

## Cursor Implementation of Linked Lists

- **Reason 1:** Many Languages do not support pointers (e.g. Basic, Fortran).
  - If linked lists are required and pointers are not available, then an alternate implementation must be used.
  - The alternate method we will describe here is known as a **cursor implementation**.
- **Reason 2:** If data max length is **known**, using Array is **faster**.

Two features present in a pointer implementation of linked lists:

1. The data are stored in **array** are nodes, each array element (node) contains **data** and a **pointer** to the next node.
2. A new node can be obtained from the system's global memory by a call to **malloc** (memory **allocation**) and released by a call to **free** methods.

Our cursor implementation must be able to simulate these two features:

- The logical way to satisfy 1<sup>st</sup> feature is to have a global array of nodes. For any cell in the array, its array index can be used in place of an address. The following gives the type declarations for a cursor implementation of linked lists:

```
public class Node<T extends Comparable<T>> {  
    T data;  
    int next;  
  
    public Node(T data, int next) {  
        this.data = data;  
        this.next = next;  
    }  
  
    public void setData(T data) { this.data = data; }  
    public T getData() { return data; }  
    public int getNext() { return next; }  
    public void setNext(int next) { this.next = next; }  
  
    public String toString() { return "[" + data+ " , " + next + "]"; }  
}
```

- We must now simulate 2<sup>nd</sup> feature by allowing the equivalent of **malloc** and **free** for nodes in the array.
  - To do this, we will keep a list (the **freelist**) of nodes that are not in any list. The list will use **node 0** as a header. The initial configuration is shown in the following figure: →→→→
- A value of **next** is the equivalent of a pointer to next node.
- The following code to create an array of free nodes:

```
Node<T>[ ] cursorArray = new Node[11];
```

i	data	next
0	null	1
1	null	2
2	null	3
3	null	4
4	null	5
5	null	6
6	null	7
7	null	8
8	null	9
9	null	10
10	null	0

- The initialization of **cursorArray** is a straightforward loop:

```
public int initialization(){
    for(int i=0;i<cursorArray.length-1;i++)
        cursorArray[i] = new Node<>(null, i+1);
    cursorArray[cursorArray.length-1] = new Node<>(null, 0);
    return 0;
}
```

- To perform an **malloc**, the first element (after the header) is removed from the **freelist**:

```
public int malloc() {
    int p = cursorArray[0].next;
    cursorArray[0].next = cursorArray[p].next;
    return p;
}
```

- To perform a **free**, we place the cell at the front of the **freelist**:

```
public void free(int p){
    cursorArray[p] = new Node(null, cursorArray[0].next);
    cursorArray[0].next = p;
}
```

- The following are a list of functions to test whether a linked list is **null**, **empty**, or whether a specific node is the **last**:

```
public booleanisNull(int l){
    return cursorArray[l]==null;
}

public booleanisEmpty(int l){
    return cursorArray[l].next == 0;
}

public booleanisLast(int p){
    return cursorArray[p].next == 0;
}
```

- To create a new linked list, first you have to allocate one free node using **malloc** function, then make a new point that next points to **0** as follow:

```
public int createList(){
    int l = malloc();
    if(l==0)
        System.out.println("Error: Out of space!!!");
    else
        cursorArray[l] = new Node("-",0);
    return l;
}
```

- The following code is used to add a new data to a specific linked list:

```
public void insertAtHead(T data, int l){  
    if(isNull(l)) // list not created  
        return;  
    int p = malloc();  
    if(p!=0){  
        cursorArray[p] = new Node(data, cursorArray[l].next );  
        cursorArray[l].next = p;  
    }  
    else  
        System.out.println("Error: Out of space!!!");  
}
```

- The following code is used to traverse a linked list:

```
public void traversList(int l) {  
    System.out.print("list_ "+l+"-->");  
    while(!isNull(l) && !isEmpty(l)){  
        l=cursorArray[l].next;  
        System.out.print(cursorArray[l]+"-->");  
    }  
    System.out.println("null");  
}
```

- The following code is used to find a specific data in a linked list:

```
public int find(T data, int l){  
    while(!isNull(l) && !isEmpty(l)){  
        l=cursorArray[l].next;  
        if(cursorArray[l].data.equals(data))  
            return l;  
    }  
    return -1; // not found  
}
```

- Sometimes you need the previous location of a specific data in a linked list:

```
public int findPrevious(T data, int l){  
    while(!isNull(l) && !isEmpty(l)){  
        if(cursorArray[cursorArray[l].next].data.equals(data))  
            return l;  
        l=cursorArray[l].next;  
    }  
    return -1; // not found  
}
```

- The following code is used to delete some data from a linked list:

```
public Node delete(T data, int l){  
    int p = findPrevious(data, l);  
    if(p!=-1){  
        int c = cursorArray[p].next;  
        Node temp = cursorArray[c];  
        cursorArray[p].next = temp.next;  
        free(c);  
    }  
    return null;  
}
```
