## CHAPTER 1

**1.1** Base-10: 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32  
Octal: 20 21 22 23 24 25 26 27 30 31 32 33 34 35 36 37 40  
Hex: 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F 20  
Base-13 A B C 10 11 12 13 14 15 16 17 18 19 23 24 25 26

**1.2** (a) 32,768 (b) 67,108,864 (c) 6,871,947,674

**1.3**  $(4310)_5 = 4 * 5^3 + 3 * 5^2 + 1 * 5^1 = 580_{10}$

$$(198)_{12} = 1 * 12^2 + 9 * 12^1 + 8 * 12^0 = 260_{10}$$

$$(735)_8 = 7 * 8^2 + 3 * 8^1 + 5 * 8^0 = 477_{10}$$

$$(525)_6 = 5 * 6^2 + 2 * 6^1 + 5 * 6^0 = 197_{10}$$

**1.4** 14-bit binary: 11\_1111\_1111\_1111  
Decimal:  $2^{14} - 1 = 16,383_{10}$   
Hexadecimal: 3FFF<sub>16</sub>

**1.5** Let b = base

(a)  $14/2 = (b + 4)/2 = 5$ , so b = 6

(b)  $54/4 = (5*b + 4)/4 = b + 3$ , so  $5 * b = 52 - 4$ , and b = 8

(c)  $(2 * b + 4) + (b + 7) = 4b$ , so b = 11

**1.6**  $(x - 3)(x - 6) = x^2 - (6 + 3)x + 6*3 = x^2 - 11x + 22$

Therefore:  $6 + 3 = b + 1m$  so b = 8

Also,  $6*3 = (18)_{10} = (22)_8$

**1.7** 68BE = 0110\_1000\_1011\_1110 = 110\_100\_010\_111\_110 = (64276)<sub>8</sub>

**1.8** (a) Results of repeated division by 2 (quotients are followed by remainders):

$431_{10} = 215(1); 107(1); 53(1); 26(1); 13(0); 6(1) 3(0) 1(1)$   
Answer: 1111\_1010<sub>2</sub> = FA<sub>16</sub>

(b) Results of repeated division by 16:

$431_{10} = 26(15); 1(10)$  (Faster)  
Answer: FA = 1111\_1010

**1.9** (a)  $10110.0101_2 = 16 + 4 + 2 + .25 + .0625 = 22.3125$

(b)  $16.5_{16} = 16 + 6 + 5*(.0615) = 22.3125$

(c)  $26.24_8 = 2 * 8 + 6 + 2/8 + 4/64 = 22.3125$

(d)  $FAFA.B_{16} = 15 \cdot 16^3 + 10 \cdot 16^2 + 15 \cdot 16 + 10 + 11/16 = 64,250.6875$

(e)  $1010.1010_2 = 8 + 2 + .5 + .125 = 10.625$

1.10 (a)  $1.10010_2 = 0001.1001_2 = 1.9_{16} = 1 + 9/16 = 1.563_{10}$

(b)  $110.010_2 = 0110.0100_2 = 6.4_{16} = 6 + 4/16 = 6.25_{10}$

Reason:  $110.010_2$  is the same as  $1.10010_2$  shifted to the left by two places.

 \end{array}$$

The quotient is carried to two decimal places, giving  $1011.11$

Checking:  $111011_2 / 101_2 = 59_{10} / 5_{10} \cong 1011.11_2 = 58.75_{10}$

(c) To simulate the circuit, it is assumed that the inputs  $xy = 00$  have been applied sufficiently long for the circuit to be stable before  $xy = 01$  is applied. The testbench sets  $xy = 00$  at  $t = 0$  ns, and  $xy = 1$  at  $t = 10$  ns. The simulator assumes that  $xy = 00$  has been applied long enough for the circuit to be in a stable state at  $t = 0$  ns, and shows  $F = 0$  as the value of the output at  $t = 0$ . The waveforms show the response to  $xy = 01$  applied at  $t = 10$  ns.

Note that the subtraction operator performs 2's complement subtraction. So 8'h55 – 8'hAA adds the 2's complement of 8'hAA to 8'h55 and gets 8'hAB. The sign bit is not included in the model, but hand calculation shows that the 9<sup>th</sup> bit is 1, indicating that the result of the operation is negative. The magnitude of the result can be obtained by taking the 2's complement of 8'hAB.

5.5

The truth table describes a combinational circuit.  
 The state table describes a sequential circuit.  
 The characteristic table describes the operation of a flip-flop.  
 The excitation table gives the values of flip-flop inputs for a given state transition.  
 The four equations correspond to the algebraic expression of the four tables.

$$d(A, B, C, x) = \Sigma (10, 11, 12, 13, 14, 15)$$

The machine is self-correcting, i.e., the unused states transition to known states.

(b) With JK flip=flops, the state table is the same as in (a).

*Flip-flop inputs*

$J_A = B'x$        $K_A = 1$   
 $J_B = A + C'x'$        $K_B = C'x + Cx'$   
 $J_C = Ax + A'B'x'$        $K_C = x$   
 $y = A'x$   
 The machine is self-correcting  
 because  $K_A = 1$ .

5.20 From state table 5.4:  $T_A(A, B, x) = \Sigma(2, 3, 6)$ ,  $T_B(A, B, x) = \Sigma(0, 3, 4, 6)$ .

5.21 The statements associated with an **initial** keyword execute once, in sequence, with the activity expiring after the last statement completes execution; the statements associated with the **always** keyword execute repeatedly, subject to timing control (e.g, #10).

## CHAPTER 6

- 6.1** The structure shown below gates the clock through a nand gate. In practice, the circuit can exhibit two problems if the load signal is asynchronous: (1) the gated clock arrives in the setup interval of the clock of the flip-flop, causing metastability, and (2) the load signal truncates the width of the clock pulse. Additionally, the propagation delay through the nand gate might compromise the synchronicity of the overall circuit.

- 6.2** Modify Fig. 6.2, with each stage replicating the first stage shown below:

<i>Load</i>	<i>Clear</i>	<i>D</i>	<i>Operation</i>
0	0	$A_0$	No change
0	1	0	Clear to 0
1	x	$I_0$	Load input

Note: In this design, *load* has priority over *clear*.

- 6.3** Serial data is transferred one bit at a time. Parallel data is transferred n bits at a time ( $n > 1$ ).

A shift register can convert serial data into parallel data by first shifting one bit a time into the register and then taking the parallel data from the register outputs.

A shift register with parallel load can convert parallel data to a serial format by first loading the data in parallel and then shifting the bits one at a time.

- 6.4** 101101  $\Rightarrow$  1101; 0110; 1011; 1101; 0110; 1011

- 6.5** (a) See Fig. 11.19: IC 74194

(b) See Fig. 11.20. Connect two 74194 ICs to form an 8-bit register.

6.6 First stage of register:

6.7 First stage of register:

6.8  $A = 0010, 0001, 1000, 1100$ . Carry = 1, 1, 1, 0

6.9 (a) In Fig. 6.5, complement the serial output of shift register B (with an inverter), and set the initial value of the carry to 1.

$K_Q = xy' \oplus$   
 $D = Q \oplus x \oplus y$

- 6.10** See solution to Problem 5.7.  
 Note that  $y = x$  if  $Q = 0$ , and  $y = x'$  if  $Q = 1$ .  $Q$  is set on the first 1 from  $x$ .  
 Note that  $x \oplus 0 = x$ , and  $x \oplus 1 = x'$ .

 (b) A count up counter.

 (b) With complemented flip-flops connected to  $C$ .

**6.13**

- 6.14** (a) 4; (b) 9; (c) 10
- 6.15** The worst case is when all 10 flip-flops are complemented. The maximum delay is  $10 \times 3\text{ns} = 30\text{ ns}$ .  
 The maximum frequency is  $10^9/30 = 33.3\text{ MHz}$

**6.16** Q8 Q4 Q2 Q1 : 1010      1100      1110    Self correcting  
 Next state:      1011      1101      1111  
 Next state:      0100      0100      0000

1010 → 1011 → 0100  
 1100 → 1101 → 0100  
 1110 → 1111 → 0000

**6.17** With  $E$  denoting the count enable in Fig. 6.12 and D-flip-flops replacing the J-K flip-flops, the toggling action of the bits of the counter is determined by:  $T_0 = E$ ,  $T_1 = A_0E$ ,  $T_2 = A_0A_1E$ ,  $T_3 = A_0A_1A_2E$ . Since  $D_A = A \oplus T_A$  the inputs of the flip-flops of the counter are determined by:  $D_{A0} = A_0 \oplus E$ ;  $D_{A1} = A_1 \oplus (A_0E)$ ;  $D_{A2} = A_2 \oplus (A_0A_1E)$ ;  $D_{A3} = A_3 \oplus (A_0A_1A_2E)$ .

**6.18** When  $up = down = 1$  the circuit counts up.

	$up$	$down$	$x$	$y$	Operation
	0	0	0	0	No change
	0	1	0	0	Count down
	1	0	1	0	Count up
	1	1	0	0	No change

Add this to Fig. 6.13

$$x = up (down)'$$

$$y = (up)'down$$

**6.19 (b)** From the state table in Table 6.5:

$$D_{Q1} = Q_1'$$

$$D_{Q2} = \sum (1, 2, 5, 6)$$

$$D_{Q4} = \sum (3, 4, 5, 6)$$

$$D_{Q8} = \sum (7, 8)$$

$$\text{Don't care: } d = \sum (10, 11, 12, 13, 14, 15)$$

Simplifying with maps:

$$D_{Q2} = Q_2Q_1' + Q_8Q_2'Q_1$$

$$D_{Q4} = Q_4Q_1' + Q_4Q_2' + Q_4Q_2Q_1$$

$$D_{Q8} = Q_8Q_1' + Q_4Q_2Q_1$$

**6.23** Use a 3-bit counter and a flip-flop (initially at 0). A start signal sets the flip-flop, which in turn enables the counter. On the count of 7 (binary 111) reset the flip-flop to 0 to disable the count (with the value of 000).

## CHAPTER 8

- 8.1**
- (a) The transfer and increment occur concurrently, i.e., at the same clock edge. After the transfer,  $R2$  holds the contents that were in  $R1$  before the clock edge, and  $R2$  holds its previous value incremented by 1.
  - (b) Decrement the content of  $R3$  by one.
  - (c) If ( $S_1 = 1$ ), transfer content of  $R1$  to  $R0$ . If ( $S_1 = 0$  and  $S_2 = 1$ ), transfer content of  $R2$  to  $R0$ .

**8.2**

**8.3**

**8.4**

- 8.5**
- The operations specified in a flowchart are executed sequentially, one at a time. The operations specified in an ASM chart are executed concurrently for each ASM block. Thus, the operations listed within a state box, the operations specified by a conditional box, and the transfer to the next state in each ASM block are executed at the same clock edge. For example, in Fig. 8.5 with  $Start = 1$  and  $Flag = 1$ , signal  $Flush_R$  is asserted. At the clock edge the state moves to  $S_2$ , and register  $R$  is flushed.

8.6

Note: In practice, the asynchronous inputs  $x$  and  $y$  should be synchronized to the clock to avoid metastable conditions in the flip-flops..

Note: To avoid counting a person more than once, the machine waits until  $x$  or  $y$  is de-asserted before incrementing or decrementing the counter. The machine also accounts for persons entering and leaving simultaneously.

8.7

RTL notation:

$S0$ : Initial state: if (start = 1) then ( $RA \leftarrow data\_A$ ,  $RB \leftarrow data\_B$ , go to  $S1$ ).

$S1$ :  $\{Carry, RA\} \leftarrow RA + (2's \text{ complement of } RB)$ , go to  $S2$ .

$S2$ : If (borrow = 0) go to  $S0$ . If (borrow = 1) then  $RA \leftarrow (2's \text{ complement of } RA)$ , go to  $S0$ .

The simulation results shown below match Fig. 8.13.

**8.14** The state code 2'b10 is unused. If the machine enters an unused state, the controller is written with default assignment to *next\_state*. The default assignment forces the state to *S\_idle*, so the machine recovers from the condition.

**8.15** Modify the test bench to insert a reset event and extend the clock.

**8.16**

RTL notation:

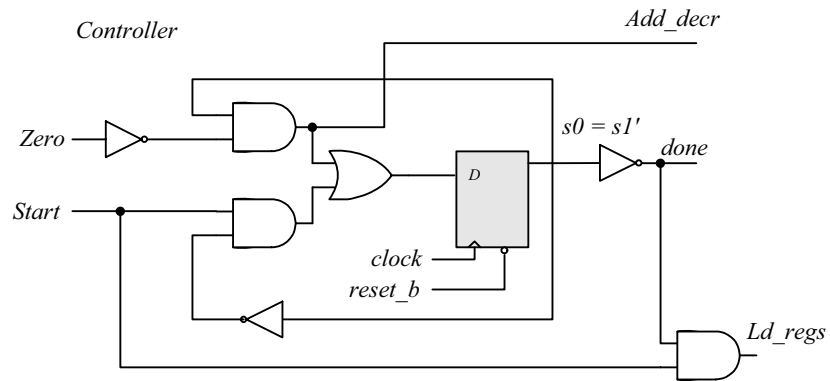

*s0*: (initial state) If *start* = 0 go back to state *s0*, If (*start* = 1) then  $BR \leftarrow multiplicand$ ,  $AR \leftarrow multiplier$ ,  $PR \leftarrow 0$ , go to *s1*.

*s1*: (check *AR* for Zero) *Zero* = 1 if  $AR = 0$ , if (*Zero* = 1) then go back to *s0* (*done*) If (*Zero* = 0) then go to *s1*,  $PR \leftarrow PR + BR$ ,  $AR \leftarrow AR - 1$ .

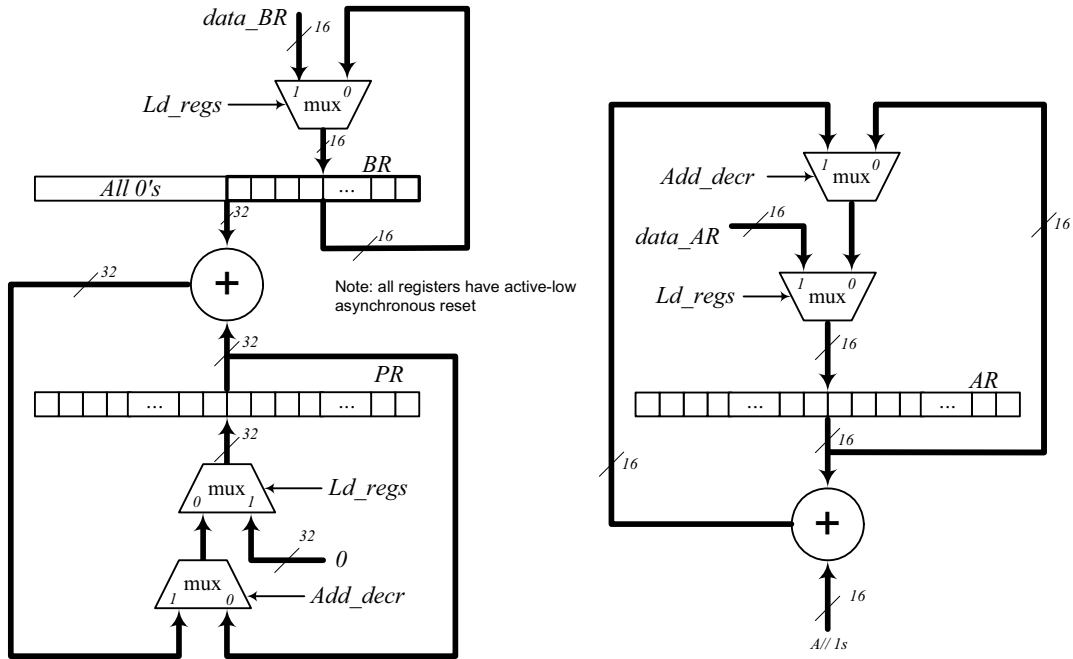

The internal architecture of the datapath consists of a double-width register to hold the product (*PR*), a register to hold the multiplier (*AR*), a register to hold the multiplicand (*BR*), a double-width parallel adder, and single-width parallel adder. The single-width adder is used to implement the operation of decrementing the multiplier unit. Adding a word consisting entirely of 1s to the multiplier accomplishes the 2's complement subtraction of 1 from the multiplier. Figure 8.16 (a) below shows the ASMD chart, block diagram, and controller of the circuit. Figure 8.16 (b) shows the internal architecture of the datapath. Figure 8.16 (c) shows the results of simulating the circuit.

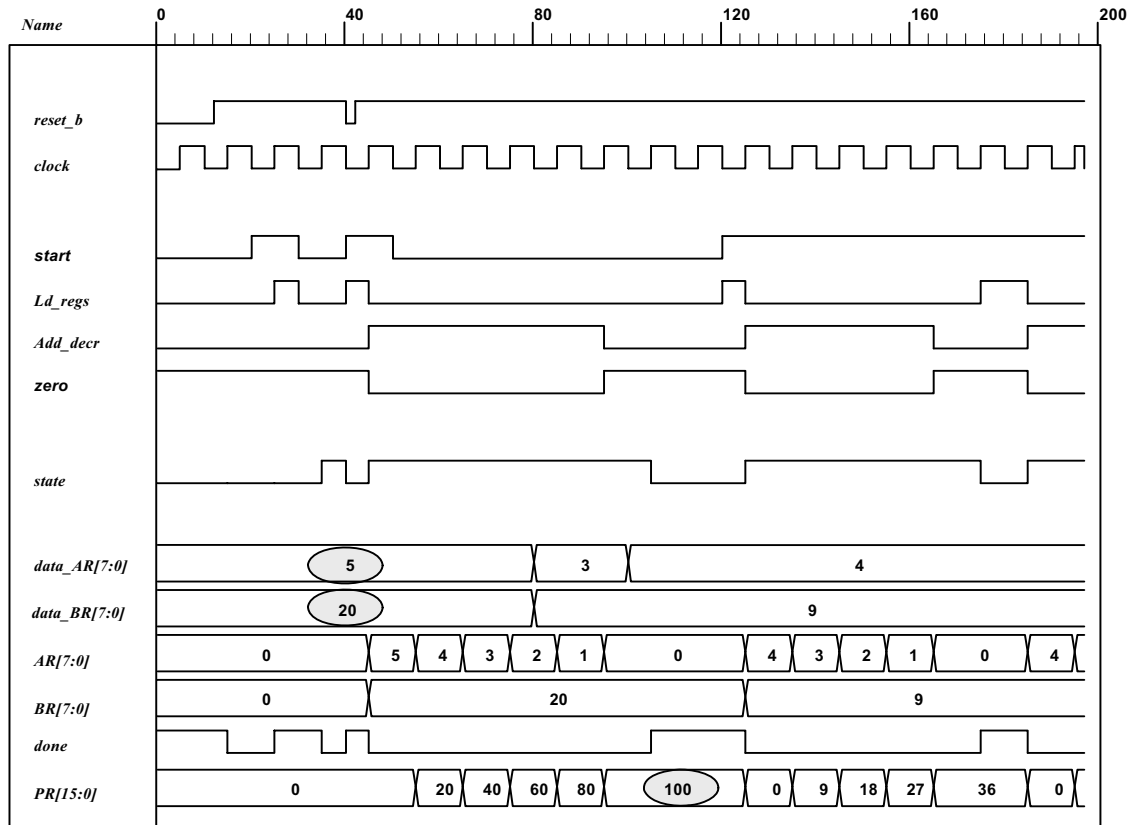

Note: Form Zero as the output of an OR gate whose inputs are the bits of the register AR.

**8.23** As shown in Fig. P8.23 the machine asserts *Load\_regs* in state *S\_load*. This will cause the machine to operate incorrectly. Once *Load\_regs* is removed from *S\_load* the machine operates correctly. The state *S\_load* is a wasted state. Its removal leads to the same machine as shown in Fig. P8.15b.

Assume that the states are encoded one-hot as  $T_0, T_1, T_2, T_3$ . The select lines of the mux are generated as:

$$s_1 = T_2 + T_3$$

$$s_0 = T_1 + T_3$$

The signal to load  $R_4$  can be generated by the host processor or by:

$$load = T_0 + T_1 + T_2 + T_3$$

The bytes of data will be read sequentially. Registers *Q* and *B* are organized to act as byte-wide parallel shift registers, taking 8 clock cycles to fill the pipe. The least significant byte of the multiplicand enters the most significant byte of *Q* and then moves through the bytes of *Q* to enter *B*, then proceed to occupy successive bytes of *B* until it occupies the least significant byte of *B*, and so forth until both *B* and *Q* are filled. Wait states are used to wait for *Run* and *Send\_Data*.

Simulation results: Loading multiplicand (0f0000aa<sub>H</sub>) and multiplier (0a0000ff<sub>H</sub>), 4 bytes each, in sequence, beginning with the least significant byte of the multiplicand.

Note: *Product* is not valid until *Done\_Product* asserts. The value of *Product* shown here (255<sub>10</sub>) reflects the contents of {*C*, *A*, *Q*} after the multiplier has been loaded, prior to multiplication.

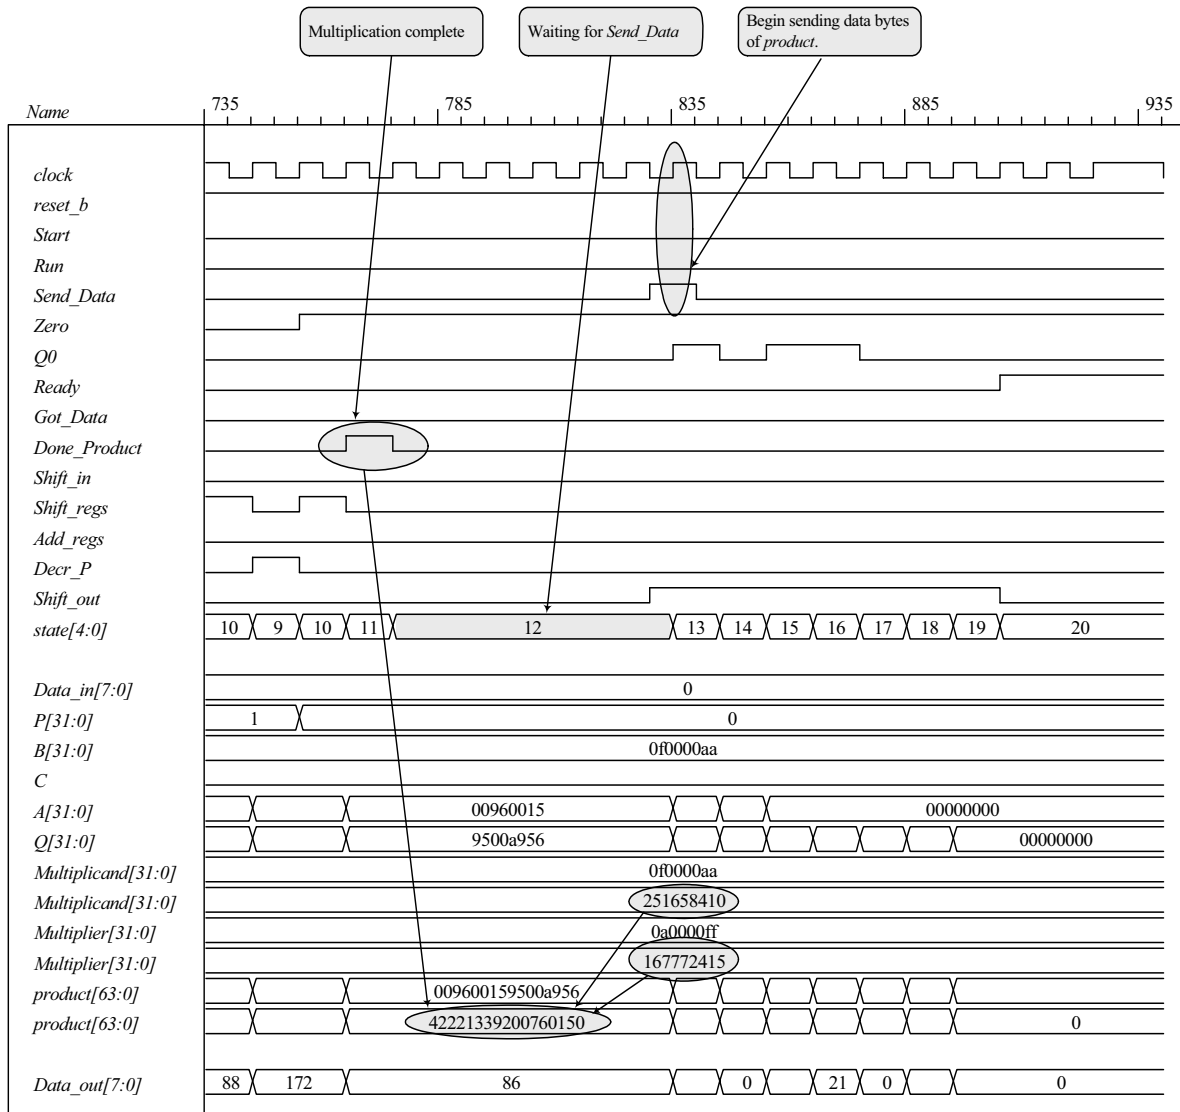

Note: The machine ignores a premature assertion of *Run*.

Note: *Got\_Data* asserts at the 8<sup>th</sup> clock after *Start* asserts, i.e., 8 clocks to load the data.

Note: *Product*, *Multiplier*, and *Multiplicand* are formed in the test bench.

Note: Product (64 bits) is formed correctly

## CHAPTER 9

**9.1 (a)** Asynchronous circuits do not use clock pulses and change state in response to input changes. Synchronous circuits use clock pulses and a change of state occurs in response to the clock transition.

**(b)** The input signals change one at a time when the circuit is stable.

**(c)** The circuit is in a stable state when the excitation variables ( $Y$ ) are equal to the secondary variables ( $y$ ) (see F. 9.1). Unstable otherwise.

**(d)** The total state is the combination of binary values of the internal state and the inputs.
