Analog Electronics ENEE236

Amplifiers Frequency Response

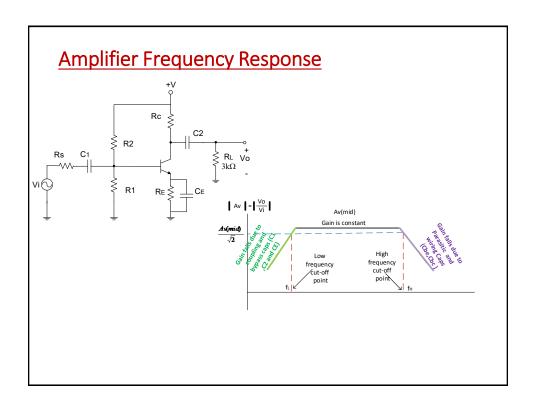

Instructor Nasser Ismail

<u>Amplifier Frequency Response</u>

- Audio frequency signals such as speech and music are combination of many different sine waves, occurring simultaneously with different amplitude and frequency in the following range (20Hz-20kHz (audible noise), other types of signals have their own range.
- In order for the output to be an amplified version of the input, the amplifier must amplify each and every component in the signal by the same amount
- The Bandwidth must cover the entire range of frequency components if considered amplification is to be achieved

Instructor: Nasser Ismail

First 2015 2016

Av $= \frac{Vo}{Vi}$

Av(mid)

or "Passband"

• The impedance of a cap is

$$X_c = \frac{1}{2\pi fC}$$

when $f < f_L$ the coupling caps C1 and C2, and the bypass cap C_E cannot be considered as short circuit since their impedance is not small enough

when $f > f_H$ the internal caps Cbc and Cbe for a BJT (or Cgs and Cgd), cannot be considered as open circuit since their impedance is not high enough

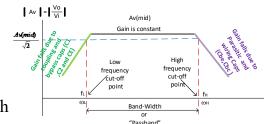

Corner Frequency

we define the corner (break and cut - off) frequency as:

$$|A(j\omega_L)| = \frac{Av(mid)}{\sqrt{2}}$$
$$|A(j\omega_H)| = \frac{Av(mid)}{\sqrt{2}}$$

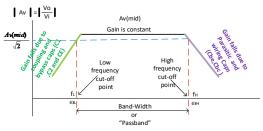

$$|A(j\omega_H)| = \frac{Av(mid)}{\sqrt{2}}$$

$$\omega_{\rm H} - \omega_{\rm L} = BW$$
 - Bandwidth

Midrange = midband $\cong 10\omega_{L} - 0.1\omega_{H}$

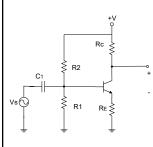

Corner Frequency

Midrange = midband $\cong 10\omega_{L} - 0.1\omega_{H}$

- This is the range for which the capacitors (C1, C2 and CE) are considered short circuit while the parasitic caps are considered open circuit (this is the range we have considered so far in previuos chapters)

Series Capacitance and low frequency response

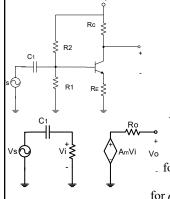

Vo = AmV1

$$Vi = \frac{Ri}{Ri + \frac{1}{j\omega C1}} \text{Vs} \rightarrow \text{Vo} = \frac{Am.Ri}{Ri + \frac{1}{j\omega C1}} \text{Vs}$$

$$\frac{\text{Vo}}{\text{V}_{\text{s}}} = \frac{Am.Ri}{Ri + \frac{1}{j\omega C1}} = A(j\omega)$$

$$\rightarrow |A(j\omega)| = \frac{Am.Ri}{\sqrt{(Ri)^2 + \left(\frac{1}{\omega C1}\right)^2}}$$

Series Capacitance and low frequency response

$$|A(j\omega)| = \frac{Am.Ri}{\sqrt{(Ri)^2 + \left(\frac{1}{\omega C1}\right)^2}}$$
$$= \frac{Am}{\sqrt{1 + \left(\frac{\omega_{C1}}{\omega}\right)^2}};$$

where $\omega_{C1} = \frac{1}{\text{Ri.C1}}$ is the break frequency due to C1

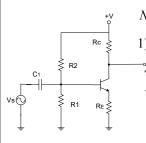

For Am = 1

. for $\omega = \omega_{C1} \rightarrow 20\log |A(j\omega)| = 20\log Am - 20\log 0.707 = -3dB$

for $\omega = 0.1\omega_{C1} \rightarrow 20\log |A(j\omega)| = -20\log 10 = -20dB \leftarrow \text{ High pass}$

filter

Series Capacitance and low frequency response

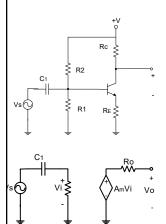

Note:

- 1) If there is only one cap, we find $\omega_{C1} = \frac{1}{Rth1.C1}$ and $\omega_{L} = \omega_{C1}$
- $^{\circ}$ 2) If there is two caps C1 and C2 with $\omega_{\scriptscriptstyle C1}$ and $\omega_{\scriptscriptstyle C2}$, then

$$\mathbf{A}(\mathbf{j}\omega) = Am \left(\frac{1}{1 + \left(\frac{\omega_{c1}}{j\omega} \right)} \right) \left(\frac{1}{1 + \left(\frac{\omega_{c2}}{j\omega} \right)} \right)$$

Series Capacitance and low frequency response

in order to find $\omega_{_L},$ we find magnitude of the gain at $\omega_{_L}$

$$\left| A(j\omega_{_{\rm L}}) \right| = \frac{Am}{\sqrt{2}}$$

solving yields

$$\omega_L^2 = \frac{\omega_{C1}^2 + \omega_{C2}^2}{2} + \frac{\sqrt{\omega_{C1}^4 + 6\omega_{C1}^2 \omega_{C2}^2 + \omega_{C2}^4}}{2}$$

Series Capacitance and low frequency response

1) let $\omega_{C1} = 616$ rad/sec and $\omega_{C2} = 17.86$ rad/sec

here $\omega_{c_1} >> \omega_{c_2}$

 $\omega_{\rm L} = 616.5 \, \text{rad/sec}$

2) let $\omega_{_{C1}} = 200~\text{rad/sec}\,$ and $\omega_{_{C2}} = 750~\text{rad/sec}\,$

here $\omega_{c2} >> \omega_{c1}$

 $\omega_{_L} = 798 \text{ rad/sec}$

$$\omega_{L}^{2} = \frac{\omega_{C1}^{2} + \omega_{C2}^{2}}{2} + \frac{\sqrt{\omega_{C1}^{4} + 6\omega_{C1}^{2}\omega_{C2}^{2} + \omega_{C2}^{4}}}{2}$$

In both cases and in general

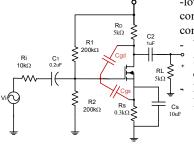

if $\omega_{c_1} >> \omega_{c_2}$

 $\omega_{C1} < \omega_{L} < \omega_{C1} + \omega_{C2}$

Biggest $\omega_{CI} < \omega_{L} < \text{sum of all } \omega_{C}$'s

Low Frequency Response Example

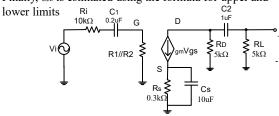

• Calculate the low frequency corner frequencies due to C1,C2, Cs and estimate ω . ?

-low frequency ac small signal equivalent circuit is constructed (here all high frequency caps Cgs, Cgd are considered as open circuits)

We consider one capacitor each time, while all other low frequency caps are considered short circuit and its corresponding ω is found

Finally, ω_L is estimated using the formula for upper and

Instructor: Nasser Ismail First 2015 2016

ENEE236 BZU-ECE

Effect of each Capacitor at ωL

• We Calculate the low frequency corner frequencies due to each cap acting alone while all others are considered as short circuit

1) consider C1 (while C2 and Cs are shorted)

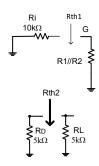

$$\omega_{c1} = \frac{1}{C1.Rth1} = 45.45 \text{ rad/sec};$$

*Rth*1 is the thevenin impedance seen by C1 while all independant sources are set to zero

Rth1 = Ri + (R1//R2)

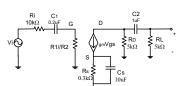

2) consider C2 (while C1 and Cs are shorted)

$$\omega_{c2} = \frac{1}{C2.Rth2} = 100 \text{ rad/sec};$$

*Rth*1 is the thevenin impedance seen by C1 Rth2 = $R_D + R_L$

Effect of each Capacitor & ωι

- We Calculate the low frequency corner frequencies due to cap acting alone while all others are considered as short circuit
 - 3) consider Cs (while C1 and C2 are shorted)

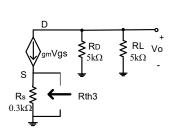

$$\omega_{c3} = \frac{1}{Cs.Rth3} = 1050 \text{ rad/sec};$$

*Rth*3 is the thevenin impedance seen by Cs remember rds = ∞

$$Rth3 = Rs / \frac{1}{gm}$$

4) estimation of the ω_L

$$1050 < \omega_{L} < 1195.5$$

Design of ωL

- Previous method explained how to estimate value of <u>oc</u> in an analysis problem where all capacitor values are given, but what happens if it was desired to design an amplifier with certain <u>oc</u> and the task was to find capacitor values?
- Design criteria to be used is:

$$\omega_{CE} = (0.7 - 0.8)\omega_{L}$$

$$\omega_{CL} = \omega_{C2} = (0.1 - 0.15)\omega_{L}$$

C1,C2 are input and output coupling capacitors $C_{\rm E}$ is bypass capacitor // to $R_{\rm E}$ emitter stabilizing resistor or Rs source resistor make sure that $\omega_{\rm CE} + \omega_{\rm C1} + \omega_{\rm C3} = \omega_{\rm L}$

Shunt Capacitance and High frequency response

$$Vo = AmVi$$

$$Vi = \frac{Ri / \frac{1}{j\omega C_A}}{\left(Ri / \frac{1}{j\omega C_A}\right) + Rs} Vs \rightarrow \frac{Vo}{Vs} = A(j\omega)$$

$$A(j\omega) = Am \frac{Ri / \frac{1}{j\omega C_A}}{\left(Ri / \frac{1}{j\omega C_A}\right) + Rs} \rightarrow |A(j\omega)| = Av(mid) \frac{1}{\sqrt{1 + \left[\omega C_A(Rs / Ri)\right]^2}}$$

$$= Am \left(\frac{Ri}{Ri + Rs}\right) \left(\frac{1}{1 + j\omega C_A(Rs / Ri)}\right)$$

$$\rightarrow |A(j\omega)| = Am \frac{Ri}{Ri + Rs} \cdot \frac{1}{\sqrt{1 + \left[\omega C_A(Rs / Ri)\right]^2}}$$

$$\rightarrow at \omega = \omega_H = \omega_{CA}$$

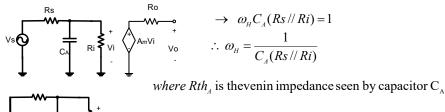

$$\therefore |A(j\omega_H)| = Av(mid) \frac{1}{\sqrt{2}}$$

$$\rightarrow at \omega = \omega_H = \omega_{CA}$$

$$\therefore |A(j\omega_H)| = Av(mid) \frac{1}{\sqrt{2}}$$

$$\rightarrow \omega_H C_A(Rs / Ri) = 1$$

Shunt Capacitance and High frequency response

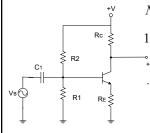

For Av(mid) = 1

for $\omega = \omega_{CA} \rightarrow 20\log |A(j\omega)| = 20\log Av(mid) - 20\log 0.707 = -3dE$

for $\omega = 10\omega_{C4} \rightarrow 20\log |A(j\omega)| = -20\log 10 = -20dB \leftarrow low pass$ filter

Shunt Capacitance and High frequency response

Note:

1) If there is only one cap, we find $\omega_{CA} = \frac{1}{R_{hh}C1}$ and $\omega_{H} = \omega_{CA}$

 $^{+}$ 2) If there is two caps C $_{\rm A}$ and C $_{\rm B}$ with $\omega_{\rm CA}$ and $\omega_{\rm CB}$, then

$$A(j\omega) = Av(mid) \frac{1}{1 + \left(\frac{j\omega}{\omega_{CA}}\right)} \frac{1}{1 + \left(\frac{j\omega}{\omega_{CB}}\right)}$$

in order to find ω_{H} , we find magnitude of the gain at ω_{H}

Vo
$$|A(j\omega_H)| = \frac{Av(mid)}{\sqrt{2}} = \frac{Av(mid)}{\left[1 + \left(\frac{j\omega}{\omega_{CA}}\right)\right]\left[1 + \left(\frac{j\omega}{\omega_{CB}}\right)\right]}$$

Shunt Capacitance and High frequency response

By solving for the magnitude of the gain $A(j\omega)$ at $\omega = \omega_H$ yeilds for an approximation for the lower and upper limit to estimate ω_H for $\omega_{CA} >> \omega_{CB}$

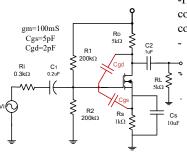

$$\frac{1}{\frac{1}{\omega_{CA}} + \frac{1}{\omega_{CB}}} < \omega_{H} < \omega_{CB}$$

$$\frac{\omega_{_{CA}}.\omega_{_{CB}}}{\omega_{_{CA}}+\omega_{_{CB}}}<\omega_{_{H}}<\omega_{_{CB}}$$

 $lower \ limit < \omega_{_H} < Smallest \ \omega$

High Frequency Response Example

• Calculate the high frequency corner frequencies due to Cgs,Cgd and estimate ω_H ?

- -High frequency ac small signal equivalent circuit is constructed (here all low frequency caps C1, C2 and C3 are considered as short circuits)
 - We consider one capacitor each time , while all others are considered open circuit and its corresponding ω is found Finally, ω_{H} is estimated using the formula for upper and lower limits

Effect of each Capacitor & ω_H

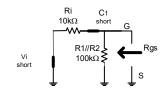

- We Calculate the high frequency corner frequencies due to each high frequency cap acting alone while all others are considered as open circuit
- 1) Consider Cgs (while Cgs is open, C1, C2 & Cs are shorted)

$$\omega_{\text{\tiny Cgs}} = \frac{1}{Cgs.Rgs}$$

Rgs is the thevenin impedance seen by Cgs

$$Rgs = R1//R2//Ri$$

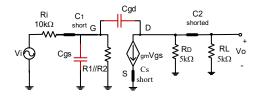

$$\omega_{Cgs} = 668.45$$
 Mrad/sec;

Effect of each Capacitor & ω_H

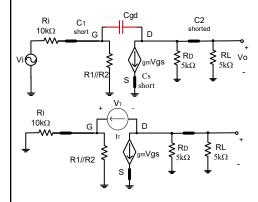

2) Consider Cgd (while Cgs is open, C1,C2 & Cs are shorted)

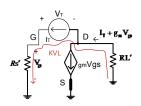

$$\omega_{\rm Cgd} = \frac{1}{Cgd.Rgd}$$

Effect of Capacitor Cgd

• Calculation of Rgd is done through test current /voltage method

KVL: $RL'(I_{T} + g_{m}V_{gs}) + I_{T}Rs' = V_{T}$ but $V_{gs} = V_{g} - V_{s} = Rs'I_{T}$ substituting yeilds $RL'(I_{T} + g_{m}Rs'I_{T}) + I_{T}Rs' = V_{T}$ $Rgd = \frac{V_{T}}{I_{T}} = RL' + Rs' + g_{m}RL'Rs'$ $RL' = R_{D}//R_{L} \quad and \quad Rs' = Ri//R1//R2$

Effect of each Capacitor & ω_H

Now

$$\omega_{\text{\tiny Cgd}} = \frac{1}{Cgd.Rgd} = 48.54 \text{ Mrad/sec};$$

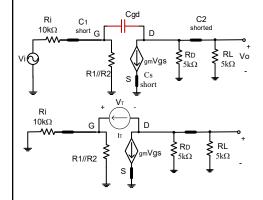

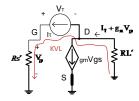

3) Estimation of the ω_{H}

$$\frac{\left(\omega_{\rm gd} \bullet \omega_{\rm gs}\right)}{\left(\omega_{\rm gd} + \omega_{\rm gs}\right)} < \omega_{\rm H} < 48.45$$
$$45.25 < \omega_{\rm H} < 48.45$$

Effect of each Capacitor & ω_H

- Calculation of Rgd is done through
- test current /voltage method

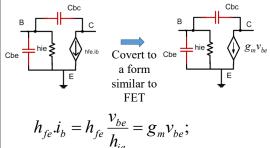

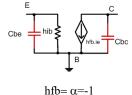

$$\begin{aligned} & \text{KVL}: \text{RL}'(\text{I}_{\text{T}} + \text{g}_{\text{m}} \text{V}_{\text{gs}}) + \text{I}_{\text{T}} \text{Rs}' = \text{V}_{\text{T}} \\ & \text{but} \quad \text{V}_{\text{gs}} = \text{V}_{\text{g}} - \text{V}_{\text{s}} = \text{Rs}' \text{I}_{\text{T}} \\ & \text{substituti ng yeilds} \\ & \text{RL}'(\text{I}_{\text{T}} + \text{g}_{\text{m}} \text{Rs}' \text{I}_{\text{T}}) + \text{I}_{\text{T}} \text{Rs}' = \text{V}_{\text{T}} \\ & \text{Rgd} = \frac{V_{T}}{I_{T}} = \text{RL}' + R\text{s}' + \text{g}_{\text{m}} \text{RL}' R\text{s}' \\ & \text{RL}' = \text{R}_{\text{D}} / / \text{R}_{\text{L}} \quad \text{and} \quad R\text{s}' = \text{Ri} / / \text{R1} / / \text{R2} \end{aligned}$$

BJT High Frequency Response

- Capacitors Cbe and Cbc
- CE and CC model

CB model

where

$$\frac{n_{fe}}{h_{ie}} = g_n$$

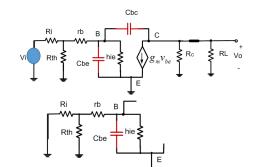

CE Example:

- Estimate the high corner frequency for the following BJT amplifier
- 1) Effect of Cbe (Cbe is considered open) High Frequency Small Signal equivalent Circuit

$$\omega_{be} = \frac{1}{C_{be}.R_{be}};$$

where R_{be} is the thevenin impedance seen by C_{be}

$$R_{be} = ((Ri//Rth) + rb)//hie$$

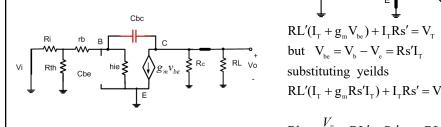

CE Example:

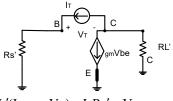

2) Effect of Cbc (Cbe is considered open)

$$\omega_{bc} = \frac{1}{C_{bc}.R_{bc}};$$

where R_{bc} is the thevenin

impedance seen by $C_{bc} and it is found by <math display="inline">V_{\scriptscriptstyle T}/I_{\scriptscriptstyle T}$ method

 $RL'(I_{\scriptscriptstyle T} + g_{\scriptscriptstyle m}Rs'I_{\scriptscriptstyle T}) + I_{\scriptscriptstyle T}Rs' = V_{\scriptscriptstyle T}$

$$Rbc = \frac{V_T}{I_T} = RL' + Rs' + g_m RL'Rs'$$

$$Rs' = \frac{(Ri/(Rth + rb))}{hie}$$

CE Example:

• Given the following values in previous example

$$g_m = 33.5 \text{ mS}$$

hie =
$$8.77 \text{ k}\Omega$$

$$hfe = 294$$

$$Rs = 1 k\Omega\Omega R1//R2 = 16.67 k\Omega$$

$$rb = 20 \Omega$$
; $Cbc = 1.8 pF$; $Cbe = 17.25 pF$

$$Rc = 5 k\Omega$$
; $RL = 2 k\Omega$

calculate:

$$\omega_{bc} = \frac{1}{C_{bc}.R_{bc}} = 66.7 \text{ Mrad/sec}$$

$$\omega_{be} = \frac{1}{C_{be}.R_{bc}} = 12.67 \text{ Mrad/sec}$$

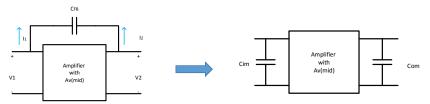

Estimate $\omega_{\rm H}$

$$\frac{\left(\omega_{\rm be} \bullet \omega_{\rm bc}\right)}{\left(\omega_{\rm be} + \omega_{\rm bc}\right)} < \omega_{\rm H} < \omega_{\rm be}$$

$$10.65 < \omega_{\rm H} < 12.67$$

Miller Theorem (another method to solve previous example)

- Miller theorem is used to simplify the analysis of inverting amplifiers only at high frequencies
- The feedback capacitor Cbc or Cgd is decomposed into two capacitors , one at the input Cim and one at the output Com , whose values are found using the following formulas:

Input Miller Capacitance

$$C_{\scriptscriptstyle IM} = C_{\scriptscriptstyle FB} \big[1 - Av(mid) \big]$$

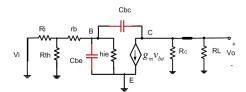

Output Miller Capacitance

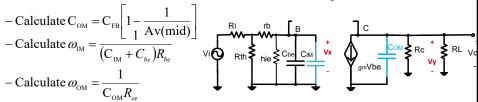

$$C_{OM} = C_{FB} \left[1 - \frac{1}{Av(mid)} \right]$$

CE Example using Miller Theorem:

- Estimate the high corner frequency for the following BJT amplifier using miller theorem
- Calculate $A_v(mid) = \frac{Vy}{Vx}$ Calculate $C_{IM} = C_{FB}[1 Av(mid)];$ $C_v = C_v$

- Estimate $\omega_{\rm L}$

CB Example:

- Estimate the high corner frequency ω_{H} for the following BJT amplifier
- 1) Effect of Cbe (Cbc is considered open)

$$\omega_{be} = \frac{1}{C_{be} R_{be}}$$
; where R_{be} is the thevenin

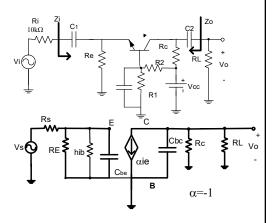

impedance seen byCbe

 $R_{be} = ((Rs // RE)) // hib$

2)Effect of Cbc

$$\omega_{bc} = \frac{1}{C_{bc}.R_{bc}};$$

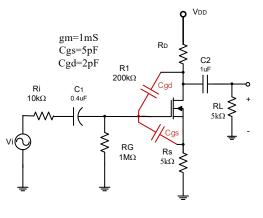

where $R_{bc} = R_L //R_C$

Homework: Amplifier Frequency Response

• Estimate the value of **low** and **high** frequency corner frequencies and calculate the mid-range voltage gain of the following amplifier

Important
