the oldest and most common type of transplant surgery.
- It is used to treat clients with End-Stage Renal Disease (ESRD).
- It reverses majority of pathophysiological changes associated with kidney failure.

Preoperative Care

A regular dialysis schedule should be maintained until the time of transplant if possible.

Client teaching for self-care

- Advise client that dialysis may be needed during the first few weeks postoperatively since there is a 20% chance that the transplanted kidney will not function immediately.
- Review rationale for immunosuppressant therapy and need to comply with treatment regimen.
- Stress importance of reducing the risk of infection after surgery.
- Maintain vascular access patency and clearly identify vascular access site
- Additional diagnostic testing:
 - GI X-rays
 - Abdominal ultrasound
 - Voiding cystourethrogram

Postoperative Care

- Care of the donor:
 - Pain management
 - Ambulation
 - Respiratory care
- Care of the recipient:
 - Maintain fluid and electrolyte balance
 - Monitor I&O hourly
 - Titrate IV fluids to replace output amount for the first 12–24 hours
 - Monitor for hypokalemia
 - Monitor for sudden decrease in urine output

- Monitor Foley catheter patency
- Monitor for signs of infection
- Monitor for hypertension

Client teaching for self-care

- Medications: oral and written instruction.
- S&S of infection or rejection:
 - Flank pain
 - Fever
 - Changes in urinary pattern
 - Sudden weight gain
 - Difficulty breathing
 - Edema
- Maintain any activity restrictions, which usually include
 - avoiding heavy lifting (more than 20 lb) for 6 weeks to allow time for the incision to heal and the scar gain strength;
 - no return to work for 6–12 weeks; and
 - refraining from sexual intercourse for 4–6 weeks.
- Weight and cholesterol monitoring: steroids increase appetite and increase risk of hyperlipidemia; cyclosporine also increases risk of lipidemia.
- Pregnancy prevention during first year if appropriate to establish good renal function and decrease dosage of immunosuppressant drugs.
- Follow-up appointments.

CORNEA TRANSPLANT

- Cornea transplant is a common type of transplant and is the most successful of all tissue transplants
- It is carried out for those clients who have corneal damage due to infection, injury, or hereditary condition that has resulted in vision loss
- It can be done as long as the retina is intact.
- It is usually done as an outpatient procedure.

Preoperative care:

- Prep client based on type of anesthesia to be administered
- Assess VS

Postoperative care:

- Ensure eye patch is in place
- Assess VS

Client teaching for self-care

- Eye protection.
- Activity restrictions.

- Medication use and compliance.
- Follow-up appointments.

LIVER TRANSPLANT

- Major transplant indicators:
 - Chronic irreversible liver disease
 - Primary malignant tumors of the liver and biliary tree
 - Fulminant hepatic failure
 - Biliary atresia

Preoperative care:

- Explain any special postoperative considerations: NG tube, IV fluids, ICU, etc
- Teach preventive postoperative exercises: deep breathing, leg exercises, use of rails for turning
- Additional diagnostic labs:
 - Liver function test
 - Portal vein sonogram & Doppler
 - Abdominal CT scan
 - Liver biopsy

Postoperative care:

- Promote oxygenation.
- Ensure fluid and electrolyte balance.
- Maintain GI tube patency.
- Maintain low-protein diet.
- Monitor for rejection.
- Monitor for S&S of infection.

Client teaching for self-care

- S&S of infection and rejection
- Medication use and compliance
- Changes in medication routine
- When to notify physician

HEART TRANSPLANT

- Major transplant indicators:
 - Cardiomyopathy
 - Valvular heart disease
 - Ventricular aneurysm
 - Viral myocarditis
 - Congenital malformations
 - Arteriosclerotic coronary artery disease

Preoperative care:

- Similar to other cardiac preoperative care

- Additional diagnostic labs:
 - Endomyocardial biopsy
 - ABG
 - Chest X-ray
 - Pulmonary function testing
 - Ventilation/perfusion scan
 - Chest CT scan
 - Echocardiogram
 - Doppler study
 - Duplex scan of legs
 - Cardiac catheterization

Postoperative care:

- Monitor cardiac function
- Maintain fluid and electrolyte balance
- Monitor renal function
- Monitor for S&S of infection
- Monitor for S&S of rejection

**Client teaching for self-care**

- Medication use and compliance.
- S&S of infection and rejection.
- Possible need for cardiac rehabilitation.
- Risk factor reduction.
- Required follow-up schedule.

BONE MARROW TRANSPLANT

- Bone marrow transplant is commonly used as a treatment for some types of leukemia and lymphoma.
- It is done during a remission phase.

- Goals:
 - Replace diseased marrow with healthy.
 - Save healthy bone marrow from treatment effect for implantation posttreatment.
 - Replace diseased stem cells with healthy stem cells.

Preoperative care:

- Intensive regimen of chemotherapy and total body irradiation for immunosuppression and to kill residual tumor cells.
- Maintain strict isolation to reduce risk of infection.
- Monitor for S&S of infection.

**Client teaching for self-care**

- Importance of following isolation procedures.
- Postoperative isolation expectations.
- Provide emotional support.

Postoperative care:

- Maintain strict isolation, usually for 2–4 weeks.
- Provide emotional support.
- Assess psychological status.
- Monitor closely for S&S of infection.
- Monitor for signs of rejection.
- Monitor for signs of bleeding.
- Reduce risk for injury by padding any sharp surfaces.
- Potentially fatal complications.
 - Graft versus host disease

**Assessment Alert**

Monitor for skin erythema
—Interstitial pneumonia

PLASTIC SURGERY

Types of plastic surgery

- Cosmetic surgery
 - Reshapes normal structures of the body
 - Done to improve the client's appearance and self-esteem
- Reconstructive surgery
 - Performed on abnormal structures of the body, caused by birth defects, developmental abnormalities, trauma or injury, infection, tumors, or disease

- Done to improve function or to create a normal appearance
- Procedure performed is the lowest on the reconstructive ladder that will accomplish the goal: simple procedures such as wound closures are first rung and highly complex procedures such as microsurgery to reattach severed limbs occupy the top rung
- May require complex planning and a number of procedures done in stages

—Children may need long-term follow-up and additional procedures to accommodate to changes caused by growth

Psychological considerations:

- Creates both physical changes and changes in self-esteem
- Insight into personal goals and why plastic surgery is desired is essential to good postoperative adjustment to the results
- Plastic surgery needs to be done for self not out of the desire to please or impress someone else
- Expectations need to be realistic
- Surgery should be planned when the client is free of personal stress, or physical or emotional burden and during the initial consultation questions will be asked not only about how the client feels about his or her appearance, how he or she believes others view him or her, and how he or she would like to look and feel but about potential sources of stress such as relationships, home life, and work. longer and more difficult recovery periods
- Clients who are obsessed with a very minor defect or those with serious mental illness exhibiting delusional or paranoid behavior are not appropriate candidates for plastic surgery.
- Consider the feelings of the child and the parents
- Feelings about self-image tend to change with maturity; therefore, cosmetic surgery should never be forced on a teenager

Postoperative considerations:

- Recuperation time after plastic surgery varies with the procedure and with the health status of the client
 - Generally, assistance is needed for the first 2 days; more, if small children need to be cared for
 - Slow-walking routine is usually begun on the second postoperative day
 - Regular aerobic and more vigorous activities are avoided during the first 2 weeks in order to decrease the risks of bleeding, swelling, and bruising
 - Weight lifting and contact sports typically are allowed at 1 month
- Feelings of “let-down,” the “blues,” or even depression are common starting about the third day after surgery and lasting a few days or several weeks. Many factors contribute to this but the stress of the postoperative appearance and the waiting for healing or for completion of a staged procedure plays a significant role
- Adjustment to the changed body appearance also takes time: the more dramatic the change, the longer the adjustment period. A sense of unfamiliarity with one’s reflection is not uncommon.
- Brisk walks, light social activity, small outings, and a source of emotional support aid adjustment.

Complications:

Potential complications include infection; excessive bleeding such as hematomas, significant bruising and impaired

wound healing; and problems related to anesthesia and surgery.

Smoking, connective tissue disease, skin damage from radiation therapy, decreased circulation to area of surgery, impaired immunity, and malnutrition increase the risk of complications.

AUGMENTATION MAMMAPLASTY

- Augmentation mammoplasty involves insertion of inflatable implants filled with saline to increase breast size.
- It is usually performed as an outpatient procedure under local anesthesia with sedation, or general anesthesia.

Postoperative course: Temporary soreness, swelling, change in nipple sensation, and bruising. Breast sensitive to stimulation for a few weeks.

Complications: May require removal or replacement

- Deflation
- Formation of scar tissue around the implant making the breast feel tight or hard
- Bleeding
- Infection
- Permanent increased or decreased sensation in nipples or breast

Nursing Process Elements

Client teaching for self-care

- Avoid physical contact with breasts for 3–4 weeks.
- Return to work in 2–3 days if not required to lift more than 15 lb.
- Report bleeding/drainage, increased swelling, redness, or pain.
- Expect scars to fade slowly over several months to a year or more.
- Inform technician that mammography requires a special technique.

MASTOPEXY

- Mastopexy is the elevation and reshaping of sagging breasts by removing excess skin and repositioning breast tissue and nipples.
- It is usually performed as an outpatient procedure under local anesthesia with sedation, or general anesthesia.

Postoperative course:

Temporary bruising, swelling, discomfort, numbness, dry breast skin.

Complications:

- Heavy scarring (keloid)
- skin loss
- infection
- Unevenly positioned nipples
- Permanent loss of feeling in nipples or breast

**Nursing Process Elements****Client teaching for self-care**

- Avoid strenuous activities for 4 weeks.
- Return to work in 7–14 days.
- Report bleeding/drainage, increased swelling, redness, or pain.
- Expect scars to fade slowly over several months to a year or more.
- Gravity, pregnancy, aging, and weight changes may cause new sagging.

CHEMICAL PEEL

- Solution of phenol or trichloroacetic acid (TCA) is used to peel away surface layers of the skin.
- It removes superficial wrinkles, blemishes, sun damage, and uneven pigment.
- It works best on fair, thin skin.
- It is usually done as an outpatient procedure without anesthesia though sedation and EKG monitoring is used in some cases. Hospital admission may be required for a full-face phenol peel.

Postoperative course: Temporary throbbing, tingling, swelling, redness; acute sensitivity to sun. New skin forms in 7–21 days after a phenol peel; 5–10 days with TCA. Permanent lightening of treated skin and loss of ability to tan also occur when phenol is used.

Complications:

- Tiny whiteheads (resolve with time)
- Infection
- Scarring
- Flare-up of skin allergies
- Fever blisters
- Cold sores
- Permanent abnormal color changes and rarely, cardiac arrhythmias with phenol

**Nursing Process Elements****Client teaching for self-care**

- Effects of phenol peels are permanent but new wrinkles can develop; effects of TCA are temporary.
- Resume normal activities in 2–4 weeks.
- Full healing and resolution of erythema takes 3–6 months.

COLLAGEN/FAT INJECTIONS

- Collagen/Fat injections are used to fill out facial creases, furrows or sunken areas, or to add fullness to lips or backs of hands.
- This method is most effective on thin, dry, light-colored skin.
- The effect lasts a few months to a year.
- It is an outpatient procedure; no anesthesia for collagen injections; local anesthesia for fat injections.
- Skin test to check for allergy is required prior to collagen injections.

Postoperative course: Temporary stinging, throbbing, or burning sensation; mild erythema; edema.

Complications:

- Irregular contour
- Infection
- Also with Collagen: allergic reaction including rash, hives, swelling, or flu-like symptoms; possible triggering of connective tissue or autoimmune diseases

DERMABRASION

- Dermabrasion is the removal of the surface layers of the skin by scraping with a high-speed rotary wheel.
- It is used to smooth out surface irregularities such as acne scars and fine wrinkles, especially around the mouth. It may require more than one session.
- It is usually done as an outpatient procedure with a numbing spray, local or general anesthesia.

Postoperative course: Temporary tingling, burning, itching, swelling, redness; acute sun sensitivity; lightening and loss of tanning capacity of treated skin.

Complications:

- Permanent color changes
- Tiny whiteheads (resolve with time)
- Infection
- Scarring
- Flare-up of skin allergies

- Fever blisters
- Cold sores

Nursing Process Elements

Client teaching for self-care

- Effects are permanent although new wrinkles can develop with aging.
- Return to work 2 weeks.
- Avoid strenuous activities for 4–6 weeks.
- Expect redness for about 3 months.
- Avoid sun exposure until pigmentation returns in 6–12 months.

OTOPLASTY

- Otoplasty involves setting prominent ears back closer to the head, or reducing the size of large ears. It is most often done on children between the ages of 4 and 14 years.
- It is an outpatient procedure done under general anesthesia on young children and under general or local anesthesia with sedation on older children or adults.

Postoperative course: Temporary throbbing, aching, swelling, redness, and numbness.

Complications:

- Infection of cartilage
- Excessive scarring
- Formation of a blood clot requiring drainage
- Mismatched or artificial-looking ears
- Recurrence of the protrusion

Nursing Process Elements

Client teaching for self-care

- Return to school in 5–7 days.
- Avoid strenuous activities and contact sports for 1–2 months.

BLEPHAROPLASTY

- Blepharoplasty is the removal of excess fat, skin, and muscle to correct drooping upper eyelids and puffy bags below the eyes.

- It is usually done as an outpatient procedure under local anesthesia with sedation; may be done under general anesthesia.

Postoperative course: Antibiotics may be applied to sutures. Sutures removed in 3–7 days. Temporary discomfort, tightness of lids, swelling, bruising. Temporary dryness, burning, itching of eyes. Excessive tearing, sensitivity to light for first few weeks. Independent activity by day 2. Wearing sunglasses, may feel comfortable going out in public as to the store by day 3–4, and with makeup able to return to work in 5–7 days.

Complications:

- Temporary blurred or double vision
- Infection
- Bleeding
- Swelling at the corners of the eyelids
- Dry eyes
- Formation of whiteheads
- Asymmetrical eyelids
- Scarring
- Difficulty in closing eyes completely (usually temporary)
- Pulling down of the lower lids (may require surgical correction)
- Blindness (extremely rare)

Nursing Process Elements

Client teaching for self-care

- Apply iced compresses to reduce swelling and discoloration.
- Do not read for 2–3 days.
- Do not wear contact lenses for 2 weeks or more.
- Return to work in 5–10 days; can use makeup to cover bruising.
- Avoid strenuous activities and use of alcohol for 3 weeks.
- Expect bruising and edema to persist for several weeks.

RHYTIDECTOMY

- Rhytidectomy is the removal of excess fat, tightening of muscles, and redraping of the skin to reduce sagging facial skin, jowls, and loose neck skin.
- It is usually done as an outpatient procedure under local anesthesia with sedation; sometimes under general anesthesia and occasionally admission for 1–2 days.

Postoperative course:

- Bruising, swelling, numbness, and tenderness of skin for 2–3 weeks; tight feeling, dry skin

- Rest for 24 hours head elevated and without neck flexion to support circulation, decrease edema, and reduce risk of bleeding
- Independent activity resumed by day 2
- Dressings removed in 3–5 days; face cleansed of drainage; antibiotic ointment applied
- Generally, swelling decreased sufficiently in 5–7 days that the client is comfortable going out in public
- Men need to shave behind ears because beard-growing skin is repositioned there

Complications:

- Injury to the nerves that control facial muscles or feeling (usually temporary but may be permanent)
- Infection
- Bleeding
- Poor healing/excessive scarring
- Asymmetry or change in hairline

***Nursing Process Elements******Client teaching for self-care***

- Keep the head elevated and the neck straight when in bed.
- Rest for 48 hours then gradually resume activity.
- Return to work in 10–14 days; earlier if not in public view.
- Resume more strenuous activity such as lifting or bending in 2 weeks or more; these actions encourage edema and bleeding.
- Take nonnarcotic analgesics, but not any containing aspirin, as directed for discomfort.
- Drink nourishing liquids through a straw and gradually add soft foods and progress to a regular diet as chewing comfort allows.
- Do not shampoo hair until all sutures have been removed; use hair dryer on warm only because of the risk of burns because of decreased sensitivity of the skin/ears.
- Limit exposure to sun for several months.
- Effect typically lasts for 5–10 years.

FACIAL IMPLANTS

- Shaped implants are used to change the basic shape and balance of the face
- Can build up a receding chin, add prominence to cheekbones, or reshape the jawline.
- Usually an outpatient procedure performed under local anesthesia with sedation, or under general anesthesia; occasionally requires overnight admission.

Postoperative course: Temporary discomfort, swelling, bruising, numbness, and/or stiffness. After jaw surgery, the client cannot open mouth fully for several weeks. Appearance is normal in 2–4 weeks.

Complications:

- Shifting or malpositioned implant
- Infection which may require more surgery or removal
- Unnatural shape due to excessive tightening and hardening of scar tissue around an artificial implant

***Nursing Process Elements******Client teaching for self-care***

- Return to work in about a week.
- Avoid activity that could jar or bump face for 6 weeks or more.

FOREHEAD LIFT (BROWLIFT)

- Removal of excess tissue, adjustment of muscles and tightening the forehead skin to minimize forehead creases, drooping eyebrows, hooding over eyes, furrowed forehead and frown lines. Traditionally done by means of an incision across the top of the head just behind the hairline; may also be done endoscopically by means of three to five short incisions.
- Usually an outpatient procedure performed under local anesthesia with sedation; occasionally under general anesthesia.

Postoperative course: Temporary swelling, numbness, headaches, bruising. Possible itching and hair loss with traditional procedure. Bruising takes 2–3 weeks to abate.

Complications:

- Injury to facial nerve, causing loss of motion, muscle weakness, or asymmetrical look
- Infection
- Marked scarring

***Nursing Process Elements******Client teaching for self-care***

- Return to work in 7–10 days, usually sooner after an endoscopic forehead lift.
- Resume more strenuous activity in several weeks.
- Limit sun exposure for several months.
- Effect typically lasts for 5–10 years.

HAIR REPLACEMENT SURGERY

- Hair replacement surgery involves use of client's own hair to fill in balding areas.
- Techniques include scalp reduction, tissue expansion, strip grafts, scalp flaps, or clusters of punch grafts (plugs, mini plugs, and microplugs).
- It is most successful on men with male pattern baldness after hair loss has stopped.
- It may require multiple procedures over 18 months or more.
- It is usually an outpatient procedure performed under local anesthesia with sedation. Flaps and tissue expansion may be done with general anesthesia.

Postoperative course: Temporary achy, tight scalp. Unnatural look in early stages.

Complications:

- Unnatural look
- Infection
- Excessive scarring
- Failure to “take”
- Loss of scalp tissue and/or transplanted hair

Nursing Process Elements

Client teaching for self-care

- Return to work usually in 2–5 days.
- Resume more strenuous activities in 10 days to 3 weeks.
- Final result will not be apparent for up to 18 months depending on procedure.

LASER FACIAL RESURFACING

- Laser facial resurfacing uses a CO₂ laser to smooth the face and fine wrinkles, soften lines around the eyes and mouth, and minimize facial scars and unevenly pigmented areas.
- It may require more than one session.
- It is usually an outpatient procedure under local anesthesia with sedation.

Postoperative course: Temporary swelling and discomfort. Lightening of treated skin. Acute sun sensitivity. Increased sensitivity to makeup. Pinkness or redness in skin that may persist for up to 6 months. Pigmentation returns in 6–12 months.

Complications:

- Burns or injuries caused by laser heat
- Scarring

- Abnormal changes in skin color
- Flare-up of viral infections such as cold sores and rarely development of other infections

Nursing Process Elements

Client teaching for self-care

- Return to work in 2 weeks.
- Resume more strenuous activities in 4–6 weeks.
- Avoid sun exposure for 6–12 months and then only light exposure.
- Does not stop aging: New wrinkles/expression lines may form as skin ages.

LIPOSUCTION

- Liposuction is the removal of exercise-resistant fat deposits with a tube and vacuum suction device.
 - Tumescent technique: Fat cells are infused with saline solution and a local anesthetic before suctioning to reduce postoperative bruising and swelling.
 - Ultrasound-assisted lipoplasty (UAL): Fat is liquefied via an ultrasound probe inserted under the skin before suctioning is begun, used when large amounts of fat must be removed or when area is fibrous.
- Common sites for liposuction are chin, cheeks, neck, upper arms, above breasts, abdomen, buttocks, hips, thighs, knees, calves, ankles, etc.
- Local, epidural, or general anesthesia may be used.
- It is usually an outpatient procedure though extensive procedures may require short admission.

Postoperative course: Temporary bruising, swelling, numbness, soreness, and burning sensation.

- Drainage from incision sites with tumescent technique
- Compression garment or tape kept in place for 7–10 days
- Full recovery from swelling and bruising: 1–6 months or more. Use of tumescent technique or UAL may decrease postoperative bruising and swelling

Complications:

- Asymmetry
- Rippling or bagginess of skin
- Pigmentation changes
- Fluid retention
- Hypovolemic shock from excessive fluid loss
- Infection
- Thermal burn injury caused by the heat from the ultrasound device with UAL

Nursing Process Elements

Clinical Alert

Anticoagulants are contraindicated for liposuction clients because of the risk of bleeding.

Client teaching for self-care

- Rest for 12 hours, then gradually resume activity.
- Apply ice packs to surgical area to decrease edema.
- Take nonaspirin, nonnarcotic pain relievers for discomfort.
- Return to work in 1–2 weeks.
- Resume more strenuous activity in 2–4 weeks.
- Full result of the surgery on the body contour may not be seen for 8–16 weeks because of edema.
- Eat a sensible diet and exercise to avoid weight gain, which can negate the effect of the surgery.

MALE BREAST REDUCTION

- Male breast reduction involves reduction of enlarged, female-like breast in men using liposuction and/or excision of excess glandular tissue.
- It is usually an outpatient procedure performed under general or local anesthesia.

Postoperative course: Temporary bruising, swelling, numbness, soreness, and burning sensation.

Complications:

- Infection
- Fluid accumulation
- Injury, rippling, or bagginess of the skin.
- Asymmetry
- Pigmentation changes that may become permanent if exposed to sun
- Excessive scarring if tissue was cut away

Nursing Process Elements

Client teaching for self-care

- Return to work in 3–7 days.
- Resume more strenuous activity in 2–3 weeks.
- Expect swelling and bruising for 3–6 months.

NOSE SURGERY (RHINOPLASTY)

- Nose surgery involves permanent reshaping of the nose by reducing or increasing size, removing hump, changing shape of tip or bridge, narrowing span of nostrils, or changing angle between nose and upper lip.
- It may also relieve some breathing problems.
- It is usually an outpatient procedure performed under local anesthesia with sedation, or under general anesthesia.

Postoperative course: Temporary swelling, bruising around eyes and nose, headaches, some bleeding, and stiffness.

Complications:

- Infection
- Small burst blood vessels resulting in tiny, permanent red spots
- Incomplete improvement requiring additional surgery

Nursing Process Elements

Client teaching for self-care

- Resume work in 1–2 weeks.
- Resume more strenuous activities in 2–3 weeks.
- Avoid hitting or sunburning the nose for 8 weeks. Final appearance: 1 year or more.

ABDOMINOPLASTY (TUMMY TUCK)

- Abdominoplasty is the removal of excess fat and skin and tightening muscles of abdominal wall to flatten the abdomen.
- Depending on extent of procedure either in or outpatient with either general anesthesia, or local anesthesia with sedation.

Postoperative course: Temporary pain, swelling, soreness, numbness of abdominal skin, bruising, and tiredness for several weeks or months. Generally takes 2–4 days before clients can move around independently.

Complications:

- Blood clots
- Infection
- Bleeding under the skin flap
- Poor healing with conspicuous scarring or skin loss

Nursing Process Elements

Client teaching for self-care

- Return to work in 2–4 weeks; desk job as early as 5–10 days.

- Avoid more strenuous activity for 4–6 weeks or more.
Fading and flattening of scars: 3 months to 2 years.

BOTOX® INJECTION

- Botox injection is a form of botulinum toxin.
- It is used to temporarily reduce or eliminate frown lines, forehead creases, crows feet near the eyes, and thick bands in the neck.
- It works by blocking nerve impulses causing temporary paralysis of the muscles that cause wrinkles.
- It is effective in relieving migraine headaches, excessive sweating, and muscle spasms in the neck and eyes.

WOUND CLOSURE

- Direct closure: used for skin-surface wounds that have straight edges.
- Skin grafts: used for wide wounds that cannot be directly closed.
 - Split-thickness skin graft: consists of surface layers of skin usually taken from anterior thigh; commonly used to treat burn wounds; revascularizes quickly but is susceptible to trauma, lacks sensation, tends to contract; has impaired sweating ability, and a poor cosmetic appearance; called a mesh graft when many tiny slits are cut in it to allow stretching to cover a large area.
 - Full-thickness skin graft: entire area of skin removed from donor site which then is closed with sutures; used for deep, large burn wounds or to cover jointed areas where maximum skin elasticity and movement are needed.
 - Composite graft: consists of skin, fat and sometimes cartilage; used when the wound needs underlying support.
 - Autograft: tissue transferred from donor site to wound site on same person.
 - Location of the donor site is determined in part by the size and color of the skin patch needed.
 - Donor sites are covered with a transparent dressing for moist healing or single layer, nonadherent gauze for dry healing with a pressure dressing in place for 24–48 hours to control bleeding.
 - Donor sites heal in about 2 weeks and can be used over and over again.
 - New skin at donor site of a split-thickness graft has less pigment than the original skin.
 - Allograft (homograft): graft tissue comes from a different person; sloughs off after 3–10 weeks.
 - Heterograft (xenograft): tissue used is from an animal; sloughs in 3–7 days and then is replaced until wound is

healed or otherwise grafted; used to limit fluid loss, control temperature, and decrease risk of infection.

- For a graft to take, it must have a good blood supply and be immobilized so that newly forming capillaries are not destroyed.
- Petrolatum-impregnated dressings used to prevent graft from drying out and not “taking.”
- Pressure dressing used for 24–48 hours to control bleeding on both graft and donor sites.
- Successful graft appears pink and is attached to wound bed at time of first dressing change in about 3 days.

Think Smart/Test Smart

A successful graft appears pink and is attached to the wound bed. This means that the nurse must regularly assess the color and attachment of the graft. The graft appears pink because it has a good blood supply; if the blood supply is not good, the graft will be pale. There are many ways understanding of these concepts can be tested. A question might ask which S&S indicates that a graft has taken—pink color would be a correct answer. On the other hand, the question might ask which assessment finding indicates a grafting procedure is unsuccessful. In this case, pallor could be the correct answer. Other related questions could ask what assessments would be part of the plan of care for a client with a graft or how should the nurse interpret an assessment finding of pink coloration of a graft placed 4 days ago. Answers to these questions are color and adherence to the wound bed for the first question; and successful graft, the graft has taken, the graft has a good blood supply or revascularization has occurred are possible answers to the second question.

- Tissue expansion
 - An expander (balloon-like device) is inserted under the skin near the area to be repaired and then gradually filled with salt water over time, causing the skin to stretch and grow.
 - Time involved varies with size of area to be repaired and characteristics of the client.
 - Provides a near-perfect match of skin color, sensation, and texture.

—Decreases risk of tissue loss because the skin remains connected to its original blood and nerve supply.

—Scars are less apparent than those in flaps or grafts.

- Flap Surgery/Microsurgery

—Microsurgery allows reattachment of amputated parts.

—Flaps allow transplantation of large sections of tissue, muscle, or bone from one area of the body to another with the original blood supply intact.

—A flap is a section of living tissue with its own blood supply.

- Random-pattern flaps: blood supply is from random vessels
- Axial-pattern flaps: have identifiable arterial and venous vessels
- Local flap
 - Piece of skin and underlying tissue that lies adjacent to the wound.
 - Flap remains attached at one end so it maintains its original blood supply, and is repositioned over the wounded area.
- Regional flap
 - Section of tissue moved to a new site that is attached by a specific blood vessel to its original site.
 - Pedicle: name given to the tissue that houses the blood vessels going to a flap.
 - Pedicles are tunneled under other tissues, e.g., for breast reconstruction, the pedicle may be in the abdomen or in the axilla depending on whether the graft is taken from the abdomen or the back.
- Musculocutaneous flap (muscle and skin flap)
 - Used when the area to be covered needs more bulk and a greater blood supply, e.g., in breast reconstruction
- Microvascular free flap
 - Section of tissue and skin that is completely detached from its original site and reattached to its new site by hooking up all the tiny blood vessels.
 - Free flaps do not have a pedicle because a new blood supply has been created.

Nursing Process Elements

- Assess graft for adherence to wound bed, color, and signs of epithelialization, vascularization, and new granulation.

Also assess for signs of infection: redness including redness of skin surrounding the graft, foul odor, and purulent drainage.

- Check circulation peripheral to the graft.
- Inspect any splints or other immobilization devices for proper application and placement.
- Assess donor sites for healing or signs of infection.
- Maintain immobility of grafted area and ensure dressing does not move.
- Elevate graft site if possible to promote drainage and prevent damage to new capillaries from increased intravascular pressure.
- Keep flap and area of pedicle free of pressure to prevent interference with blood supply and resultant flap necrosis.
- Use bed cradle or other device to keep bed linens off graft and donor sites.
- Prevent shearing of graft because this destroys any ingrowth of capillaries.
- Use strict aseptic technique during graft care until graft is taken.
- Medicate for pain; donor sites are more painful than graft sites.

Client teaching for self-care

After direct wound closure

- Keep wound dry and covered for 24 hours.

After grafting

- Wear pressure garments as prescribed over graft area.
- If grafting involves an extremity, keep it elevated.
- Dress in layers to prevent injury from cold.
- When healed, massage graft/donor site with lanolin or cocoa butter at least once per day for 8 weeks to a year and a half to decrease itch, increase blood flow, and soften skin.
- Take care to protect graft site from trauma including sunburn because of its loss of feeling.

COMPLICATIONS RELATED TO COMMON HEALTH ALTERATIONS

Complications of common health alterations are listed in Table 18–1.

Table 18–1 Complications from Health Alterations

| Primary Problem | Potential Complications | Clinical Notes |
|--|---|---|
| Pericarditis | Pericardial effusion Cardiac tamponade | Abnormal collection of fluid between pericardial tissue layers: rapid increase in fluid compresses heart and causes pericardial tamponade. Slow increase causes distant heart sounds, cough, mild dyspnea. Compression of heart due to collection of fluid in pericardial sac causes critical drop in cardiac output due to interference with ventricular filling and pumping. Major indicator of tamponade: pulsus paradoxus—pulse that markedly decreases in amplitude during inspiration: Diminished or absent carotid or femoral pulse during inspiration; drop in systolic BP of 10 mm Hg or more during inspiration. |
| Infective endocarditis | Heart failure Infarction of other organs Abscess Aneurysm | Due to embolization of vegetative fragments Due to infiltration of arterial wall by infective organisms |
| Heart failure | Cardiogenic shock Pulmonary edema GI problems Impaired liver function Dysrhythmias | Due to congestion and enlargement of liver and spleen with increased intra-abdominal pressure and ascites. From prolonged right heart failure. From myocardial distention. |
| Aortic aneurysm | Rupture and hemorrhage. Embolus to lower extremities. Hemorrhage, renal failure, MI, HF, cardiac tamponade, sepsis, weakness, or paralysis of lower extremities. | Risk is associated with both abdominal and thoracic aneurysms. Occurs with abdominal aortic aneurysms. Occurs with dissecting aortic aneurysms. |
| Peripheral atherosclerosis | Gangrene and amputation of an extremity. Infection and sepsis Pulmonary embolism. | |
| Deep vein thrombosis Anemia Leukemia | CHF. Neurologic: subarachnoid hemorrhage, retinal hemorrhage, seizures, coma. Pulmonary bleeding. Renal insufficiency or failure. CV: hemorrhage, thrombophlebitis. DIC. Immunologic: abscesses, septicemia. Chronic venous insufficiency. | |
| Sinusitis | Extension of infection into tissue or bone of the orbit; intracranial spread resulting in meningitis, epidural, subdural or brain abscess, or venous sinus thrombosis. | |
| Pulmonary tuberculosis | Emphysema Bronchopleural fistula Pneumothorax | From rupture of a tuberculosis lesion. From air escape at point of rupture. |

(continued on next page)

Table 18–1 (continued from previous page)

| Primary Problem | Potential Complications | Clinical Notes |
|---|---|---|
| Asthma | Respiratory failure Status asthmaticus Dehydration Respiratory infection Atelectasis Pneumothorax Cor pulmonale | S&S: Inaudible breath sounds, decreased wheeze, ineffective cough Assessment Alert: Can be mistaken for improvement because symptoms seem to be relieved. Severe, prolonged attack unresponsive to standard therapy; can lead to respiratory failure. |
| Pneumococcal pneumonia | Pleuritis | Most common complication although bacteremia can result in meningitis, endocarditis, or peritonitis. |
| Ruptured intracranial aneurysm | Rebleeding Vasospasm Hydrocephalus | Risk greatest in first 24 hours after initial bleed and on days 7–10 when clot dissolves. S&S: Sudden, severe headache, N&V, change in LOC, new neurologic deficits. Occurs 3–10 days after subarachnoid hemorrhage Causes ischemia and tissue damage in areas affected; if global causes loss of consciousness. Accumulation of CSF in ventricles; increases ICP. |
| Staphylococcus aureus and gram-negative pneumonia Multiple sclerosis | Parenchymal necrosis, lung abscess, emphysema Urinary: recurrent UTI, incontinence Neuro: seizures, dementia Blindness | |
| Myasthenia gravis | Pneumonia, aspiration Myasthenic crisis Cholinergic crisis | Dependent on degree of muscle weakness and specific muscles involved. From missed doses of medication, under medication, infection. Sudden worsening of motor weakness, tachypnea, tachycardia, severe respiratory distress, dysphagia, restlessness, impaired speech, and anxiety. From overdose of cholinergic drugs: S&S: Severe muscle weakness, vertigo, respiratory distress, GI symptoms. Differentiated from myasthenic crisis by absence of response to Tensilon. |
| Gastroenteritis Anorexia nervosa | Dehydration, hypovolemia Fluid, electrolyte and acid–base imbalance Low cardiac output, dysrhythmias Anemia Hypoglycemia Increased uric acid levels Osteoporosis Liver dysfunction | May progress to hypovolemic shock. Decreased cardiac muscle mass. |
| Bulimia nervosa | Stomatitis Fluid, electrolyte and acid–base imbalance. Dysrhythmias Esophageal tears, stomach rupture Metabolic acidosis Metabolic alkalosis Hypokalemia | If diarrhea predominates. If vomiting predominates. With both vomiting and diarrhea. |

(continued on next page)

Table 18–1 (continued from previous page)

| Primary Problem | Potential Complications | Clinical Notes |
|-----------------------------|--|--|
| GERD | Esophageal stricture. Barrett's esophagus | Causes dysphagia. Changes in cells with increased risk of esophageal cancer. |
| Peptic ulcer disease | Hemorrhage Obstruction Perforation | Most frequent complication in older adult. |
| Gastrectomy | Dumping syndrome Pernicious anemia Folic acid deficiency Deficiency of vitamin D and calcium | 5–30 minutes after eating: nausea, may vomit, epigastric pain, borborygmi, diarrhea due to hyperosmolar chyme rapidly entering small intestine; rapid increase in blood glucose triggering release of large amount of insulin. 2–3 hours after eating: hypoglycemia Lasts 6–12 months postoperative. Lack of intrinsic factor needed for absorption of B12. Impaired absorption. Impaired absorption. |
| Intestinal obstruction | Hypovolemia and shock Impaired respiration Strangulation | Leads to varied organ dysfunction including renal failure. Abdominal distention elevates diaphragm and inhibits ventilation. Impairs blood flow causing gangrene with bleeding and eventually perforation, peritonitis, septic shock. |
| Appendicitis Peritonitis | Perforation, peritonitis, abscess Hypovolemic shock Abscess formation Adhesions in abdominal cavity | S&S: Increased pain, high fever. From fluid loss into abdominal cavity. Abscess limits effectiveness of immune response and access by antibiotics. Late complication; can cause obstruction. |
| Crohn's disease | Intestinal obstruction Abscess Fistula | Due to repeated inflammation and scarring. Small bowel to small bowel: asymptomatic Small bowel to large bowel: increased diarrhea, weight loss, malnutrition Small bowel to bladder: recurrent UTI. |
| Ulcerative colitis | Hemorrhage Toxic megacolon Perforation Increased risk of colorectal cancer | Can occur with severe attacks. Acute paralysis and dilation of all or part of the colon: may be precipitated by electrolyte imbalance of narcotic medication S&S: fever, tachycardia, hypotension, dehydration, abdominal tenderness and cramping, change in defecation. Toxic megacolon increases risk. |
| Colorectal cancer | Bowel obstruction Perforation of the bowel wall | From occlusion of the lumen by the tumor mass. From infiltration by the tumor. |
| Cholelithiasis | Common bile duct obstruction | May lead to jaundice and liver damage or pancreatitis. |
| Cholecystitis | Gangrene and perforation of gallbladder with peritonitis. Empyema Fistula formation Gallstone ileus | Collection of infected fluid within the gall bladder. Between gall bladder and stomach, duodenum or colon. Blockage of the small intestine with a large gallstone. |

(continued on next page)

Table 18–1 (continued from previous page)

| Primary Problem | Potential Complications | Clinical Notes |
|-------------------------------|--|---|
| Acute pancreatitis | Intravascular volume depletion with acute tubular necrosis and renal failure ARDS Pancreatic necrosis Pancreatic abscess Pancreatic pseudocyst Pancreatic ascites | Usually occurs within 24 hours. Usually develops 3-7 days after onset of pancreatitis; most common in clients with severe volume depletion. Causes an inflammatory mass, may lead to infection, shock, and multiorgan failure. Tends to form 6 or more weeks after onset of acute pancreatitis S&S: tender epigastric mass. Encapsulated collection of fluid; may rupture and cause peritonitis S&S; increasing abdominal girth, elevated serum amylase, absence of abdominal pain. |
| Cirrhosis | Diabetes Primary hepatic cancer DIC Ruptured Esophageal varices | Distended esophageal vessels are so thin, eating rough foods may cause rupture. |
| Fractures (Limb Fractures) | Compartment syndrome | From pressure of edema or hemorrhage in a space enclosed by a fascia resulting in lack of blood flow to muscles and nerves within the space. Most often occurs within 48 hours after injury; arterial pulses may be normal even though circulation is compromised sufficiently to cause tissue damage. S&S: pain becoming severe particularly on passive flexion; paresthesias, paresis, cyanosis, kidney failure from release of myoglobin from damaged muscle. Volkmann's contracture following elbow fractures can result from compartment syndrome. |
| (Long bone fractures) | Fat embolism syndrome | Fat globules from the bone marrow enter and travel through the blood stream causing ischemia in tissues beyond point at which they lodge. Occurs within hours to weeks after injury. S&S: Neurologic changes e.g., confusion, altered LOC; respiratory distress e.g., pulmonary edema, atelectasis, ARDS; petechiae on chest, upper arms and axilla from thrombocytopenia. Prevention: early stabilization of long bone fractures. Rx: rapid identification and intervention to prevent hypoxemia, corticosteroids to reduce inflammatory response. |
| Fractures | Deep vein thrombosis Infection Delayed union, nonunion Delayed healing Chronic stump pain Phantom pain Contractures | Greatest risk with open fractures; any decrease in circulation also increases risk of infection. Risk factors: infection, impaired circulation, electrolyte imbalances, malnutrition, vasoconstriction from smoking, venous thrombosis, decreased CO. Burning pain from neuroma formation. Painful sensation in missing part. Abnormal flexion and fixation of joint above amputation occurs from lack of extension and ROM. Prolonged sitting after BK amputation leads to hip contracture. Postural exercises required for upper extremity amputation to prevent hunching to one side because of weight loss. |

(continued on next page)

Table 18–1 (continued from previous page)

| Primary Problem | Potential Complications | Clinical Notes |
|---------------------------------------|--|--|
| Osteoporosis Gout | Fractures Joint pain, deformity, restricted movement Kidney disease Renal calculi | From deposition of urate crystals (tophi). Occurs with untreated gout especially in hypertensive clients. Uric acid crystals precipitate out. |
| Systemic lupus erythematosus | Nephrotic syndrome, renal failure CVA; organic brain syndrome | OBS: memory loss, impaired cognitive function, personality changes, disorientation. |
| Chronic pancreatitis | Malabsorption and malnutrition Diabetes mellitus Pancreatic abscess, pseudocyst, stricture of the common bile duct. Increased risk of pancreatic cancer. | |
| Urinary calculi | Obstruction of urinary tract Hydronephrosis Infection | Slowly developing: may be asymptomatic Acute onset: severe symptoms which depend on location, extent, and duration of obstruction. Distention of renal pelvis and calyces resulting from back up of urine due to obstruction Slow onset: dull back or flank ache/pain Rapid onset: sharp, colicky pain often radiating to groin, N&V, abdominal pain Fever, hematuria, pyuria may accompany either. Secondary to urinary stasis. |
| Uremia | GI: peptic ulcer, bleeding Neuro: seizures, decreased LOC, coma CV: pericarditis, pericardial effusion, cerebrovascular disease, Heart failure Spontaneous abortion Spontaneous bone fracture Secondary to osteomalacia and osteoporosis. | Pericarditis occurs irritation of the pericardial sac by retained toxins; less likely if dialysis started early. |
| Radiation therapy for prostate cancer | Erectile dysfunction Urethral stricture Rectal/anal stricture Cystitis Diarrhea Proctitis Rectal ulcer Bowel obstruction Urinary incontinence | Delayed complications: develops months or years after treatment. Develops months or years after treatment. |
| Gonorrhea | PID in women Epididymitis and prostatitis in men Infection of blood and joints Blindness, sepsis, joint infection in neonate Increased susceptibility to HIV and increased risk of transmission. | Can result in chronic pain, abscesses, ectopic pregnancy, infertility. Can result in dysuria and infertility. If contracted during delivery. |
| Herpes zoster | Postherpetic neuralgia Permanent loss of vision | More common in older clients. Risk when lesions involve ophthalmic division of the trigeminal nerve. |

(continued on next page)

Table 18–1 (continued from previous page)

| Primary Problem | Potential Complications | Clinical Notes |
|--------------------|---|---|
| Diabetes mellitus | <p>Hyperglycemia, Diabetic ketoacidosis, Hyperglycemic hyperosmolar nonketotic coma. Hypoglycemia</p> <p>Neuro: Paresthesias, pain, loss of sensation, loss of fine motor control. Eye: diabetic retinopathy, cataracts, glaucoma.</p> <p>CV: orthostatic hypotension, accelerated atherosclerosis, CVA, MI, PVD, platelet disorders. Renal: hypertension, albuminuria, edema, chronic renal failure.</p> <p>Joint contractures Foot ulcers, gangrene of feet</p> <p>Atrophy of skin Increased susceptibility to infection. Periodontal disease</p> | <p>From imbalance among amount of insulin, amount of physical activity, and CHO intake, e.g., too much insulin taken, excessive work/exercise, missing a meal. Also can be due to alcohol intake and drugs such as Coumadin MAO inhibitors and salicylates. Polyneuropathies: bilateral sensory problems starting in toes and feet and moving upward are most common Hypertension, hyperlipidemia, obesity and smoking further increase risk of CV problems.</p> <p>Microcirculatory changes primarily affect eye and kidney. Microalbuminuria-(small amount) – first sign of nephropathy. Usually begin as a superficial lesion; diabetics at risk for foot trauma because of lack of sensation so don't feel pressure, pain as from shoes that don't fit correctly or an ingrown nail.</p> <p>Tb more common in diabetics. Not more frequent in diabetics but more rapidly progressive.</p> |
| Burns | <p>Infection Fluid volume deficit Electrolyte imbalance ARDS Renal, GI or hepatic dysfunction</p> | |
| Chemical skin peel | Bleaching of skin | From removal of melanocytes. |

WORKSHEET

FILL IN THE BLANKS

Fill in the blank spaces with the correct word or phrase to complete each statement.

1. Surgical removal of one or more of the fallopian tubes is referred to as a _____.
2. A _____ may be performed to control life-threatening bleeding/hemorrhage and in the event of intractable pelvic infection.
3. After a vasectomy, applying _____ to the scrotum intermittently for several hours will help to reduce swelling and relieve discomfort.

4. The client on a cardiopulmonary bypass pump is maintained in a state of hypothermia in order to _____.
5. Postoperatively, the client who has had a CABG procedure usually is instructed to avoid excessive arm movements for _____ weeks.
6. What piece of equipment must be kept at the bedside of postoperative amputees? _____.
7. To check for development of abdominal distention, the nurse measures _____.
8. When caring for a client who had a kidney removed, the nurse would expect the Jackson–Pratt drain to be removed when drainage has decreased to less than _____ ml/d.
9. The client who has had a craniotomy is at greatest risk for ICP during the first _____ hours after surgery because this is the time during which edema peaks.
10. The client with a middle fossa craniotomy should be positioned with the head of the bed elevated _____ degrees.
11. Transplantation from one part of the body to another is called a(n) _____.
12. The live donor is primarily used in _____ transplants.
13. _____ transplant is the only type of transplant done as outpatient surgery.
14. A major indicator for heart transplant is _____.
15. Graft rejection, immunosuppressant related, and _____ are the three major types of transplant-associated complications.
16. The _____ transplant client must be weighed daily.
17. In addition to loss of vision, bleeding and infection, a complication associated with eye surgery is _____.
18. The two greatest risk associated with inner ear surgery are infection and _____.
19. A life-threatening complication of a long bone fracture is a _____.
20. Infection most often occurs when an amputation is _____.
21. List four categories of medication that interact with anesthetic agents.
 - a. _____
 - b. _____
 - c. _____
 - d. _____
22. Identify three causes of airway obstruction following a surgical procedure.
 - a. _____
 - b. _____
 - c. _____

(continued)

23. List four symptoms of hemorrhage.
 - a. _____
 - b. _____
 - c. _____
 - d. _____

24. Identify two types of exercises a client can be taught to perform to decrease the postoperative complication deep vein thrombosis.
 - a. _____
 - b. _____

25. The medication commonly used to reverse the effects of opioids is _____.

26. Hypoxia can be assessed by performing _____ and _____.

27. Normal bowel sounds following a surgical procedure generally are audible within _____ hours.

28. Identify 3 examples of nonnarcotic pain management.
 - a. _____
 - b. _____
 - c. _____

29. A herbal medicine that neutralizes antibiotics is _____.

30. Arthritic changes of the cervical spine can result in _____.

31. A bluish tinge around the umbilicus that is an indicator of either intra-abdominal bleeding peritoneal bleeding is called _____.

32. List three causes of urinary retention in a postoperative client.
 - a. _____
 - b. _____

TRUE & FALSE QUESTIONS

Mark each of the following statements True or False. Correct all false statements in the space provided.

- | | | |
|---|------------|------------|
| 1. Dilation and curettage may be necessary for a woman with dysfunctional bleeding. | _____ T | _____ F |
| 2. An advantage to use of a biologic heart valve for valve replacement is that it lasts longer than a mechanical valve. | _____ T | _____ F |
| 3. Dynamic cardiomyoplasty is performed to correct hypertrophic cardiomyopathy. | _____ T | _____ F |
| 4. The pericardium can be removed without any significant harmful effects on the client. | _____ T | _____ F |

| | | |
|---|-------------|-------------|
| 5. Speech is lost with a supraglottic laryngectomy. | <u> </u> | <u> </u> |
| | T | F |
| 6. Tracheostomy suctioning is a clean procedure. | <u> </u> | <u> </u> |
| | T | F |
| 7. Clients with a tracheostomy cannot swim. | <u> </u> | <u> </u> |
| | T | F |
| 8. A pillow is placed under the stump of an above the knee amputation (AK) to support it in an elevated position. | <u> </u> | <u> </u> |
| | T | F |
| 9. Nasogastric drainage decreases as peristalsis returns after gastric surgery. | <u> </u> | <u> </u> |
| | T | F |
| 10. A client with an ileal conduit should take a shower with the urine collection bag in place. | <u> </u> | <u> </u> |
| | T | F |
| 11. Clients having a skin lesion removed by cryosurgery should be told that they will feel a tingling sensation when the freezing substance is applied. | <u> </u> | <u> </u> |
| | T | F |
| 12. Phantom breast pain can occur following a mastectomy. | <u> </u> | <u> </u> |
| | T | F |
| 13. Reducing tension on the suture lines is an important part of the care for a client with a vulvectomy. | <u> </u> | <u> </u> |
| | T | F |
| 14. Surgically induced menopause occurs in premenopausal women who have a bilateral salpingo-oophorectomy. | <u> </u> | <u> </u> |
| | T | F |
| 15. The goal of surgery done to treat glaucoma is to lower IOP. | <u> </u> | <u> </u> |
| | T | F |
| 16. The United Network for Organ Sharing (UNOS) is responsible for ensuring available organs are distributed equitably. | <u> </u> | <u> </u> |
| | T | F |
| 17. The National Organ Transplant Act established the organ donor card system. | <u> </u> | <u> </u> |
| | T | F |
| 18. Before organs can be harvested, the family must give written consent. | <u> </u> | <u> </u> |
| | T | F |
| 19. Psychological readiness and severe functional disability are not criteria for determining transplant need. | <u> </u> | <u> </u> |
| | T | F |
| 20. A complication of breast augmentation is the formation of scar tissue around the implant, which makes the breast feel tight or hard. | <u> </u> | <u> </u> |
| | T | F |
| 21. Preoperative preparation of the operative site includes shaving the site prior to the client going to the operating room. | <u> </u> | <u> </u> |
| | T | F |
| 22. Shivering during the immediate postoperative patient is indicative of a need for continued use of oxygen. | <u> </u> | <u> </u> |
| | T | F |
| 23. Hypoxemia is defined as a PO ₂ level less than 65 mmHg. | <u> </u> | <u> </u> |
| | T | F |
| 24. Clients in the PACU are usually assessed every 15 minutes. | <u> </u> | <u> </u> |
| | T | F |
| 25. A client whose skin that is cool, moist, and pale is experiencing hypotension. | <u> </u> | <u> </u> |
| | T | F |
| 26. Warm blankets are provided to clients in PACU to reduce hypothermia. | <u> </u> | <u> </u> |
| | T | F |

(continued)

| | | |
|--|------------------|------------------|
| 27. The basal metabolic rate of a client increases during surgery. | <u> </u> T | <u> </u> F |
| 28. Gynecological surgery places a client at risk for deep vein thrombosis. | <u> </u> T | <u> </u> F |
| 29. Only the use of sequential compression devices can prevent the development of deep vein thrombosis. | <u> </u> T | <u> </u> F |
| 30. A client with skeletal deformities has a higher risk of postoperative pulmonary complications. | <u> </u> T | <u> </u> F |
